# WILLAMETTE VALLEY SYSTEM OPERATIONS AND MAINTENANCE

# DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

**November 25, 2022**

# DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT FOR WILLAMETTE VALLEY SYSTEM O&M

## November 25, 2022

**Lead Agency**

U.S. Army Corps of Engineers
Portland, Oregon District

**Cooperating Agencies**

Confederated Tribes of Grand Ronde Community of Oregon
Confederated Tribes of Warm Springs
Confederated Tribes of Siletz Indians
National Marine Fisheries Service and U.S. Fish and Wildlife Service
U.S. Bureau of Reclamation
Bonneville Power Administration
United States Environmental Protection Agency
Oregon Department of Agriculture
Oregon Department of Environmental Quality
Oregon Department of Fish and Wildlife
Oregon Water Resources Department

**Proposed Action**

The Proposed Action is continued operation and maintenance of the Willamette Valley System in compliance with the ESA and all other applicable laws and regulations. The Preferred Alternative is Alternative 5.

**Affected Areas**

State: Oregon
Counties: Benton, Lane, Linn, Marion Counties

**Contact for Further Information:**

Nicklas Knudson, Project Manager
U.S. Army Corps of Engineers, Portland District
Block 300
333 SW 1st Avenue
Portland, OR 97204
Phone: 503-808-4739
Fax: 503-808-4882
Nicklas.B.Knudson@usace.army.mil

**Public Comment Deadline:** January 19, 2023

## Federal Permits, Licenses, and Entitlements to be Obtained to Implement the Proposal

There are no permit, license, or entitlement requirements related to the proposed action under review. This is a programmatic proposal review. Any permit, license, or entitlement requirement will be identified in subsequent, tiered environmental reviews as applicable.

## Abstract

The U.S. Army Corps of Engineers, Portland, Oregon District, has prepared this draft Willamette Valley System Operations and Maintenance Programmatic Environmental Impact Statement (PEIS) in accordance with the National Environmental Policy Act (NEPA). Several cooperating agencies and tribes participated in development of this PEIS by providing information and review throughout the draft PEIS process. Public involvement during the scoping process also helped to inform the draft PEIS content and development process. Scoping for the PEIS formally began on April 1, 2019, with publication of a Notice of Intent in the *Federal Register.*

To meet the many purposes of the Willamette Valley System, the U.S. Army Corps of Engineers manages a complex operation that includes storing and releasing water from the 13 system reservoirs to balance various needs and demands throughout the year such as flood control, fish and wildlife, hydropower, recreation, irrigation, water supply, water quality, and navigation.

The Proposed Action reviewed in this PEIS is continued operation and maintenance of the Willamette Valley System for specific, authorized purposes and in compliance with the Endangered Species Act (ESA) and all other applicable treaties, laws, and regulations. This PEIS review is at the program level rather than the site-specific project level (site-specific NEPA analyses would occur when projects are proposed as discussed in the PEIS).

The last PEIS that evaluated the Willamette Valley System operations was completed in 1980. Over the ensuing four decades following completion of the 1980 PEIS (1980 – 2022), operations have been modified and structural measures for fish passage and temperature control have been implemented to improve conditions for ESA-listed fish species. Information relevant to the environmental effects of operating the system has also been acquired since the 1980 PEIS was finalized, including information related to ESA-listed fish species.

The PEIS describes and evaluates impacts related to a No Action Alternative and seven action alternatives that address the Proposed Action. The alternatives are suites of measures for Willamette Valley System management options that vary among the alternatives. Measures are characterized into general categories, including flow, water quality, downstream fish passage, upstream fish passage, and measures common to all action alternatives such as gravel augmentation and operation and maintenance of adult fish facilities among others. Anticipated impacts were analyzed for all environmental and social resources potentially affected under each alternative.

The U.S. Army Corps of Engineers also identifies a Preferred Alternative in this draft PEIS.

# EXECUTIVE SUMMARY

## 1 PREFACE

The Willamette River Basin (WRB) is located entirely within the state of Oregon, beginning south of Cottage Grove, and extending approximately 187 miles to the north where the Willamette River flows into the Columbia River. The basin is more than 11,200 square miles, averages 75 miles in width, and encompasses approximately 12 percent of the total area of the state (Figure ES-2). The Willamette is the 13th largest river in the conterminous United States (U.S.) in terms of streamflow, producing more runoff per unit area than any of the 12 larger rivers. Within the watershed are most of the state's population, larger cities, and major industries. The basin also contains some of Oregon's most productive agricultural lands and supports nationally and regionally important fish and wildlife species. Thirteen of Oregon's thirty-six counties intersect or lie within the boundary of the Willamette River basin. The Willamette flows past Portland, Salem, and Eugene, the three largest cities in Oregon, en route to its confluence with the Columbia River. Many of the Willamette's own tributaries – such as the North and South Santiam, McKenzie (**Figure ES-1**), Middle Fork Willamette, Coast Fork Willamette, and Long Tom – are substantial rivers in their own rights.

**Figure ES- 1. The McKenzie River – a Willamette tributary – drains the heavily forested west slopes of the Cascade Range**

The Willamette River and its tributaries have long influenced the lives of the WRB's residents: human, fish, and wildlife alike. Since time immemorial, indigenous peoples have depended on these rivers for many resources including, but not limited to, fishing, trade, transportation, and water supply. Fish within these rivers including salmon, lamprey, sturgeon, and bull trout are also an essential component of tribal identity and culture.

**Figure ES- 2. The Willamette River Basin depicting USACE projects**

As American settlers of European descent began to appear in the WRB in the mid-1800s, the Willamette River and its tributaries became important resource for them as well. They too relied upon these rivers for transportation, trade, fish harvest, and irrigation water.

The first Euro-Americans on the Willamette encountered a broad valley with a shallow braided channel across a wide floodplain that flooded annually during winter months. As these settlers established agriculture and settlements in the Willamette Valley, the frequent flooding, including the devastating 1861 event that inundated Portland's business district for weeks, eventually led the United States (U.S.) Congress to authorize the U.S. Army Corps of Engineers (USACE) to construct, operate, and maintain a system of dams and reservoirs – the Willamette Valley System (WVS) – for flood control purposes.

Subsequently, USACE constructed 13 dams and extensive bank protection revetments along the Willamette River and its tributaries, creating the WVS by the 1970s. The WVS was originally authorized by the Flood Control Act (FCA) of 1938, including authorization for the following dam construction projects: Fern Ridge on the Long Tom River (**Figure ES-3**), Dorena and Cottage Grove in the Coast Fork Willamette sub-basin, Lookout Point on the Middle Fork Willamette River, and Detroit on the North Santiam River. Subsequent FCAs authorized Big Cliff on the North Santiam River, Green Peter on the Middle Santiam River, Foster on the South Santiam, Cougar and Blue River dams on the McKenzie River, Hills Creek and Dexter on the Middle Fork Willamette River, and Fall Creek on Fall Creek.

**Figure ES- 3. Fern Ridge was the first of 13 dams to be built in the WVS**

However, flood control – or what is commonly referred to as flood risk management (FRM) – is just one many functions of the WVS (**Figure ES-4**). Each project (dam and reservoir) has up to eight purposes authorized by Congress. These include flood control, irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and municipal and industrial water supply. The WVS dams provide approximately $1 billion in annual flood risk benefits, 26 million in hydropower revenue, and 5.4 million in recreation benefits.

**Figure ES- 4. The WVS serves multiple functions**

Many local communities and economies have developed largely from the availability of the resources provided by these authorities which have profound societal benefits to the state of Oregon.

However, these societal benefits have come at an environmental and social cost. A substantial environmental cost was imposed on native fish and on the people who depend on them – particularly Native American Tribes. The initial construction of 13 dams and reservoirs blocked the upstream and downstream migration and flooded spawning and rearing habitat of multiple salmonid species and Pacific lamprey.

In addition, while the WRB comprises just 12 percent of Oregon's land area, it contains about 70 percent of the state's population. The effects to fish from increased population growth and associated development add to the ongoing effects of operations and maintenance of the WVS. Collectively, these effects on Willamette natural-origin fish populations have contributed to their sharp population declines. Activities that have further affected fish include urbanization, development in wetlands, riparian areas, and floodplains, overfishing, water diversions, release of sanitary and industrial pollution, introduction and increase of invasive species, mining, farming, ranching, and logging. Hatchery-produced fish have also become the dominant populations in the WRB and continue to compete for resources with natural-origin fish. Furthermore, global factors outside of the WRB, such as climate change and changing ocean conditions, have had additional adverse effects to salmonids and Pacific lamprey.

Concern over ongoing, long-term population declines led to the listing of Upper Willamette River (UWR) Chinook salmon (**Figures ES-5 and ES-6**) and UWR steelhead (**Figure ES-7**), and bull trout (**Figure ES-8)** as federally threatened species under the Endangered Species Act (ESA). The National Marine Fisheries Service (NMFS) listed UWR Chinook salmon and UWR steelhead trout in 1999 and designated critical habitat in the WRB for UWR Chinook salmon and UWR steelhead in 2005. The U.S. Fish and Wildlife Service (USFWS) listed bull trout as threatened within the coterminous U.S. in 1999 and designated critical habitat in the Upper Willamette River Critical Habitat Unit (CHU) in 2010. Oregon chub were listed as endangered in 1993 and have been delisted in 2015 due to population recovery.

**Figure ES-5. "Silvery" adult Chinook salmon – recently returned from the sea**

**Figure ES-6. Adult Chinook salmon in reddish spawning colors**

**Figure ES-7 Male and female steelhead trout. Credit: NOAA Fisheries**

**Figure ES-8 Bull trout swimming upstream. Photo by: Joel Sartore/National Geographic & Wade Fredenberg/USFWS**

Subsequently, in 2008, NMFS issued a Biological Opinion (BiOp) that evaluated the effects of continued operation and maintenance (O&M) of the WVS to UWR spring Chinook salmon and winter steelhead trout. NMFS concluded that continued O&M as proposed by USACE during the ESA Section 7 consultation process was insufficient to avoid jeopardizing the continued existence of these two species in the WRB, or adverse modification of their designated critical habitat. The 2008 NMFS BiOp provided a Reasonable and Prudent Alternative (RPA), composed of a suite of actions that if implemented would be expected to not jeopardize the continued existence of UWR Chinook salmon and UWR steelhead. In 2008, USFWS also issued a BiOp outlining the effects of the WVP on Oregon chub (now delisted), bull trout, and bull trout critical habitat.  The USFWS BiOp reached a no jeopardy determination as long as the Action agencies implement the NMFS BiOp RPA and consider the effects on Oregon chub and bull trout when applying measures proscribed in the RPA.

In the decades since the WVS projects were first constructed and began operation, and especially since the 2008 BiOp, USACE and its federal, tribal, and state partners have made considerable efforts of varying effectiveness to mitigate the adverse effects of the WVS – dams and reservoirs as well as miles of river revetments (**Figure ES-9**) – on UWR spring Chinook salmon, UWR steelhead, Bull Trout and other sensitive species, such as Pacific lamprey and Oregon chub. These have included: upstream passage past the dam such as adult fish collection facilities and fish ladders (**Figure ES-10 and ES-11**); downstream fish passage operations and structures; operations and structures to improve temperature; and hatcheries for fish rearing.

## 2 INTRODUCTION

USACE has developed this Draft Programmatic Environmental Impact Statement (PEIS) for the continued O&M of the WVS, in accordance with the National Environmental Policy Act (NEPA). USACE prepared this PEIS in response to the need to review and update operations and maintenance of the 13 multipurpose projects (dams and reservoirs) and numerous revetments along the Willamette River and tributaries, in accordance with authorized project purposes, while still meeting obligations under the ESA to avoid jeopardizing the continued existence of ESA-listed species. The locations of these projects are shown in **Figure ES-12**.

To meet the many purposes of the WVS, USACE manages a complex operation that includes storing and releasing water from the 13 WVS reservoirs to balance various needs and demands throughout the year such as flood control, fish migration and habitat, hydropower power peaking, recreation, irrigation, water quality, and water supply. Intermittently, an action taken to meet one need makes it more challenging to meet one or more other needs. For example, in the fall, operators begin drafting WVS reservoirs (lowering water levels) to provide for flood risk management during the high-precipitation winter months. However, come early spring, there must be enough water available to help propel juvenile salmon (smolts) in their journey downstream toward the Pacific Ocean.

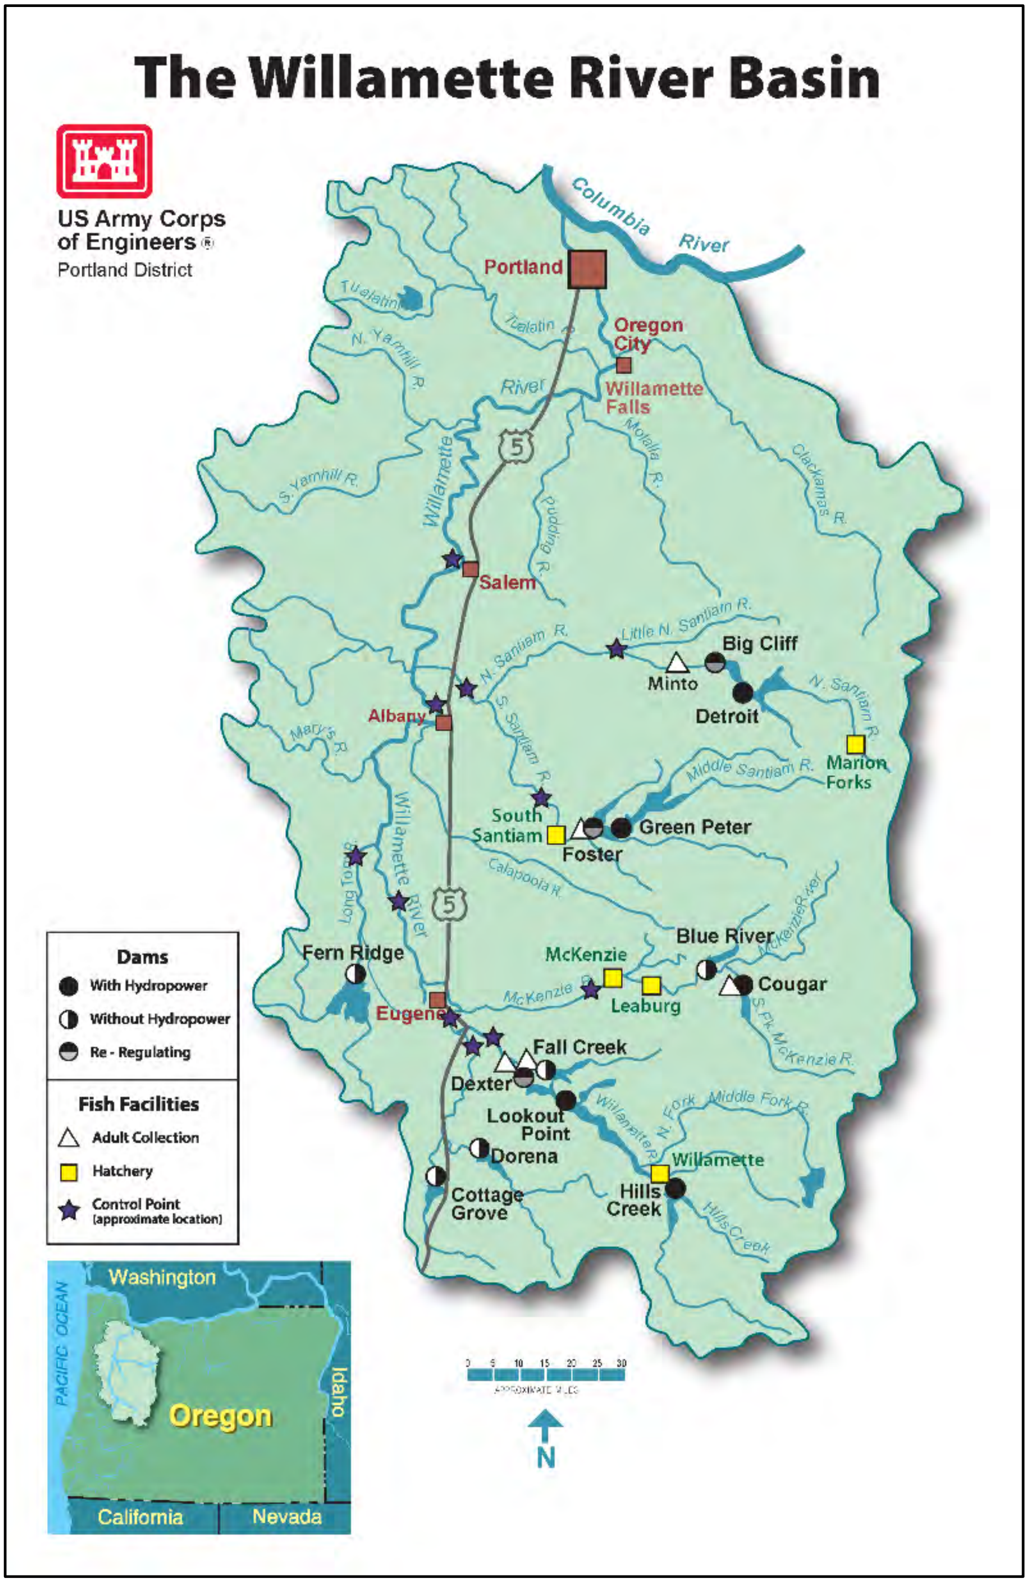

**Figure ES- 12. The WRB, showing locations of WVS projects, including dams and reservoirs, adult fish collection facilities, and fish hatcheries**

In addition, other federal agencies use the WVS include the Bonneville Power Administration (BPA), which is authorized to market and transmit the electrical power generated by the eight hydropower plants in the WVS, and the Bureau of Reclamation (BOR), which conducts water marketing to water users within the WRB. As a result, because all WVS purposes and users are important, actions that affect those purposes and users must be carefully planned, coordinated, and implemented.

As part of the WVS PEIS, USACE analyzed the environmental, economic, and social impacts of the no-action and seven action alternatives, reviewing new scientific and technical information, where applicable.

This Executive Summary provides an overview of the draft PEIS, which is a much larger document that contains highly detailed information, technical analyses, and results. The Executive Summary also furnishes an overview of the major environmental effects of the Preferred Alternative, but it is not intended to substitute for the more comprehensive draft WVS PEIS document. The draft WVS PEIS provides a detailed description of the environmental effects of not only the Preferred Alternative, but also the No Action Alternative and the other six action alternatives. Table ES-1 below identifies the major topics and chapters of the Draft PEIS. Where possible, the executive summary points to the Draft PEIS chapter and section at which the reader can find further details on a given topic.

**Table ES-1 Chapters of the draft WVS PEIS with summary of content**

| Chapter Number | Chapter Title | Chapter Content |
|---|---|---|
| **1** | Introduction | Provides background information on the NEPA, ESA, and WVS |
| **2** | Alternatives | Provides an overview of the alternatives' development process. Describes the suites of measures that comprise 7 action alternatives that meet the purpose and need of the PEIS. Describes the No Action Alternative and the 7 Action Alternatives. |
| **3** | Affected Environment and Environmental Consequences | Analyzes the direct and indirect effects of the 8 alternatives across 24 resource topic areas. |
| **4** | Cumulative Effects | Analyzes the effects of the 8 alternatives in conjunction with the trends of past, present, and reasonably foreseeable actions and their effects on each of the 24 resource topic areas. |
| **5** | Preferred Alternative | Discusses the evaluation and comparison of the 8 alternatives and the selection of the preferred alternative as well as provides an overview of the preferred alternative and the implementation and adaptive management plans. |

| Chapter Number | Chapter Title | Chapter Content |
|---|---|---|
| **6** | Public Involvement | Describes the public involvement process for the WVS PEIS. |
| **7** | Compliance with Environmental Laws, Regulations, and Executive Orders | Provides the status of environmental and cultural resources compliance and explains the plan to update compliance. |
| **8** | Glossary | Provides definitions for terms used throughout the WVS PEIS |
| **9** | List of Preparers | Lists the authors, editors, and reviewers of the WVS by discipline and chapter |
| **10** | References Cited | Lists the references cited throughout the WVS PEIS. |
| **11** | Index | Indexed Terms |
| **12** | List of Appendices | Lists the documents prepared to inform and support the WVS PEIS. |

The geographic scope of the Draft PEIS encompasses the 13 USACE projects (dam and reservoirs) on the Willamette River and the sub-basins of the following tributaries: the North Santiam, South Santiam, McKenzie, Middle Fork Willamette, Coast Fork Willamette, and Long Tom. Also included in the geographic scope are revetments along the banks of the mainstem Willamette and its tributaries, fish hatcheries, and adult fish collection facilities. The temporal scope of this analysis is assumed to be 30 years from the signing of the Record of Decision (ROD), except for the socioeconomic-related resource analysis. A 30-year horizon for the EIS was determined appropriate due to the dynamic nature of the system and the current and future needs of the communities that rely on the system.

# 3 REGIONAL INPUT

USACE carries the responsibility and legal authority for managing the WVS in coordination with its tribal, federal, and state partners, and for collaborating with these partners and other cooperating agencies under NEPA to develop this draft PEIS. When initiating and preparing the draft PEIS, USACE understood the importance of seeking broad input from a diverse array of stakeholders in the region. USACE gathered input through public and agency scoping, cooperating agencies, and tribal consultation.

## 3.1 Public Scoping

Scoping for the PEIS formally began on April 1, 2019, with the publication of a Notice of Intent (NOI) in the *Federal Register* (Vol. 84, No. 62, pp. 12,237 – 12,238). Comments were accepted until June 28, 2019. The NOI also notified the public of the scoping meetings held at various locations within the Willamette Valley from June 4 to 13, 2019. Meeting participants included private citizens, utility boards/councils; watershed councils; farm associations; non-governmental organizations (NGOs); city, state, and federal representatives; and elected officials. A total of 384 comments were received from private citizens, NGOs, governments, government agencies, and tribes. **Table ES-1** shows the number of comments received by topic. The comments were used to inform the scope of analysis, alternatives development, and effects to resources in the draft PEIS

**Table ES- 2. Public Scoping Comments Received by Topic**

| Topic | # of Comments Received |
|---|---|
| Alternatives | 183 |
| Authority | 10 |
| PEIS general | 86 |
| Environmental effects | 90 |
| Mitigation | 5 |
| Not a comment about the PEIS | 10 |
| **Total** | **384** |

The Willamette Valley System Operation and Maintenance Environmental Impact Statement Public Scoping Report includes more details on the scoping process and comments, a database of comments received, and all scoping materials (see Appendix P). Chapter 6 of the WVS PEIS summarizes additional public involvement conducted by USACE for the WVS PEIS.

## 3.2 Cooperating Agencies

As the lead agency for this draft PEIS, USACE invited agencies with jurisdiction by law or special expertise relevant to the WVS and its O&M to be cooperating agencies. Agencies that accepted cooperating agency status are listed in **Table ES-2** below, and are described briefly in Section 1.6 of the PEIS and in detail in Appendix L. These cooperating agencies contributed to the draft PEIS by providing information and input throughout the NEPA process.

**Table ES- 3. Cooperating Agencies**

| Agency |
|---|
| **Tribal** |
| Confederated Tribes of Grand Ronde Community of Oregon |
| Confederated Tribes of Warm Springs |
| Confederated Tribes of Siletz Indians |
| **Federal** |
| Bonneville Power Administration |
| U.S. Bureau of Reclamation |
| National Marine Fisheries Service |
| U.S. Fish and Wildlife Service |
| United States Environmental Protection Agency |

| **Agency** |
|---|
| **State of Oregon** |
| Oregon Department of Agriculture |
| Oregon Department of Environmental Quality |
| Oregon Department of Fish and Wildlife |
| Oregon Water Resources Department |

In addition to being cooperating agencies, BPA and BOR are action agencies for the ongoing, reinitiated ESA Section 7 Consultation with NMFS and USFWS for the ongoing O&M of the WVS. These four federal agencies have met routinely with USACE to improve understanding and provide real time feedback on the PEIS and the Preferred Alternative to inform the proposed action. This coordination has occurred at various levels including the technical team level as well as the local and regional leadership levels. Topics from these meetings were also then shared with greater cooperating agency group in monthly meetings, as appropriate and relevant.

## 3.3 Tribal Consultation

USACE is committed to a Government-to-Government relationship with the tribal governments to address issues concerning tribal self-government, trust resources, treaties, and other rights. As a result, USACE has coordinated and collaborated with the tribes during tribal consultation, Section 106 consultation, and cooperating agency process (when a tribe has accepted the role as a cooperator) to gain their perspective on the planning and management activities of water resources, fish and wildlife resources, and other natural resources.

USACE initiated tribal consultation for the NEPA process in 2018. **Table ES-3** is a list of tribes with which USACE has initiated tribal consultation on the WVS PEIS. Tribal consultation is ongoing throughout the WVS EIS process.

**Table ES- 4. Consultation with Federally Recognized Tribes and Tribal Entities for the WVS PEIS**

| **Tribe or Tribal Entity** |
|---|
| Confederated Tribes of Grand Ronde Community of Oregon |
| Confederated Tribes of Warm Springs |
| Confederated Tribes of Siletz Indians |
| Confederated Tribes of Coos |
| Lower Umpqua and Siuslaw Indians |
| Cow Creek Band of Umpqua Indians |
| Columbia River Inter-Tribal Fish Commission |
| Coquille Indian Tribe |
| Klamath Tribes |

| Tribe or Tribal Entity |
| --- |
| Nez Perce Tribe |
| Confederated Tribes of the Umatilla Indian Reservation |
| Yakama Nation of Indians |

## 3.4 Key Issues and Resource Concerns

The NEPA public scoping process for the WVS PEIS resulted in the identification of issues important to stakeholders. The list below summarizes several of the key issues and resource concerns associated with the proposed alternatives.

- ESA comments conveyed concerns on ESA-listed species (particularly to UWR Chinook salmon, UWR steelhead, and bull trout), and effects of dams to anadromous fish migration patterns, water conditions affecting fish passage and fish populations, and general ecosystem effects
- Flood Risk Management comments conveyed concerns on the WVS flood risk, preserving human and economic resources, and balancing needs for flood risk management and fish and wildlife values
- NEPA Process comments conveyed concerns on how the PEIS may affect other ongoing USACE NEPA analyses within the WVS, cumulative effects to natural resources and ecosystems within the WVS, inclusion of information in the PEIS to inform analysis on fish habitats, water allocation and storage, and streamflow.
- Water Storage and Allocation comments conveyed concerns on water storage capacity and allocation, effects on irrigation and municipal water users, and effects from changing water storage on fish and habitat.
- Water Quality comments received conveyed concerns on water contaminants, water temperature, total dissolved gas, and drinking water safety
- Recreation comments conveyed concerns on recreational opportunities, effects to recreation of algal blooms and reservoir levels, recreation employment, recreation opportunities, and recreational effects to ESA-listed species

# 4 DEVELOPMENT AND COMPARISON OF ALTERNATIVES

After scoping and consideration of public input, an interdisciplinary team of USACE experts participated in alternatives development using information and feedback from multiple federal, tribal, and state stakeholders. The team used an iterative process to identify, screen, evaluate, compare, and refine alternatives. The alternatives development process utilized the purpose and need and well as UACE identified constraints and objectives for the Proposed Action as the basis of each alternative and associated suite of measures.

This meaningful engagement with federal, tribal, and state cooperators and the public through scoping has greatly enhanced the development of alternatives and the analysis in the PEIS. Sections 2.1 and 2.2 in the PEIS describe the alternatives development process in detail. **Figure ES-17** is a diagram depicting the iterative and sequential approach used by USACE in formulating alternatives, including a Preferred Alternative.

## 4.1 Purpose and Need

The purpose and need for the proposed action are the continued O&M of the WVS in accordance with authorized project purposes, while meeting ESA obligations to avoid jeopardizing the continued existence of ESA-listed species.

The proposed action is continued operation and maintenance of the WVS for specific, authorized purposes and in compliance with the ESA and all other applicable treaties, laws, and regulations. The last PEIS that evaluated WVS systems and operations was completed in 1980. Over the ensuing four decades following completion of the 1980 PEIS (1980 – 2022), operations have been modified and structural measures for fish passage and temperature control have been implemented to improve conditions for ESA-listed fish species. New information relevant to the environmental effects of operating the WVS has also been acquired, including information related to ESA-listed fish species.

More specifically, the aim of the proposed action and alternatives is to improve salmonid passage over dams and through reservoirs to increase their survival though cost-effective means while still meeting the Congressionally authorized project purposes of the WVS. Fish passage is a limiting factor affecting the prospects of recovery for ESA-listed and other native migratory fish. Improvements to salmonid passage includes both the passage of adults migrating upstream to spawn, and juveniles (smolts) migrating downstream toward the ocean.

## 4.2 Constraints

Constraints based on the purpose of and need for the proposed action and life safety were identified. Potential alternative measures were eliminated from consideration for the following reasons:

- Flood Risk Management: Results of the preliminary modeling were used to screen any measures with potential adverse flood risk effects. Specifically, measures that would result in flood risk management changes from current protection levels were eliminated as an alternative measure.
- Dam Safety: USACE performed a preliminary evaluation of measures for dam safety considerations. Measures that would compromise dam safety and that could not be mitigated were eliminated as an alternative measure. A more detailed dam safety evaluation of components will be conducted during site-specific planning and design.

## 4.3 Objectives

Objectives for the Proposed Action are statements of the desired outcome of the PEIS, as identified by the federal agencies and scoping comments. The resulting seven primary objectives include:

1. Allow greater flexibility in water management (related to refill, drawdown timing, and other water management measures).
2. Increase opportunities for the creation of nature-based structures during maintenance of USACE-owned revetments (structures that help prevent bank erosion).
3. Allow greater flexibility in hydropower production.
4. Increase ESA-listed fish passage survival at WVS dams.
5. Improve water management during the conservation season to benefit anadromous ESA-listed fish and other authorized project purposes.
6. Reduce pollutant levels to restore impaired water quality associated with the WVS dams to benefit anadromous ESA-listed species.
7. Reduce spawning and rearing habitat competition caused by hatchery fish.

The identification of these objectives, along with the PEIS purpose and need, guided the development of a reasonable range of alternatives.

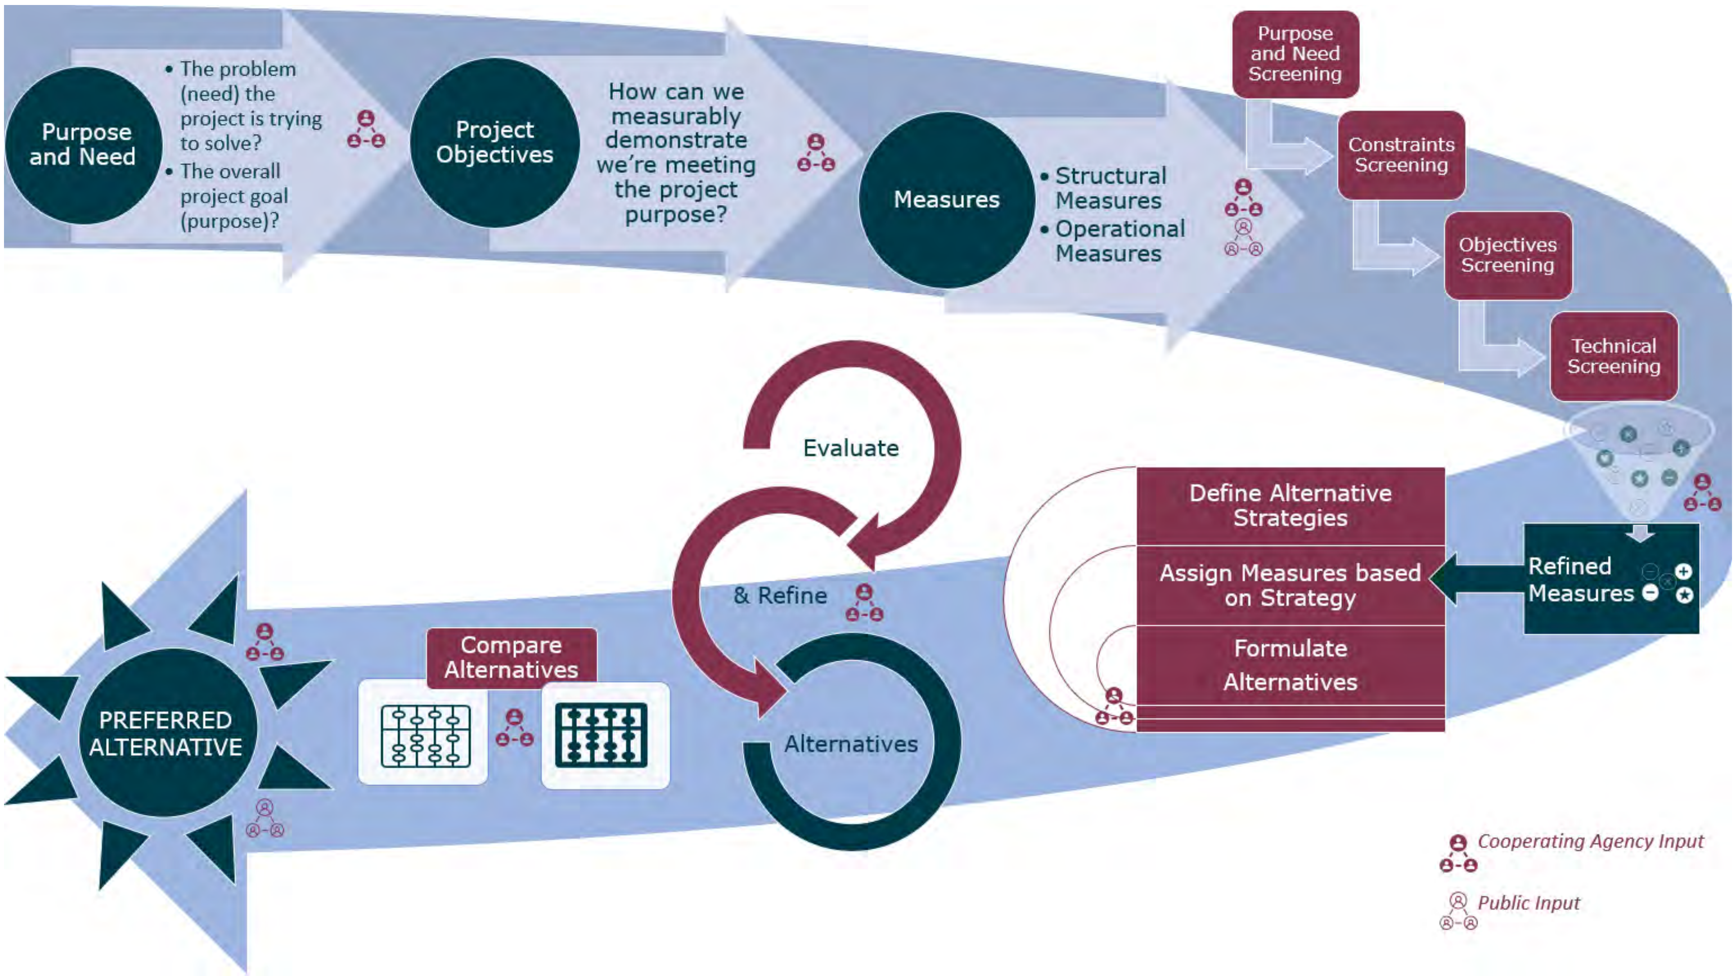

**Figure ES- 13. Diagram of Planning Process Leading to Selection of a Preferred Alternative**

## 4.4 Measures and Alternatives

Using public comments, internal cross-disciplinary working groups, and input from cooperating agencies, the USACE PEIS team identified and compiled a list of operational and structural measures, or actions, that meet seven objectives USACE developed for the Proposed Action. A measure is the action an agency would take to achieve a given objective. It describes either a physical (structural) change requiring construction or an operational change, usually in a precise location, that meets an objective, in whole or in part.

The team screened out potential measures based on criteria for meeting purpose and need for the project, achieving stated objectives, and technical considerations. The team then fashioned alternatives using combinations of the remaining measures around unifying themes or strategies. An alternative is a combination of one or more measures that, together, would address one or more of the objectives.

Building alternatives was an iterative process that increased the level of detail at each step to inform decisions concerning which alternatives to carry forward for analysis and consideration. Following initial modeling and evaluation of preliminary alternatives, new refined alternatives were developed to assess modified combinations of measures, and to distinguish the tradeoffs associated with key measures. Each alternative has an overall strategy that places emphasizes project objectives differently. **Table ES-4** summarizes the alternative strategies and associated project objectives.

After multiple rounds of screening, the measures that demonstrated the best outcomes for meeting project objectives were then compiled and bundled into a hybrid alternative (Alternative 5) that represents a fusion of the other four action alternatives.

**Table ES- 5. Project Alternative Strategies and Associated Objectives**

| Alternative | Strategy | Objectives[1] |
|---|---|---|
| No Action | Current O&M Practices | 1, 5 |
| 1 | Improve Fish Passage Through Storage-Focused Measures: Increase the probability of refilling WVS reservoirs and supplemental water delivery for authorized purposes | 1, 5 |
| 2A & 2B | Integrated Water Management Flexibility and ESA-Listed Fish Alternative | 1, 4, 6 |
| 3A & 3B | Operations Focused: Improve passage of ESA-listed fish through existing structures by modifying water control operations | 1, 4, 5, 6 |
| 4 | Structures Focused: Improve passage of ESA-listed fish by constructing fish passage and temperature control structures | 2, 4, 5, 6, 7 |
| 5 | Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative - Preferred Alternative | 1, 4, 6 |

[1]Proposed Action Objectives

1. Allow greater flexibility in water management (related to refill, drawdown timing, and other water management measures).
2. Increase opportunities for the creation of nature-based structures during maintenance of USACE-owned revetments (structures that help prevent bank erosion).
3. Allow greater flexibility in hydropower production.
4. Increase anadromous ESA-listed fish passage survival at WVS dams.
5. Improve water management during the conservation season to benefit anadromous ESA-listed fish and other authorized project purposes.
6. Reduce pollutant levels to restore impaired water quality associated with the WVS dams to benefit anadromous ESA-listed species.
7. Reduce spawning and rearing habitat competition caused by hatchery fish.

## 4.5 Assessment and Comparison of alternatives

The potential effects associated with each of the alternatives are analyzed under the following resource topics in Chapter 3 and 4 of the PEIS:

- Hydrologic Processes and River Infrastructure
- River Mechanics and Geomorphology
- Geology and Soils
- Water Quality
- Vegetation
- Wetlands
- Fish and Aquatic Habitat (including ESA-listed species and critical habitat)
- Wildlife, Birds, and Terrestrial Habitat (including ESA/sensitive species and critical habitat)
- Air Quality
- Socioeconomics
- Power and Transmission
- Water Supply (Irrigation, Municipal, and Industrial)
- Recreation
- Land Use
- Hazardous Materials
- Public Health and Safety – Hazardous Algal Blooms
- Public Health and Safety – Hazardous, Toxic, and Radioactive Waste
- Public Health and Safety – Drinking Water
- Environmental Justice
- Cultural Resources
- Visual Resources
- Noise
- Tribal Resources

For each of these resource topics and for each alternative, direct and indirect impacts or effects (environmental consequences) in Chapter 3. Direct effects are those caused by an action and occur at the same time and place. Indirect effects are those which occur later in time and/or are further removed in space (physical distance), but which are still reasonably foreseeable; indirect effects also include “induced changes” in the natural and human environments. Cumulative effects on all resources are addressed in Chapter 4. Cumulative effects are the interactive and additive effects on each of the resource topics from each alternative when combined with relevant past, present, and reasonably foreseeable future actions. All effects were assessed according to their magnitude, duration, and/or geographic extent. Effects could be considered either beneficial, adverse, both, or neither.

Programmatic analysis of the resource topics in Chapter 3 is at a broad and macroscopic scale and scope. This analysis of the resource topics focuses on the effects that are relevant at the broad scale and would factor into the decision to select the suite of measures to include in the Preferred Alternative. USACE will conduct subsequent NEPA analyses of future site-specific actions. Additional information on how USACE intends to conduct subsequent site-specific NEPA analysis and environmental compliance is in Chapter 7.

Upon completion of the effects analysis, USACE compared the benefits, environmental consequences, and tradeoffs of each of the alternatives (i.e., no-action and action alternatives). USACE developed multiple criteria to evaluate how effectively each alternative met the PEIS objectives, while considering costs and environmental, economic, and social effects. USACE then performed a tradeoff analysis using these criteria to compare the alternatives. To develop criteria, USACE considered the benefits and environmental and social consequences as reflected in Chapters 3 and 4 of the PEIS and then assessed the tradeoffs presented under each alternative within and outside of current authorities. Descriptions of the criteria, the procedure for comparing PEIS alternatives, and the results of that comparison are discussed in detail in Chapter 5 of the PEIS.

# 5 ALTERNATIVES AND COMPARISON OF EFFECTS

The sections below describe in sequence, the measures common to all alternatives, near term operational measures, and the alternatives and their effects.

## 5.1 Measures common to all Alternatives

Measures common to all action alternatives are those that would be implemented regardless of the action alternative selected because the effects would be consistent across the alternatives and do not provide a basis for differentiating between alternatives or selecting a preferred alternative. Measures common to all action alternatives include both operational measures and structural measures in multiple locations throughout the WVS. They also include new measures, existing operations, and O&M activities that would be carried forward.

As described in Section 2.4.2 of the PEIS, new measures common to all action alternatives include:

- Gravel augmentation in the North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River Dams;
- Adaptation of the Hatchery Program;
- Maintenance of revetments considering nature-based engineering or alter revetments for aquatic ecosystem restoration;
- Maintenance of Existing and New Fish Release Sites above Dams; and
- Adaptive Management and Governance Framework.

As described in Section 2.4.4 of the PEIS, existing operations that would continue under all alternatives include:

- The drawdown at Fall Creek Reservoir for downstream fish passage;
- O&M of existing Adult Fish Facilities; and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation of existing facilities

## 5.2 Near Term Operational Measures

As described in Section 2.2.5 of the PEIS, USACE is evaluating a suite of near-term operations until the structural measures in Alternatives 2A, 2B, 3A, 3B, 4, and 5 supersede or replace a near-term operation at a particular location. When all the structural measures in the selected alternative is implemented, any remaining near-term operations will cease. Where and when the suite of near-term operations is superseded or replaced by measures in Preferred Alternative is provided in the Implementation Plan for demonstrative purposes. It will be updated to reflect the selected action based on public input and the ongoing ESA consultation. The Implementation Plan is summarized in Section 5.4 of the PEIS and described in detail in Appendix N.

## 5.3 No Action Alternative

The No Action Alternative (NAA) is required by NEPA to provide the existing condition or baseline for comparison of environmental effects of the action alternatives. For the WVS, as described in Section 2.4.1 of the PEIS, the NAA consists of the ongoing O&M actions within the WVS at the start of this effort in the spring of 2019 and would have no change from current management direction or level of management intensity. These actions (measures) include water quality operations, flow operations, and downstream and upstream passage operations. For example, water would continue to be discharged through powerhouses to reduce or dilute the total dissolve gas (TDG) generated from use of spillways (**Figure ES-14**) or regulating outlets (ROs); existing adult fish facilities would continue to be operated and maintained (**Figure ES-15**); and returning adult salmonids would continue to be transported past dams and released in stream reaches above WVS reservoirs (**Figure ES-16**). Actions and operations occurring in the WVS would also include those agreed to in previous ESA consultations between USACE and the Services (NMFS and USFWS).

The NAA does not meet the purpose and need of the project because the current operating conditions of the WVS adversely affect ESA-listed fish species, specifically UWR Chinook salmon, UWR steelhead, and bull trout, and the designated critical habitat for these species.

**Figure ES- 14. Spillway and powerhouse at Detroit Dam**

**Figure ES- 15. Minto Adult Fish Facility downstream of Big Cliff Dam**

**Figure ES- 16. Releasing trout into the McKenzie River**

## 5.4 Effects of the NAA

Under the NAA, there would be no to negligible effect on hydrologic processes or flows downstream. However, this means that the NAA would not appreciably allow greater flexibility in water management related to refill, drawdown timing, and other water management measures. Because the WVS would be operated as designed and there would be no new structural modifications that would increase operational complexity, there is a low mechanical and operational risk associated with the NAA.

The estimated total annual cost estimate for the NAA is $9,279 million. The cost of each alternative, including the NAA, was evaluated using the annual costs over the 50-year period of analysis in 2021 dollars. The annual cost includes annualized first costs for design and construction as well as the annual cost for Operations, Maintenance, Repair, Replacement and Rehabilitation.

Under the NAA, power generation for combined WVS projects would continue to be marginally economically viable. The Net Present Value (NPV) for the combined WVS is about $225 million. NVP assesses the long-term economic viability of the hydropower plants (given implementation of the alternative. Reservoir storage would result in enough stored water to meet the Municipal and Industrial (M&I) and irrigation demands in almost all years. Water would be released from the reservoirs to satisfy projected demands of stored water for M&I uses at the 2050 demand level and existing (as of April 2019) irrigation water service contracts. Additionally, the recreational experience at WVS reservoirs would not change compared to baseline or current conditions, there would be no effects to average annual visits or average annual benefits, and no changes to the number of full-time jobs or the regional economic development. Overall, the NAA would perform well for hydropower and recreational interests and have marginal benefits to water storage compared to most of the action alternatives.

The NAA is deficient in meeting the ESA species focused Proposed Action objectives (objectives 4-6). Of the four extant UWR spring Chinook salmon populations (North Santiam, South Santiam, McKenzie, Middle Fork Willamette), two populations would decline and only one population would have high persistence (i.e., have low risk of extinction). In addition, under the NAA the Legacy McKenzie Chinook population would be at risk and there would be major adverse effects to the winter steelhead resulting in a high risk of extinction. The NAA would not result in habitat gains for bull trout and it is the lowest ranked of all alternatives for downstream survival.

USACE must comply with the ESA to continue to operate and maintain the WVS so the NAA cannot be selected as the Preferred Alternative. The primary purpose of the NAA in this PEIS is to serve as a reference case or baseline against which to compare the relative benefits and adverse impacts of the action alternatives.

## 5.5 Alternative 1. Improve Fish Passage Through Storage-Focused Measures

The purpose of Alternative 1, also referred to as the Project Storage Alternative, is to maximize the refill volumes of conservation pools at WVS reservoirs to meet authorized purposes that depend on full reservoirs, including M&I and irrigation water supply, recreation, and water quality, as well as to improve fish passage through the WVS dams to increase the survival of ESA-listed fish species. A detailed description of Alternative 1 is provided in Section 2.4.5 of the PEIS.

Alternative 1 is designed to increase the probability of refilling the WVS reservoirs and to use a greater portion of the total reservoir volume for conservation storage, including the inactive and power pools. There are also changes in regulated hydrology throughout the conservation season because the goal of Alternative 1 is to fill the reservoirs as often as possible and supply water from storage as long as possible late into the conservation season.

The main operational features of Alternative 1 are to reduce minimum flows to congressionally authorized minimum flow requirements as well as to augment instream flows by using the power and inactive pools. Alternative 1 also proposes only structural measures for fish passage and water quality, such as the Floating Screen Structure (FSS) shown in **Figure ES-22**.

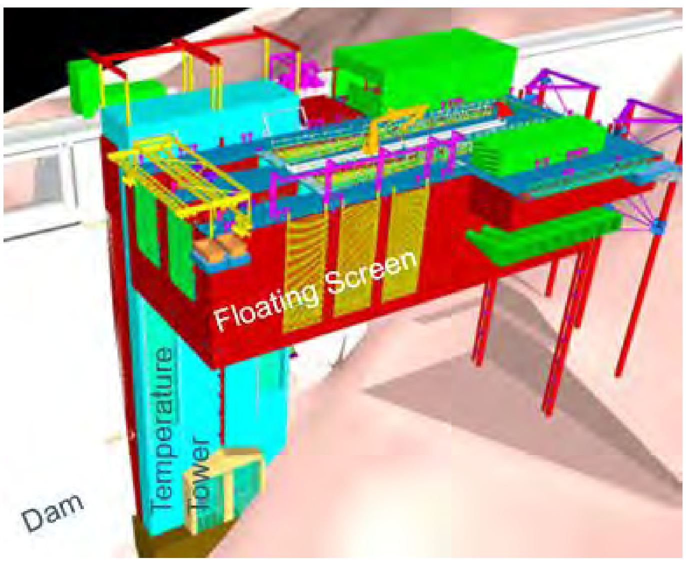

**Figure ES- 22. Schematic of a Floating Screen Structure to facilitate downstream fish passage**

## 5.6 Effects of Alternative 1

Alternative 1 is the second most expensive alternative, exceeded only by Alternative 4. This high cost is primarily driven by the cost to design, construct, operate, and maintain structural measures for temperature control, fish passage, and TDG abatement. The estimated total annual cost for Alternative 1 is $104,396 million, $95 million greater than the NAA

Under Alternative 1, flows would be reduced minimum flows to congressionally authorized minimum flow requirements which would allow for the greatest increase in total storage of all the alternatives. These flow operations replace the 2008 BiOp flows in the NAA. Additionally, many of the structural measures allow for fish passage and temperature management that do not result in lower reservoir elevations in the spring through fall. Thus, there would be a moderate beneficial effect to M&I water supply and irrigation users of the conservation storage space.

The increase in total storage and flow measures would result in the same or higher downstream flows in the summer compared to the NAA. Flow in the mainstem at Salem would be lower than in the NAA from mid-May through June, but flows would still be high and above 6,000 cubic feet per second (cfs). During the summer, flow at Salem would be higher than in the NAA, rarely dipping below 6,000 cfs, resulting in a minor beneficial effect to existing M&I water supply and irrigation users from increased summer flows during the driest years.

The additional storage in combination with water quality and fish passage structures that allow greater operational flexibility under Alternative 1 would contribute to an overall potential increase in average annual hydropower generation of 8 aMW (8 megawatts of power generated continuously over a year, or roughly enough to power 6,371 households annually). However, the high capital and O&M cost of Alternative 1 would result in the second greatest decrease in NPV from that provided by the NAA. Under Alternative 1, there would be a $1.159 billion reduction in NPV to -$934 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. There would, however, be negligible risk to local hydropower generation at Hills Creek and Cougar dams (**Figure ES-23**), which would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages resulting from weather events or fires.

**Figure ES- 23. Hydropower transmission lines leaving Cougar Dam**

Under Alternative 1, the additional storage and reduction in minimum flows would mean the reservoirs stay higher for more of the conservation season resulting in minor to moderate benefits to reservoir recreation. This translates into slight increases in annual WVS reservoir visitations, resulting in an approximate increase of $300,000 in annual economic benefits (a 1.5% increase) compared to the NAA. The regional economic development from recreation effects would be low. The regional economic impacts are associated with the negligible impacts to employment and regional output.

Despite large spending on structural measures, Alternative 1 only marginally meets the ESA-focused Proposed Action objectives (objectives 4-6). Although Alternative 1 did rank highest out of all alternatives for downstream survival and three out of four UWR spring Chinook salmon populations would reach replacement, only two out of four UWR spring Chinook salmon populations would have high persistence (e.g., a low risk of extinction). Additionally, the McKenzie Core Legacy UWR spring Chinook salmon population would remain at risk of extinction. There would also be the least habitat gains for bull trout compared to the NAA due to lack of effective downstream passage at Cougar.

Overall, due to the scale of actions required under Alternative 1, this is the second most expensive alternative. The high cost makes it unlikely this alternative would be acceptable to many stakeholders, agencies, and the public. This is compounded by the fact that Alternative 1 would result in fewer benefits to ESA species than several less costly alternatives, including Alternatives 2A, 2B, and 5. Therefore, Alternative 1 was not identified as the Preferred Alternative.

## 5.7 Alternative 2A. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)

Alternatives 2A, also referred to as the Hybrid Alternative with Cougar FSS, was developed to improve fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and meet ESA-listed fish obligations. A detailed description of Alternative 2A is provided in Section 2.4.6 of the PEIS. In Alternative 2A, the "Integrated Temperature and Habitat Flow Regime" operation replaces the 2008 BiOp flows in the NAA. This would shift the release of stored water from the spring to the summer and fall, most prominently in dry years. Flows would be reduced within a range down to minimums needed for fish survival when reservoirs are under 90% of rule curve elevation. While these minimums are less than the BiOp targets, these are adaptive within a water year and can return to levels that are higher than the BiOp flows if reservoir levels are high. Alternatives 2B, 3A, 3B, and 4 also include this flow measure.

The other main operational feature of Alternative 2A is the augmentation of instream flows by using the power and inactive pools. Alternative 2A also proposes a combination of structural measures for fish passage and temperature control. Alternative 2A does not include the structural improvements for TDG abatement found in Alternatives 1 and 4 or the fish passage and temperature structures at Hills Creek Dam found in Alternative 4. In contrast to Alternative 1 but like all other alternatives, Alternative 2A proposes operational measures utilizing the spillway and ROs for temperature management at Green Peter (**Figure ES-24**). Alternative 2A also includes a deep fall drawdown and spring spillway operations for fish passage at Green Peter, like Alternatives 2B, 3A, 3B, and 5. The only difference between Alternative 2A and 2B is in their downstream passage measure at Cougar Dam. As its name states, Alternative 2A proposes structural downstream fish passage at Cougar Dam where as Alternatives 2B proposes operational fish passage at Cougar Dam that would require significant structural components. Alternative 5 also has this difference as well as proposing a refined flow operation that slightly differs from the "Integrated Temperature and Habitat Flow Regime" operation in Alternatives 2A through 4.

**Figure ES- 24. Green Peter spillways in action on May 20, 2019**

## 5.8 Effects of Alternative 2A

Alternative 2A is the third costliest alternative (surpassed by Alternative 1 and 4) due to the numerous structural measures included. The estimated total annual cost for Alternative 2A is $67,561 million, $58 million greater than the NAA.

Alternative 2A would shift the release of stored water from the spring to the summer and fall, most prominently in dry years. The "Integrated Temperature and Habitat Flow Regime" would replace the 2008 NMFS BiOp in the NAA. Briefly, this would modify the base flow targets at a WVS reservoir if it is at more or less than 90 percent of rule curve elevation. Flows would be reduced within a range down to minimums needed for fish survival when reservoirs are under the 90 percent threshold. While these minimums would be less the BiOp targets in the NAA, these would be adaptive within a water year and could return to levels that are actually higher than the BiOp flows if reservoir levels are high.

This operation is designed to increase access to habitat through providing additional conversation storage to help manage temperatures later in the conservation season. The increase in total storage and flow measures results in the same or higher downstream flows in the summer compared to the NAA. The Integrated Flow Regime would require additional flow through June based on the air temperature, compared to the 2008 BiOp flows proposed under the NAA. Therefore, flows later in the summer and fall would be higher than the NAA due to the additional accumulated stored water. Under Alternative 2A, flow in the mainstem at Salem would be lower than in the NAA from April through June about 25% of the time, but flows would still be high, usually above 10,000 cfs. During the summer, flow at Salem would be higher than in the NAA, rarely dropping below 6,000 cfs. Alternative 2A would have a negligible effect to existing water rights for M&I water supply and irrigation in the spring and would have a minor incidental beneficial effect in the summer by increasing summer flows in the driest years.

The additional storage under Alternative 2A would contribute to an overall increase in average annual hydropower generation by 4 aMW (roughly enough to power 3,185 households annually). However, the high capital and O&M cost of Alternative 2A results in the greatest decrease in NPV from that provided by the NAA. Under Alternative 2A, there would be a $863 million reduction in NPV to -$638 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. However, there would be negligible risk to local hydropower generation, since Hills Creek and Cougar dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages resulting from weather events or fires.

Under Alternative 2A, reservoirs stay higher for more of the conservation season, resulting in minor to moderate benefits to reservoir recreation. This translates into slight increases in annual visitations, resulting in an approximate increase of $169,000 in annual economic benefits (a 0.83% increase) compared to the NAA. The regional economic impact from recreation effects would be medium. The regional economic impacts are associated with the potential loss of 1.7 jobs in the South Santiam Basin due to the drawdown at Green Peter and a moderate reduction in regional output.

Alternative 2A most effectively meets the ESA focused Proposed Action objectives (objectives 4-6) of any alternative. It ranks second for downstream survival with all four UWR Chinook salmon populations reaching replacement, and three out of four UWR Chinook salmon populations with high persistence (e.g., low risk of extinction). Alternative 2A also reduces the risk to the McKenzie Core Legacy population and provides more habitat gains for bull trout compared to the NAA due to the inclusion of effective downstream passage at Cougar.

In contrast to Alternative 2A, Alternatives 2B and 5 result in only two of the three UWR Chinook populations with high persistence. This is the biggest difference in how Alternative 2A performs for the ESA objectives compared to these other two alternatives. Alternative 2A is almost identical to Alternatives 2B and 5. The major difference in measures between Alternative 2A and Alternatives 2B and 5 is the downstream fish passage measure proposed at Cougar Dam. Alternative 2A proposes a FSS and Alternatives 2B and 5 propose a deep drawdown to pass fish through the Diversion Tunnel. The difference in the number of populations with high persistence is because the ESA models assume increases in downstream survival with a structure at Cougar Dam than through a deep drawdown operation.

Although 2A performs the best at meeting the ESA focused Proposed Action objectives (objectives 4-6), USACE deemed Alternatives 2A, 2B, and 5 very comparable in the beneficial impact for ESA listed species. However, Alternative 2A is slightly less certain in meeting ESA focused objectives at Cougar compared to Alternatives 2B and 5. This is due to the uncertainty associated with how well the FSS would collect fish.

Currently, there are few existing FSSs on which to base predictions on how well this type of structure would collect fish at Cougar Dam. Existing evidence highlights the wide variation in performance for these structures, and there is little data available for existing FSS's where Chinook are present upon which to base the Cougar FSS designs. This is in large part because the FSS at Cougar would have to operate at a large range of depths and would be located within a narrow cul-de-sac of the reservoir. No other existing FSSs collect fish at the magnitude of depth ranges that would be required or have the physical site constraints present at Cougar Reservoir. Finally, if collection rates proved to be low with an FSS at Cougar there are minimal post-operation mitigation options for improving collection with currently available technology.

The uncertainty that an FSS would effectively collect juvenile fish migrating downstream at Cougar Dam – coupled with uncertain mitigation options to improve such a structure-compounded with the high cost to design, construct and operate the facility, lead USACE to not select Alternative 2A as the Preferred Alternative.

## 5.9 Alternative 2B. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)

Alternative 2B, also referred to as the Hybrid Alternative with Cougar Diversion Tunnel Modification, was developed to improve fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and meet ESA-listed fish obligations. A detailed description of Alternative 2B is provided in Section 2.4.7 of the PEIS. Alternative 2B is almost exactly like Alternative 2A and 5. The difference between Alternatives 2A and 2B is the fish passage measure at Cougar Dam. Alternative 2A uses a structure that operates with existing reservoir fluctuations to pass fish downstream, whereas Alternative 2B includes an operation where the reservoir is drawn down to use the diversion tunnel to pass fish (**Figures ES-25 and ES-26**). Alternative 5 also differs from Alternative 2B by proposing a refined flow operation that modifies from the "Integrated Temperature and Habitat Flow Regime" operation in Alternatives 2A through 4 based on discussions with cooperators on how the "Integrated Temperature and Habitat Flow Regime" could be improved to better meet the species needs during the lowest low flows.

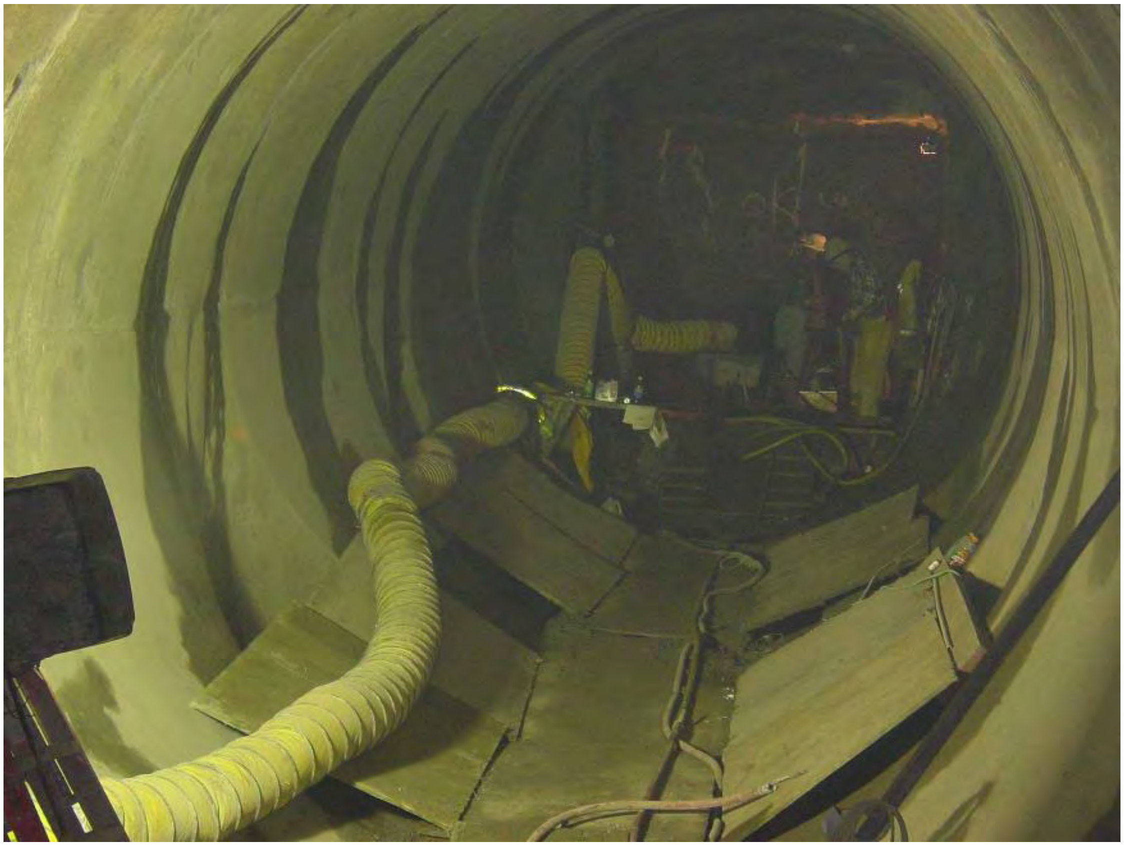

**Figure ES- 25. Working inside the Cougar diversion tunnel**

**Figure ES- 26. Downstream view of Cougar diversion tunnel in action in 2016**

## 5.10 Effects of Alternative 2B

Alternative 2B would be the fourth costliest alternative to implement (surpassed by Alternatives 1, 2A, and 4) due to the incorporation of numerous structural measures. The estimated total annual cost for Alternative 2B is $62,291 million, $53 million greater than the NAA.

Under Alternative 2B, there is an estimated decrease in total system-wide storage of 64,000 acre-feet from the NAA (1,640,000 acre-feet) primarily due to the diversion tunnel fish passage operation at Cougar. The small decrease in system-wide conservation storage would have a minor adverse effect to M&I water supply and irrigation users of the conservation storage.

Under Alternative 2B, flow targets in the summer and fall would be met more frequently due to the additional accumulated stored water at WVS reservoirs other than Cougar and Green Peter. However, compared to NAA, the spring and early summer flows are similar or somewhat lower across the WVS. This is a result of the spring drawdown at Cougar Dam that occurs during the NAA refill period. The reduced storage at Cougar means that other WVS reservoirs, notably in the Middle Fork of the Willamette River subbasin, would be required to release additional water to meet mainstem Willamette River flow targets.

The drawdown of the Cougar Reservoir would effectively eliminate the use of stored water for water supply from Cougar. However, the Blue River Reservoir would fill more than under the NAA, partially offsetting the lost storage from Cougar Reservoir. Cougar Dam is also situated on the South Fork of the McKenzie River, and its flow is a small portion of the overall McKenzie River flow. The flow on the McKenzie River would be only slightly less in the driest years as compared to the NAA due to additional flow from Blue River. Therefore, Alternative 2B would have a negligible effect to live flow water rights in the McKenzie sub-basin. Due to the expected limited level of demand for stored water on the McKenzie River, Alternative 2B would be expected to have only a minor adverse effect to M&I water supply and irrigation users in the McKenzie sub-basin.

The decrease in storage would contribute to an overall decrease in average annual hydropower generation by 18 aMW (roughly enough to power 14,334 households annually). This, coupled with the high cost of Alternative 2B, results in a $933 million reduction in NPV to -$638 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. In addition, the fish passage operation at Cougar Dam would result in infrequent, temporary major adverse effects on transmission services to Blue River. Deep fall and spring drawdowns would compromise Cougar Dam's ability to operate islanded (isolated) and serve this community under temporary weather or fire related outage conditions. Generation at Hills Creek Dam would remain able to operate islanded (isolated), providing transmission services to Oakridge, like the NAA.

Although there would be a negligible adverse effect on recreation across the WVS, the decrease in storage at Cougar Reservoir would result in major adverse effects to reservoir recreation at this location. However, as there are no jobs associated with recreation at Cougar Reservoir, the regional economic effects remain similar to those under Alternative 2A. Alternative 2B results in the smallest increases in annual visitations, resulting in an approximate increase of $12,000 in annual economic benefits (a 0.06% increase) compared to the NAA. The regional economic impact from recreation effects is medium. The regional economic impacts are associated with the potential loss of 1.7 jobs in the South Santiam Basin due to the drawdown at Green Peter and a moderate reduction in regional output.

Alternative 2B effectively meets the ESA focused Proposed Action objectives (objectives 4-6), surpassed only by Alternative 2A. Alternative 2B ranks fourth for downstream survival with all Chinook populations reaching replacement. Alternative 2B also reduces risk to the McKenzie Core Legacy population and provides more habitat gains for bull trout compared to the NAA due to the inclusion of effective downstream passage at Cougar. In contrast to Alternative 2A, Alternative 2B results in only three of the four Chinook populations with high persistence. This is the biggest difference in how Alternative 2B performs for the ESA focused Proposed Action objectives compared to Alternative 2A, a result of the downstream fish passage measure proposed at Cougar Dam. The difference in the number of populations with high persistence is because the ESA models assumes increases in downstream survival with a structure at Cougar Dam than through a deep drawdown operation.

There is some uncertainty due to the major modifications to the existing infrastructure at Cougar that would need to occur to use the diversion tunnel as a regular outlet for the Dam. The diversion tunnel was originally constructed to be used temporarily during dam construction and was not designed to be operated on a regular basis. Without detailed investigation and designs, the dam safety and operational feasibility of drawing down to the diversion tunnel annually for fish passage is uncertain. However, unlike the FSS for which there are currently no known mitigation actions for addressing the fish collection risks, there are clear engineering pathways for managing risk associated with dam safety and operational feasibility of a dam outlet.

In sum, Alternative 2B effectively meets the ESA focused Proposed Action objectives (objectives 4-6) at lower risk and substantially lower costs than Alternative 2A. However, Alternative 2B was not chosen as the Preferred Alternative because conversations with cooperators resulted in refinements to the “Integrated Temperature and Habitat Flow Regime” operation. These refinements are included in Alternative 5, the Preferred Alternative. Alternative 2B is identical to Alternative 5 but for these refinements to the “Integrated Temperature and Habitat Flow Regime” measure.

## 5.11 Alternative 3A. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)

Alternatives 3A, also referred to as the Operations-Focused Fish Passage Alternative, would primarily use WVS dam operations for water quality and fish passage. A detailed description of Alternative 3A is provided in Section 2.4.8 of the PEIS. Alternative 3A does not include structural measures for temperature control, TDG abatement, or downstream fish passage like Alternatives 1 and 4 and much of Alternatives 2A, 2B, and 5. An important part of the operational focus is the increased use of different flow outlets from the dams to control temperature, with the spillway supplying warmer water from the upper reservoir and the deeper outlets – ROs and turbines – supplying cooler water. Alternative 3A would also implement spring and fall drawdowns at some WVS reservoirs for volitional downstream fish passage. Additionally, where Alternative 1, 2A, 2B, 4, and 5 only proposed a new adult fish facility for upstream fish passage at Green Peter Dam, Alternative 3A proposes new adult fish facilities at Hills Creek and Blue River as well.

Alternative 3A is very similar to Alternative 3B, with different combinations of spring drawdowns and spring spill operations across the WVS for downstream fish passage. Alternatives 3A and 3B also differ in the drawdowns for fish passage operations at Cougar Dam. Under Alternative 3A, the spring and fall drawdowns would target the Cougar RO (**Figure ES-27**), whereas the Alternative 3B drawdowns would target the much lower diversion tunnel (like Alternatives 2B and 5). By making these distinctions between Alternatives 3A and 3B, the Draft PEIS allows for the unique impacts associated with each of these operations for downstream passage to be identified at Cougar and the tradeoffs between them to be assessed and compared, which was important to cooperators.

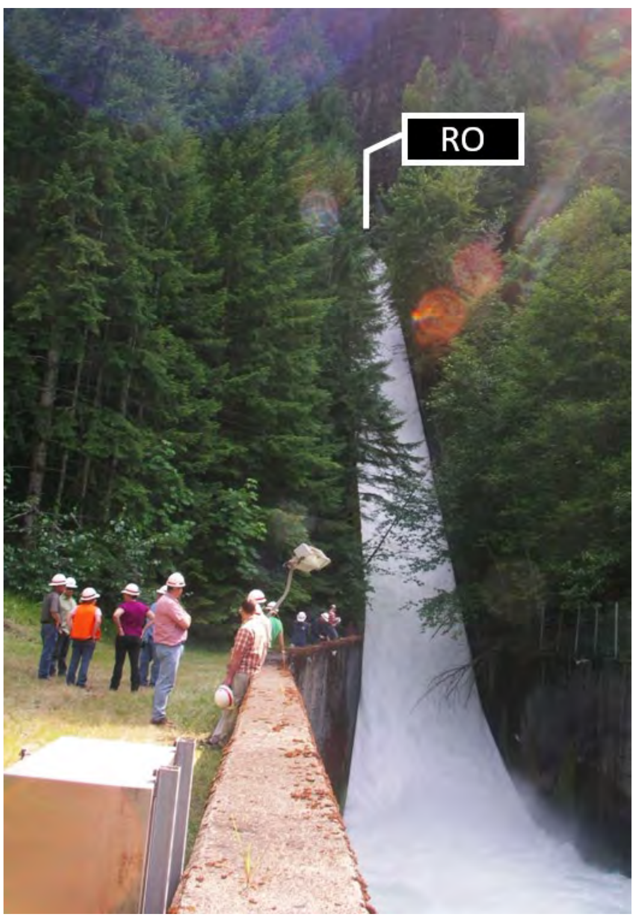

**Figure ES- 27. Cougar regulating outlet and RO channel in action**

Like Alternatives 2A, 2B, 3B, and 4, the "Integrated Temperature and Habitat Flow Regime" operation replaces the 2008 BiOp flows in the NAA under Alternative 3A. Alternative 3A also augments instream flows by using the power and inactive pools and allows reservoirs to draft below the NAA rule curves to meet minimum flow requirements. This usually occurs during the fall of drier years at reservoirs that do not have a fall drawdown operation.

## 5.12 Effects of Alternative 3A

Alternative 3A would be the least costly alternative to implement because it incorporates the fewest structural measures.  Alternative 3A would be approximately $86 million less annually than the costliest alternative, Alternative 4. The estimated total annual cost for Alternative 3A is $26,442 million, $17 million greater than the NAA.

By combining spring spill and drawdowns with fall drawdowns at six of the 11 storage projects, Alternative 3A has major adverse effects to system-wide conservation storage. These operations would result in a 56% reduction of system-wide storage compared to the NAA, or 590,000 acre-feet. Depending on how and when the Fish and Wildlife conservation storage allocation is takes priority over other consumptives uses it would leave very little conservation storage available for M&I water supply or AI. Therefore, Alternative 3A would have a major adverse effect to M&I water supply and irrigation.

In addition, under Alternative 3A, flows during dry years would be lower than in the NAA starting in April, dropping below 5,000 cfs in August. This would likely cause downstream water users in the system to be shut off more due to low flow conditions than under current conditions, resulting in a moderate adverse effect to M&I water supply and irrigation.

The decrease in storage would contribute to an overall decrease in average annual hydropower generation by 87 aMW (roughly enough to power 69,283 households annually). Coupled with the cost of Alternative 3A, there would be a $853 million reduction in median NPV to -$628 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. Additionally, the fish passage operations that reduce the power pool at Hills Creek and Cougar Dams would result in infrequent, temporary major adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to serve these communities under temporary storm or fire related outage conditions.

Alternative 3A is one of two alternatives that results in decreases in annual visitations. This would be a major, long term adverse effect to recreation in the WVS, resulting in an approximate decrease of $769,000 in annual economic benefits (a 3.76% decrease) compared to the NAA. The effects to recreation would also have a high regional economic impact with close to a 50% reduction in recreation-related jobs in the North Santiam and Middle Fork Willamette subbasins and a reduction in regional output greater than $150,000 in multiple basins.

In addition to having adverse effects on hydropower, water supply, and recreation, Alternative 3A does not effectively meet all the ESA focused Proposed Action objectives (objectives 4-6). Although all four UWR Chinook salmon populations would reach replacement under Alternative 3A, only one out of four UWR Chinook salmon populations would have high persistence (e.g., low risk of extinction) which does not improve on the NAA. Additionally, Alternative 3A ranks fifth for downstream survival and the McKenzie Core Legacy population is at risk of extinction. However, there would be habitat gains for bull trout compared to the NAA.

Although one of the least costly alternatives, Alternative 3A performs poorly for the ESA focused Proposed Action objectives (objectives 4-6) while significantly decreasing total storage with adverse effects to hydropower, water supply, and recreation. Additionally, the deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to operate islanded and serve Blue River and Oak Ridge communities under temporary storm or fire related outage conditions. These adverse effects without appreciable benefits to ESA-listed species makes it unlikely this alternative would be acceptable to stakeholders, agencies, and the public. Therefore, Alternative 3A was not identified as the Preferred Alternative.

## 5.13 Alternative 3B. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)

Alternatives 3B, also referred to as the Operations-Focused Fish Passage Alternative using Diversion Tunnel at Cougar, would primarily use WVS dam operations for water quality and fish passage (**Figures ES-28 and ES-29**). A detailed description of Alternative 3B is provided in Section 2.4.9 of the PEIS. Alternative 3B is very similar to Alternative 3A but differ on downstream fish passage operations in the spring and drawdowns for fish passage operations at Cougar Dam. Under Alternative 3B, the spring and fall drawdowns at Cougar Dam would target the diversion tunnel (like Alternatives 2B and 5), resulting in a much lower drawdown than Alternative 3A which proposes drawing down to the RO. By making these distinctions between Alternatives 3A and 3B, the Draft PEIS allows for the unique impacts associated with each of these operations for downstream passage to be identified at Cougar and the tradeoffs between them to be assessed and compared, which was important to cooperators.

## 5.14 Effects of Alternative 3B

Alternative 3B would be the second least costly alternative to implement due to incorporation of few structural measures. Alternative 3A would be the only less costly alternative in comparison. This is because Alternative 3B includes a lower drawdown operation at Cougar Dam that requires additional costs to modify the DT, as discussed under the Alternative 2B tradeoffs which also has a fish passage measure utilizing the DT at Cougar. The estimated total annual cost for Alternative 3B is $30,652 million, $21 million greater than the NAA.

By combining spring spill and drawdowns with fall drawdowns at 6 of the 11 storage projects, Alternative 3B would substantially affect the ability to store water system-wide. These operations would result in a 50% reduction of water stored system-wide compared to the NAA, or 669,000 acre-feet. Depending on how and when the Fish and Wildlife conservation storage allocation is takes priority over other consumptives uses it would leave very little conservation storage available for M&I water supply or AI. Therefore, Alternative 3B would have a major adverse effect to M&I water supply and irrigation.

**Figure ES- 28. Foster Dam spillway in action; operational spillway releases would be used at Foster and five other WVS dams in Alternative 3B**

**Figure ES- 29. Partial drawdown at Hills Creek Reservoir; under Alternative 3B, spring and/or fall drawdowns would occur at Hills Creek and five other WVS reservoirs**

Unlike Alternative 3A, the goal in Alternative 3B is to fill Detroit Reservoir for a spring spill fish passage operation; hence flows at Salem in Alternative 3B would rarely drop below 5,000 cfs in the summer, though they are lower than in the NAA in dry years. Alternative 3B includes a drawdown at Hills Creek instead of Lookout Point, so water flowing through Hills Creek can be stored in Lookout Point, preserving a larger amount of water than in Alternative 3A. However, the reduced flows compared to the NAA may cause some water users in the system to be shut off more than under current conditions, but not as much as in Alternative 3A.

The decrease in storage would contribute to an overall decrease in average annual hydropower generation by 79 aMW (roughly enough to power 62,912 households annually - see Section 3.12.3.2 for details). This, coupled with the cost of Alternative 3B, would result in a $829 million reduction in median NPV to -$604 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. Additionally, the fish passage operations at Hills Creek and Cougar Dams would result in infrequent, temporary major adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to serve these communities under temporary storm or fire related outage conditions.

Alternative 3B results in the largest decreases in annual visitations. This would be a major, long term adverse effect to recreation in the WVB, resulting in an approximate decrease of $1,274,000 in annual economic benefits (a 6.23% decrease) compared to the NAA. The effects to recreation would also have a high regional economic impact with a 50% reduction in recreation related jobs in the South Santiam subbasin and a reduction in regional output greater than $150,000 in multiple basins.

In addition to having adverse effects on hydropower, water supply, and recreation, Alternative 3B does not effectively meet all the ESA focused Proposed Action objectives (objectives 4-6). Under Alternative 3B all four UWR Chinook salmon populations would reach replacement and two out of four UWR Chinook salmon populations would have high persistence (i.e., low risk of extinction). However, Alternative 3B ranks sixth for downstream survival (the lowest ranking of the action alternatives). Additionally, the McKenzie Core Legacy population would be at risk of extinction and there would be no habitat gains for bull trout compared to the NAA.

Although one of the least costly alternatives, Alternative 3B performs poorly for ESA focused Proposed Action objectives (objectives 4-6) while significantly decreasing total storage with adverse effects to hydropower, water supply, and recreation. Additionally, the deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to provide electricity to nearby communities under temporary storm or fire related outage conditions. These adverse effects, without appreciable benefits to ESA-listed species makes it unlikely this alternative would be acceptable to stakeholders, agencies, and the public. Therefore, Alternative 3B was not identified as the Preferred Alternative.

## 5.15 Alternative 4. Improve Fish Passage with Structures-Based Approach

Alternative 4 takes a structures-based approach to improve fish passage through the WVS dams to increase the survival of ESA-listed fish. A detailed description of Alternative 4 is provided in Section 2.4.10 of the PEIS. Like Alternative 1, Alternative 4 proposes only structures for water quality and downstream fish passage, shifting the release of stored water from the spring into the summer and fall and augmenting instream flows by using the power and inactive pools. In contrast to Alternative 1, Alternative 4 proposes the “Integrated Temperature and Habitat Flow Regime” operation, the targets of which are generally higher and more variable than those in the congressionally authorized minimum flow requirements proposed under Alternative 1. As its name and purpose imply, Alternative 4 also proposes the most structural measures for fish passage and water quality of any alternative.

In contrast to Alternative 1, Alternative 4 includes a fish passage structure and water temperature control tower at Hills Creek Dam (**Figure ES-30**) and a fish passage structure at Cougar Dam but replaces the water temperature control tower at Green Peter Dam proposed in Alternative 1 with using operational measures to utilize the spillway and ROs for temperature management. In contrast to Alternative 1, 2A, 2B, and 5, Alternative 4 proposes an upstream passage structure at Hills Creek Dam and not at Green Peter Dam. These are the defining differences for comparison of the relative costs and benefits associated with the different combinations of structural measures.

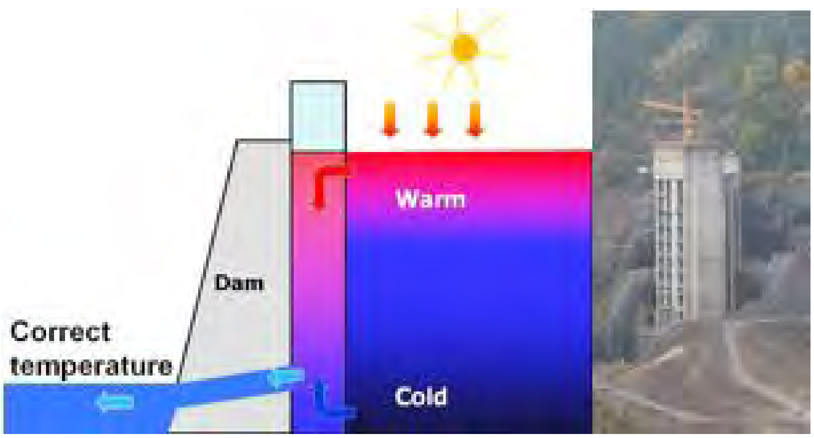

**Figure ES- 30. Schematic of water temperature control tower and actual tower under construction at Cougar Dam; under Alternative 4, water temperature control towers are proposed at 4 dams**

## 5.16 Effects of Alternative 4

Alternative 4 would be the costliest alternative to implement, primarily driven by the cost to design, construct, operate, and maintain the structural measures for temperature control, fish passage, and TDG abatement. Alternative 4 proposes the most structural measures of any alternative. The estimated total annual cost for Alternative 4 is $113,001 million, $104 million greater than the NAA.

Under Alternative 4, like Alterative 2A, there is an estimated increase in total storage of 122,000 acre-feet from the NAA. The combination of lower spring flow targets and no reservoir drawdowns during the conservation season would allow for the increase from the NAA in stored water. The Integrated Flow Regime would require additional flow based on the air temperature, compared to the 2008 BiOp flows implemented under the NAA. Therefore, flows later in the summer and fall would be higher than the NAA due to the additional accumulated stored water.

The additional storage would contribute to an overall slight increase in average annual hydropower generation by 1 aMW (roughly enough to power 796 households annually - see Section 3.12.3.7 for details). However, the high capital and O&M cost of Alternative 4 results in the second greatest decrease in NPV from that provided by the NAA. Under Alternative 4, there would be a $1.162 billion reduction in median NPV to -$937 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. There would also be negligible risk to local hydropower generation as Hills Creek and Cougar Dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages resulting from weather events or fires.

Under Alternative 4, the additional storage would mean the reservoirs stay higher for more of the conservation season, resulting in minor to moderate benefits to reservoir recreation. This translates into slight increases in annual visitations, resulting in an approximate increase of $167,000 in annual economic benefits (a 0.82% increase) compared to the NAA. The regional economic impact from recreation effects is medium. The regional economic impacts are associated with a moderate reduction in regional output and the potential loss of 1.7 jobs in the South Santiam and McKenzie subbasins due to the drawdown at Green Peter and operations at Blue River Dam.

Despite the greatest spending on structural measures for ESA-listed species needs, Alternative 4 does not perform the best for meeting ESA focused Proposed Action objectives (objectives 4-6). Like Alternative 1, although Alternative 4 ranks moderately well for downstream survival (third) and three out of four UWR Chinook salmon populations would reach replacement, only two out of four UWR Chinook salmon populations would have high persistence (i.e., low risk of extinction). In contrast to Alternative 1, Alternative 4 does reduce risk to the McKenzie Core Legacy population and provides more habitat gains for bull trout compared to the NAA due to the inclusion of effective downstream passage at Cougar. Alternative 2A performs better than Alternative 4 for the replacement, persistence, and downstream survival and Alternatives 2B and 5 for the replacement.

Due to the scale of actions required under Alternative 4, this is the most expensive alternative. The high cost makes it unlikely this alternative would be acceptable to many stakeholders, agencies, and the public. In addition, Alternative 4 results in fewer benefits to ESA species than several less costly alternatives, including Alternatives 2A, 2B, and 5. Therefore, Alternative 4 was not identified as the Preferred Alternative.

## 5.17 Alternative 5. Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel) - Preferred Alternative

Alternative 5 was selected as USACE's Preferred Alternative. The Preferred Alternative improves fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and meet ESA-listed fish obligations. A detailed description of Alternative 5 is provided in Section 2.4.11 of the PEIS.

Alternative 5 was developed after the formulation and analysis of all other action alternatives to allow for modeling results to inform formulation of the Preferred Alternative. Following the review of the alternatives' modeling results, Alternative 2B was initially selected as the Preferred Alternative. However, after engaging with cooperators USACE determined that the integrated temperature and habitat flow regime proposed in Alternative 2A should be refined to improve outcomes for ESA species. The Preferred Alternative, Alternative 5, is the same as Alternative 2B except that the integrated temperature and habitat flow regime has been replaced by the refined integrated temperature and habitat flow regime.

The Preferred Alternative contains both structural and operational measures to meet the Purpose and Need Statement and objectives developed for the PEIS Proposed Action as described in alternative 2B. The measures are intended to improve conditions for ESA-listed fish while providing flexibility for USACE to meet water demands for fish and wildlife, water supply, hydropower generation, and recreation in the WRB.

Following completion of ESA consultation with NMFS and USFWS, the Final PEIS will also explain components of the Preferred Alternative that are refined in response to ESA consultation, and responses to comments from the interested parties on the Draft PEIS. The Final PEIS will also revise the effects analysis in relation to refined components.

## 5.18 Effects of Alternative 5

The tradeoffs under Alternative 5 are the same as those discussed under Alternative 2B except that Alternative 5 would have a greater reduction by $6 million in NPV compared to Alternative 2B. In **Table ES-6**, a summary comparison of impacts, they are shown as identical but for the NPV reduction.

Under the refined integrated temperature and habitat flow regime, flows would be subject to change throughout the season based on realized hydrology and annual water management decisions. Additional water may be released from the projects to achieve temperature targets in the mainstem at Salem. These targets and minimum flow thresholds at Detroit/Big Cliff, Lookout Point/Dexter, and Foster would be modified according to the flow targets provided in Appendix A. Associated modeling parameters and results for each alternative that includes this measure are provided in Appendix B.

Like Alternative 2B, Alternative 5 is the fourth costliest alternative (exceeded by Alternatives 1, 2A, and 4) due to the numerous structural measures it includes. The estimated total annual cost for Alternative 2B is $62,291 million, $53 million greater than the NAA.

Under Alternative 5, there is an estimated decrease in total system-wide storage of 64,000 acre-feet from the NAA primarily due to the fish passage operation at Cougar. The small decrease in system-wide conservation storage would have a minor adverse effect to M&I water supply and irrigation users of the conservation storage.

Under Alternative 5, flow targets in the summer and fall would be met more frequently due to the additional accumulated stored water at WVS reservoirs other than Cougar and Green Peter. However, compared to NAA, the spring and early summer flows are similar or somewhat lower across the WVS. This is a result of the spring drawdown at Cougar Dam that occurs during the NAA refill period. Reduced storage at Cougar means that other WVS reservoirs, notably in the Middle Fork of the Willamette River subbasin, would be required to release additional water to meet mainstem Willamette River flow targets.

The drawdown of the Cougar Reservoir would effectively eliminate the use of stored water for water supply from Cougar. However, the Blue River Reservoir would fill more than under the NAA, partially offsetting the lost storage from Cougar Reservoir. Cougar Dam is also situated on the South Fork of the McKenzie River, and its flow is a small portion of the overall McKenzie River flow. The flow on the McKenzie River would be only slightly less in the driest years as compared to the NAA due to additional flow from Blue River. Therefore, Alternative 5 would have a negligible effect to live flow water rights in the McKenzie sub-basin. Due to the expected limited level of demand for stored water on the McKenzie River, Alternative 5, like 2B, would be expected to have only a minor adverse effect to M&I water supply and irrigation users in the McKenzie sub-basin.

The decrease in storage would contribute to an overall decrease in average annual hydropower generation by 18 aMW (roughly enough to power 14,334 households annually). Under Alternative 5, there would be a $939 million reduction in median NPV to -$714 million as compared to the NAA. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. In addition, the fish passage operation at Cougar Dam would result in infrequent, temporary major adverse effects on transmission services to Blue River. Deep fall and spring drawdowns would compromise Cougar Dam's ability to serve this community under temporary weather or fire related outage conditions. Generation at Hills Creek Dam would remain operable providing transmission services to Oakridge in emergency situations, like the NAA.

Alternatives 5 and 2B result in the smallest increases in annual visitations, resulting in an approximate increase of $12,000 in annual economic benefits (a 0.06% increase) compared to the NAA. Although this would be a negligible adverse effect on recreation across the WVS, the decrease in storage at Cougar Reservoir would result in major adverse effects to reservoir recreation at this location. However, as there are no jobs associated with recreation at Cougar Reservoir, the regional economic effects remain similar to those under Alternative 2A. The regional economic impact from recreation effects is medium. The regional economic impacts are associated with the potential loss of 1.7 jobs in the South Santiam Basin due to the drawdown at Green Peter and a moderate reduction in regional output.

Like Alternative 2B, Alternative 5 effectively meets the ESA focused Proposed Action objectives (objectives 4-6), surpassed only by Alternative 2A. Alternatives 5 and 2B rank fourth for downstream survival with all UWR Chinook salmon populations reaching replacement. Alternative 5 also reduces risk to the McKenzie Core Legacy population and provides more habitat gains for bull trout compared to the NAA due to the inclusion of effective downstream passage at Cougar.

In contrast to Alternative 2A, Alternatives 5 and 2B result in only three of the four UWR Chinook salmon populations with high persistence. This is the biggest difference in how Alternatives 5 and 2B perform for the ESA objectives compared to Alternative 2A, a result of the downstream fish passage measure proposed at Cougar Dam. Alternative 2A proposes a FSS and Alternatives 5 and 2B propose a deep drawdown to pass fish through the diversion tunnel. The difference in the number of populations with high persistence is because the ESA models assume increases in downstream survival with a structure at Cougar Dam than through a deep drawdown operation. However, there is higher confidence that the diversion tunnel operation at Cougar will be successful making the likelihood of meeting the PEIS ESA objective more certain to occur thus it was selected.

# 6 SUMMARY COMPARISON OF EFFECTS OF ALTERNATIVES TABLE

Using the evaluation criteria described in Chapter 5 of the PEIS, **Table ES-6** summarizes and compares the most important effects of the action alternatives against the No Action Alternative baseline.

The effects on those resources listed in Section 4.4 of this Executive Summary but not shown in **Table ES-6** are generally of lower magnitude, typically ranging from negligible to minor and sometimes moderate. These effects are discussed in detail in the appropriate resource sections of Chapter 3 of the PEIS.

**Table ES- 6. Alternatives Criteria Comparison to NAA.**

| Criteria | Metric | No Action Alternative | Alt 1 | Alt 2A | Alt 2B | Alt 3A | Alt 3B | Alt 4 | Alt 5 |
|---|---|---|---|---|---|---|---|---|---|
| Effectiveness meeting Objective 1 | Change in Conservation Storage from NAA (acre-feet) | 1,329,000 | +168,000 | +122,000 | -64,000 | -590,000 | -669,000 | +122,000 | -98,536 |
| Effectiveness meeting Objective 1 | Impact to flows compared to NAA. | – | Low | Low | Medium | High | High | Low | Medium |
| Effectiveness meeting Objective 3 | Change in NPV from NAA ($ millions) | $225 | -$1,159 | -$863 | -$933 | -$853 | -$829 | -$1,162 | -$939 |
| Effectiveness meeting Objectives 4-6 | Chinook Populations reaching replacement | 2 of 4 Chinook populations reach replacement. | +1 population | +2 populations | +2 populations | +2 populations | +2 populations | +1 population | +2 populations |
| Effectiveness meeting Objectives 4-6 | Chinook Populations' persistence | 1 of 4 Chinook populations with high persistence. | +1 population | +2 population | +1 population | +0 populations | +1 population | +1 population | +1 population |
| Effectiveness meeting Objectives 4-6 | Legacy Chinook Population risk | Legacy Chinook population is at risk | No change in risk | Risk reduced | Risk reduced | No change in risk | No change in risk | Risk reduced | Risk reduced |

| Criteria | Metric | No Action Alternative | Alt 1 | Alt 2A | Alt 2B | Alt 3A | Alt 3B | Alt 4 | Alt 5 |
|---|---|---|---|---|---|---|---|---|---|
| Effectiveness meeting Objectives 4-6 | Downstream survival relative rank: 1=best, 7=worst | 7 | 1 | 2 | 4 | 5 | 6 | 3 | 4 |
| Effectiveness meeting Objectives 4-6 | Bull trout habitat gains | No habitat gains for bull trout. | Least habitat gains for bull trout. | Habitat gains for bull trout. | Habitat gains for bull trout. | Habitat gains for bull trout. | No habitat gains for bull trout. | Habitat gains for bull trout. | Habitat gains for bull trout. |
| Estimated Total Annual Cost | Millions of US $ | $9 | +$95 | +$58 | +$53 | +$17 | +$21 | +$104 | +$53 |
| Economic impact to recreation | Change in Average Annual NED Recreation Benefits (total for all reservoirs in millions of dollars) from NAA | $20.45 | +$0.31 | +$0.17 | +$0.02 | -$0.76 | -$1.27 | +$0.17 | +$0.02 |
| Acceptability Criteria: Economic | Impact to regional economic development from Recreation Effects | – | Low | Medium | Medium | High | High | Medium | Medium |

[1]Note: No color indicates no, negligible, or minor effects. Blue indicates a positive/beneficial effect, yellow indicates a moderate negative/adverse effect, and orange indicates a high negative/advise effect.

# 7 CONCLUSION

This PEIS for the WVS evaluates both the beneficial and adverse effects on the human environment of various ways of managing the WVS in pursuit of its authorized purposes, while at the same time attempting to enhance fish passage and habitat conditions for Upper Willamette fish species, particularly UWR Chinook salmon, UWR steelhead, and bull trout.

In keeping with established procedures of the NEPA, the WVS PEIS identifies the purpose and need of the proposed action, develops an array of reasonable alternatives, describes the affected environment for each resource assessed, and analyzes direct, indirect, and cumulative effects of pursuing the no action and action alternatives on those resources. The PEIS presents the analysis of the No Action Alternative and the seven action alternatives – 1, 2A, 2B, 3A, 3B, 4, and 5. Each of these alternatives has been evaluated for its merits and deficiencies in the WVS PEIS.

USACE identifies Alternative 5 as its Preferred Alternative. Alternative 5, a composite, was formulated after the other alternatives were evaluated in coordination, consultation, or collaboration with key stakeholders. The Preferred Alternative improves fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and meet ESA-listed fish obligations. At this juncture, USACE believes Alternative 5 is the most effective at achieving the objectives of the WVS PEIS.

# CHAPTER 1 - INTRODUCTION

The Willamette Valley System, referred to as the WVS or “the project”, is a combination of 13 *U.S. Army Corps of Engineers-managed* multipurpose dams, reservoirs, and revetments collectively referred to as “projects” or individually as “a project.” Additionally, the WVS includes U.S. Army Corps of Engineers (USACE) riverbank protection projects, fish passage facilities, adult fish facilities, and hatchery programs in the Willamette River Basin (WRB) in Oregon. These projects, facilities, and programs contain physical and operational “components.”

The various purposes of the WVS were authorized by Congress in the Flood Control Acts (FCA) between 1938 and 1962, the Water Supply Act of 1958, and the Water Resources Development Act of 1986. In these acts Congress designated the purpose for each project, which can include a combination of the following:

- flood control (more commonly referred to today as flood risk management (FRM))
- hydropower
- fish and wildlife
- recreation
- navigation
- irrigation (referred to as agricultural irrigation (AI))
- municipal and industrial (M&I) water supply
- water quality

The Portland District, USACE, operates and maintains the WVS to meet the purposes of the projects as authorized by Congress. The system-wide environmental effects of these ongoing operations and maintenance (O&M) activities were last analyzed in an Environmental Impact Statement (EIS) in 1980. Since that time conditions in the WRB have changed and new information has become available. Biological Opinions (BiOps) have also been issued pursuant to compliance with the Endangered Species Act (ESA) of 1973, as amended, seeking to lessen the effects of the O&M of the WVS on threatened and endangered (T&E) species.

**Table 1.1-1. Summary of Terminology in the PEIS**

| Term | Definition |
|---|---|
| Willamette Valley System (WVS) | The 13 USACE-managed dams, reservoirs, and revetments in the analysis area. |
| Project(s) | The overall project is the WVS. Individual projects are also identified within the WVS. |

| Term | Definition |
|---|---|
| Components | Current or ongoing structural elements of projects, facilities, and programs within the WVS. |
| Actions | Proposed or ongoing measures incorporated under each alternative to meet the purpose and need for the proposed action. Is synonymous with "measures." |
| Measures | Proposed components or actions that would be taken under each alternative to meet the purpose and need for the proposed action. Is synonymous with "actions." |
| Analysis Area | The area of primary study for resources described as the affected environment in Chapter 3.0. The analysis area in this PEIS is the Willamette River Basin (WRB). |

**Chapter Organization**

Chapter 1 is organized as follows:

- **1.1 Regulatory Background** - Describes the history of environmental compliance for operations and maintenance of the WVS and explains the regulatory framework for the WVS draft Programmatic Environmental Impact Statement (PEIS).
- **1.2 Geographic and Temporal Scope** - Identifies the spatial bounds and time frame of the study.
- **1.3 Proposed Action and Purpose and Need** - Defines the NEPA purpose of and need for the proposed action.
- **1.4 Cooperating Agencies** - Identifies cooperating agencies and describes their involvement in preparation of the draft PEIS.
- **1.5 USACE-managed Dams and Reservoirs in the Willamette Valley System** - Describes the setting, components, and operations of the WVS.
- **1.6 USACE Programs in the Willamette River Basin** - Describes the Willamette River Basin Bank Protection Program; the Willamette Hatchery Mitigation Program; adult fish facilities; and research, monitoring, and evaluation activities.
- **1.7 Authorized Purposes** - Details the authorized purposes for the WVS.
- **1.8 System Operation and Annual Operational Planning -** Describes the system operations planning used for meeting several objectives for current operation of the dams and reservoirs.
- **1.9 Ongoing USACE Planning and Environmental reviews in the Region** – Describes ongoing and related projects by the USACE that are planned or ongoing in the region.

## 1.1 REGULATORY BACKGROUND

The most recent NEPA evaluation for O&M of the WVS was an EIS completed in 1980. Since that time, project-specific NEPA evaluations have been conducted, but none for O&M of the system as a whole. Over the years, conditions in the WRB have changed primarily with respect to continued population growth and associated development, new information relevant to effects on threatened and endangered species, and operations have been modified and structural improvements implemented for fish passage and temperature control. These changes combined with the extent of time since the last WVS O&M NEPA evaluation necessitated the preparation of a new EIS.

USACE determined that a programmatic approach to NEPA evaluation would be most appropriate because the WVS is made up of many physical and operational components. Additionally, O&M can be implemented in different ways at different times on different components. The programmatic approach is further described below in Section 1.1.1.1. In addition to NEPA and ESA compliance, consideration of treaties, applicable laws, regulations, and executive orders is also required for this project. A detailed description of these compliances can be found in Chapter 7. For context, NEPA and the ESA are discussed in further detail below.

### 1.1.1 The National Environmental Policy Act

NEPA was established to ensure that the federal government appropriately considers the potential effects on the human environment of major federal actions. USACE is proposing updates to its O&M of the WVS and in doing so must comply with NEPA, the Council on Environmental Quality's NEPA-implementing regulations (40 CFR Part 1500-1508)[1], and the USACE NEPA-implementing regulations (33 CFR Part 230). As a general overview, NEPA requires responsible agencies to do the following:

- Identify the proposed action.
- Identify the purpose of and need for the proposed action.
- Identify all reasonable alternatives to meet that need as well as the alternative of taking no action.
- Identify, evaluate, and compare the effects on the human environment that could arise from each of the alternatives, as well as the No Action Alternative (NAA).
- Publish the above information in an environmental document for review by the public and other agencies.
- Consider public and agency comments before making its decision on the proposed action.

[1] CEQ is in the process of revising NEPA regulations. Because the regulations were not finalized when this PEIS was initiated, USACE noticed the public that the PEIS complies with the 1978 CEQ NEPA implementing regulations as amended. Additionally, the PEIS follows the most current CEQ guidance on use of programmatic NEPA reviews, December 18, 2014.

The proposed action under review in this PEIS and the purpose of and need for the proposed action are discussed in Section 1.3.

#### *1.1.1.1 Programmatic Review under the National Environmental Policy Act*

The NEPA compliance process can be conducted for a specific project or for an entire program as defined by CEQ guidance.

> Programmatic NEPA reviews address the general environmental issues relating to broad decisions, such as those establishing policies, plans, programs, or suite of projects, and can effectively frame the scope of subsequent site- and project-specific Federal actions. A well-crafted programmatic NEPA review provides the basis for decisions to approve such broad or high-level decisions such as identifying geographically bounded areas within which future proposed activities can be taken or identifying broad mitigation and conservation measures that can be applied to subsequent tiered reviews…
>
> One advantage of preparing a programmatic NEPA review for repetitive agency activities is that the programmatic NEPA review can provide a starting point for analyzing direct, indirect, and cumulative impacts. Using programmatic NEPA reviews allows an agency to subsequently tier to this analysis, and analyze narrower, site- or proposal-specific issues. This avoids repetitive broad level analyses in subsequent tiered NEPA reviews and provides a more comprehensive picture of the consequences of multiple proposed actions (CEQ, 2014).

Operation and maintenance of the WVS fits this guidance. The system consists of multiple projects, components, and activities within a shared geography, central Oregon's WRB, and are managed individually and in concert dynamically over time to achieve the authorized purposes of the projects and to avoid jeopardizing ESA-listed species.

The multiple activities being considered are various physical and operational components for continued O&M of the system and various formulations of operational changes, modifications of existing structures, and construction of new structures.

The overall operation and management of the WVS can, therefore, be conceptualized and evaluated as a program in this PEIS. Subsequent, site-specific O&M and ESA-compliance actions can then be tiered under, or incorporate by reference in, the PEIS as they arise.

The PEIS process is the same as other NEPA EIS review processes. As with site-specific NEPA reviews, programmatic reviews analyze potential effects under a range of reasonable alternatives but at the broader scale. The PEIS is made available for public comment. Following consideration of these comments and any new information identified from draft PEIS issuance, the lead agency prepares its decision on the alternative, or combination of alternative components, to implement. This decision is documented in a Record of Decision, or ROD.

Preparation of a PEIS will support efficient future NEPA compliance documentation for individual USACE projects by reducing repetitive analyses. A programmatic approach addresses the general environmental issues relating to broad decisions establishing WVS policies, plans, programs, and suite of projects, and effectively frames the scope of subsequent site- and project-specific USACE actions that can be applied to subsequent tiered reviews.

The WVS PEIS process is further described in Section 7.2.

### 1.1.2 The Endangered Species Act

The ESA of 1973 (16 United States Code [USC] § 1531 et seq.), and its subsequent amendments, was established for the conservation of threatened and endangered species and the habitat they require for survival. The purpose of the law is to both protect and recover imperiled species and the habitats or ecosystems upon which the species depend.

Species that are in danger of extinction may be listed by the National Marine Fisheries Service (NMFS) and/or the United States Fish and Wildlife Service (USFWS) (together referred to as the Services) under the ESA as a threatened or endangered species, thereby providing certain protections to the species. The ESA also authorizes the Services to designate certain areas as "critical habitat" for the survival of a listed species or sub-species (Critical habitat is defined in the ESA in Section 3(5)(A)(B)(C)).

In addition to the above, Section 7(a)(2) of the ESA states that federal agencies shall, in consultation with the Services, ensure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. In fulfilling the requirements of Section 7(a)(2), each agency must use the best scientific and commercial data available.

The Services listed species under the ESA after USACE finalized its 1980 WVS EIS. Bull trout were listed as threatened in 1998, and the Upper Willamette River (UWR) spring Chinook salmon and UWR winter steelhead were listed as threatened in 1999. The Oregon chub was de-listed by the USFWS in 2015, meaning that it no longer falls under the protection of the ESA.

Additionally, several Evolutionarily Significant Units (ESUs) are listed by NMFS for UWR spring Chinook salmon and UWR winter steelhead (NWFSC, 2015). An ESU is a Pacific salmon population or group of populations that is substantially reproductively isolated from other conspecific2 populations and that represents an important component of the evolutionary legacy of the species.

The two listed ESUs present an important aspect of intraspecific biodiversity (i.e., genetic diversity within a given species) and an important component in the evolutionary legacy of the two listed salmonid species within the WRB.

[2] "Conspecific" is defined as belonging to the same species.

USACE, the Bureau of Reclamation (BOR), and the Bonneville Power Administration (BPA), consulted with the Services after these species were listed. Subsequently, NMFS issued the *ESA Section 7(a)(2) Consultation, Biological Opinion (BiOp) and Magnuson-Stevens Fishery Conservation & Management Act Essential Fish Habitat Consultation on the Willamette River Basin Flood Control Project* (2008 NMFS BiOp) on July 11, 2008 (NMFS, 2008).

The 2008 NMFS BiOp evaluated the effect of continued O&M of the WVS on UWR spring Chinook salmon and UWR winter steelhead. NMFS concluded that the action proposed during consultation would not avoid a finding of jeopardy or adverse modification of designated critical habitat for UWR spring Chinook salmon and UWR winter steelhead. The BiOp stipulated a Reasonable and Prudent Alternative (RPA), which was a suite of actions expected to avoid the likelihood of jeopardizing the continued existence of listed species or destroying or adversely modifying designated critical habitat.

USFWS published the BiOp for the *Continued Operation and Maintenance of the Willamette River Basin Project and Effect to Oregon Chub, Bull Trout, and Bull Trout Critical Habitat Designated Under the Endangered Species Act* (2008 USFWS BiOp) in 2008, outlining the effects of the WVS on Oregon chub (delisted in 2015), bull trout, and bull trout critical habitat (USFWS, 2008). USFWS reached a no jeopardy determination in its 2008 BiOp provided USACE, BOR, and BPA implemented the 2008 NMFS BiOp RPA and considered the effects on Oregon chub and bull trout when applying measures covered in the RPA.

Since 2008, USACE has been implementing the RPA provided in the 2008 NMFS BiOp. Over time, this has changed O&M of the WVS sufficiently to necessitate additional analyses under NEPA with a PEIS. USACE has also re-initiated formal consultation under Section 7 of the ESA for the continued O&M of the WVS and to implement operations and construct projects to address fish passage and water quality. This NEPA process will inform the ESA Section 7 consultation process. The WVS ESA compliance status is further described in Section 7.4.

## 1.2 GEOGRAPHIC AND TEMPORAL SCOPE

### 1.2.1 Geographic Scope

The area of analysis, or geographic scope, for assessing the direct, indirect, and cumulative effects of the proposed action is generally the WRB. More specifically, the proposed action takes place within the six sub-basins that contain the WVS and the mainstem Willamette River into which these sub-basins feed.

<u>WVS Sub-basins</u>

Middle Fork Willamette

Coast Fork Willamette

McKenzie River

Long Tom

South Santiam

North Santiam

#### *1.2.1.1 The Willamette River Basin*

The Willamette River is a major tributary of the Columbia River, which is the largest river in the Pacific Northwest and one of the largest in North America. The Willamette River lies entirely within the state of Oregon and is the 13th largest river in the United States (U.S.) by annual flow volume.

A river basin, also referred to as a watershed, is an area of land that that drains to an outlet to another water body. Sub-basins in the watershed are drained by tributaries to the main river. The WRB is approximately 11,500-square-miles and is drained by the Willamette River, which flows north through a fertile valley in western Oregon (USACE, 2019a). The WRB is located entirely within the State of Oregon, beginning south of Cottage Grove and extending approximately 187 miles to the north where it flows into the Columbia River (Figure 1.2-1).

The Willamette River is the 13th largest river in the conterminous U.S. in terms of streamflow and produces more runoff per unit area than any of the 12 larger rivers (EPA, 2013). The WRB averages 75 miles in width and encompasses approximately 12 percent of the total area of the state (USACE, 2019a).

The WRB is bound by three mountain ranges: the Cascade Range to the east, the Coast Range to the west, and the Calapooya Mountains to the south. Maximum elevations exceed 10,000 feet in the Cascade Range, 4,000 feet in the Coast Range, and 6,000 feet in the Calapooya Mountains.

Major Cascade Range tributaries include the Santiam, McKenzie, Middle Fork of the Willamette, Molalla, and Clackamas Rivers. The Willamette River is also fed by major tributaries from the Coast Range, including the Long Tom, Marys, Luckiamute, Yamhill, and Tualatin Rivers. At the south end of the basin, the Coast Fork of the Willamette River emerges from the Calapooya Mountains and joins the mainstem Willamette River near the City of Springfield (USACE, 2019a).

Although there are six sub-basins within the WVS, the WRB encompasses 12 sub-basins, or smaller basins within the larger WRB. These are the Lower Willamette, Tualatin, Molalla-Pudding, Yamhill, Clackamas, South Santiam, North Santiam, Middle Willamette, McKenzie, Coast Fork Willamette, Middle Fork Willamette, and Upper Willamette sub-basins. As discussed above, six of these sub-basins contain dams; these sub-basins encompass the WVS.

The Willamette Valley has been inhabited since recorded time and continues to be the home of members of several tribes. When non-native settlers arrived in the Willamette Valley in the mid-1800s, the valley was broad with a shallow braided channel across a wide floodplain that was flooded annually in winter. As homesteaders developed agricultural and suburban communities in the Willamette Valley they encountered frequent floods, including the devastating 1861 event that flooded the Portland business district for weeks. This led Congress to authorize USACE to construct, operate, and maintain the WVS for flood control purposes with authorizations beginning in 1938.

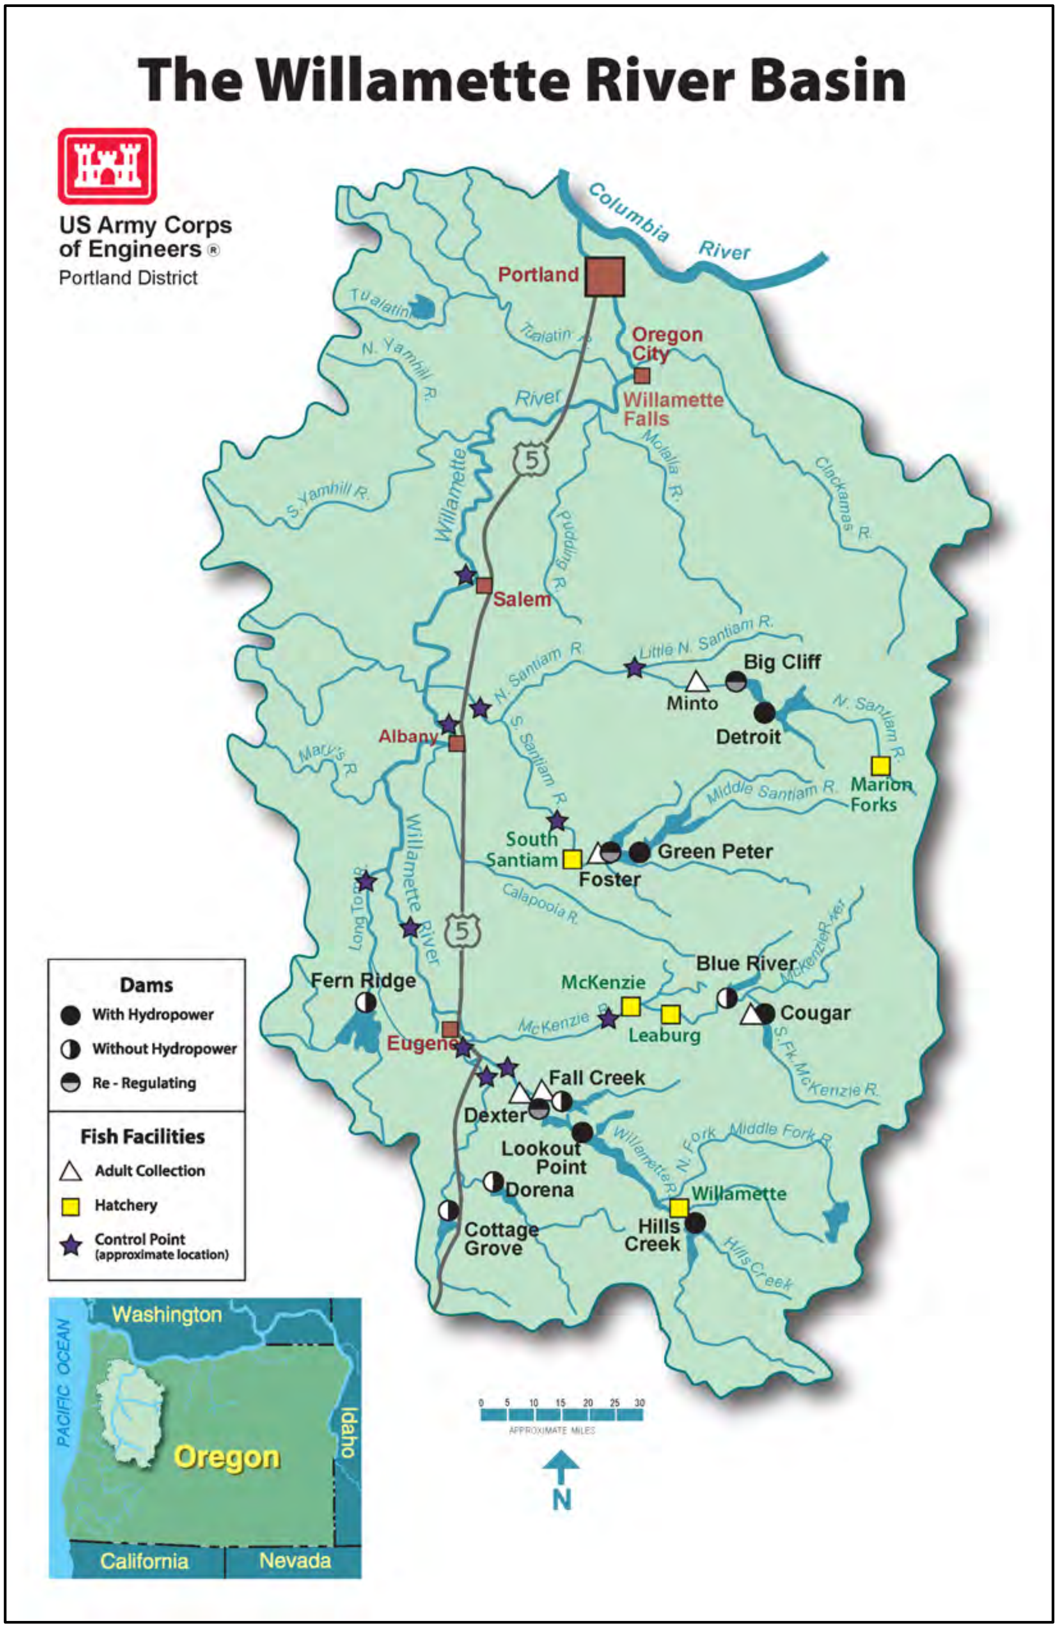

**Figure 1.2-1. USACE-managed Facilities in the Willamette River Basin**

#### *1.2.1.2 Non-USACE-managed Dams and Structures in the Willamette River Basin*

In addition to the 13 USACE-managed dams in the WRB, there are 247 other dams dispersed throughout the WRB managed by other entities (USACE, 2020h). Most of these non-USACE-managed dams are more than 50 years old and are small to medium-sized facilities; there are few large dams and reservoirs in the WRB. Most dams are below 30 feet in height, and only a few reservoirs have water storage capacity that exceeds 1,000 acre-feet. Most have under 500 acre-feet of storage capacity, and many less than 100 acre-feet. More than 90 percent of these 247 dams are earth-fill.

Most of the dams are privately owned; some are owned by municipalities, public utilities, and the USFWS, BOR, or U.S. Forest Service (USFS). Most purposes are for irrigation, recreation, fish- and wildlife-related planning, and to a smaller extent, hydroelectricity, and municipal and industrial water supply.

Of these 247 non-USACE-managed dams in the WRB in its entirety, only 38 dams are in WRB sub-basins containing WVS dams/reservoirs. Additionally, approximately 105 bank protection structures originally built by USACE along WRB riverbanks are at present maintained by local, non-USACE sponsors in the WRB (other structures continue to be maintained by USACE; Section 1.6.1). These structures include riprap revetments, steel pile bulkheads, timber bulkheads, drift barriers, and earthen embankments to "armor" riverbanks and protect them from erosive floodwaters.

Combined with USACE-managed dams and reservoirs, these widely dispersed structures support the growing human population and economic activity in the WRB by providing water (both agricultural irrigation and municipal/industrial supply), generating electricity, and recreational opportunities. However, they also affect the WRB's hydrology and salmon runs by obstructing upstream and downstream migration and altering spawning and rearing habitat.

### 1.2.2 Temporal Scale

The temporal scope of analysis for the PEIS is 30 years from the signing of the Record of Decision (ROD). USACE considered several factors when defining the temporal scale, such as the ability to project data with confidence for the resources that would be affected, the time frame for implementation for the actions considered, and similar NEPA documents published by USACE.

## 1.3 PROPOSED ACTION AND PURPOSE AND NEED

The proposed action is continued operation and maintenance of the WVS for specific, authorized purposes and in compliance with the ESA and all other applicable treaties, laws, and regulations.

The purpose of and need for the proposed action is to ensure USACE manages the WVS for its authorized purposes as required by Congress while also meeting its requirements under the

ESA (Chapter 1.0). Management of the WVS for its authorized purposes necessitates ongoing and future operation of the system and maintenance at any given project that responds to changes in WRB conditions and new information related to system operations and technology, the affected environment, polices, and regulations such as the ESA.

## 1.4 COOPERATING AGENCIES

As the lead agency for this PEIS, USACE invited agencies with jurisdiction by law or special expertise relevant to the WVS and its O&M to be cooperating agencies in compliance with 40 CFR 1501.6. Cooperating agencies listed on the cover page contributed to the PEIS by providing information and input throughout the PEIS planning and document preparation process. Additional information on each agency is provided in Appendix L.

In addition to being cooperating agencies, BPA and BOR are action agencies for the ongoing and upcoming ESA Section 7 consultation with NMFS and USFWS, respectively, for the O&M of the WVS. These four federal agencies have met weekly with USACE to improve understanding and provide real-time feedback on the PEIS in general; this engagement informed the formulation and evaluation of the proposed action and the preferred alternative. Coordination was carried out at the technical team level, local leadership level, and regional leadership level. NEPA related topics were discussed with the greater cooperating agency group in the monthly meetings.

## 1.5 USACE-MANAGED DAMS AND RESERVOIRS IN THE WILLAMETTE RIVER BASIN

Congress authorized USACE to construct, operate, and maintain the WVS for flood control purposes beginning in 1938. Subsequently, USACE constructed 13 dams and extensive bank protection revetments along the Willamette River and its tributaries, creating the WVS by the 1970s. The WVS was originally authorized by the Flood Control Act (FCA) of 1938, including authorization for the following dam construction projects: Fern Ridge on the Long Tom River, Dorena and Cottage Grove in the Coast Fork Willamette sub-basin, Lookout Point on the Middle Fork Willamette River, and Detroit on the North Santiam River.

Subsequent FCAs authorized the following dams: Big Cliff on the North Santiam River, Green Peter on the Middle Santiam River, Foster on the South Santiam, Cougar and Blue River on the McKenzie River, Hills Creek and Dexter on the Middle Fork Willamette River, and Fall Creek on Fall Creek, a tributary to the Middle Fork Willamette River.

The WVS includes 100 miles of revetments along the mainstem and tributaries of the Willamette River. The WVS also includes five fish hatcheries.

All 13 dams are operated for multiple uses (See Section 1.7 for detail on authorized purposes). While the WVS is operated as a whole, each dam and reservoir within the WVS is authorized for a specific set of purposes by Congress. Three are re-regulating dams (i.e., used to even out peak discharges of water utilized for power generation at an upstream dam, thereby controlling downstream river level fluctuations). Eight of the 13 dams are operated as hydropower dams (USACE, 2019b).

The locations of the 13 USACE-managed dams and reservoirs in the WVS are shown in Figure 1.2-1. Dams with or without hydropower are indicated, as well as which dams are re-regulating dams. Adult fish collection facilities, hatcheries, and control points of the dams are also shown.

This system of dams and revetments prevent about $900 million annually in flood damages to the Willamette Valley. Urbanization of the floodplain has continued - partially due to the reduction and management of flooding in the WRB resulting from the WVS. Since the construction of the WVS, the population in the geographic area of this system has continued to grow substantially (USACE, 2019a).

Table 1.5-1 summarizes authorized purposes for each project in the WVS.

Table 1.5-2 identifies the dam length, height, elevation, reservoir length, area when full, number of generators, and total output of generators for each of the 13 projects, organized by sub-basin.

Table 1.5-3 identifies tributaries in the WRB and the river mile (RM) location for their respective confluences with the Willamette River.

Following the summary tables is a brief description of each WVS project, organized by WRB sub-basin. The sub-basins and projects are presented in the approximate order of where their flow enters the Willamette River from upstream to downstream.

**Table 1.5-1. Authorized Purposes by Project in the WVS**

### 1.5.1 Middle Fork Willamette Sub-basin

The Middle Fork Willamette sub-basin is situated at the southern (upstream or headwaters) end of the WRB and has a drainage area of about 1,569 square miles, or 14 percent of the entire WRB (Figure 1.5-1). This sub-basin ranges in elevation from 450 feet at Eugene, Oregon, to 8,790 feet at Diamond Peak. Most of this sub-basin is located within national forests and contains four WVS reservoirs: Hills Creek, Lookout Point, Dexter, and Fall Creek.

#### *1.5.1.1 Hills Creek*

Hills Creek Dam and Reservoir is located on the Middle Fork Willamette River 4 miles southwest of Oakridge, Oregon (Figure 1.5-2). The dam is an earth-fill structure that was completed in 1962 with a gated concrete spillway and outlet works for regulating reservoir levels (USACE, 2020a; USACE, 2015). The reservoir provides 350,000 acre-feet of storage and controls runoff for a 390-square-mile drainage area. The dam has two hydropower generating units capable of producing a total of 36 megawatts (MW). This project is authorized for the purposes of flood control, irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and water supply (USACE, 2020a).

#### *1.5.1.2 Lookout Point*

Lookout Point Dam and Reservoir is located on the Middle Fork Willamette River about 22 miles southeast of Eugene, Oregon (Figure 1.5-3). The dam is an earth and gravel-filled structure with concrete gated spillways (USACE, 2020a). The majority of the construction of Lookout Point Dam, including the powerhouse, was completed in 1953. Lookout Point Reservoir provides 438,200 acre-feet of storage.

All three hydropower generating units at this project were completed by 1955 (USACE, 2015) and have a combined capacity of 146 MW (USACE, 2020a). This project is authorized for the purposes of flood control, irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and water supply.

#### *1.5.1.3 Dexter*

Dexter Dam and Reservoir is located on the Middle Fork of the Willamette River about 22 miles southeast of Eugene, Oregon and 3 miles downstream of Lookout Point Dam . The dam is an earth and gravel-fill embankment structure with concrete gated spillways that regulate power-generating water releases from Lookout Point Dam. The total generation capacity of the hydropower units is 17 MW (USACE, 2020a).

Dexter Dam was completed in 1954 and was authorized for the purposes of hydropower, recreation, and water supply (USACE, 2020a). Dexter Reservoir provides 27,300 acre-feet of storage.

#### *1.5.1.4 Fall Creek*

Fall Creek Dam and Reservoir is located on Fall Creek, a tributary of the Willamette River, about 20 miles southeast of Eugene, Oregon (USACE, 2020a) (Figure 1.5-5). The dam is a rockfill structure with a gated concrete spillway and outlet works for regulating reservoir levels. Fall Creek Reservoir provides 116,000 acre-feet of storage.

Construction of this project was completed in 1965. This project controls runoff from 184 square miles of drainage area and is authorized for the purposes of flood control, irrigation, navigation, fish and wildlife, water quality, recreation, and water supply (USACE, 2020a).

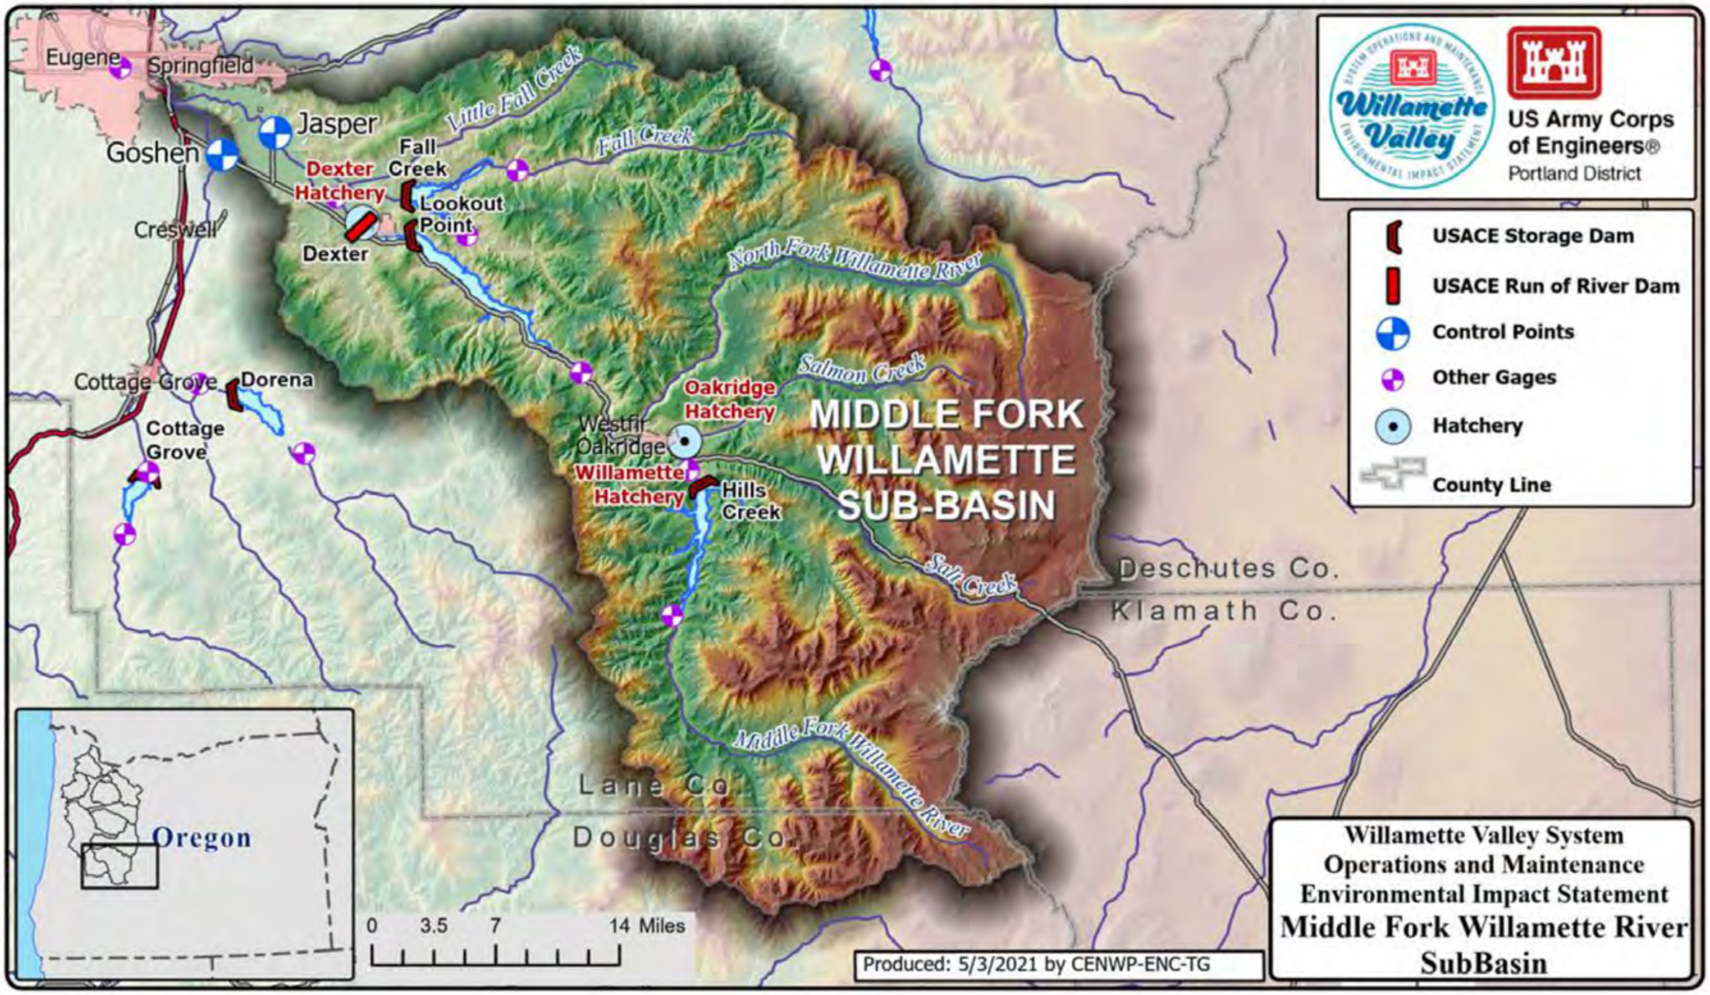

**Figure 1.5-1. Middle Fork Willamette Sub-basin**

**Figure 1.5-2. Hills Creek Dam and Reservoir**

**Figure 1.5-3. Lookout Point Dam and Reservoir**

**Figure 1.5-4. Dexter Dam and Reservoir**

**Figure 1.5-5. Fall Creek Dam and Reservoir**

### 1.5.2 Coast Fork Willamette Sub-basin

The Coast Fork Willamette sub-basin is situated in the southwestern portion of the WRB, directly to the west of the Middle Fork sub-basin described above (Figure 1.5-6). It has a drainage area of approximately 669 square miles, or about 6 percent of the entire WRB.

Elevations in the Coast Fork drainage sub-basin range from about 450 feet at Eugene, Oregon, to 6,000 feet at the headwaters. The drainage headwaters consist largely of steep, rugged, heavily forested mountainous terrain dissected by narrow river valleys. This sub-basin contains two WVS projects: Cottage Grove and Dorena.

#### *1.5.2.1 Cottage Grove*

Cottage Grove Dam and Reservoir sits on the Coast Fork of the Willamette River about 5 miles south of Cottage Grove, Oregon (Figure 1.5-7). The dam is an earth-fill structure with a concrete spillway and controls runoff from 104 square miles of land in the Coast Fork Willamette River watershed. Construction of this project was completed in 1942.

The reservoir provides 31,800 acre-feet of storage. This project is authorized for the purposes of flood control, irrigation, navigation, fish and wildlife, water quality, recreation, and water supply (USACE, 2020a).

#### *1.5.2.2 Dorena*

Dorena Dam and Reservoir is located on the Row River, a tributary of the Willamette River, about six miles east of Cottage Grove, Oregon (Figure 1.5-8). The dam is an earth-fill structure with a concrete spillway and controls runoff from 265 square miles of drainage area. The reservoir provides 72,100 acre-feet of storage. This project was completed in 1949 and is authorized for the purposes of flood control, irrigation, navigation, fish and wildlife, water quality, recreation, and water supply (USACE, 2020a).

Dorena Dam also includes a privately-operated hydropower unit that began operation in 2014 and is licensed by Federal Energy Regulation Commission. The unit consists of two turbines: one high flow and one low flow. Only one of the units is in operation at any given time, meaning that roughly half of the generating capacity is utilized depending on flow conditions.

The hydropower unit is a run-of-the-river plant that utilizes the flows released from the Dorena Lake reservoir. The run-of-the-river designation means that the plant does not control flows, but rather uses the flows dictated by USACE operation of Dorena Dam. Any hydropower production at Dorena Dam is incidental to how USACE operates the dam and does not substantially affect any of the USACE multipurpose missions.

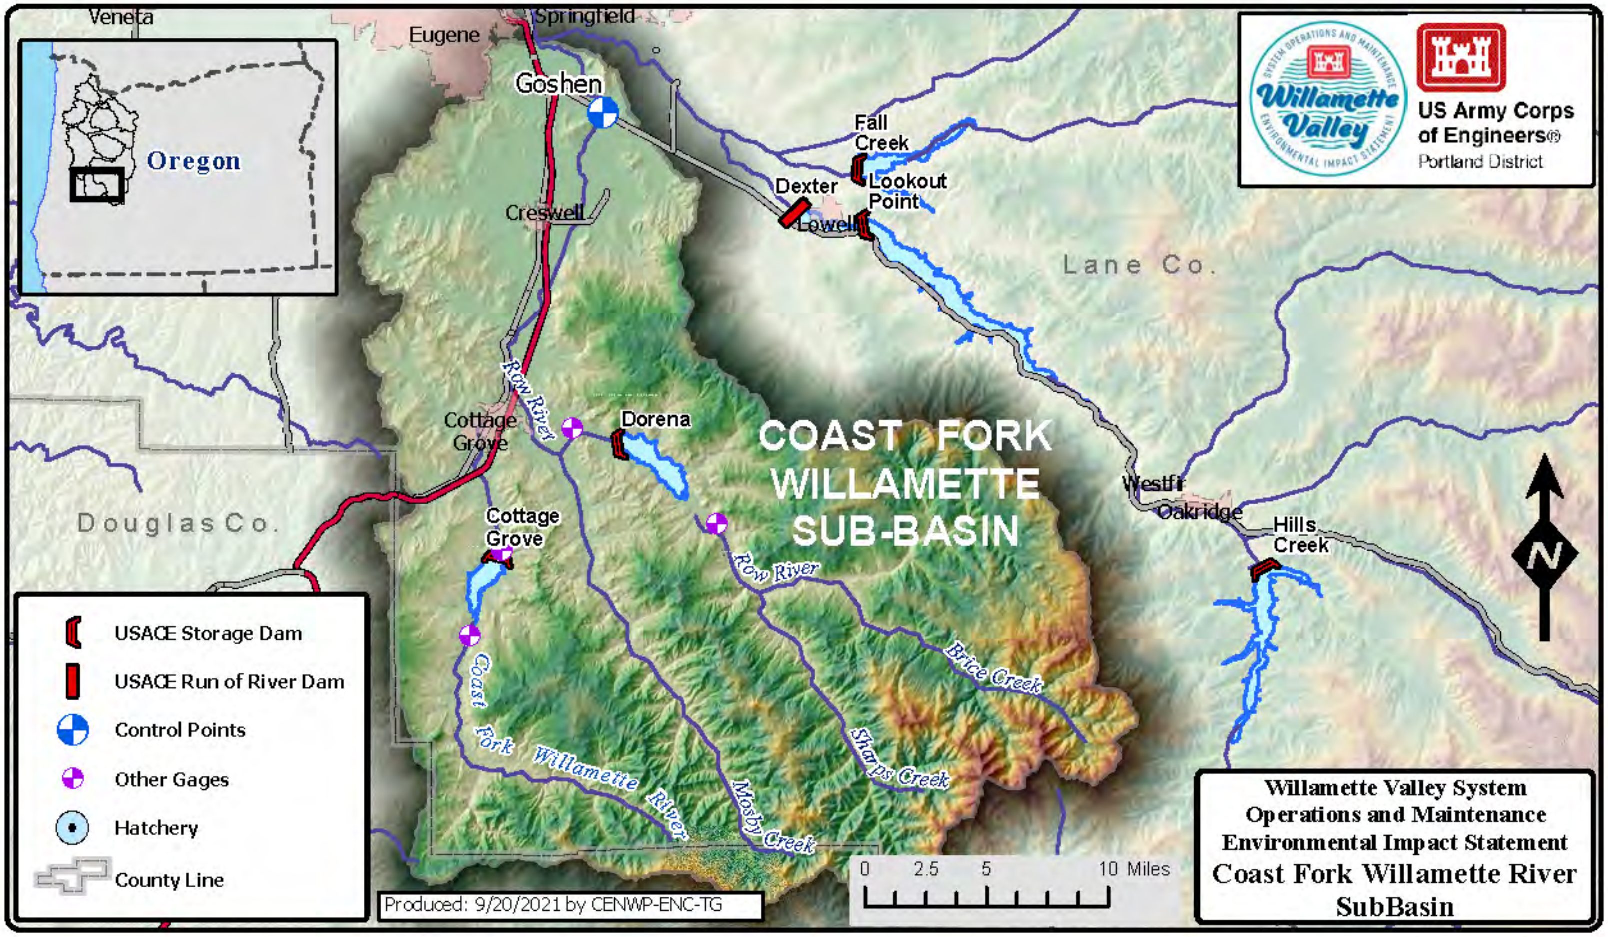

**Figure 1.5-6. Coast Fork Willamette Sub-basin**

**Figure 1.5-7. Cottage Grove Dam and Reservoir**

**Figure 1.5-8. Dorena Dam and Reservoir**

### 1.5.3 McKenzie River Sub-basin

The McKenzie River sub-basin is situated in the southeast portion of the WRB and has a drainage area of approximately 1,300 square miles, or 12 percent of the WRB (Figure 1.5-9). The McKenzie River is about 90 miles long and joins the mainstem Willamette River a few miles north of Eugene, Oregon. Elevations within the sub-basin range from 350 feet to 6,650 feet. Higher elevations in the headwaters of the sub-basin are rugged and heavily forested.

The McKenzie River sub-basin contains two WVS projects: Blue River and Cougar. Two non-federal projects are also located in the McKenzie River sub-basin: Carmen-Smith Hydroelectric Project on the upper McKenzie River and Leaburg-Walterville Hydroelectric Project on the lower McKenzie River.

#### *1.5.3.1 Blue River*

Blue River Dam and Reservoir is located on a tributary of the McKenzie River about 38 miles east of Eugene, Oregon (USACE, 2020a) (Figure 1.5-10). The dam is a rockfill structure with a gated concrete spillway. The reservoir provides 82,800 acre-feet of storage and controls runoff from an 88-square-mile drainage area (USACE, 2020a).

This project was completed in 1969 and is authorized for the purposes of flood control, irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and water supply (USACE, 2020a). It should be noted that while hydropower is one of this project’s authorized purposes, no generators have been constructed or installed at this project.

#### *1.5.3.2 Cougar*

Cougar Dam and Reservoir is located on the South Fork McKenzie River, a Willamette tributary, about 42 miles east of Eugene, Oregon. Cougar Reservoir has a storage capacity of 189,000 acre-feet and controls runoff from an area of 208 square miles (USACE, 2020a). The dam is a rockfill structure with a gated concrete spillway that was completed in 1964.

This project is authorized for the purposes of flood control, irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and water supply. The total capacity of the two hydropower generating units at this project is 30 MW (USACE, 2020a). In 2004, USACE completed construction of a water temperature control (WTC) tower at Cougar Dam, which improved downstream conditions for ESA-listed fish species (Figure 1.5-12).

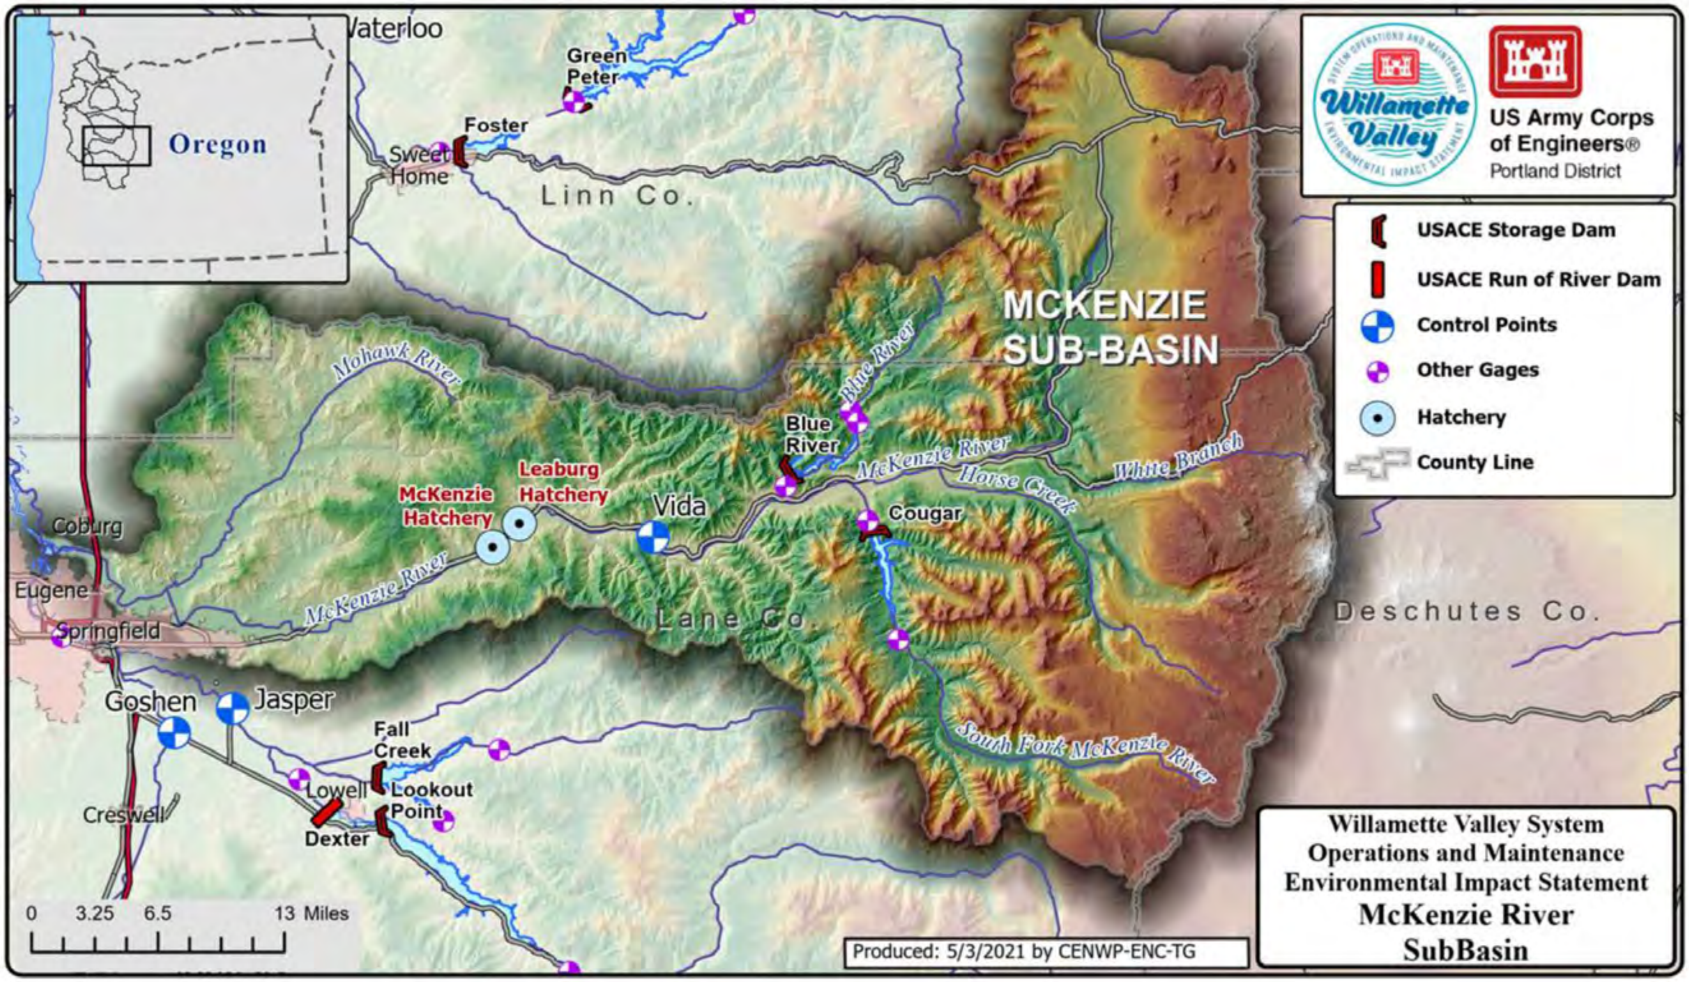

**Figure 1.5-9. McKenzie River Sub-basin**

**Figure 1.5-10. Blue River Dam and Reservoir**

**Figure 1.5-11. Cougar Dam and Reservoir**

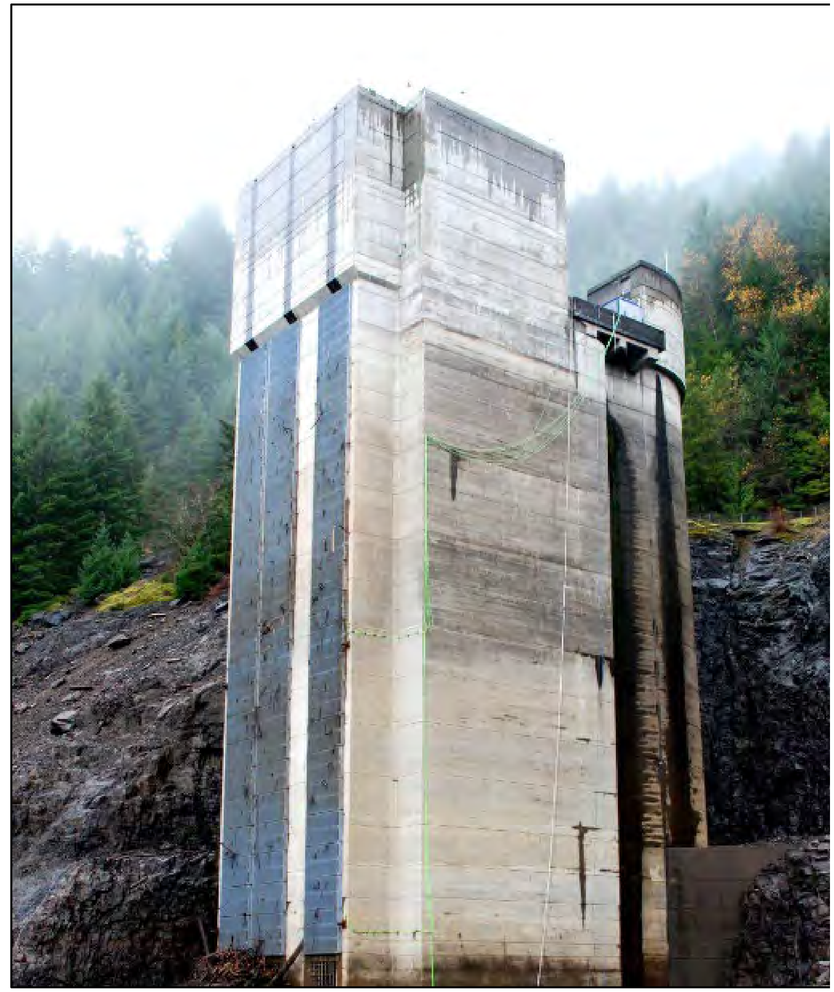

**Figure 1.5-12. Water Temperature Control Tower at Cougar Dam**

### 1.5.4 Long Tom River Sub-basin

The Long Tom River sub-basin is situated in the southwest portion of the WRB, north of the Coast Fork sub-basin. It is relatively low-lying, with a maximum elevation of 2,125 feet (Figure 1.5-13). The Long Tom River sub-basin includes one WVS project: Fern Ridge. Below Fern Ridge Dam, the Long Tom River meanders before joining the mainstem Willamette River north of Monroe, Oregon. The Long Tom River below Fern Ridge Dam is channelized with embankments. The river was shortened from 36.5 miles to 23.6 miles.

A series of seven drop structures were also built with the intent to reduce channel velocity and decrease erosion, while still moving water downstream efficiently. Three of the seven drop structures, one at Monroe (RM 6.7), one at the Stroda property (RM 10.2), and one just upstream of Ferguson Road (RM 12.7), are constructed of concrete and range in height from 7.5 feet-11.5 feet. The remaining four are smaller rock riffle weirs and are located in the uppermost 4 miles of the constructed channel. Operation and maintenance of all seven structures is minimal.

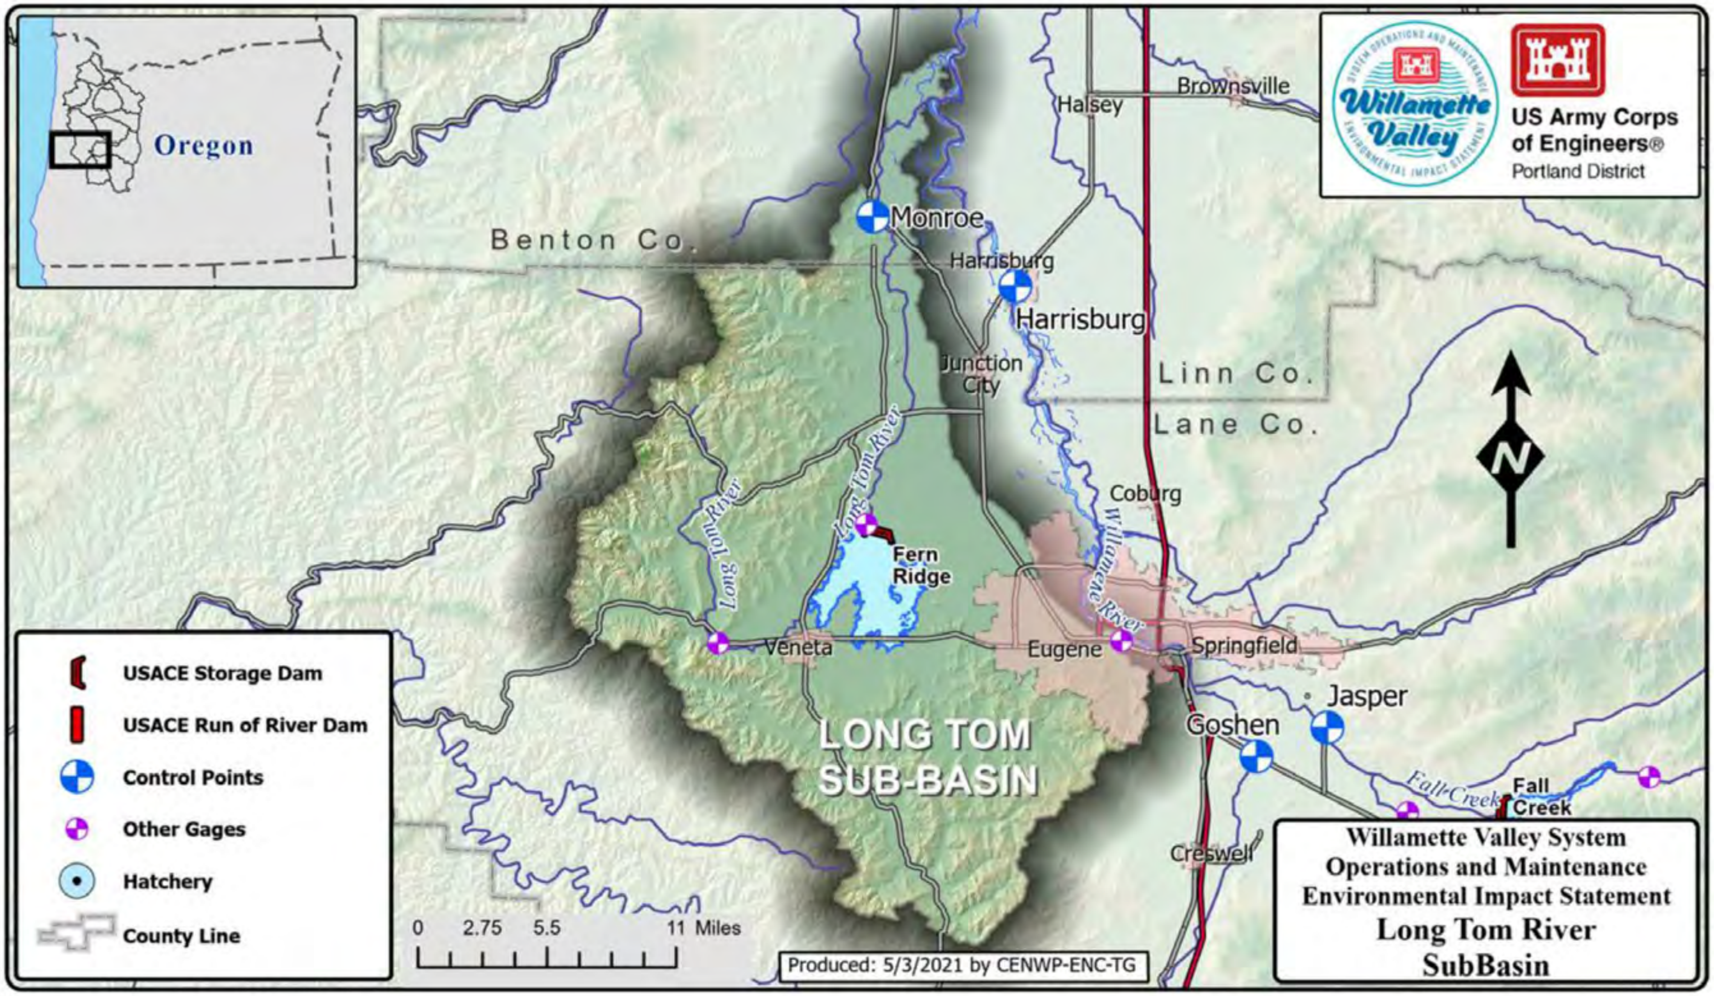

**Figure 1.5-13. Long Tom River Sub-basin**

#### *1.5.4.1 Fern Ridge*

Fern Ridge Dam and Reservoir is on the Long Tom River, a tributary of the Willamette River, about 12 miles west of Eugene, Oregon (Figure 1.5-14); it is the only dam in the WVS west of Interstate 5. Fern Ridge Dam is an earth-fill structure that includes a gated concrete spillway and outlet works for regulating reservoir levels. The dam was completed in 1941 and was the first WVS dam constructed by USACE (USACE, 2020a).

The reservoir provides 97,300 acre-feet of storage and controls runoff from a 275-square-mile drainage area. This project is authorized for the purposes of flood control, irrigation, navigation, fish and wildlife, water quality, recreation, and water supply (USACE, 2020a).

In 1950, a project was completed that altered the lower Long Tom River from the dam to its confluence with the Willamette River. Alterations to the Long Tom River were made to control the subsequent flooding created by the Fern Ridge dam construction, enabling USACE to maintain the FRM mission downstream of the dam.

In 1965 the dam was raised 1.6 feet for additional storage and in 1987 the spillway and outlet works were modified. A Supervisory Control and Data Acquisition system was installed to control the spillway gates in 1992 (USACE, 2015).

In 2005-2006, USACE repaired the failed internal drainage system in the earth-fill embankment, which had caused depressions and seepage on the downstream dam slope. Repair work included excavation of the downstream face of the dam, replacement of the drainage system, and reconstruction of the embankment (DJC, 2005).

**Figure 1.5-14. Fern Ridge Dam and Reservoir**

### 1.5.5 South Santiam River Sub-basin

The Santiam River sub-basin is situated in the east-central part of the WRB and encompasses a drainage area of approximately 1,827 square miles, or about 16 percent of the WRB. This sub-basin includes the North, Middle, and South Santiam Rivers (Figure 1.5-15). The Santiam River sub-basin elevations range between 200 feet and 10,495 feet and average 2,040 feet above mean sea level.

The South Santiam River, roughly 66 miles long, drains an area of approximately 1,040 square miles in geologically older terrain. The Middle Santiam River, a tributary of the South Santiam River, flows through steep, heavily forested mountain terrain, draining an area of 287 square miles.

The Middle and South Santiam rivers meet in Foster Reservoir; from there, the South Santiam flows northwest to near Jefferson where it joins the North Santiam River to form the mainstem Santiam River. The mainstem Santiam River flows for 11.7 miles to its confluence with the Willamette River. There are two WVS projects in the South Santiam sub-basin: Green Peter and Foster.

#### *1.5.5.1 Green Peter*

Green Peter Dam and Reservoir is located on the Middle Santiam River (within the South Santiam River sub-basin), 11 miles northeast of Sweet Home, Oregon (Figure 1.5-16). The dam is a concrete structure with a gated spillway. Construction of this project was completed in 1967 and it is authorized for the purposes of flood control, irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and water supply.

The Green Peter Reservoir provides 409,800 acre-feet of storage. The total output of this project's two hydropower generating units is 98 MW (USACE, 2020a).

#### *1.5.5.2 Foster*

Foster Dam and Reservoir is located on the South Santiam River at the confluence of the South Santiam and Middle Santiam Rivers, approximately 4 miles northeast of Sweet Home, Oregon (Figure 1.5-17). Foster Dam is a rockfill structure with a concrete gated spillway used to regulate power-generating water releases from Green Peter Dam and flows from the South Santiam River (USACE, 2020a).

Construction of this project was completed in 1968. Foster Reservoir provides 55,900 acre-feet of storage. This project is authorized for the purposes of flood control, irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and water supply. The total output of this project's two hydropower generators is 24 MW (USACE, 2020a).

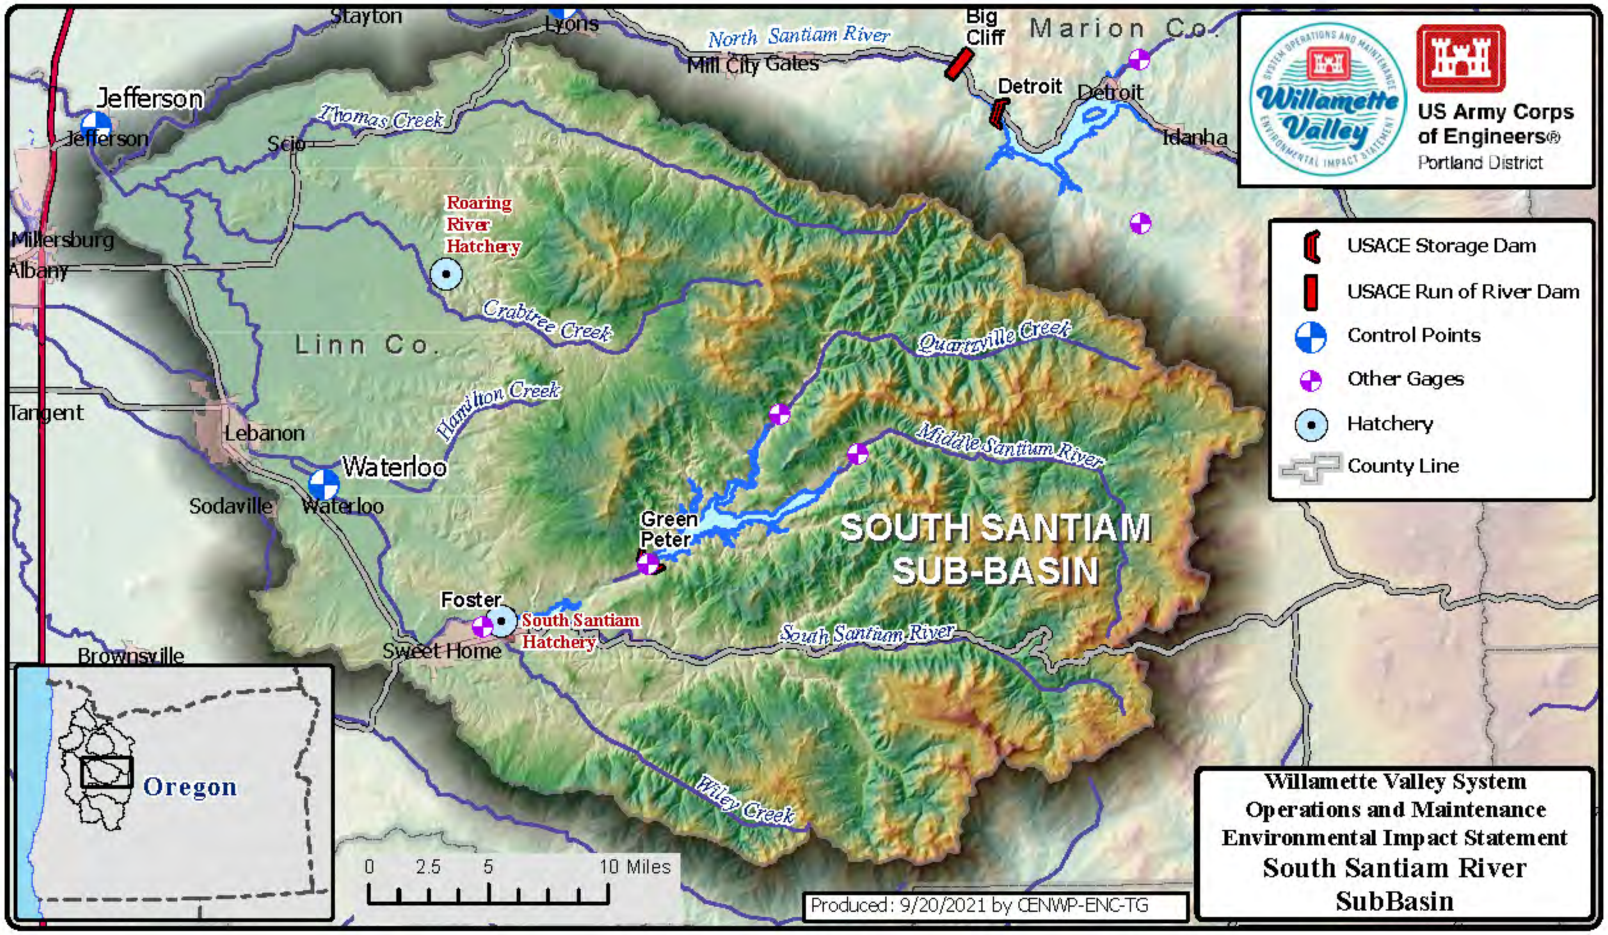

**Figure 1.5-15. South Santiam River Sub-basin**

**Figure 1.5-16. Green Peter Dam and Reservoir**

**Figure 1.5-17. Foster Dam and Reservoir**

### 1.5.6 North Santiam River Sub-basin

The North Santiam River sub-basin is situated in the east-central portion of the WRB and is about 92 miles long (Figure 1.5-18). It drains an area of approximately 655 square miles, or about six percent of the WRB.

The sub-basin contains heavily forested watersheds and high plateaus with scattered volcanic peaks and rugged slopes in the Cascades. The North Santiam sub-basin contains two WVS projects: Detroit and Big Cliff.

#### *1.5.6.1 Detroit*

Detroit Dam and Reservoir is located on the North Santiam River approximately 50 miles southeast of Salem, Oregon (Figure 1.5-19). At full pool elevation (1,569 feet), Detroit Reservoir covers an area of 3,580 acres with 428,800 acre-feet of usable storage at the confluence of the North Santiam and Breitenbush Rivers (USACE, 2019b).

The concrete gravity dam was constructed primarily for FRM (USACE, 2020a), though its authorized purposes also include irrigation, navigation, hydropower, fish and wildlife, water quality, recreation, and water supply.

In 1953 construction was completed, the spillway gates and two generators were installed, and initial power from the first generator was delivered to the Bonneville Power Administration (USACE, 2015). The total output of this project’s two hydropower generators is 127.8 MW (USACE, 2020a).

#### *1.5.6.2 Big Cliff*

Big Cliff Dam and Reservoir is located about 3 miles downstream of the Detroit Dam on the North Santiam River, about 45 miles southeast of Salem, Oregon (Figure 1.5-20). Big Cliff Dam is a re-regulating, concrete structure with gated spillways. Big Cliff Reservoir is a small reservoir that provides 6,430 acre-feet of storage. It is used to even out peak discharges of water utilized for power generation at Detroit Dam, thereby controlling downstream river level fluctuations (USACE, 2019b).

This project was completed in 1954 and is authorized for the purposes of hydropower, recreation, and water supply. The total output of this project’s single generator is 23 MW (USACE, 2020a).

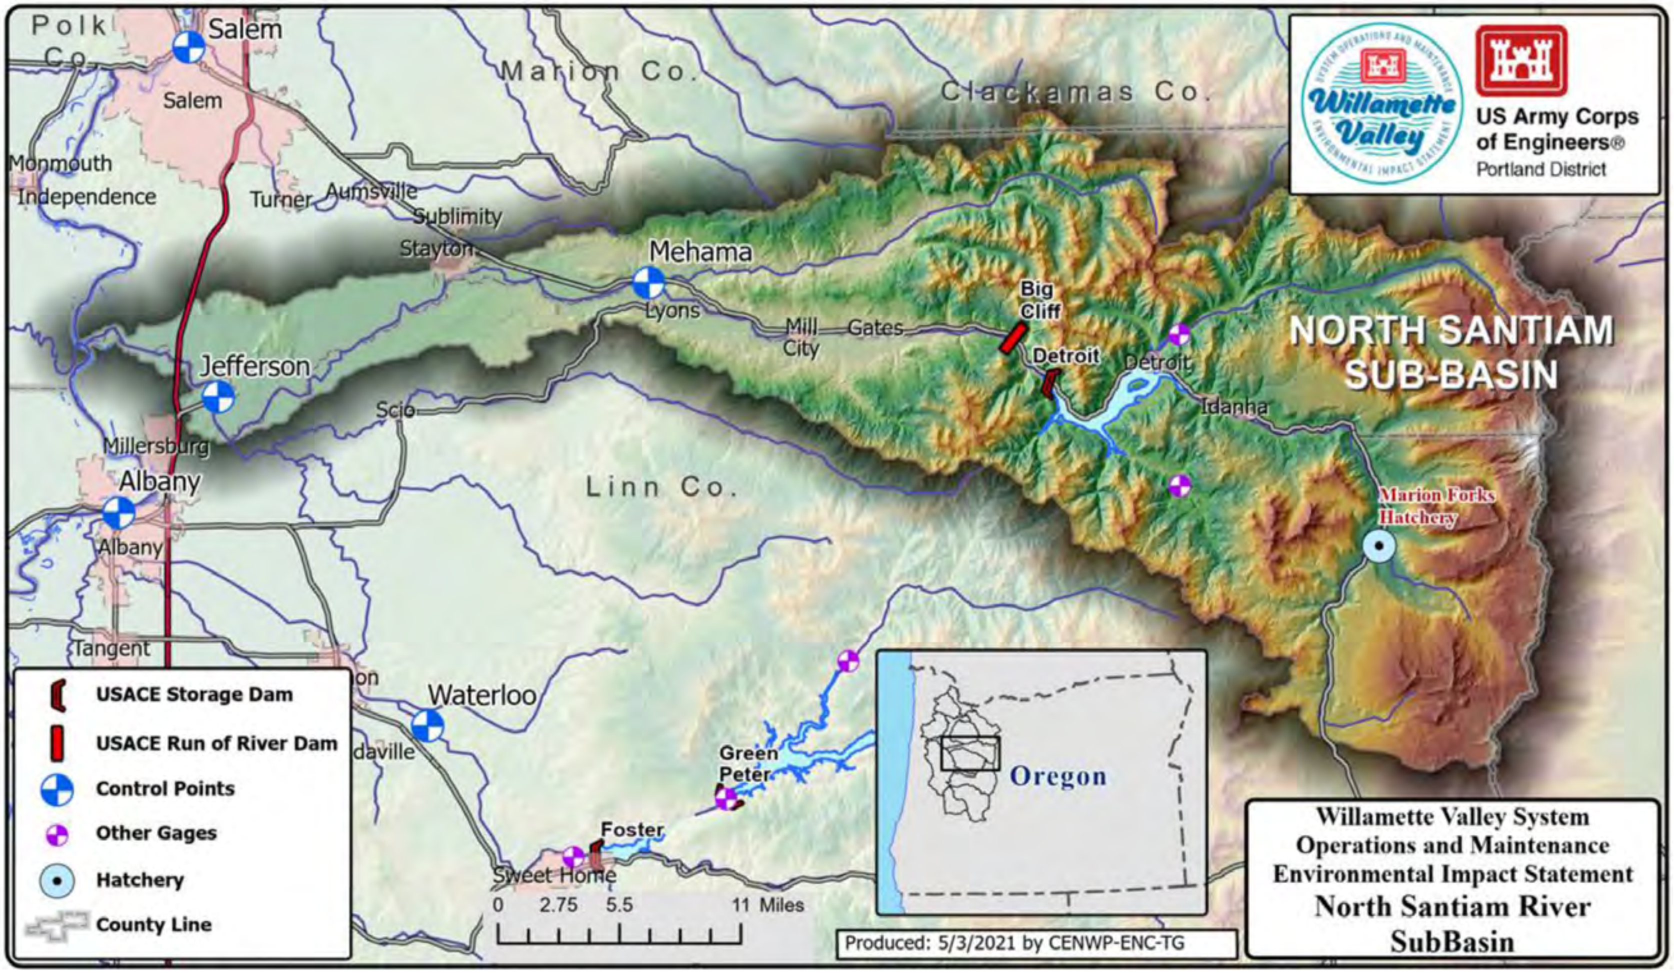

**Figure 1.5-18. North Santiam River Sub-basin**

**Figure 1.5-19. Detroit Dam and Reservoir**

**Figure 1.5-20. Big Cliff Dam and Reservoir**

## 1.6 USACE PROGRAMS IN THE WILLAMETTE RIVER BASIN

In addition to operations of the dams and reservoirs throughout the WVS, USACE manages several ongoing programs in the WRB. These include the Willamette River Basin Bank Protection Program (WRBBPP), the Willamette Hatchery Mitigation Program; Adult Fish Collection facilities; and the Research, Monitoring, and Evaluation (RM&E) program.

### 1.6.1 Willamette River Basin Bank Protection Program

USACE is responsible for the WRBBPP, originally authorized by the 1936 FCA. Authorization of the WRBBPP allowed USACE to construct and maintain 450,000 linear feet of bank protection works. In 1971, the Senate and House Committees on Public Works expanded the program's scope to 510,000 linear feet (USFWS, 2008). The program uses bank protection structures (e.g., riprap revetments, steel pile bulkheads, timber bulkheads, drift barriers, and earthen embankments) to prevent bank erosion (USACE, 2000).

The Water Resources Development Act (WRDA) of 1950 required local sponsorship for any new bank protection projects and transferred responsibility for maintenance of revetments constructed after 1950 from USACE to the local sponsor (USFWS, 2008).

USACE was responsible for the construction of 223 flood control structures in the WRB. Of these structures 193 structures are still active; 88 of these are maintained by USACE; 105 structures are maintained by their local sponsor (USACE, 2000).

A hydraulic, hydrologic, and geomorphic investigation of consequence was conducted in 2013 for 60 USACE-maintained revetment projects in the WRB. The remaining 28 USACE-maintained revetments were excluded from the study because they were either destroyed or located substantially off the main channel and are no longer serving their intended purpose. Though requested, a lack of funding over the past decades has prevented significant maintenance, repair, or replacement of the structures under USACE's control.

### 1.6.2 Willamette Hatchery Mitigation Program

Construction of the dams adversely impacted UWR spring Chinook salmon, UWR winter steelhead, resident trout, including the ESA-listed bull trout, and Pacific lamprey by physically blocking their migrations to and from habitat upstream of the dams and by inundating some habitat through the creation of reservoirs. In addition, construction of the dams and reservoirs submerged existing hatcheries on the Middle Fork Willamette, North Santiam, and South Santiam Rivers and required the relocation of existing hatchery brood egg-collection stations on the Middle Fork Willamette, McKenzie, North Santiam, and South Santiam Rivers.

The WVS was authorized with the full recognition that it would cut off extensive areas of upstream habitat for migratory salmon and steelhead (House Document 81-531, App. J, 1732 (1950)) (HD531). To mitigate for the loss of migratory corridors and inundation of habitat and existing hatcheries, Congress also authorized USACE to carry out the Willamette Hatchery

Mitigation Program to produce and release hatchery salmon, steelhead, and resident trout in the WRB.

HD531 also acknowledged that the projects could adversely impact anadromous fishes because they created physical barriers to migration and habitat loss associated with controlled inundation for the reservoirs. Consequently, HD531 provided for production mitigation to offset fish losses due to construction and operation of Willamette Valley projects.

Congress did not define detailed goals for the fish mitigation program (e.g., the level of fish production to be achieved), allowing USACE to determine how to implement the program within the WRB, whether through hatchery programs, passage improvements, or a combination of those measures. Although some of the dams built in the 1960s included fish passage features, including Foster, Green Peter, Fall Creek and Cougar dams, these facilities were unsuccessful (Schwartz and McCroskey, 2021). USACE also developed hatchery programs to mitigate for adverse impacts to fish passage.

USACE funds the operation and maintenance of five hatcheries for mitigation and conservation within the WVS (Figure 1.6-2). The USACE hatchery program is conducted in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins. The hatchery programs within these sub-basins include UWR spring Chinook salmon, UWR summer steelhead, and rainbow trout. These five hatcheries contribute to the UWR Chinook salmon Evolutionarily Significant Unit[3] (ESU). UWR summer steelhead and rainbow trout are produced exclusively for sport harvest interests. The purpose of the conservation hatchery program is to supplement the natural origin population and support reintroduction of spring UWR Chinook salmon in the WVS due to very low abundances, high extinction risks, and lack of fish passage at some WVS projects.

Recently completed Hatchery Genetic Management Plans (HGMPs), prepared jointly by ODFW and USACE for compliance with the ESA, provide the most up-to-date definition of hatchery fish production commitments for the USACE Willamette Hatchery Mitigation Program (NMFS, 2019)[4]. Hatchery performance goals are driven by standards and performance targets identified in the HGMPs for the North Santiam, South Santiam, McKenzie, and Middle Fork WRB. A brief description of the five hatcheries in these four sub-basins is provided below (Figure 1.6-2).

---

[3] Under the Endangered Species Act, an evolutionarily significant unit—or ESU— is a Pacific salmon population or group of populations that is substantially reproductively isolated from other conspecific populations and that represents an important component of the evolutionary legacy of the species.

[4] "HGMPs are technical documents that thoroughly describe the composition and operation of each individual hatchery program. The primary goal of an HGMP is to describe biologically-based artificial propagation management strategies that ensure the conservation and recovery of ESA-listed salmon and steelhead populations. [NMFS], who oversees the ESA for salmon and steelhead, uses the information provided by HGMPs to evaluate impacts on salmon and steelhead listed under the Endangered Species Act. Completed HGMPs may also be used for regional fish production and management planning by federal, state, and tribal resource managers" (https://wdfw.wa.gov/fishing/management/hatcheries/hgmp).

The McKenzie Hatchery was originally an Oregon state hatchery but was expanded by USACE to mitigate the effects of USACE dams on UWR Chinook salmon within the McKenzie River Sub-basin. Leaburg Hatchery was built on the McKenzie River to mitigate for lost fishing opportunities caused by construction of the dams on Willamette Basin rivers. The Leaburg Hatchery rears summer steelhead and Chinook salmon. The ODFW maintains and operates the hatcheries with funds from USACE and the State of Oregon. USACE also promotes resident fisheries throughout the McKenzie River basin through the continued support of Leaburg Hatchery and as a partner with several agencies in efforts to support Oregon chub populations and recover the ESA-listed bull trout within the McKenzie River Sub-basin (USACE, 2020a).

Marion Forks Hatchery (Figure 1.6-1) in the North Santiam River Sub-basin was constructed in 1951 to compensate for the loss of salmon and steelhead habitat caused by construction of both the Detroit and Big Cliff dams without adult fish passage. Minto Fish Facility is an adult fish collection facility located downstream of Big Cliff Dam. USACE constructed the Minto Fish Facility to collect adult UWR Chinook salmon as broodstock (mature individuals used for breeding purposes) to supply eggs for Marion Forks Hatchery (USACE, 2019b).

**Figure 1.6-1. Rearing ponds at Marion Forks Fish Hatchery in the North Santiam Sub-basin**

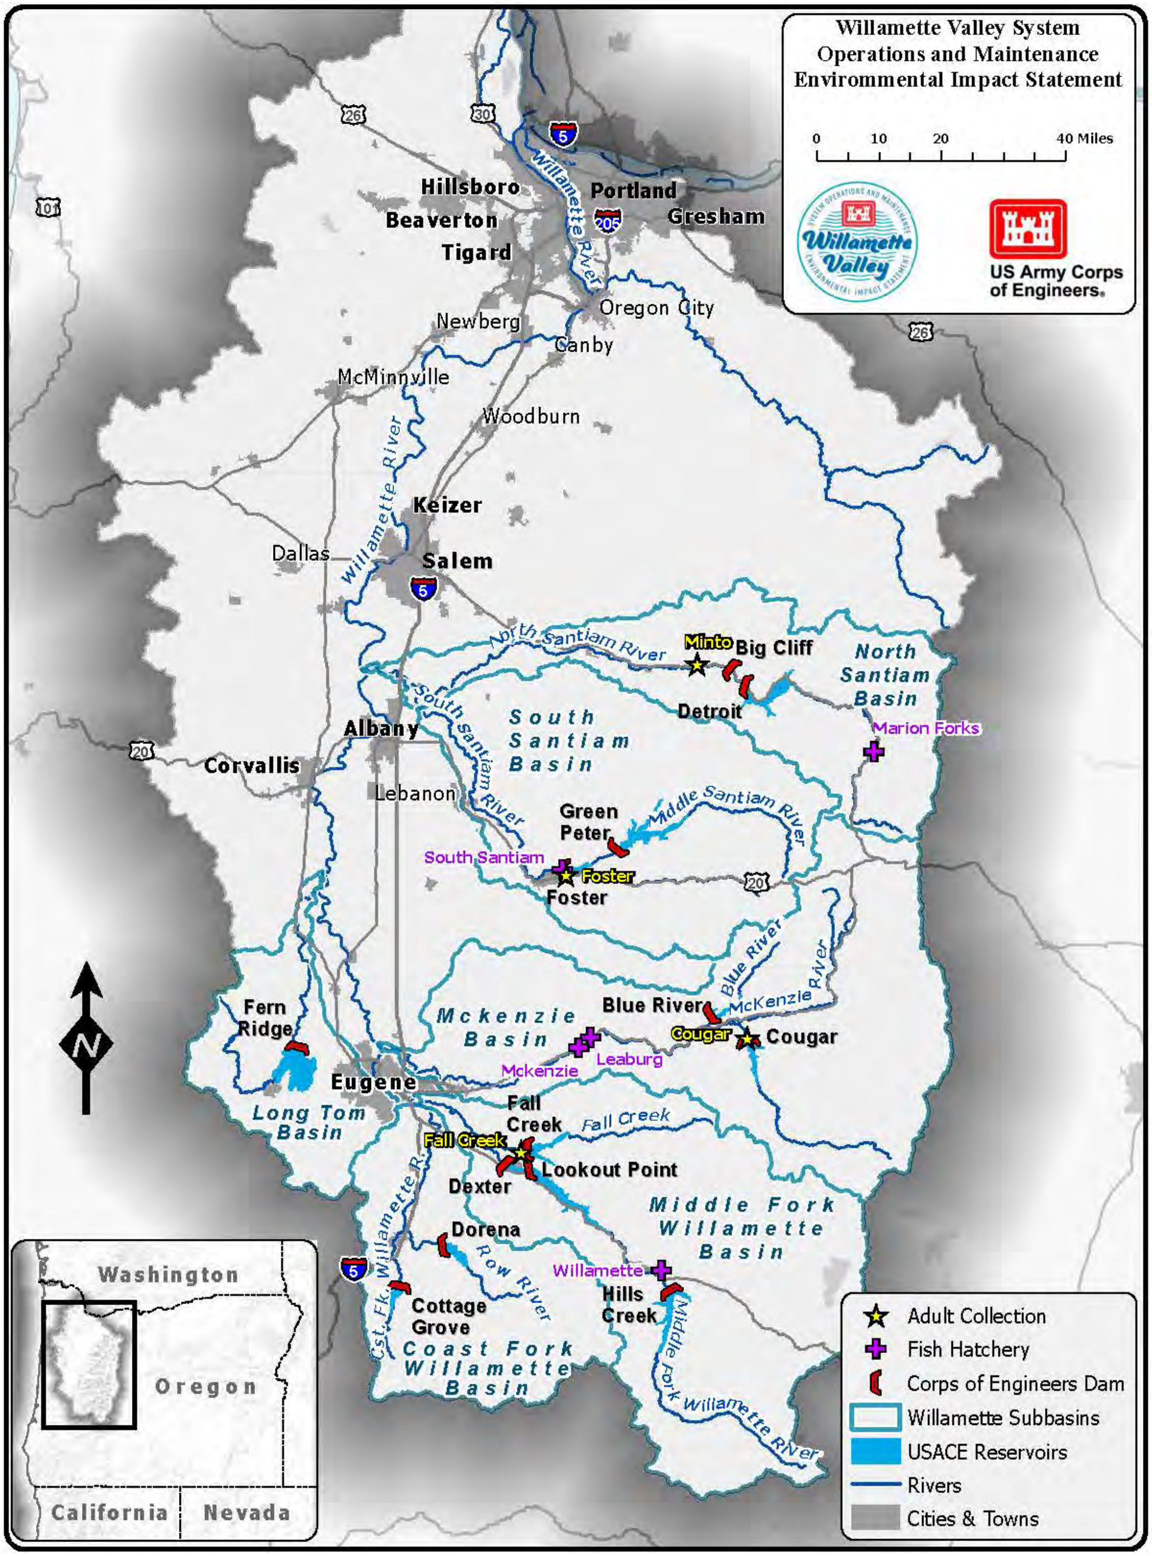

**Figure 1.6-2. WVS Fish Hatcheries and Adult Fish Collection Facilities**

### 1.6.3 Adult Fish Collection Facilities

Dams and reservoirs pose barriers to fish migration, both for their upstream and downstream migrations. For some fish species this can have enormous consequences on the population. In an effort to help reduce these effects and assist with the upstream fish migration, USACE operates and maintains adult fish collection facilities located at Foster, Fall Creek, Minto (downstream of Big Cliff), Cougar (Figure 1.6-3), and Dexter dams (Figure 1.6-2). These facilities, with the exception of the Dexter adult fish collection facility, have been redesigned to accommodate adult salmon and steelhead collection, sorting, outplanting, recycling (summer steelhead), monitoring, and juvenile acclimation of spring UWR Chinook salmon.

Although the design and current operations of the facilities is focused on UWR spring Chinook salmon and UWR winter steelhead, the adult fish collection facilities are also used to pass any native migratory fish species which are collected during the trap operations, including lamprey. Due to the lack of lamprey trapping infrastructure, lamprey passage is a very rare.

Fish that are collected and require transport are loaded in specialized trucks designed for the safe transportation and release of fish (Figure 1.6-4). For fish released above the dam, many release sites have dedicated infrastructure (e.g., release pipes), to reduce injuries and mortality.

**Figure 1.6-3. Cougar Dam Adult Fish Collection Facility**

**Figure 1.6-4. Trap and Haul Tanker Truck**

### 1.6.4 Research, Monitoring and Evaluation

The 2008 NMFS BiOp recognized that information necessary for making informed adaptive management decisions[5], in addition to tracking and documenting progress toward achievement of the RPA measures, was lacking. Additional information was needed on local environmental conditions, specific effects of the WVS on UWR spring Chinook salmon and UWR steelhead, operational constraints, technical feasibility, and effectiveness of action taken to achieve substantive RPA measures. The 2008 NMFS BiOp, therefore, included the development of a comprehensive RM&E program in the RPA to obtain the required information. The RM&E program is run with considerable coordination and input from the WATER team set up by the 2008 BiOp to provide this input[6].

[5] Adaptive management is a systematic approach for improving resource management by learning from management outcomes…An adaptive approach involves exploring alternative ways to meet management objectives, predicting the outcomes of alternatives based on the current state of knowledge, implementing one or more of these alternatives, monitoring to learn about the impacts of management actions, and then using the results to update knowledge and adjust management actions (USFWS, 2009).

[6] WATER, a collaborative advisory body made up of USACE, other federal and state agencies with fisheries and water resource management responsibilities in the WRB, and affected tribes, was established under the 2008 BiOps to coordinate with USACE on operation of the WVS. See Section 1.8.9.

## 1.7 AUTHORIZED PURPOSES

Congress authorized USACE to construct, operate, and maintain the WVS for flood control purposes beginning in 1938. Subsequently, USACE constructed 13 dams and extensive bank protection revetments along the Willamette River and its tributaries, creating the WVS by the 1970s (Section 1.5). The various purposes of the WVS were authorized by the Congress in the Flood Control Acts (FCA) between 1938 and 1962, the Water Supply Act of 1958, and the Water Resources Development Act of 1986. In these acts Congress designated the purpose for each project (Chapter 1.0) (Table 1.5-1). These purposes are described below.

Each of the 13 dams and reservoirs within the WVS are operated according to a water control manual that is authorized by Engineering Regulation 1110-2-240. These manuals provide specific information to meet the congressionally authorized purposes of FRM, generation of hydropower, water supply, irrigation, navigation, recreation, and fish and wildlife. The manuals also detail operations, procedures, and rule curves for each project.

Each manual includes a Drought Contingency Plan, which addresses flow needs, drought management organizations, a drought assessment process, and a framework to carry out a drought response. The draft Master Water Control Manual for the Willamette Valley Project is a compilation of all water control manuals for the 13 dams and reservoirs (USACE, 2015). The draft Manual will be completed following a NEPA review tiered from this PEIS.

### 1.7.1 Flood Risk Management

A primary function of the WVS is FRM. The dams are operated as a system providing FRM on six major tributaries affecting approximately 27 percent of the watershed area upstream of Portland, Oregon. Since 1994, the average annual value of damages prevented by FRM operation of the WVS has been estimated at $900 million (USACE, 2019a). This number is likely low given the growth and development of the WRB. Flood storage is discussed in more detail in Section 1.8.

To efficiently execute its FRM mission, USACE coordinates with multiple partnering agencies.

- National Oceanic and Atmospheric Administration's (NOAA's) Northwest River Forecast Center (NWRFC) is responsible for flood forecasting and is co-located with the National Weather Service (NWS), which is responsible for both meteorological forecasting and the issuance of flood warnings. These two offices coordinate closely with the USACE's Portland District for dissemination of river information and forecasts.
- The Natural Resources Conservation Service (NRCS) is responsible for obtaining hydrologic data. The NRCS Snow Survey monitors snow water content and cumulative precipitation at many stations in the WRB. Both the NRCS and NWS develop volume runoff forecasts in the spring of each year based on data provided by these field stations. These data are essential for planning for the best use of available water to meet the multiple purposes of the WVS.

- The U.S. Geological Survey (USGS) in Portland, with field assistance from their Eugene office, has the responsibility of collecting, calibrating, and publishing streamflow and water quality data in the WRB.

### 1.7.2 Hydropower

Federal hydroelectric power facilities are installed at eight of the 13 USACE projects in the WRB. The volume of water flowing over a dam and the change in elevation, known as fall or 'head,' from one point to another determines the amount of available energy in moving water. In general, the greater the water flow and the higher the head (fall), the more electricity a hydropower plant can produce.

Hydropower plants are located at the base of dams. At a hydropower plant, water moving over a dam flows through a pipe, or penstock, and then pushes against and turns blades in a turbine to spin a generator to produce electricity (Figure 1.7-1).

In the WVS, all flow over or past dams is directed through the hydropower plants, or generating facilities, unless there are special circumstances which require the use of another outlet. Special circumstances include operations for downstream fish passage, operational temperature control, turbine power outages, or outflow that exceeds turbine capacity. The locations, dam type, types of generation, and capacities are shown in Figure 1.7-2.

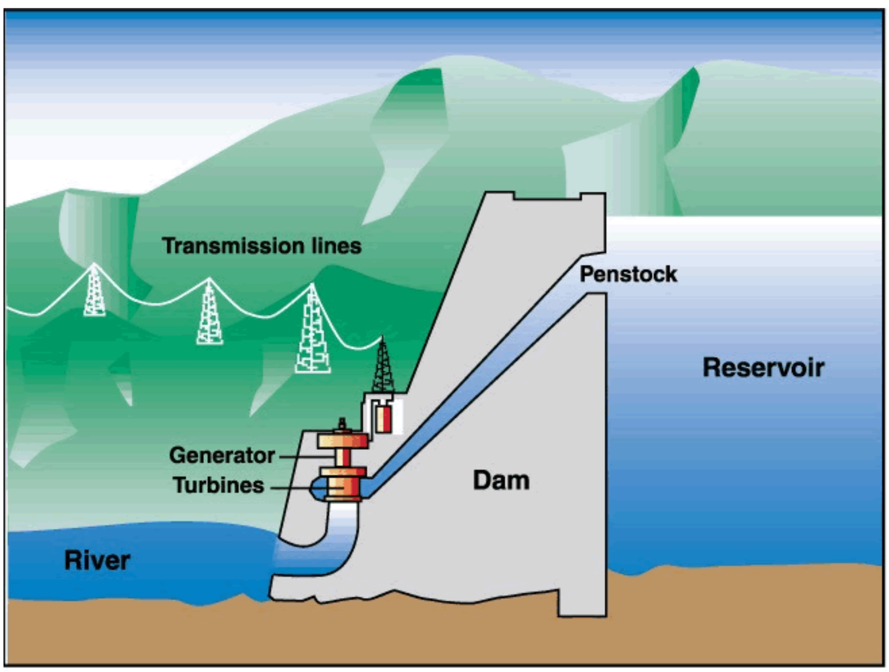

**Figure 1.7-1. Diagram of a Hydropower Dam**

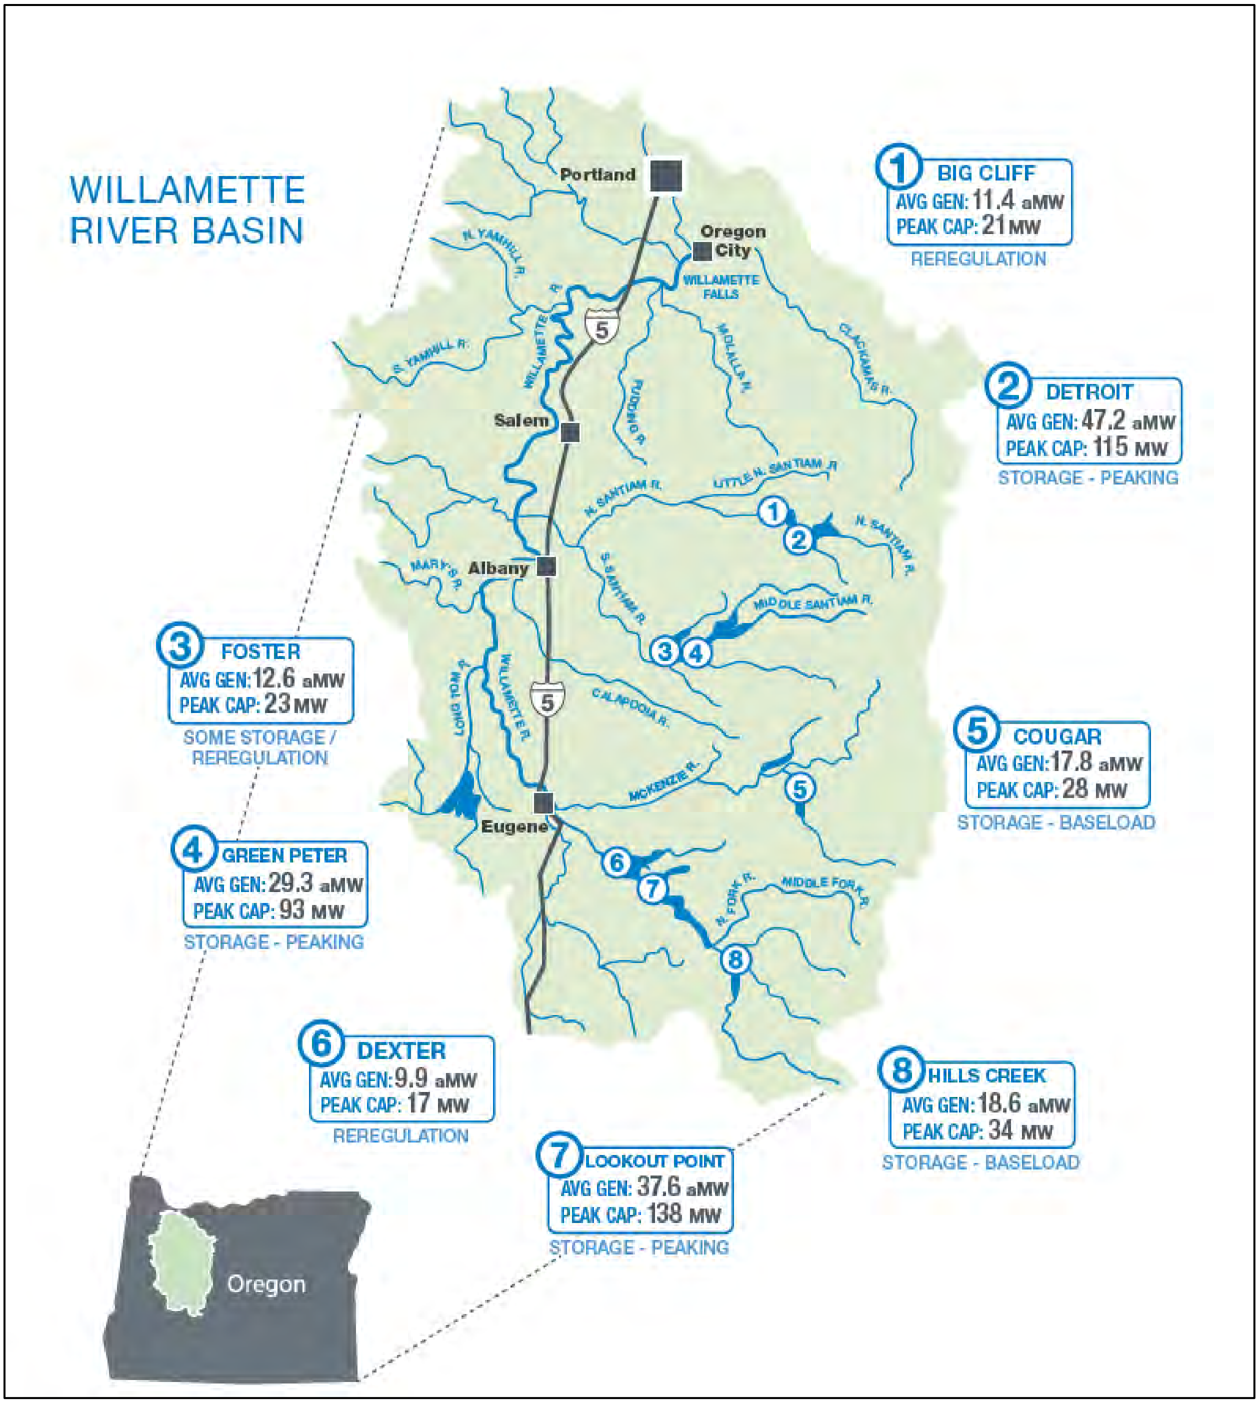

**Figure 1.7-2. Locations, Dam Type, and Capacities of Hydropower Units in the WVS**

Operation of the power transmission facilities (Figure 1.7-3.) at the projects is a highly coordinated effort between USACE and BPA. BPA is a non-profit, federal power marketing administration located in the Pacific Northwest that is responsible for maintaining the safety and reliability of the transmission grid and for marketing the electrical energy generated at the WVS projects (Appendix L).

**Figure 1.7-3. Transmission Lines Exiting Powerhouse at Detroit Dam**

There are two main types of federal hydropower projects in the WVS: storage projects that receive unregulated inflow and reregulation projects that receive and moderate dynamic flows from upstream dams; one dam in the system performs both storage and reregulation functions. Generation from the storage projects is often based upon daily, weekly, and seasonal fluctuations in power demand ("load") and flows downstream are, therefore, subject to fluctuations that require reregulation.

The reregulation reservoirs are used to absorb the fluctuations in flows from their upstream storage projects and ensure that downstream river flows are more uniform for protection of aquatic habitat and human life, and bank stability. Power generation at the combination reregulation projects is uniformly consistent throughout the day.

Lookout Point, Detroit, and Green Peter are storage projects whose outflows are reregulated by dams located downstream: Dexter, Big Cliff, and Foster, respectively. The Foster project also acts as a storage facility because it receives a large portion of unregulated inflow from the South Santiam River along with the controlled flows from Green Peter. The Hills Creek and Cougar storage projects do not have reregulation dams located downstream but do generate hydropower. Dorena Dam has a private hydropower facility regulated by FERC, and power generated is not part of the BPA system. Table 1.7-1, illustrates the average annual power generated at each project.

**Table 1.7-1. Annual Power Production (aMW)**

| Project | Average Annual Generation (aMW) | Peak Cap (MW) |
|---|---|---|
| Big Cliff | 11.4 | 21 |
| Cougar | 17.8 | 28 |
| Detroit | 47.2 | 127.8 |
| Dorena* | 3.2 | 8 |
| Dexter | 9.9 | 17 |
| Foster | 12.6 | 23 |
| Green Peter | 29.3 | 93 |
| Hills Creek | 18.6 | 34 |
| Lookout Point | 37.6 | 138 |
| Total: | **187.6** | **477** |

*Dorena Dam is a privately owned hydropower facility regulated by the Federal Energy Regulatory Commission (FERC).

Hydropower operations are generally flexible and can enable electricity generation to vary with daily and seasonal demand. During the critical power production period from October through March, reservoirs at hydropower facilities have allocated storage space for power generation, called the "power pool." This is water that is stored for when there are generally high demands for electricity. Power pools are managed in accordance with the water control diagrams and plans.

### 1.7.3 Fish and Wildlife

The WVS is operated and maintained in a manner that supports fish and wildlife. Projects provide opportunities for sport fishing and wildlife hunting, improving habitat, and preserving wildlife. Actions can include efforts to restore ecological function, promote species biodiversity, and monitor sensitive species. Operations support habitat within the reservoirs and augment stream flows downstream of dams during dry months. Current specific operations for ESA-listed fish are described under the NAA.

### 1.7.4 Recreation

Recreation use and development is authorized at all the WVS projects. Recreational facilities are provided at all USACE projects and along most of the downstream reaches. USACE cooperates with the USFS, Oregon State Parks, ODFW, and Linn and Lane Counties to build and manage a system of water-related recreation facilities.

Recreational demand in the basin places pressure on maintaining reservoirs at high levels for summer and early fall months. Many boat ramps and marinas become unusable when reservoir levels become abnormally low during the peak recreation season due to drought or other factors.

### 1.7.5 Navigation

Navigation was authorized at most of the projects in the WVS. However, HD531 recognized low channel depths due to increased withdrawal of streamflow as an impediment to navigation upstream of Willamette Falls.

Storing excess spring runoff and releasing this stored water during the low flow season would provide adequate channel depth from Corvallis through the Willamette Falls. However, the upper river above Willamette Falls Locks is no longer utilized by commercial navigation. HD531 noted that the flows released for navigation on the mainstem Willamette River, with flow targets at Albany and Salem[7], would also reduce the pollution concentrations in the river, providing for improved water quality and fish life.

The current minimum flows released per the 2008 NMFS BiOp are at least as high as those noted in HD531. Therefore, the navigation purpose is met by release of water for water quality and biological needs.

### 1.7.6 Municipal and Industrial Water Supply

The Water Supply Act of 1958 (Public Law 85-500) added water supply as an authorized purpose at USACE projects. However, the need for M&I storage was found to be relatively low at the time that the storage capacity of the reservoirs was planned.

The Willamette River and its tributaries are a major source of water for municipal and industrial needs. To date, M&I systems have been developed and rely on natural flow in the WRB. However, population growth is leading to a demand for water that exceeds existing supplies for many M&I systems throughout the basin. This need was one of the factors that led to the WBR Feasibility Study project, which resulted in the reallocation of 159,750 acre-feet from conservation storage to M&I water supply.

To date, there are no agreements for using storage from any of the Willamette project reservoirs for M&I water supply, but there is considerable interest among water suppliers in the WRB. See Section 1.8.2 for additional information on recent conservation pool allocations for water supply.

### 1.7.7 Irrigation

Agriculture is a key trade sector in Oregon, ranking first in volume of exported products and third in value of exported products. About 80 percent of Oregon's agricultural production leaves the state, with about half going to domestic markets and half to international.

AI diversions in the WRB are not centralized. There are eight irrigation districts in the study area; however, most irrigation needs are met via individual wells or diversions. In the WRB,

[7] A flow target is the volume of water intended to be met at a given location. HD531 identifies Albany, Oregon and Salem, Oregon as locations where minimum flows are to be met.

there are more than 18,000 water rights permitted for irrigation uses, representing 65 percent of all authorized water rights.

There are presently no supplemental USACE releases intended specifically for irrigation use except at Detroit and Fern Ridge Reservoirs. Withdrawals associated with BOR's irrigation water service contracts are generally met within normal dam operations and releases.

### 1.7.8 Water Quality

HD531 authorizes the release of water for "stream purification" by diluting pollution levels. Congress anticipated that the water released for navigation purposes would "increase discharges on the upper Willamette River threefold and approximately double present low-water discharges on the lower river" (H.R. DOC. NO. 75-544), diluting pollution levels in the Willamette River. Pollution abatement via dilution was focused on dissolved oxygen, pathogenic bacteria, and solids.

In the 1996 WRDA (Pub. L. No. 104-303) and 1999 WRDA (Pub. L. No. 106-53), Congress authorized the construction of a water temperature control tower at Cougar Dam to manage water temperatures downstream of the dam for the benefit of spring Chinook salmon and native trout, including bull trout, which were listed as threatened under the ESA in 1999.

## 1.8 SYSTEM OPERATION AND ANNUAL OPERATIONAL PLANNING

Operation of the WVS generally follows a seasonal cycle and is dynamically managed to meet several related, but sometimes conflicting, objectives. These objectives include providing adequate flood storage space for managing floods downstream; providing sufficient water levels for water quality, recreation, and fish and wildlife; providing adequate water releases for water quality and fish and wildlife; providing adequate water supply for irrigation and M&I uses; and maximizing power generation within the requirements imposed by other objectives.

The four-season cycle that is generally followed includes the winter FRM season, spring refill, summer conservation season, and fall release; these seasons are graphically represented in Figure 1.8-1.

Table 1.8-1 highlights reservoir water control operations in each month. Note that the exact timeline can shift depending on the project and season. Operations can occur simultaneously, such as outflow reduction and conservation pool refill to maximum, which both occur during the spring refill season.

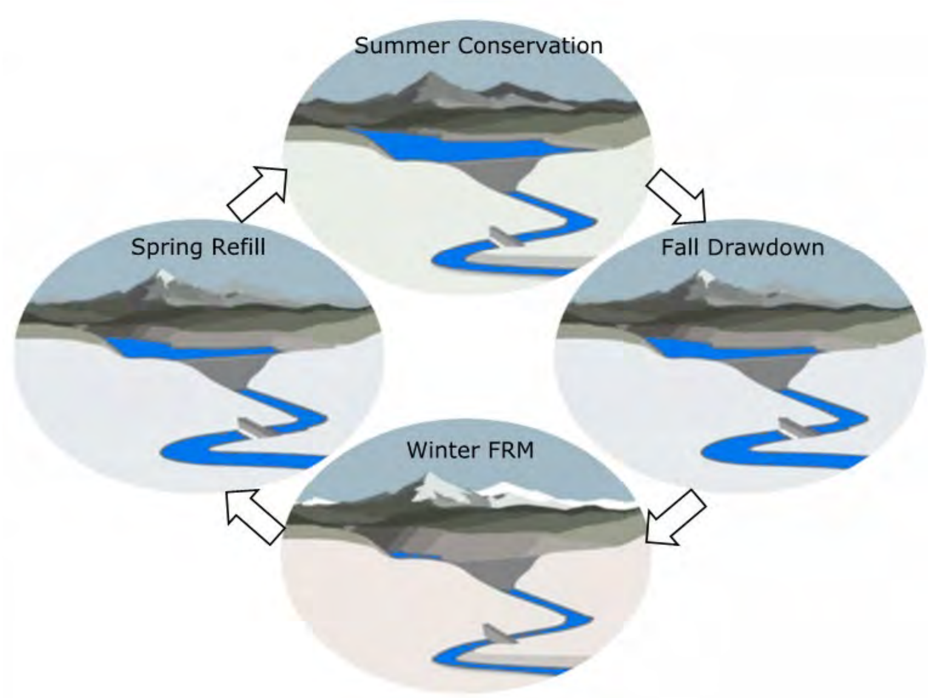

**Figure 1.8-1. Seasonal Operations of the Willamette Valley System**

**Table 1.8-1. Generic Reservoir Water Control Operations by Month**

| Months | Operation | Description |
|---|---|---|
| November - January | Winter Flood Risk Management Season | Projects maintained near minimum conservation pool elevations. During storm events, inflows are retained, and water is released downstream to minimize flooding effects. |
| February - May | Spring Conservation Pool Refill | Refill of the reservoirs according to the water control diagram during the conservation season is largely dependent on rain events, but maximum conservation pool is generally reached from mid-April to mid-May. |
| April - November | Summer Conservation Season | Inflow is gradually stored in reservoirs and later used for purposes such as irrigation, water supply, recreation, power production, and meeting minimum flows for fish and wildlife. |
| September - November | Fall Reservoir Release | USACE begins releasing water from all storage reservoirs to meet the authorized conservation season purposes and regain capacity for FRM. The reservoirs are drafted to their minimum conservation pool to achieve their full FRM potential by about the end of November. |

Operating the WVS to meet multiple purposes is in part made possible by releasing water through outlets located at various depths in each dam. When a WVS dam sufficient stored water, surface water can be released over the spillway.

Spillways are structures that either form part of a dam or are found just beside it. These outlets pass floodwater safely, and in a controlled way, over a dam, around it or through it. Many WVS dam have spillways with gates that allow operators to control flow over the spillway anytime the reservoir is high enough for other reasons than just flood control such as for fish passage and downstream temperature management. Once the reservoir water elevation goes below the operational elevation of the spillway this outlet is no longer available for releasing water.

Water is also released through the regulating outlets (ROs) located at a lower elevation on the dam, deeper in the reservoir. These consist of pipes, box culverts, or tunnels with gates or valves to regulate the flow rate.

Hydropower dams have an additional outlet, the penstock, that directs water through the turbines to produce power. A basic outlet configuration for a hydropower dam is presented graphically in **Error! Reference source not found.** below.

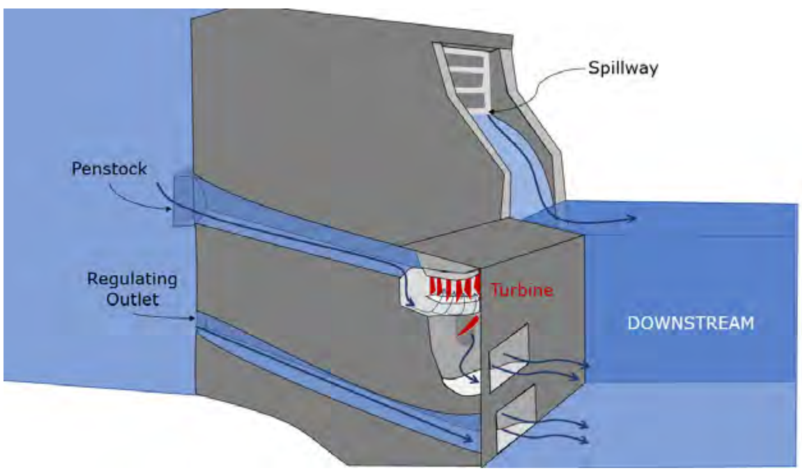

**Figure 1.8-2. Basic graphical representation of a hydropower dam outlet configuration**

The multiple outlets and USACE operational procedures allow some flexibility in WVS operations as USACE attempts to meet the diverse and changing needs of the region based on information that becomes available over the course of the operating year. Many factors cause short-term operational adjustments. For example, sometimes periods of heavy rain cause higher flows in the fall. In a dry year, minimum fish flows and other constraints dictate how much water the projects must discharge.

The actual operations take place in what is described as “real time,” that is, decisions must be made in a few minutes, days, or at most, a few weeks. Operators regulate the system to satisfy all the various purposes contained in the annual operating plan. In-stream conditions for fish, generator outages, the weather, and even the timing of recreational events can influence operational decisions. There are also periodic maintenance activities that affect reservoir levels.

The general procedures for reservoir elevation and water control, as well as the annual system operation processes and activities, are described in this section.

### 1.8.1 Reservoir Pools and Water Control

Overall, reservoir water storage capacity can be conceptualized as a series of layered pools making up the overall reservoir pool. The pools can indicate designated purposes or management targets and occupy elevation bands that shift by season or specific operating conditions.

A typical WVS reservoir would include maximum, conservation, flood, power if it is a power producing project or an inactive pool if it is not power producing, and a dead pool (located below any outlets which makes water in this area inaccessible for release through the dam). These pools may change throughout the year and are presented graphically in **Error! Reference source not found.** below.

The maximum pool is the maximum level to which the reservoir surface is allowed to rise during normal operating conditions. The conservation pool storage is allocated for M&I, AI, fish and wildlife, but supports water quality and recreation. The conservation pool may overlap some of the same elevation bands as the flood pool, but the maximum conservation pool does not rise to the elevation of the overall reservoir maximum pool.

The flood pool contains space that is used during storm events to retain flood waters to reduce downstream risks. The flood pool has further designated minimum, summer, primary, and secondary pools that pertain to different management conditions. The summer flood storage pool is the space above the maximum conservation pool up to the reservoir maximum pool. When this pool is filled, it is called full pool.

The power storage pool lies below the conservation and flood pools. It contains water used for the generation of hydroelectric power and has designated maximum and minimum pools. The inactive pool is designed to trap sediment and is the lowest storage area in a reservoir.

To manage for the different purposes and seasonal needs, USACE utilizes water control diagrams. Individual water control diagrams depict the allocated pools and elevations, also known as water-year-based rule curves, over the course of a year for each project. **Error! Reference source not found.** is a typical water control diagram that indicates the general trends throughout the year and vary by project. These water control diagrams are contained in the water control manuals for each individual project, along with detailed operations and procedures. The draft Master Water Control Manual integrates the operation of the individual dams and reservoirs to meet the system-wide goals of the WVS (Section 1.7).

All projects with hydropower facilities include storage space designated for power generation during the critical power period from October to March. This storage is relatively small and is between minimum conservation pool and minimum power pool elevations (Figure 1.8-3). The power pool is generally kept full to increase the hydraulic head, defined as the potential energy of water due to its height above the bottom of the dam, for power generation.

Departures from the rule curves (storage targets) during reservoir refill may be necessary due to the need for regulation of floods, excessive snowpack above the reservoirs, inadequate water supply, or critical power needs. Refill can be delayed when high runoff is expected, as this provides additional storage for flood damage reduction operations. Generally, each reservoir may fill at a rate no faster than shown in the rule curve unless the reservoir is being managed for downstream floods.

Excess flood water stored above the rule curve during the conservation storage season is released targeting discharges at or below downstream channel capacity. During dry conditions, the reservoir may be higher than the rule curve to reduce the risk of not filling the reservoir. When the water supply is inadequate to maintain both minimum flows and the scheduled rate of filling, maintaining minimum in-stream flows downstream of a dam generally takes precedence, per the 2008 NMFS BiOp.

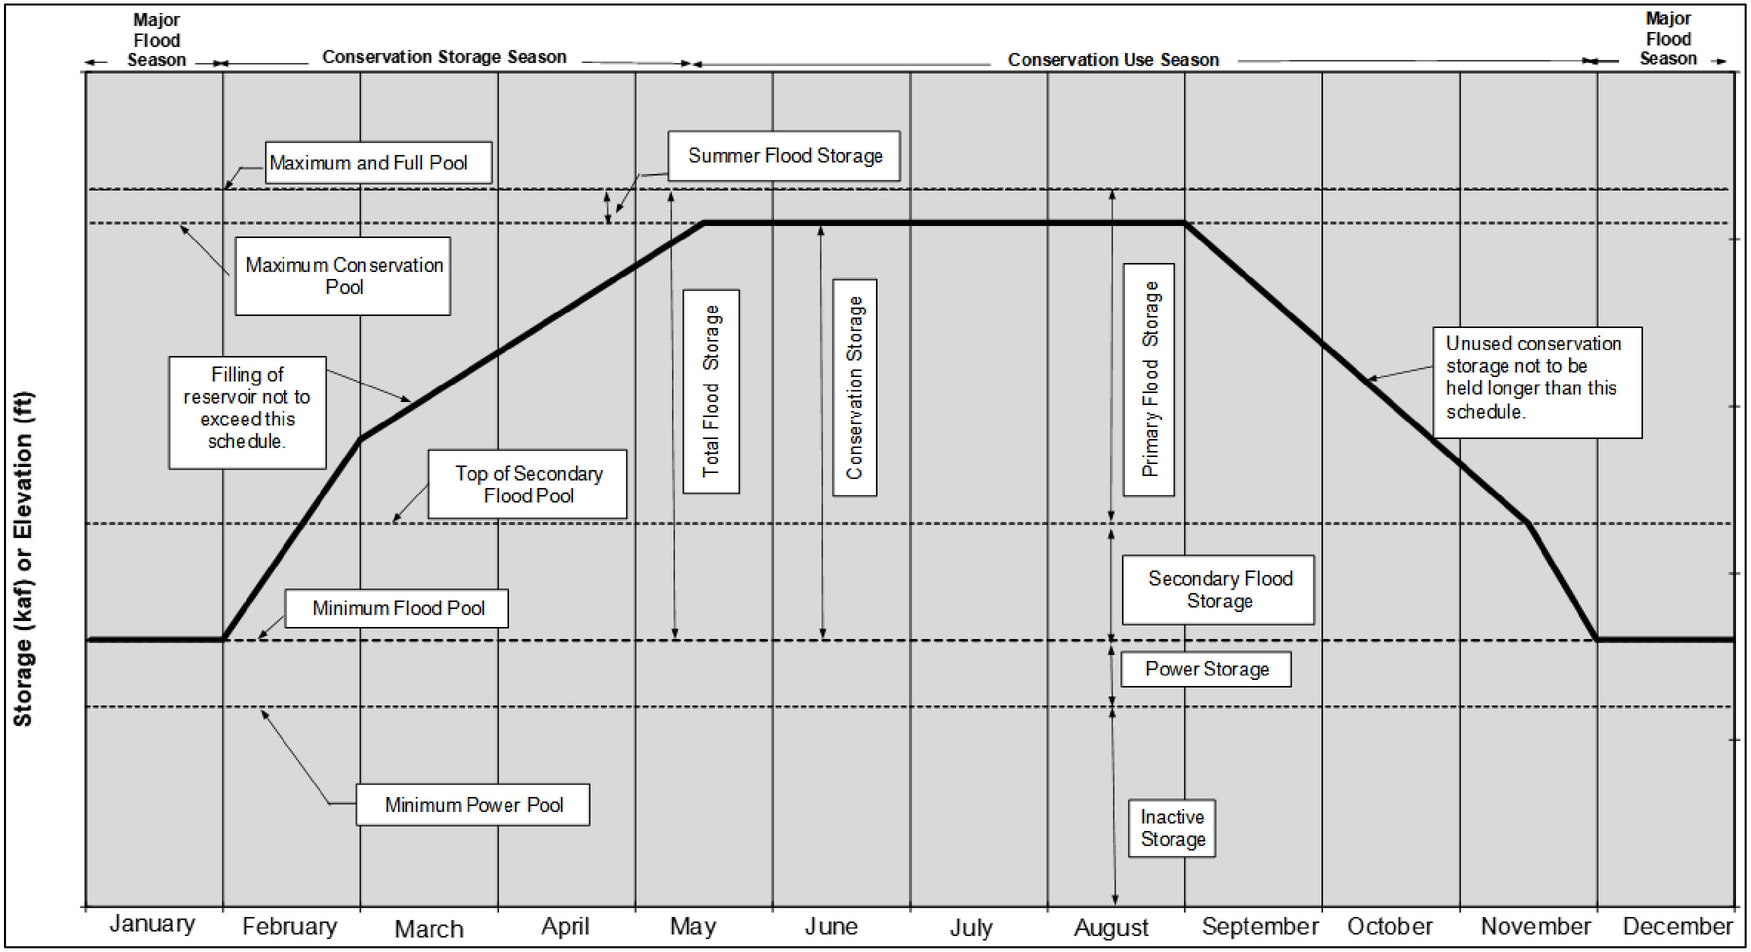

**Figure 1.8-3. Typical Water Control Diagram for WVS Dams and Reservoirs**

### 1.8.2 Conservation Pool Allocation

USACE and OWRD recently completed the WBR Feasibility Study (discussed in Appendix L) to examine current and projected water needs and demands in the WRB for fish and wildlife, M&I water supply, and AI. The WBR Feasibility Study Chief's Report[8] was signed in December 2019.

In December 2020, Congress authorized the substantial reallocation of the conservation storage space in the WVS reservoirs for three purposes: fish and wildlife, M&I water supply, and AI in accordance with the Chief's Report. The conservation pool storage was divided as shown in Table 1.8-2.

**Table 1.8-2. Authorized Use Allocation of Combined Conservation Storage**

| Purpose | Acre-feet of Combined Storage Space |
|---|---|
| Fish and Wildlife | 1,102,600 |
| Agricultural Irrigation (AI) | 327,650 |
| Municipal and Industrial (M&I) Water Supply | 159,750 |

The allocations were based on a forecasted peak water demand in the year 2070, following the 50-year planning horizon of the feasibility study. Because USACE incorporated a 30-year planning horizon for this PEIS, the demand for M&I water supply and AI was calculated to the year 2050.

In 2019, NMFS issued a jeopardy BiOp for the WBR (NMFS, 2019). The RPA measure 2 of the 2019 NMFS BiOp for the WBR includes a cap on new water storage for M&I use at 11,000 total acre-feet until certain conditions were met. It further restricted USACE from executing any agreements in the Santiam Basin until NMFS issued a written statement that instream water rights are in place and providing sufficient protection to flows intended to benefit fish. USACE determined it is reasonable to assume this cap would be lifted in the future, allowing USACE to enter into agreements for the full allocation, which is projected to occur over the next 50 years.

AI was anticipated to be a significant use of water stored in the project reservoirs when the WVS was first authorized by Congress. BOR administers water service contracts for irrigators within 15 water service contract reaches. Irrigation use from the WVS reservoirs in the WRB has not increased as initially projected and is not expected to increase in the future at levels near the scope and scale originally envisioned. As of October 2022, there were 266 BOR Water Service Contracts for 82,815 acre-feet of water per year (approximately 5 percent of the conservation storage).

[8] A Chief's Report is a report from the USACE Chief of Engineers developed when a water resources project would require Congressional authorization - or a change to existing project authorization. After the final feasibility report is submitted to USACE headquarters, a Chief's Report is developed.

At the current low level of use for water service contracts, USACE does not make special operational adjustments, such as increasing flow releases, to meet contract requirements at most projects, except for Fern Ridge and Detroit. However, in deficit water years, the 2008 NMFS RPA requires BOR to curtail water contract diversions. In other years, the RPA requires USACE to release more than minimum flow to ensure the contract users do not take water intended for fish purposes from Fern Ridge and Detroit. In “deficit" water years, as defined in the 2008 NMFS BiOp, a partial water supply or no water supply may be available to satisfy some existing and new irrigation contracts. Water deliveries may be ceased or curtailed under these conditions, per RPA 3.4. (NMFS, 2008).

### 1.8.3 Water Control Annual Planning

Operational planning for the conservation release season begins with the January water supply forecast and continues through October[9]. The conservation season is approximately from April through October but can extend through November when the minimum conservation pool is reached, including the spring filling season and the summer conservation season. Forecasts are required during the conservation storage period to assess the timing and capability of refilling to the desired maximum conservation storage elevation of individual projects.

Forecasts during this period are needed to maintain spring mainstem flows based on the minimum flow objectives for ESA-listed species included in the 2008 NMFS BiOp. A document titled *Willamette Basin Project Conservation Release Season Operating Plan* (Conservation Plan) is prepared annually to provide flow requirements based on the basin water supply for that year. The Conservation Plan identifies flow and storage needs for each tributary and USACE reservoir in the WVS and mainstem Willamette control points based on the anticipated total system storage in mid-May from the April forecast. Flow requirements in the Conservation Plan are consistent with flow targets outlined in the 2008 NMFS BiOp.

The hydrology of the Willamette Basin is not conducive to long-range runoff forecasting for daily reservoir regulation purposes. A major portion of the runoff during November through March occurs as a direct result of rainfall. Detailed forecasts are not quantitatively predictable beyond 24 to 48 hours.

While climate information is being produced by the NOAA Climatic Data Center, long-range streamflow forecasts beyond those required for the conservation release season described are not used for the WVS since all projects operate on a fixed rule curve that requires the reservoirs to be at minimum conservation pool during the winter flood season, and then to refill during the spring.

A Drought Contingency Plan provides a plan of action if a potential drought situation were to occur. Like the long-range forecasts, drought forecasts beyond those required for the conservation release season are not used for regulation of the WVS since all projects operate

[9] The information presented in this section has been adapted from the Master Water Control Manual for the Willamette Valley Project (2015).

on individual, fixed, rule curves. Prediction of winter/spring droughts is nearly impossible due to the variability of our regional weather systems.

### 1.8.4 Streamflow and Water Quality

WVS dams were designed and constructed to modify, control, and regulate the streamflow characteristics of their tributaries and the mainstem Willamette River. In general, WVS operations have resulted in higher flows in the summer and reduced peak flows in the winter than historical flows. These hydrologic effects modify fish habitat characteristics in the downstream reaches.

WVS is operated in a manner that helps mitigate adverse effects of the projects, including maintenance of flows downstream of the projects and in the mainstem of the Willamette River. Augmenting downstream mainstem Willamette flows at Albany and Salem is important for water quality and fish and wildlife purposes.

The 2008 BiOps require USACE to release flows at WVS dams to achieve streamflow minimums in the tributaries and mainstem Willamette throughout the year and to stay below maximum flows during key spawning periods in the tributaries. Mainstem minimum flow targets for adequate and abundant water years are listed in Table 2.2-4, and the tributary minimum and maximum flow targets are provided in Table 2.2-3 in the NAA description provided in Section 2.4.11. Additionally, the 2008 BiOps established ramping rates that dictate how quickly flows are increased or decreased. USACE strives to adhere to the established ramping rates except during emergencies and flood control operations. The flow targets and ramping rates are described in the 2008 NMFS BiOp RPA measures 2.2 to 2.6.

Streamflow augmentations increase flows during the low water period and benefit sanitary conditions along the mainstem by diluting pollution, moderating extreme temperatures, and increasing the dissolved oxygen content of WRB streams, resulting in a beneficial effect on fish and wildlife. Flow targets and ramping rate requirements discussed above and provided in Section 2.4.1.1 aid in achieving consistency with the 2008 BiOps.

Water quality management objectives in the WVS include control of instream water temperature and reduction in Total Dissolved Gas (TDG) concentrations in river reaches below dams. Details on operations to address temperature targets and TDG are described in the NAA under Sections 2.4.1.2.1 and 2.4.1.2.2.

### 1.8.5 Operational Considerations for Hydropower

USACE performs ongoing, coordinated water management actions at the dams to increase or decrease electricity generation in response to the needs of the federal transmission system. These needs include management of operating reserves and the accommodation of planned or emergency transmission line outages.

At times project releases are limited by different constraints like ESA requirements. Operational changes are coordinated with the Services if they deviate from criteria in the 2008 BiOps during non-flood operations. In emergency situations and in managing the system to avoid emergencies, power system operations would be prioritized to protect human health and safety as well as the safety and reliability of the power grid.

### 1.8.6 Operational Considerations for Recreation

Recreational facilities are provided at all USACE projects. Recreational demand in the basin puts pressure on maintaining reservoirs near maximum conservation pool for the entire recreational season. A drawdown priority for the projects to meet tributary and mainstem flow targets continues to evolve over time given hydrologic conditions and in-stream biological needs. Detroit, Fern Ridge, Cottage Grove, Dorena, and Foster Reservoirs have been identified as having the highest recreational demand within the WVS, and all but Detroit lack the capacity to significantly augment mainstem flows. These are the last reservoirs to be drawn down to meet flow requirements on the mainstem of the Willamette River, as measured at Albany and Salem.

The conservation pools at these reservoirs are typically maintained at as high an elevation as possible until early September, and projects with lower recreation demand are used first for meeting summer flow requirements at Albany and Salem.

Additional information on USACE management of recreational facilities can be found in Section 1.9.

### 1.8.7 Environmental Flows

Dam releases that benefit downstream ecosystem health are termed environmental flows, or e-flows. E-flow targets were developed through a process of collecting and synthesizing relevant hydrologic and ecological information and expert knowledge into a set of flow recommendations, summarized in a USACE Memorandum for the Record, dated July 17, 2015 (USACE, 2015l).

E-flow implementation has been developed by USACE in coordination with The Nature Conservancy at multiple projects within the WRB. The implementation of e-flows is event-driven, meaning they are based on regulator/operator judgement. Maximizing e-flows is valuable to efficiently manage aquatic habitats as it creates both opportunities for, and the means to manage, fish spawning, incubation, and other habitat needs. Fish populations and other aquatic organisms are adapted to these variable flow conditions.

Each seasonal flow contributes to some aspect of ecosystem health. Fall flows occur from October to November, winter high flows occur from November to February, and smaller spring flows occur from March to June. E-flows recommendations have been developed for the Middle Fork Willamette River, McKenzie River, and the North, South, and mainstem Santiam Rivers. Flow recommendations are defined by event duration, number of events per year, range of flow magnitude, and frequency.

E-flow operations are governed by the Water Control Manual operational requirements for each project and the 2008 NMFS BiOp. The general intent is to maximize opportunities for achieving e-flows while considering operational constraints and forecast uncertainty. E-flow operations require the use of stored water to achieve environmental goals. This can be particularly difficult to achieve during hydrologically and meteorologically dry water years.

### 1.8.8 Operation, Maintenance, Repair, Replacement, and Rehabilitation

After a water resources project is constructed, the operation, maintenance, repair, replacement, and rehabilitation (OMRR&R) phase begins. During this phase, ongoing activities are conducted to support the function of a project.

The OMRR&R phase includes a spectrum of activities that range from regular maintenance activities, such as the repainting a rusty guardrail or replacement of lightbulbs, to major maintenance and rehabilitation activities such as the repair, replacement, or rehabilitation of entire facility components (e.g., the replacement of the slide gate seals or repair of hydraulics in a dam). OMRR&R activities occur at all facilities in the WVS including within and around the dams and powerhouses, the adult fish facilities, and the hatcheries.

This section describes the distinction between regular and major operation, maintenance, repair, replacement, and rehabilitation and outlines how activities under each are addressed in this PEIS.

#### *1.8.8.1 Scheduled/Routine Maintenance*

Routine maintenance is defined as the maintenance, repair, or replacement of existing fixtures or parts in which no changes are made to original design or purpose, to ensure that WVS facilities run safely. Routine maintenance includes those activities that are predictable and repetitive, but not those that would constitute major repairs or rehabilitation of a capital asset. This type of preventative and corrective maintenance is coordinated and planned to occur at regular intervals and is also referred to as scheduled maintenance.

Routine maintenance is performed on all WVS hatcheries, fish facilities, spillway components, generating units, and supporting systems to ensure project reliability and to comply with federal regulatory requirements. Routine maintenance is coordinated through a regional forum, such as the Willamette Fish Passage Operations & Maintenance[10] (WFPOM) and WATER (Section 1.8.8), to minimize effects to ESA-listed fish species by designating in-water-work-windows and other construction constraints.

---

[10] The Willamette Fish Passage Operations and Maintenance (WFPOM) forum develops recommendations for ongoing operations and maintenance activities that may affect listed fish species. This forum also includes technical discussions relating to hatchery programs. This forum is responsible for providing input on annual changes to the Willamette Fish Operations Plan, which dictates how facilities must operate to minimize impacts to ESA-listed species.

The routine maintenance program allows staff at USACE, BOR, and BPA to proactively plan and schedule capital improvement programs based on equipment condition and degradation to ensure system operations remain safe, reliable, and in compliance with applicable laws and regulations.

These activities are described in the Operations and Maintenance Manuals for each facility. The library of Operations and Maintenance Manuals is incorporated here by reference; Appendix A provides an annotated bibliography of these manuals.

#### *1.8.8.2 Unscheduled and Non-routine Maintenance*

Unscheduled maintenance is reactive maintenance that addresses issues as they arise. It can occur any time there is a problem, unforeseen maintenance issue, or emergency that requires a project feature, such as a generating unit, be taken offline to resolve the problem. The timing, duration, and extent of these events are unforeseeable. Unscheduled maintenance events are coordinated through the appropriate teams under a regional forum, such as the WFPOM and WATER, to minimize negative effects on fish.

Non-routine maintenance is proactively planned but not performed at regular intervals (e.g., unit overhauls, major structural modifications, or rehabilitations). Non-routine maintenance includes tasks that may be more imperative in nature than routine maintenance and these tasks may or may not constitute major maintenance and rehabilitation.

Major maintenance and major rehabilitation are defined in Engineering Circular 11-2-222. Major maintenance is defined as a non-repetitive item of work or aggregate items of related work for which the total estimated cost exceeds the limit set forth by Engineering Circular 11-2-222, and that does not qualify as major rehabilitation.

Major rehabilitation is defined as structural modifications to restore or ensure continuation of an existing facility's functions or outputs. This does not include normal maintenance of existing capabilities or prevention of deterioration. Examples of non-routine maintenance include power plant modernization and major upgrades of project features.

Non-routine maintenance and major maintenance and rehabilitation may be considered major federal actions. Each action would be assessed for environmental compliance prior to implementation and may be subject to NEPA review.

### 1.8.9 Coordination of WVS Operations with Other Agencies

USACE is ultimately responsible for the O&M of the WVS. However, USACE also coordinates with or collects input from regional stakeholders such as NMFS, BPA, USFWS, USFS, tribes, ODFW, ODEQ, Northwest Power and Conservation Council, and other partners on operations and natural conditions that may affect their interests. WATER, a collaborative advisory body made up of USACE, other federal and state agencies with fisheries and water resource management responsibilities in the WRB, and affected tribes, was established under the 2008

BiOps to coordinate with USACE on operation of the WVS. One forum for this coordination is the WFPOM team, which annually develops the Willamette Fish Operation Plan (WFOP).

The WFOP describes year-round O&M activities at USACE WVS projects to protect and enhance ESA-listed fish species as well as non-listed species of concern. The WFOP guides USACE actions related to fish protection and passage at the 13 WVS dams. Other USACE documents and agreements related to fish passage at these projects are consistent with the WFOP.

Although USACE is the final decisionmaker on all water management decisions in the WVS, USACE also considers input from regional stakeholders through a forum known as the Flow Management and Water Quality Team (FMWQT). The FMWQT is a technical team organized under WATER. The FMWQT meets monthly to provide flow forecast updates and gather input on decisions related to flow management. Special operations related to fish protection and passage identified in the WFOP are coordinated through the FMWQT.

## 1.9 ONGOING USACE PLANNING AND ENVIRONMENTAL REVIEWS IN THE REGION

In addition to the PEIS, USACE has several other ongoing environmental review efforts in the WRB. These reviews are either not directly related to long-term operation and maintenance of the WVS or ESA compliance, involve nonfederal sponsors, do not rise to the level of a programmatic NEPA document, or have insufficient information to be considered as related to the scope of the PEIS. Some of these reviews involve reasonably foreseeable future actions and are described in Chapter 4. Details about each of these ongoing reviews are provided below.

### 1.9.1 Master Plans

USACE is currently undertaking a multi-year effort to revise six Master Plans for USACE-managed lands withing the WVS grouped by sub-basin. These Master Plans would replace the outdated, existing individual and regional Master Plans.

A Master Plan is a strategic land use management document that guides the comprehensive management and development of all recreational, natural, and cultural resources throughout the life of a USACE Civil Works project. Master Plans are required for USACE Civil Works projects, which are administered by USACE for management of natural and manmade resources.

The Master Plans cover many resources, including but not limited to water, fish and wildlife, vegetation, cultural, aesthetic, interpretive, recreational, and mineral. The Master Plans do not address operations for flood risk management, water quality, water supply, hydropower, navigation, fish and wildlife, recreation, or maintenance the dams and fish facilities.

The process of updating Master Plans encompasses interrelated tasks involving the review and analyses of environmental, recreational, and socioeconomic trends within a generalized conceptual framework. This framework includes regional and ecosystem needs, project resource capabilities and suitability, expressed public interests that are compatible with project authorized purposes, and environmental sustainability elements. USACE must ensure that Master Plan revisions reflect equal attention to the economy, the environment, and effective management of project resources and facilities at the appropriate scale. The six Master Plans and their associated programmatic NEPA documents shall be prepared in accordance with and include the requirements of all laws, regulations, guidance, and polices.

### 1.9.2 Interim Risk Reduction Measures

USACE is continuously assessing its dams as part of its comprehensive dam safety program to better understand dam safety risks and inform future actions. The USACE Dam Safety Program periodically assesses and reassesses risks to all WVS dams on a 5-year cycle.

When risks are identified, there is a process for elevating them for more detailed analysis and design to ensure risks are adequately addressed. The assessment process identifies and analyzes many risks using the latest science and engineering methods and standards. This process is described in more detail in Appendix H.

Many of the risks analyzed are often not consequential or probable enough to merit further action. However, in 2020, after completing a detailed analysis of the seismic risk at Detroit and Lookout Point Dams, it was concluded that immediate action to mitigate the risk at these dams was necessary.

Per Engineering Regulation, ER 1110-2-1156 (USACE Publications), "USACE has specific public safety responsibility, when a project has known safety issues, to take appropriate interim risk reduction measures including reservoir releases. USACE statutory responsibilities require operation of dams in a manner that reduces the project's probabilities of failure when there are known issues with the integrity of the project."

This determination resulted in development of Interim Risk Reduction Measures (IRRM) to address these risks until a permanent solution could be assessed and designed. IRRMs at these dams required pool restriction on the maximum pool elevation. In other words, the maximum elevation the associated reservoirs are allowed to reach each summer is lower than the authorized maximum identified in the water control manuals.

The USACE Portland District is engaged in dam safety studies for the remaining dams in the basin. Additional dam safety IRRMs may be recommended at different projects. Those actions will have site-specific environmental compliance including NEPA reviews.

### 1.9.3 Court-ordered Injunction Measures

On September 1, 2021, the U.S. District Court for the District of Oregon issued an injunction in *NEDC v. USACE*[11]*.* The order directed USACE to implement injunctive actions intended to improve conditions for fish passage and water quality in the WVS to avoid irreparable harm to

---

[11] Northwest Environmental Defense Center, et al. v. United States Army Corps of Engineers, et al., No. 3:18-cv-00437-HZ (D. Or. September 1, 2021).

ESA-listed salmonids until the completion of the reinitiated ESA Section 7 consultation with NMFS. The Court ordered operations will continue until consultation concludes.

Additionally, the Court ordered operational changes and three structural modifications to existing projects. The three structural modification projects have undergone, or are currently undergoing, separate site-specific NEPA processes to assess the direct, indirect, and cumulative impacts of their effects on the human environment. As the direct and indirect effects of these projects will be fully assessed by their individual NEPA documents, they are not included in Chapter 3 of this draft PEIS. However, as ongoing environmental reviews within the WRB, Chapter 4 includes the operation and maintenance of these ongoing and future projects in the cumulative effects analysis. A description of the three Court-ordered projects is provided in Table 1.9-1.

**Table 1.9-1. Court-ordered Structural Improvements**

| Dam | Description | Status |
|---|---|---|
| Dexter | Design and construct upgrades to the Dexter adult fish facility. | Design is underway with a schedule to start construction in Summer of 2023. |
| Big Cliff | Determine whether operational measures alone are sufficient to maintain acceptable total dissolved gas levels below Big Cliff Dam and, if not, design and construct a structural solution for mitigating excess total dissolved gas levels during spill operations. | The Corps determined that operational fixes are not sufficient and developed a schedule for design and construction of TDG abatement at Big Cliff Dam. |
| Cougar | Determine whether structural improvements/modifications need to be made to Cougar Dam's ROs to ensure safer fish passage and reduce total dissolved gas levels and, if so, design and construct a structural solution. | The Expert Panel recommended resurfacing of the RO chute by 30 September 2023 and an alternatives study to be completed by 30 June 2023. |

### 1.9.4 Fern Ridge Vegetation Management Plan

USACE is evaluating whether to expand vegetation management practices utilized at Fern Ridge Reservoir throughout the rest of USACE-operated lands within the WRB. These practices include prescribed burning, mechanical and manual control, herbicide applications, and seed collection and plant propagation, which are intended to improve and maintain diverse native plant communities while preventing, eliminating, or reducing the presence or spread of invasive, noxious, and nuisance plants. A site-specific NEPA Environmental Assessment is currently ongoing for this project.

### 1.9.5 Dexter Shoreline Management

The existing Dexter Shoreline Management Plan is being reviewed to determine necessary revisions to the Plan, including real estate license requirements. The Shoreline Master Plan addresses the rules and regulations, shoreline allocations, and USACE requirements for permitting shoreline use facilities, activities, or development.

Within some of the designated land use areas, USACE plans to issue permits and real estate licenses to private landowners to construct new docks, modify or maintain existing docks, modify vegetation, and construct upland support structures so long as these activities are consistent with a revised Shoreline Master Plan. A site-specific NEPA Environmental Assessment is currently ongoing for this project.

### 1.9.6 Long Tom River Ecosystem Restoration Project

The City of Monroe and Confederated Tribes of Siletz Indians, along with the partnership of the Long Tom Watershed Council, are collaborating with USACE to advance an ecosystem restoration project on the Long Tom River, under USACE's Continuing Authority Program Section 1135, Project Modifications for Improvement of the Environment for ecosystem restoration (WRDA, 1986). This group recognizes that the Long Tom River is a vital watershed for its potential high-quality juvenile salmon rearing habitat, as well as spawning and rearing habitat for cutthroat trout, lamprey, and other native species.

Prior to construction of the Fern Ridge Dam, the lower Long Tom River was a low-gradient river characterized by a narrow channel with high sinuosity. After completion of the dam, the downstream reaches of the Long Tom lacked the channel capacity to convey routine water releases from the reservoir. In 1943, USACE implemented a project resulting in construction of a straighter, deeper, and wider channel with a series of seven drop structures. These drop structures were built with the intent to reduce channel velocities and to decrease erosion.

A drop structure, also known as a grade control, sill, or weir, is a manmade structure, typically small and built on minor streams, to pass water to a lower elevation while controlling the energy and velocity of the water as it passes over. Unlike most dams, drop structures are usually not built for water impoundment, diversion, or to raise a water level. They are mostly built on watercourses with steep gradients to serve other purposes such as water oxygenation and erosion prevention.

While effective at helping to maintain channel stability, drop structures create barriers to fish passage. According to NMFS West Coast Region's Anadromous Salmonid Passage Design Manual, "Drop structure barriers involve a combination of local hydraulic conditions downstream of a barrier and the swimming capabilities of the species and life stage to block migration (Powers and Orsborn, 1985). They create hydraulic conditions that exceed the swimming or leaping capabilities of the fish to overcome the hydraulic condition. Examples include velocity barriers, vertical drop barriers, and velocity drop barriers" (NMFS, 2022).

A site-specific NEPA Environmental Assessment is currently ongoing for this project.

# CHAPTER 2 - ALTERNATIVES DEVELOPMENT AND EVALUATION

Federal agencies must consider all reasonable alternatives to a proposed action (40 CFR § 1502.14). Alternatives must be presented in comparative form, sharply defining the issues and providing a clear basis for choosing among alternatives. The federal agency responsible for this PEIS is USACE, Portland District. As the lead agency, USACE must:

1. Evaluate reasonable alternatives to the proposed action, and, for alternatives that the agency eliminated from detailed study, briefly discuss the reasons for their elimination.
2. Discuss each alternative considered in detail, including the proposed action, so that reviewers may evaluate their comparative merits.
3. Include a No Action Alternative (NAA).
4. Identify the agency's preferred alternative, if one exists.
5. Include appropriate mitigation measures not already included in the proposed action or alternatives.

As described in Section 1.1.1.1, this is a programmatic NEPA review. As such, the range of reasonable alternatives was assessed in consideration of the USACE objective to meet the purpose of and need for the programmatic proposed action and to consider public, external agency, and tribal input.

**Proposed Action**

The proposed action is continued operation and maintenance of the WVS for specific, authorized purposes and in compliance with the ESA and all other applicable treaties, laws, and regulations.

**Purpose and Need**

The purpose of and need for the proposed action is to ensure (1) USACE manages the WVS for its authorized purposes as required by Congress while (2) also meeting its requirements under the ESA (Chapter 1.0). Management of the WVS for its authorized purposes necessitates ongoing and future operation of the system and maintenance at any given project that responds to changes in WRB conditions and new information related to system operations and technology, the affected environment, polices, and regulations such as the ESA.

## 1. Summary of Authorized Purposes Specific to the Proposed Action and Purpose and Need

Details of the purposes for each project within the WVS are provided in Section 1.7. As a summary, the various purposes of the WVS were authorized by Congress in the Flood Control Acts (FCA) between 1938 and 1962, the Water Supply Act of 1958, and the Water Resources

Development Act of 1986. In these acts Congress designated the purpose for each project, which can include a combination of the following:

- flood control (more commonly referred to today as flood risk management (FRM))
- hydropower
- fish and wildlife
- recreation
- navigation
- irrigation (referred to as agricultural irrigation (AI))
- municipal and industrial (M&I) water supply
- water quality

**2. Summary of ESA Requirements Specific to the Proposed Action and Purpose and Need**

USACE must operate and maintain the WVS for specific project purposes but cannot jeopardize the continued existence of a species listed as threatened or endangered or result in the destruction or adverse modification of designated critical habitat by the Services (Section 1.1.2). As such, an alternative was only considered to be reasonable and carried forward for detailed analyses if these ESA requirements could be met.

Listed species affected by the WVS O&M in the analysis area are bull trout (listed as threatened in 1998), UWR spring Chinook salmon (listed as threatened in 1999), and UWR winter steelhead (also listed as threatened in 1999) (Section 1.1.2).

Dams along the Willamette River and its tributaries block access to substantial portions of spawning and rearing habitat for these listed species and degrade remaining downstream riverine habitats (NMFS, 2008; USFWS, 2008). Fish passage is believed to be a limiting factor affecting the prospects of recovery for ESA-listed and other native migratory fish and include (NMFS, 2008[12]) both the passage of adults migrating upstream to spawn, and juveniles (smolts) migrating downstream toward the ocean. Altered water temperatures and flows also contribute to adverse impacts on bull trout, UWR spring Chinook salmon, and UWR winter steelhead and their habitats (NMFS, 2008[13]; USFWS, 2008[14]).

As described in Section 1.1.2, several ESUs of UWR spring Chinook salmon and UWR winter steelhead are listed as federally threatened or endangered (NWFSC, 2015). Improvements to fish passage and water quality are necessary to comply with the ESA for listed fish and listed salmonid ESUs (Section 1.1.2, Section 1.7.7, Section 1.8.3).

[12] In NMFS, 2008, Subsection 3.2.1.4.3, Multipurpose Dams
[13] In NMFS, 2008, Subsection 3.2.2.4.1, Tributary and Willamette Mainstem Habitat
[14] In USFWS, 2008, Section 5.5, Water Quality

**Decision-making**

The intent in preparing the PEIS is to assist the USACE decisionmaker in making an informed decision, at the program level, through detailed analyses of various alternative O&M options. These analyses will be used to balance interests among various natural resource and human environment impacts and regulatory requirements. The alternatives incorporate combinations of O&M activities to address this balance.

**Future Activities and Subsequent NEPA Analyses**

Construction activities associated with implementation of proposed new structural measures or structural measures to make proposed operations viable may require site-specific analyses tiered from this programmatic NEPA review to disclose localized impacts such as ground disturbance, layout, etc. Limited analyses of the potential site-specific implementation of the general construction activities are included in this PEIS in the resource effects analysis in Chapter 3 to provide a range of potential effects. However, site-specific alternatives development and evaluation would determine the actual features and activities included during the subsequent tiered analyses once the site-specific design objectives and constraints are assessed.

**Chapter Organization**

This chapter discusses the formulation and evaluation of alternatives to meet the purpose and need and is arranged as follows.

- **2.1 Alternatives Development Process** - Summarizes the alternatives development process, including scoping, and the decision-making pr2ocess.
- **2.2 Final Measures Developed for Action Alternatives -** Describes two sets of measures that are carried forward in various action alternatives and the general construction activities associated with measures requiring construction.
    - Measures for flow management, water quality management, and fish passage
    - The Near-term Operations Measures based on the 2021 Court-ordered injunction operations (Section 1.9).
- **2.3 Alternatives Considered but Eliminated from Detailed Study** - Describes the alternatives that were not carried forward for detailed analysis and the reasons for their elimination.
- **2.4 Alternatives Considered in Detail** - Describes the NAA, seven action alternatives that would meet the USACE proposed action and purpose and need statement described in Section 1.3, and measures that are common to all action alternatives.

**Table 1.9-1. Summary of Terminology in the PEIS**

| Term | Definition |
|---|---|
| Willamette Valley System (WVS) | The 13 USACE-managed dams, reservoirs, and revetment in the analysis area. |
| Project(s) | The overall project is the WVS. Individual projects are also identified within the WVS. |
| Components | Current or ongoing structural elements of projects, facilities, and programs within the WVS. |
| Actions | Proposed or ongoing measures incorporated under each alternative to meet the purpose and need for the proposed action. Is synonymous with "measures." |
| Measures | Proposed components or actions that would be taken under each alternative to meet the purpose and need for the proposed action. Is synonymous with "actions." |
| Analysis Area | The area of primary study for resources described as the affected environment in Chapter 3.0. The analysis area in this PEIS is the Willamette River Basin (WRB). |

## 2.1 ALTERNATIVES DEVELOPMENT PROCESS

### The Scoping Process

NEPA requires that lead agencies engage in "an early and open process to determine the scope of issues to be addressed and for identifying the significant issues related to a proposed action" (40 CFR 1501.7). Under the scoping process, lead agencies must conduct several tasks such as inviting participation by other affected federal, state, and local agencies and tribes; determining the scope of significant issues; identifying and eliminating issues that would not be significant to the scope; etc. The results of several of these tasks helps to inform the alternatives development process. Each of the required scoping tasks were conducted by USACE for this PEIS.

In relation to scoping, key purposes and policies of NEPA are to ensure that environmental information is available to citizens before decisions are made (40 CFR 1500.1(b)) and to "encourage and facilitate public involvement in decisions which affect the quality of the human environment" (40 CFR 1500.2(d)). Decisions can include determinations on the range of reasonable alternatives and the scope of those alternatives (i.e., the alternative descriptions and content). As such, agencies involve the public in the scoping process to fulfill these NEPA requirements.

Public involvement for the USACE proposed action began with publication of a 2019 Notice of Intent to prepare an EIS in the Federal Register and inviting participation by the public and other entities. Through the scoping process, USACE solicited input from stakeholders such as tribes, the public (both private citizens and non-governmental organizations [NGOs]), and other agencies. A Scoping Report was prepared at the conclusion of the public scoping process that summarizes the process and comments received (Appendix P).

**Interdisciplinary Preparation and Cooperating Agency Involvement**

To comply with the requirement to engage and consult with other agencies, USACE formed an interdisciplinary team (made up of various technical experts from USACE) that collaborated with basin stakeholders and tribes. Potential federal and state cooperating agencies were also identified and invited to participate in the PEIS development process. Combined, interdisciplinary team, cooperating agencies, tribes, and public input helped to inform the scope of the PEIS including the alternatives development process.

**Overview of the Alternatives Development Process**

Alternatives were developed in accordance with CEQ's NEPA implementing regulations (40 CFR §1502.14). The USACE process involved three key steps: (1) identify primary constraints that would apply to any measure under any alternative, (2) identify primary management and environmental objectives that would also meet the purpose and need for the proposed action, and (3) combining results from the first two steps into formation of a range of alternatives deemed reasonable because they met conditions in Steps 1 and 2.

The following is a summary of this process. Appendix A provides detail on the alternative development process.

**Step 1: Identify Constraints**

Constraints based on the purpose of and need for the proposed action and life safety were identified. Potential alternative measures were eliminated from consideration for the following reasons:

Flood Risk Management (FRM)

Results of the preliminary modeling were used to screen any measures with potential adverse flood risk effects. Specifically, measures that would result in FRM changes from current protection levels were eliminated as an alternative measure.

Dam Safety

USACE performed a preliminary evaluation of measures for dam safety considerations. Measures that would compromise dam safety and that could not be mitigated were eliminated as an alternative measure. A more detailed dam safety evaluation of components will be conducted during site-specific planning and design.

**Step 2: Identify Objectives**

Objectives that would meet the purpose and need for the proposed action in addition to safety risk were identified. The objectives below were identified from the public scoping comments and by the USACE interdisciplinary team, cooperating agency, and tribal input.

1. Allow greater flexibility in water management (related to refill, drawdown timing, and other water management measures) as compared to current operational requirements in water control diagrams and manuals.

2. Increase opportunities for the creation of nature-based structures during maintenance of USACE-managed revetments (structures that help prevent bank erosion) as compared to opportunities under current operations. Nature-based structures are landscape features that are used to provide engineering functions relevant to FRM, while providing economic, environmental, or social benefits.

3. Allow greater flexibility in hydropower production as compared to current operational requirements in water control manuals.

4. Increase anadromous15 ESA-listed fish passage survival at WVS dams as compared to conditions under current operations.

5. Improve water management during the conservation season (related to refill, drawdown timing, and other water management measures), as compared to current operational requirements in water control diagrams and manuals, to benefit anadromous ESA-listed fish and other authorized project purposes.

6. Reduce pollutant levels to restore impaired water quality associated with the WVS dams to benefit anadromous ESA-listed species.

7. Reduce spawning and rearing habitat competition caused by hatchery fish.

**Step 3: Develop a Preliminary Range of Reasonable Alternatives**

A list of measures, or actions, that would meet at least one of the objectives was developed. These measures were formulated based on input from the public scoping comments and cooperating agencies.

Potential measures were then screened. Each measure had to meet the purpose and need for the proposed action, life safety constraints, and achieve at least one of the seven objectives. Each measure also had to be technically feasible, and not result in unacceptable adverse

[15] USACE assumed that formulating improvements for UWR spring Chinook salmon and UWR winter steelhead would also meet needs for other fish species and life stages, such as bull trout.

environmental effects. Appendix A provides detail on measures eliminated from incorporation into an alternative.

Those measures retained after applying screening were then incorporated into alternative options. Measures were incorporated in combinations or around unifying management strategies. An alternative is, therefore, a combination of one or more measures that, together, would address one or more of the USACE objectives described above.

**Step 4: Refine Preliminary Alternatives**

The alternatives described in this PEIS were developed through an iterative process. As information was revealed during the development process, the level of understanding and detail increased, which allowed a hard look at any given potential alternative. This iterative development process fostered informed decisions about the range of alternatives such as how to refine a given alternative or what should be eliminated from alternative descriptions (e.g., a measure or an element of a measure).

Following initial modeling and evaluation of preliminary alternatives, new refined alternatives were developed to assess slightly different combinations of measures and provide clarity on the tradeoffs associated with key measures. The alternatives development process focused on creating strategies to meet at least one objective under individual alternatives (Table 2.1-1). Each alternative strategy placed a different emphasis on the project objectives described in Step 2.

**Table 2.1-1. Project Alternative Strategies and Associated Objectives**

| Alternative | Strategy | Obj. 1[1] | Obj. 2[1] | Obj. 3[1] | Obj. 4[1] | Obj. 5[1] | Obj. 6[1] | Obj. 7[1] |
|---|---|---|---|---|---|---|---|---|
| NAA | Current O&M Practices | X | – | – | – | X | – | – |
| 1 | Improve Fish Passage Through Storage-Focused Measures: Increase the probability of refilling WVS reservoirs and supplemental water delivery for authorized purposes | X | X | X | X | X | X | X |
| 2A, 2B, & 5 | Integrated Water Management Flexibility and ESA-Listed Fish Alternative | X | X | – | X | X | X | X |
| 3A & 3B | Operations Focused: Improve passage of ESA-listed fish through existing structures by modifying water control operations | – | X | – | X | X | X | X |
| 4 | Structures Focused: Improve passage of ESA-listed fish by constructing fish passage and temperature control structures | X | X | X | X | X | X | X |

[1]Note: Objectives include:

1. Allow greater flexibility in water management.
2. Increase opportunities for of nature-based engineering during maintenance of revetments.
3. Allow greater flexibility in hydropower production.
4. Increase anadromous ESA-listed fish passage survival at WVS dams.

5. Improve conservation season water management to benefit anadromous ESA-listed fish and other authorized project purposes.
6. Reduce pollutant levels to restore impaired water quality associated with the WVS dams to benefit anadromous ESA-listed species.
7. Reduce spawning and rearing habitat competition caused by hatchery fish.

**Step 5. Finalize the Range of Alternatives for Incorporation into the Draft PEIS**

The alternatives development process was finalized following the refinement process described in Step 4. The final development process included identification of measures to be incorporated into alternative descriptions as describe below.

The final alternatives analyzed in this PEIS are presented in Section 2.4.4 through Section 2.4.9. Environmental consequences described in Chapter 3 were analyzed under each of these alternatives. These consequences were then compared among the alternatives in Chapter 5.

**Step 6. Evaluate and Compare the Alternatives for Selection of the Preferred Alternative**

The final step was to evaluate and compare each alternative to be analyzed in the PEIS to inform the selection of the Preferred Alternative. USACE utilized a multicriteria decision-making process to assess how well each alternative met the objectives. The criteria were also used to assess tradeoffs between alternatives. Chapter 5 provides additional detail on development of the Preferred Alternative.

## 2.2 FINAL MEASURES DEVELOPED FOR ACTION ALTERNATIVES

This section describes the measures, after screening, that have been incorporated under the alternatives described in Section 2.4.4 through Section 2.4.9 where applicable. Measures are characterized into general categories, including flow, water quality, downstream fish passage, upstream fish passage, and measure common to all action alternatives.

Measures addressing flow were developed to meet Objective 1 and 3 or Objectives 4, 5, and 6 (described in Section 2.1). Water quality measure were developed to address temperature and total dissolved gas [TDG] parameters to meet Objectives 4, 5, and 6. Passage measures were developed to meet Objective 4.

Some measures are location specific, in that the measure was developed to address a problem associated with a specific USACE facility; these locations are identified in the following measure descriptions. Other measures more broadly applied to a subbasin, all facilities, or the system. These were associated with either aquatic habitat downstream of dams or with general O&M required to run the WVS facilities. One measure associated with both downstream habitat and O&M was specifically developed to address Objective 2. Finally, a single measure was developed to address Objective 7.

Each measure was assigned a unique identification number at the start of the measure development process. This identification number was carried through the measure screening process and is provided in parentheses in the measure titles. For example: Provide Pacific Lamprey Passage and Infrastructure (#52) – this is Measure Number 52. This section provides summary measure descriptions.

### 2.2.1 Flow Measures

The amount of water flowing in a river is important to support all life stages of fish species and affects the water quality of the water body. Physical habitat and water quality associated with streamflow are central for meeting the habitat needs of aquatic biota in riverine ecosystems. Thermal conditions can annually exceed biological thresholds in the WRB regardless of streamflow conditions.

This section describes operational measures that would manage streamflow on tributaries and on the mainstem Willamette River through releases from USACE dams.

#### *2.2.1.1 Integrated Temperature and Habitat Flow Regime (#30a)*

Under this measure, dynamic dam outflows would be implemented to increase fish survival and passage. Dynamic dam outflows are also known as adaptive streamflow, or adaptive fish flows. These terms refer to dam flow management techniques that vary based on the amount and temperature of water required by fish below the dam. This flow regime is described in Appendix A, and the associated modeling parameters and results are provided in Appendix B.

The proposed integrated temperature and habitat flow regime is based on three components:

- Alternative flow targets that incorporate magnitude, seasonal variation, and annual hydrologic conditions;
- Opportunistic/adaptable water releases for real-time water temperature management; and
- Fall maximum outflows from Detroit/Big Cliff, Green Peter/Foster, Cougar, and Lookout Point/Dexter Dams.

In developing the integrated temperature and habitat flow regime, USACE assumed that prioritizing adult UWR spring Chinook salmon would also meet critical habitat needs for other fish species and life stages, such as bull trout. Under this priority, USACE could also address pre-spawn mortality, which is the rate at which targeted fish species die before they are able to spawn (reproduce) and thus contribute to the population.

Pre-spawn mortality substantially constrains productivity of UWR spring Chinook salmon, so by directly addressing pre-spawn mortality, these adaptive fish flows are addressing a critical factor to avoid jeopardizing this listed species. USACE developed these adaptive fish flows by considering the timing of their freshwater migration, holding, and spawning, all three of which extend from early spring to the fall months.

Flow targets for wet and dry years for the major tributaries regulated by WVS dams on the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette Rivers were developed based on hydrologic conditions in any given year. These flow targets depend on how much the reservoir fills in the conservation season. The flow targets from the NMFS 2008 BiOp were carried forward for other dams and sub-basins.

Fish flows under this regime also incorporate temperature pulse flows during the period from May through June. Temperature pulse flows reduce and stabilize water temperature during important timeframes for UWR spring Chinook salmon and UWR winter steelhead, mitigating warmer air temperatures to the extent possible. These adaptive flows are in addition to the base flow releases.

The specific flow targets for adaptive flow releases were based on the observed relationship between flow, air temperature, and water temperature during 2001-2018. If air temperature were forecasted to be above the threshold, additional flow from the WVS dams would occur according to the limits defined for each period. Source of flow augmentation would be determined based on current conditions of the reservoirs and adaptively managed to meet the specific need. These proposed fish flow targets are intended to reduce thermal stress on ESA-listed fish and reduce mortality during extreme heat.

Redds are instream nests created by female salmonids to lay eggs and are also crucial to early-stage juveniles, or fry. Some redd areas can become dewatered after reservoirs are drafted for FRM, reducing egg and fry survival. Ensuring higher flows in these areas can encourage spawning and reduce egg and fry mortality. Therefore, as a part of this measure, from September 1 to October 15, maximum outflows from Detroit/Big Cliff, Green Peter/Foster, Cougar, and Lookout Point/Dexter Dams would be applied to protect against redd dewatering. The spawning flow level was chosen to help balance the need to encourage spawning in areas that would remain wetted after reservoir drafting and the need to increase flows to draft reservoirs for flood management.

#### *2.2.1.2 Refined Integrated Temperature and Habitat Flow Regime (#30b)*

This measure is a modification of Measure #30a with changes to the mainstem and tributary flow targets. Flows are subject to change throughout the season based on realized hydrology and annual water management decisions. Additional water may be released from the projects to achieve temperature targets in the mainstem as measured at Salem, as noted in Measure #30a.

Under this measure, mainstem flow targets at Salem and minimum flow thresholds at Detroit/Big Cliff, Lookout Point/Dexter, and Foster Dams would be modified according to the flow targets provided in Appendix A. The associated modeling parameters and results for each alternative that includes this measure are provided in Appendix B.

#### *2.2.1.3 Augment Instream Flows by Using the Power Pool (#304)*

Under this measure, water stored within power pools would be used to supplement downstream flows to assist in meeting minimum tributary flows during the summer and late fall. Using water from the power pool would occur when natural stream flows are not adequate to provide the biologically justified flows. The measure would only be implemented to meet ESA obligations and not to provide water to meet consumptive needs of downstream M&I and irrigation users.

Due to the annual variability in hydrologic conditions throughout the basin, a set priority for use of the power pools is not possible and would be determined on an as-needed basis according to flow conditions in the tributaries (Table 1.5-3). An annual coordination process would be defined. The draft limits would be based on project location (Table 2.3-1).

**Table 2.2-1. Minimum Power Pool Elevations and Storage Volume**

| Project | Lowest Proposed Draft Limit (Minimum Power Pool Elevation) (feet) | Minimum Conservation Pool Elevation (feet) | Power Pool Storage Volume (acre-feet) | Power Pool Storage (percent of total storage) |
|---|---|---|---|---|
| Detroit | 1,425 | 1,450 | 36,375 | 21.2 |
| Green Peter | 887 | 922 | 62,600 | 36.5 |
| Lookout Point | 819 | 825 | 11,377 | 6.6 |
| Hills Creek | 1,414 | 1,448 | 48,800 | 28.5 |
| Cougar | 1,516 | 1,532 | 8,700 | 5.1 |

The re-regulating reservoirs at Dexter and Big Cliff Projects do not have power pool storage. Foster Dam has the smallest amount of power pool storage in the WVS (3.6 acre-feet); the available amount is negligible in comparison to the other reservoirs with power pool storage in the WVS. Therefore, Dexter, Big Cliff, and Foster Projects are not included with this measure.

#### *2.2.1.4 Augment Instream Flows by Using the Inactive Pool (#718)*

Under this measure, instream flows would be augmented using the inactive pool. The inactive pool is designed to trap sediment and is the lowest storage area in a reservoir.

The inactive storage by volume for these four reservoirs is listed in Table 2.3-2. Because the inactive pool is the last available storage in a reservoir, inactive pool water is traditionally reserved for extreme droughts, emergencies, and used only after the conservation pool has been emptied. Drafting into inactive storage increases the risk of not refilling the reservoirs depending on the water year.

**Table 2.2-2. Inactive Storage Volume by Project**

| Project | Inactive Storage Volume (acre-feet) | Inactive Storage (percent of total storage) |
|---|---|---|
| Blue River | 3,430 | 1.0 |
| Cottage Grove | 3,139 | 0.9 |
| Dorena | 7,355 | 2.0 |
| Fall Creek | 9,505 | 2.6 |

Using the inactive pools would assist in meeting minimum flows at the downstream control points (shown in Figure 2.3-1) during the late summer and fall (shown in Figure 2.3-1). The reservoirs are generally not drafted below their minimum conservation pools unless hydrologic conditions result in reservoir inflows less than what is needed to provide downstream minimum flows.

Water stored in the designated inactive pools would be used to support biological flow targets when natural stream flows are inadequate to provide the biologically justified flows. This measure would allow the water stored in the inactive pool to be used when needed without additional analysis on a case-by-case or year-by-year basis.

The lowest outlet in the reservoir would be used to draft the reservoir to the desired elevation without a need for structural modifications. If the minimum conservation pool elevation is reached before September 1, the elevation would be dropped to the low flow target. If the minimum conservation pool elevation is reached after September 1, the existing flow target would be retained.

**Figure 2.2-1. Study Area Sub-basins and Control Points (illustrates USACE-managed dams only)**

#### *2.2.1.5 Reduce Minimum Flows to Congressionally Authorized Minimum Flow Requirements (#723)*

Under this measure, minimum flows would be reduced to the Congressionally authorized minimum flows to benefit reservoir refill objectives. This would allow reservoirs to capture more spring runoff rather than releasing it.

The spring and summer tributary flow targets would be based on operating equipment limitations at the projects and would occur year-round. The summer mainstem flow targets are based on the flow targets identified in HD531 for Albany and Salem and would occur from June through September (Table 2.2-3 and Table 2.2-4).

**Table 2.2-3. Tributary Flows from HD531 at Project Locations**

| Dam | Minimum Flow (cfs)1 | Remarks on Limits |
|---|---|---|
| Detroit/Big Cliff | 1000/750 | 1 Feb – 30 Jun = 1000 cfs<br>1 Jul – 30 Nov = 750 cfs |
| Blue River | 30 | 1 Feb – 30 Jun = 30 cfs<br>1 Jul – 30 Nov = 30 cfs |
| Cottage Grove | 75/50 | 1 Feb – 30 Jun = 75 cfs<br>1 Jul – 30 Nov = 50 cfs |
| Cougar | 300/200 | 1 Feb – 30 Jun = 300 cfs<br>1 Jul – 30 Nov = 200 cfs |
| Dorena | 190/100 | 1 Feb – 30 Jun = 190 cfs<br>1 Jul – 30 Nov = 100 cfs |
| Fall Creek | 30 | 1 Feb – 30 Jun = 30 cfs<br>1 Jul – 30 Nov = 30 cfs |
| Fern Ridge | 50/30 | 1 Dec – 30 Jun = 50 cfs<br>1 Jul – 30 Nov = 30 cfs |
| Green Peter/Foster | 50 | 1 Feb – 30 Nov = 50 cfs<br><br>HD531 was adopted prior to Foster Dam being proposed; hence the minimum flow released at Green Peter Dam is the 50 cfs but also that needed to ensure Foster minimum flows. |
| Foster | 800 – 400 | 1 Feb – 30 Apr = 800 cfs<br>1 May – 31 May = 750<br>1 Jun – 30 Jun = 600<br>1 Jul – 30 Nov = 400 cfs |

| Dam | Minimum Flow (cfs)1 | Remarks on Limits |
|---|---|---|
| | | Foster was not included in HD 531; therefore, minimum flow from Foster Dam is the combined minimum for Green Peter and Cascadia Dams. |
| Hills Creek | 100 | 1 Feb – 30 Jun = 100 cfs<br>1 Jul – 30 Nov = 100 cfs |
| Lookout Point/Dexter | 1200/1000 | 1 Feb – 30 Jun = 1200 cfs<br>1 Jul – 30 Nov = 1000 cfs |

cfs=cubic feet per second

**Table 2.2-4. Mainstem Flows**

| Control Point | Date | Augmentation for Fish Habitat and Water Quality (cfs)*1 |
|---|---|---|
| Salem | Jun 1 – Nov 30 | 6,500 |
| Albany | Jun 1 – Nov 30 | 5,000 |

*Note: Numbers provided are per HD531

[1]cfs = cubic feet per second

### 2.2.2 Water Quality Measures

Water quality downstream of a dam can affect all life stages of fish species. Temperature is an important environmental factor affecting salmonid distribution, behavior, and physiology (Groot and Margolis, 1991; Brett 1995; Newell and Quinn, 2005) and affects their distributions and migratory behavior (Behnke, 1992; Quinn, 2005).

Downstream water temperatures in the WVB affected by the dams disrupt fish spawning and rearing life stages because water is too warm in the fall/winter and too cool in the summer/spring. Most of the WVS dams are considered high head dams, meaning they are over 100 feet tall. As a result, their deep reservoirs experience thermal stratification in summer.

Thermal stratification occurs when the warming of the reservoir’s surface by the sun causes water density variations and cooler, denser water settles to the bottom of the reservoir. A layer of warmer water floats on top.

The coldest water will be released in the summer if the only available outlets for releasing water are the deep regulating outlets (ROs) or if a deep penstock is being used to create power (Figure 1.8-2).

WRB rivers have been historically warmer in the summer than under current conditions. Fish adapted to the historical, warm summer conditions; therefore, the unseasonably cool water released from the reservoirs disrupts their life stages in summer. By fall, most of this cool water has been released, leaving mostly warm surface water at a time when rivers would historically be cooling off with increased precipitation, further disrupting salmonid life stages. In the winter a lake may "turnover" meaning cooler water will move to the surface and any remaining warmer water will move to the bottom.

Total dissolved gas (TDG) supersaturation also negatively effects environmental effects fish and other aquatic species (EPA, 1973). Discharging water through the spillway or ROs entraps air in the plunge pools downstream from the dams, leading to increasing TDG in the downstream river (Qu L. et al., 2011). TDG supersaturation can easily cause fish to suffer from gas bubble disease (GBD) by producing air bubble blockages in the blood, heart, and gill filaments (Johnson E. et al., 2005). GBD can cause a variety of physiological impairments to fish and negatively impact their typical life processes, increasing the mortality of both adult and juvenile fish (Weitkamp et al., 1980).

Based on Clean Water Act (CWA) requirements, state and resource agencies have implemented temperature total maximum daily loads (TMDLs) for both temperature and TDG. A TMDL is a plan for restoring impaired waters that identifies the maximum amount of a pollutant that a body of water can receive while still meeting water quality standards.

The TMDLs in the WRB provide temperature targets throughout the year to coincide with life cycle stages of ESA listed fish. This section describes the structural and operational measures to address temperature and TDG. Details specific to each basin/reservoir are provided where appropriate.

#### *2.2.2.1 Construct Water Temperature Control Towers (#105)*

Under this measure, Selective Withdrawal Structures (SWS), often referred to as Water Temperature Control (WTC) towers, would be constructed to help regulate water temperatures downstream of projects. Figure 1.5-10**Error! Reference source not found.** shows a WTC completed at Cougar Dam in 2005. This shows one possible design that could be constructed at other dams in the WVS.

SWSs blend warmer surface water with cooler deep water by using multiple gates at varying elevations within the reservoir to meet CWA and ESA requirements downstream of the proposed project locations (

Figure 2.3-2). The SWSs would allow USACE to send this blended water through the powerhouses and continue to generate power while still meeting downstream water quality targets. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for the construction of each SWS tower.

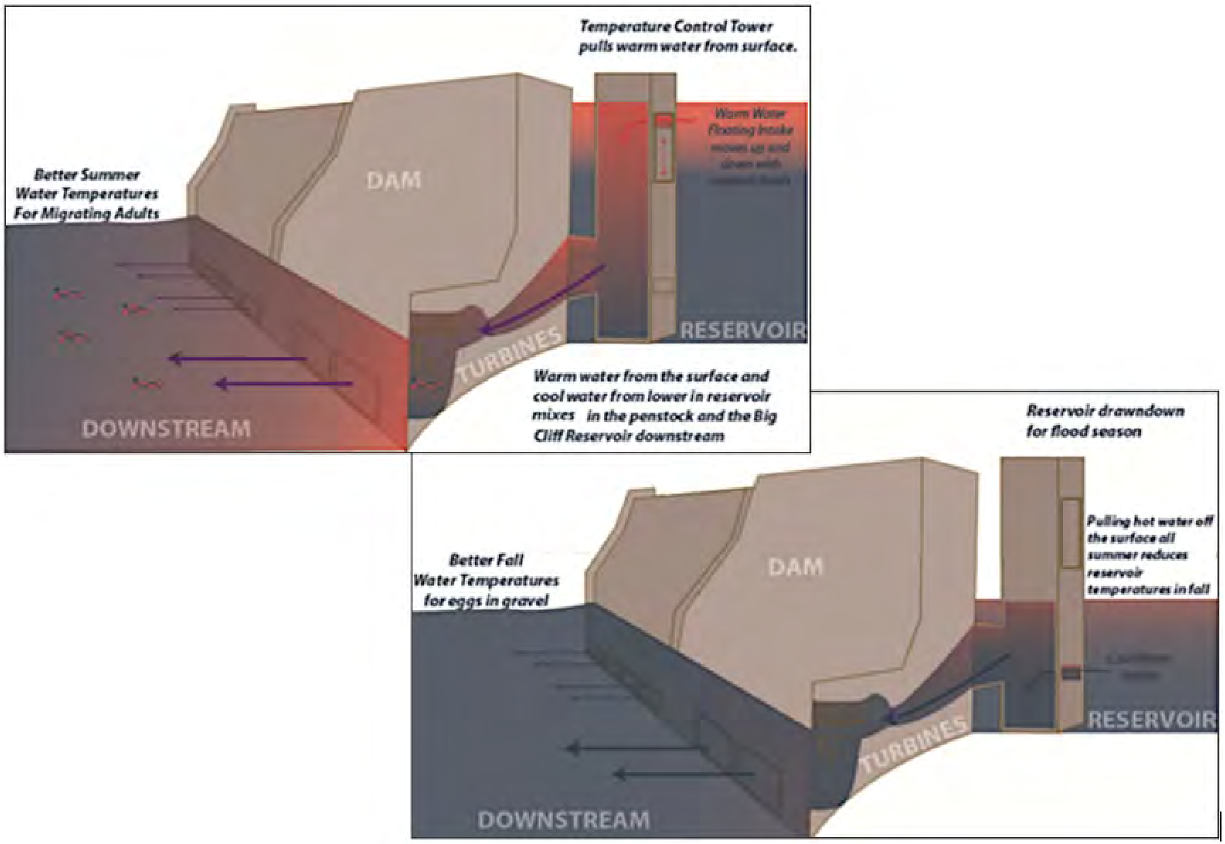

**Figure 2.2-2. Graphic Representation of SWS Operation (at Detroit Dam)**

### *2.2.2.2 Use Regulating Outlets for Temperature Management (#166)*

Under this measure, projects that have regulating outlets (RO) would release relatively cool water from the ROs during the fall to benefit natural UWR spring Chinook salmon egg incubation. Table 2.3-5 provides the dams where this measure is proposed, the outlet elevation for each and any restrictions.

**Table 2.2-5. Outlet Elevations and Current Restrictions**

| RO Location | Outlet Elevation (feet) | Current Restrictions |
|---|---|---|
| Green Peter | 745 | No restrictions |
| Lookout Point | 724 | No restrictions |
| Detroit Upper | 1,335 | Usable when lake is below 1,541 feet |
| Detroit Lower | 1,260 | Usable when lake is below 1,460 feet |

The WVS reservoirs experience strong temperature stratification during the spring, summer, and fall before reservoir turnover. Generally, warm water rises and cool water sinks, resulting in the stratification of reservoirs with the warmest water on the surface and the coldest at the bottom. When the reservoir is stratified, there is an opportunity at some dams to release relatively cool water from the ROs below the power intakes. This water is comparatively cooler than that released through the turbines and can provide a benefit for spring Chinook salmon egg incubation downstream.

Regulating outlets consist of tunnels and gates through the dams. They are designed to provide a means of releasing reservoir water apart from turbine outlets and spillways. Regulating outlets are used to manage a range of flows from low flow all the way up to activation of the spillway and can be used in combination with the spillway to manage very high flows. Figure 2.3-3 illustrates a configuration of ROs, spillway, and penstock outlet at Detroit dam.

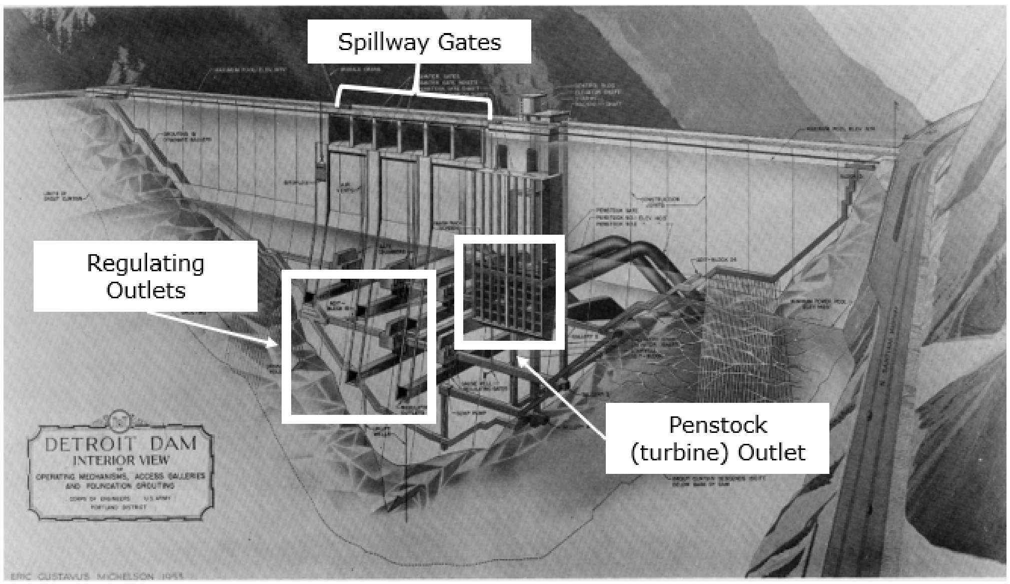

**Figure 2.2-3. Interior View of Detroit Dam Showing the Outlet Configuration**

Depending on the dam, the RO and spillway can be used simultaneously. There is limited benefit of this measure at Lookout Point and Green Peter Dams due to the close proximity of the ROs to the turbines. Likewise, the ability of the lower ROs to expel cold water during fall provides limited benefit as the operation has a relatively short duration (a few weeks) before flood season begins and the reservoirs begin to refill.

While the ROs were designed for use during high flows, they were not specifically designed for regular usage at relatively low flow or frequent gate changes, as is often desired for temperature management. The ROs are also aging and would need to be reinforced and modernized if they are to be used routinely with high head pressure (during times when the lake is full).

For example, under this measure at Detroit Dam, the lining of the RO tunnels may need to be reinforced and gate reliability would likely need to be improved to limit the effects of cavitation, a corrosive process that can lead to major damage to dam structures (Figure 2.3-4) and scouring of the dam when head pressure exceeds 200 feet above an outlet. Use of additional outlets would provide additional capability to release cooler flows in the late fall (typically November). Work to address cavitation and gate reliability would be performed as a part of normal maintenance activities.

This measure would be implemented in the timeframe between October 1 and November 15. The implementation frequency and duration of this measure would be dependent on the seasonal reservoir hydrology and temperature conditions as well as the observed conditions downstream of the project.

**Figure 2.2-4. Photo of Cavitation Damage to Upper RO Tunnel**

#### *2.2.2.3 Structural Improvements to Reduce Total Dissolved Gas (#174)*

Under this measure, structural improvements would be implemented to reduce TDG. Measures may include:

- Structural modifications focused on the redesign of current outlets, spillways, or stilling basins that should not increase erosional scouring forces that would decrease structural integrity of the dam.
    - Deflectors (Figure 2.3-5) installed at the base of spillways that redirect the spill jet, which transports air bubbles deep into the stilling basin, to a horizontal jet that maintains entrained air closer to the water surface. Allowing the entrained air to dissipate more quickly, thus reducing the probability of fish contracting GBD.
    - Boulder augmentation or debris jams that create more natural riffles downstream of dams and help de-gas supersaturated water.
    - Implementation of spill patterns that distribute spill bay flows uniformly across the entire spillway to help reduce downstream TDG.
    - Constructing pipe extensions on the downstream side of ROs to submerge releases in the stilling basin and reduce jet impact on the tailwater surface.

- Integration of TDG management in the design of new SWSs. While SWSs reduce, to some degree, the amount of spill that typically occurs during operational temperature management and, therefore the amount of TDG, elevated TDG would still likely exist during high flow events, turbine outages, or turbine maintenance. Therefore, the design of new SWSs should incorporate how/if to address TDG abatement.
- Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for the construction of this measure at each location.

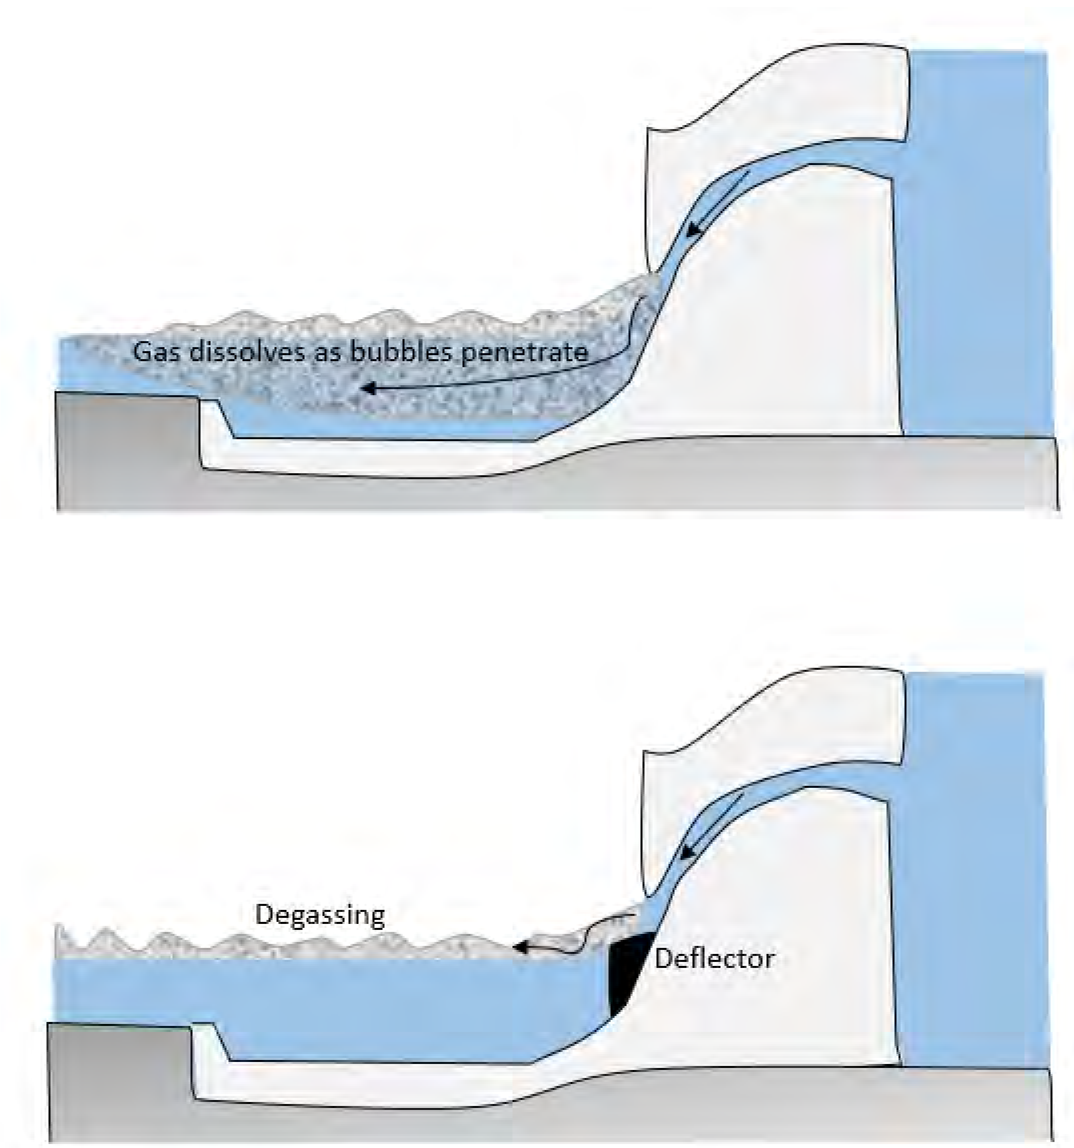

**Figure 2.2-5. Spillway Deflector Reducing Total Dissolved Gas**

### *2.2.2.4 Foster Dam Fish Ladder Temperature Improvement (#479)*

Currently, upstream fish migration at Foster Dam has been observed to be delayed, and consensus among regional fisheries managers is that the temperature of the water in the fish ladder is too cold to attract fish in the spring and early summer (May and June). This measure would provide more normative temperatures at the fish ladder entrance. Under this measure, a structural modification to Foster Dam would be implemented to reduce delay of upstream-migrating UWR spring Chinook salmon and UWR winter steelhead by increasing the water temperature in the fish ladder.

During the later spring and summer months, the Foster forebay is temperature stratified. The existing water supply for the fish ladder is located at the powerhouse intakes at a depth where the water is coldest when the reservoir is stratified. As a result, the temperature of the flow issuing from the pre-sort pool at the top of the fish ladder and from the ladder entrances is too cold compared to the historic or ambient river temperatures.

The major feature of this measure is construction of a new Forebay Warm Water Supply (FWWS) pipe that would draw warm water from near the surface of the reservoir in the Foster forebay. The existing water supply pipe would remain in use, and a network of pipes and valves would allow the two water sources to be mixed to achieve desired temperatures at the adult fish facility.

The temperature targets were developed as a function of the upstream South Santiam River, with maximum target temperatures constrained by needs for fish health. A juvenile fish exclusion screen would be provided upstream of the FWWS intake to keep juvenile fish from entering the pipe.

Figure 2.3-6 provides a piping schematic and identifies the four temperature target locations. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for the construction of this measure.

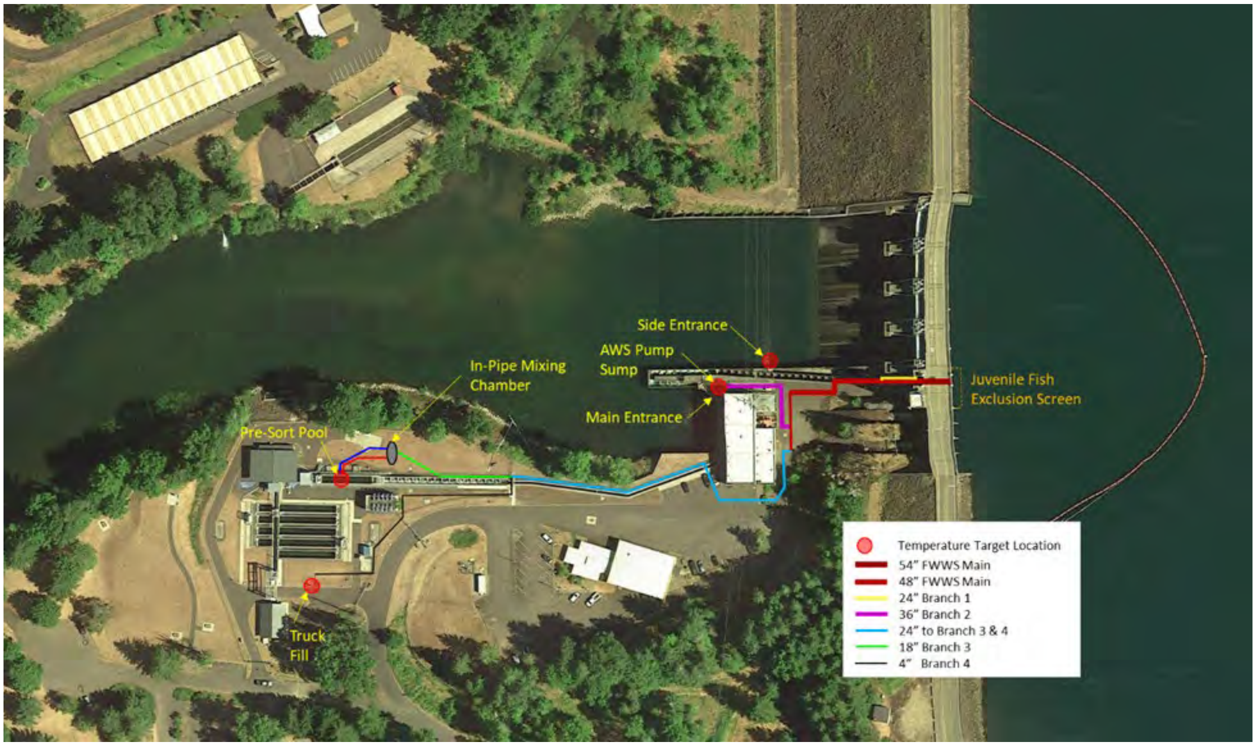

**Figure 2.2-6. FWWS Piping Schematic with Temperature Target Locations (at Foster Dam)**

### *2.2.2.5 Use Spillways to Release Warm Surface Water in Summer (#721)*

Under this measure, spillways would be used to further improve downstream water temperature management into the fall (Table 2.3-6). A larger volume of warm surface water from the reservoirs could be released by extending the use of the spillway, while deeper cold water could be reserved for later in the fall and early winter when necessary for fish incubation (Figure 2.3-7). The actual mix between outlets would depend on temperature targets. At Detroit, Lookout Point, Hills Creek, and Green Peter Dams, the minimum flow of 60 percent of total outflow during a specified period would be targeted.

Structural modifications would be required to use the spillways at Hills Creek and Blue River for this measure because they were designed for only occasional use in FRM operations. The Hills Creek Dam spillway channel (Figure 2.3-8) and spillway gates would require modifications to allow for low flow rates and a useable low-flow channel that would not affect the powerhouse.

The fish weir at Foster Dam would also need to be modified to implement this measure.

Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for necessary modifications at Hills Creek, Blue River, and Foster Dams.

**Table 2.2-6. Spillway Elevation and Durations for Warm Surface Water Releases**

| Location | Spillway Elevation (feet) | Approximate Duration (dates) |
|---|---|---|
| Lookout Point | 888 | June 1 – August 1 |
| Hills Creek | 1,495 | May – July |
| Blue River | 1,321 | May – July |
| Foster | 597 | May – July |
| Green Peter | 969 | June1 – August 1 |
| Detroit | 1,541 | April 15 – August 30 |

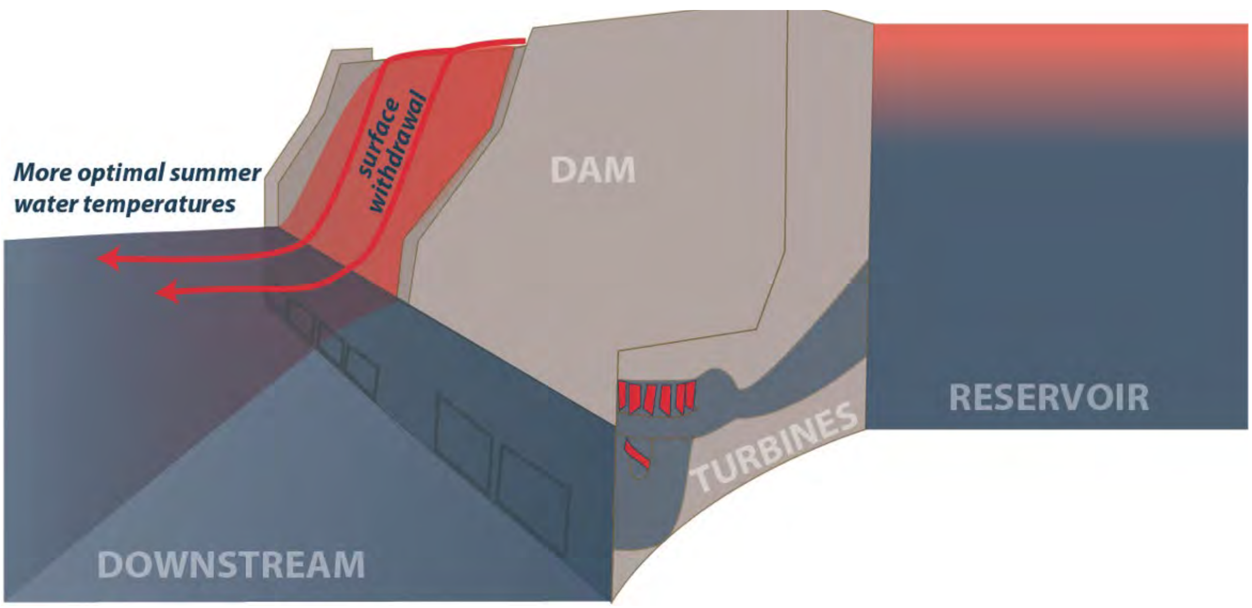

**Figure 2.2-7. Graphic Representation of Warm Water Surface Spill over a Dam's Spillway**

**Figure 2.2-8. Hills Creek Dam Spillway Channel**

### 2.2.3 Downstream Fish Passage Measures

Juvenile UWR spring Chinook salmon and UWR winter steelhead located upstream of WVS dams must pass the dam to migrate downstream on their way to the ocean. The fish will actively search for a way downstream and are strongly directed by the current. Juvenile salmonids are also surface oriented, meaning they migrate close to the water surface and are not likely to dive in search of a passage through deep outlets.

Some dam passage routes are also safer than others. The safest and easiest to find a way through a dam is usually a spillway. However, a large volume of water, and therefore strong current, also passes through the dam's turbines. This can be a dangerous and difficult course for juvenile fish. This section describes the structural and operational measures to improve downstream fish passage. Details specific to each basin/reservoir are provided where appropriate.

#### *2.2.3.1 Deeper Fall Reservoir Drawdown for Downstream Fish Passage (#40)*

Under this measure, reservoir elevation would be decreased in the fall to 25 feet over a dam’s ROs (or at Cougar Dam the Diversion Tunnel [DT]) to improve downstream passage for migrating ESA-listed and other fish. Fish are more likely to survive passage when the water elevation over the outlet is relatively shallow; higher elevations of water over the outlet result in lower survival rates during passage. Water levels below the outlet would not allow for passage at all. The dams and outlets at which this measure would be implemented depend on the alternative. Dams where this measure could be implemented include Detroit, Green Peter, Lookout Point, Hills Creek, Blue River, and Cougar Dams.

At Cougar Dam, this measure could alternatively involve drawing down to the RO or within 25 feet of the Diversion Tunnel (DT), located at the bottom of the reservoir (Figure 2.3-9), depending on the alternative. A drawdown to the DT at Cougar would require several dam modifications to make this operation possible and a change in operational authority.

First, dam safety concerns associated with Cougar Reservoir's fluctuating pool levels would need to be addressed. Second, redundant gate structures to allow for safe, remote, routine operation of the DT would need to be designed and constructed. Finally, the DT would need to be made accessible for O&M through the construction of a tower and bridge. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for these required modifications.

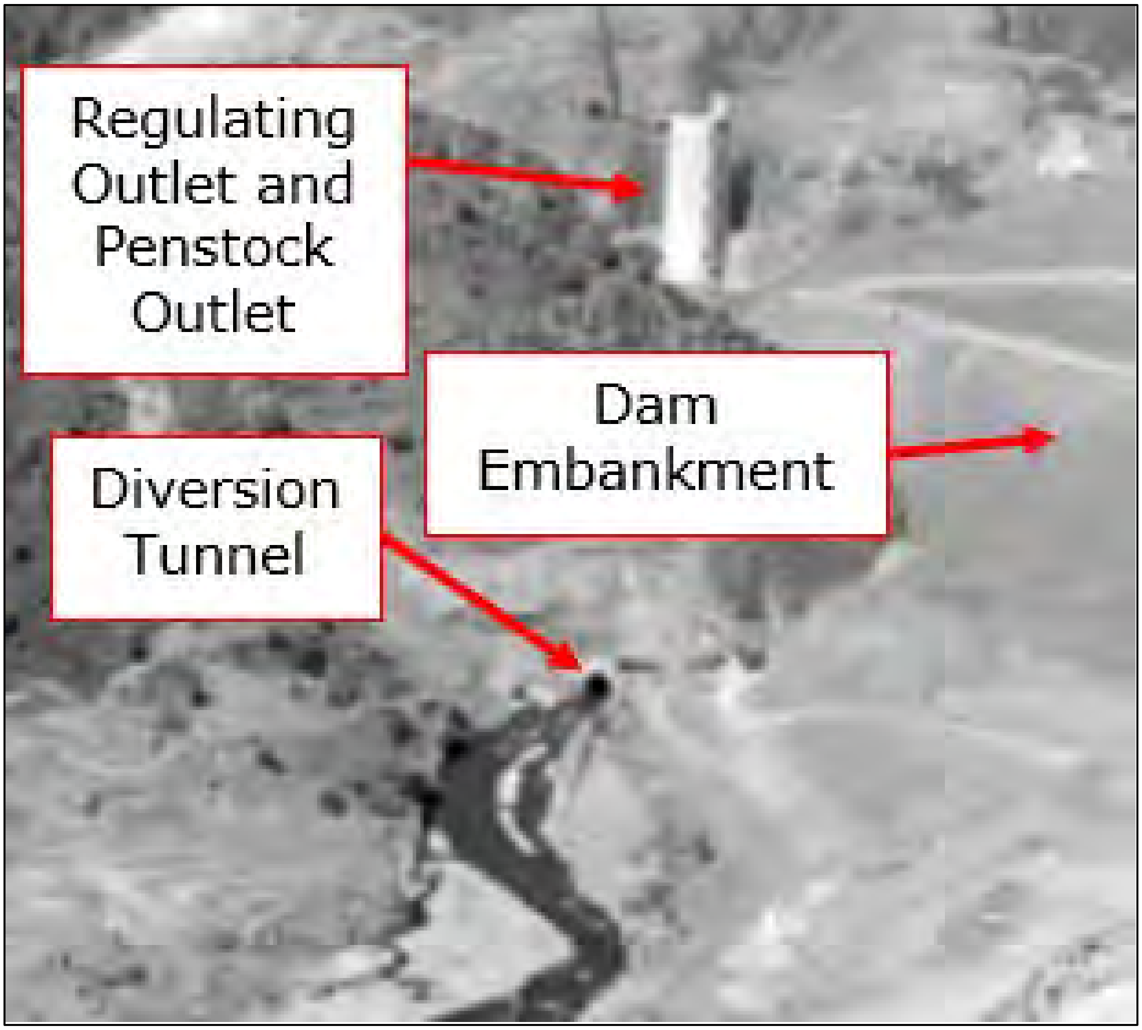

**Figure 2.2-9. 1960s Photograph of Cougar Dam Diversion Tunnel**

Drafting of each reservoir would begin on or about July 1 each year and would proceed at a rate necessary to achieve the October 1 rule curve elevation on September 1 (number 1 in Figure 2.3-10). During the September 1 to October 15 spawning season for UWR spring Chinook salmon, the total discharge from the dam would be maintained at or below the maximum flows for spawning (number 2 in Figure 2.3-10) as shown in Table 2.3-7. After the spawning season ends on October 15, the draft rate would then be revised as needed to achieve the November 15 target elevation (Table 2.3-7) on November 10 (number 3 in Figure 2.3-10).

Pool target elevations (Figure 2.3-10) would be achieved beginning at the earliest on November 15 and at the latest on December 15 (Number 4 in Figure 2.3-10, developed for demonstration only). Turbine operations would be limited from dusk to dawn and whenever reservoir elevation is at or below 50 feet over the top of the penstock; and during the dates of October 15 to December 15.

Reservoirs would be operated at the fish passage target elevations, shown in Table 2.3-7, for 21 days. Three weeks was chosen due to the observed response of juvenile UWR spring Chinook salmon to fall operations when pool elevations are reduced closer to ROs (e.g., Nesbit, 2012; Keefer et al., 2013). Observations indicate most juveniles will pass downstream during the reservoir drawdown period before the target elevation is achieved, and likely within hours to a few days after it is achieved.

Three weeks was also chosen to provide additional opportunity to pass juvenile UWR spring Chinook salmon downstream that may move downstream from the upper reservoir, while balancing time for refill back to minimum conservation pool elevation before February 1st. This would avoid impacting the ability to augment downstream flows during the following conservation season.

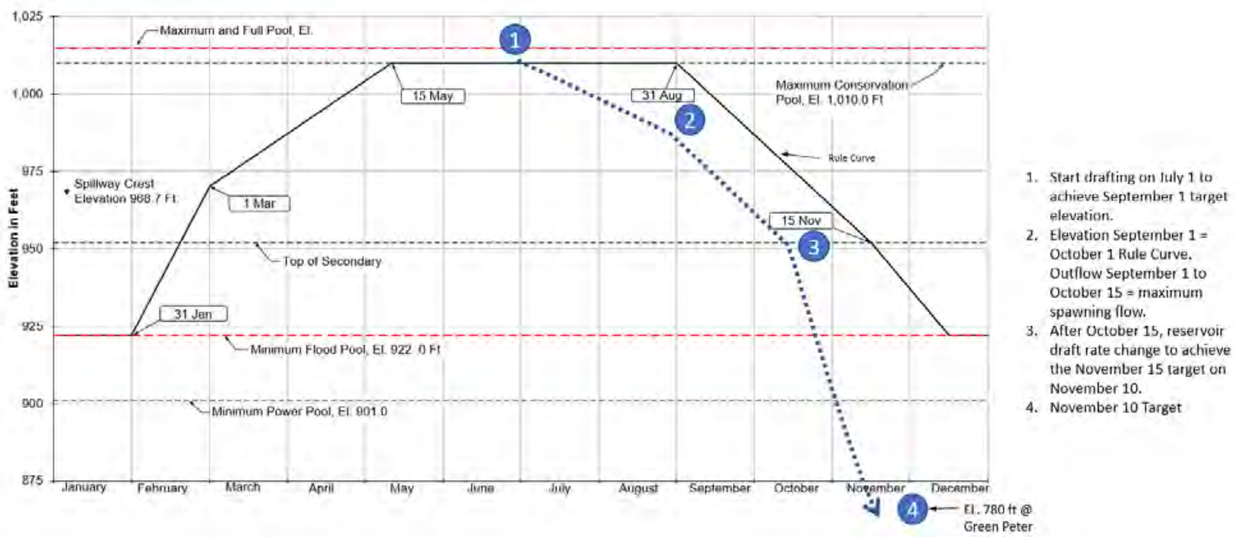

**Figure 2.2-10. Example Green Peter Rule Curve for Reservoir Drafting Approach**

**Table 2.2-7. Fall Reservoir Drawdown Target Elevations[1]**

| Dam | Target Elevation (feet) (25 feet above top of the outlet)[1] |
|---|---|
| Detroit | 1,375 |
| Green Peter | 780 |
| Lookout Point | 761 |
| Hills Creek | 1,446 |
| Blue River | 1,165 |
| Cougar RO | 1,517 |
| Cougar DT | 1,330 |

[1] These are the top of ROs (plus 25 feet) and elevations below which turbine operations would be limited between 10:00 a.m. and 6:00 p.m. daily.

Target elevations = invert elevation + height of outlet + 25 feet

#### *2.2.3.2 Pass Water over Spillways in Spring for Downstream Fish Passage (#714)*

Under this measure, water would be discharged using the spillway in late spring and early summer to increase the survival and passage rate of juvenile UWR spring Chinook salmon and UWR winter steelhead passing downstream. The spillway outflow attracts migrating juvenile salmonids, which can use the spillway flows to pass the dam rather than going through the turbines. The dams at which this measure would be implemented depend on the alternative.

Factors considered in determination of facilities that warrant implementation of this measure include the types of turbines, the hydraulic head of the dam, and the downstream biological impact due to elevated TDG levels from spill operations. Dams where this measure could be implemented include Big Cliff, Detroit, Dexter, Lookout Point, Hills Creek, Fall Creek, Green Peter, and Cougar Dams. The measure would start approximately May 1, or as soon as pool elevation allows, and run until July 1, or as long as hydrology supports the operation. The maximum pool elevation would be less than or equal to 25 feet above spillway crest.

Structural modifications would be required to safely implement this measure at Hills Creek Dam because the spillway was not designed for frequent use; it was designed to occasionally pass fill due to flooding events. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for necessary modifications at Hills Creek Dam.

#### *2.2.3.3 Deep Spring Reservoir Drawdown for Downstream Fish Passage (#720)*

Under this measure, reservoir elevation would be decreased in the spring to 25 feet over a dam’s ROs or DT to improve downstream passage for migrating ESA-listed and other fish.

At Cougar Dam this measure could alternatively involve drawing down to the RO or within 25 feet of the DT at the bottom of the reservoir, depending on the alternative (Figure 2.3-9). A drawdown to the DT at Cougar Dam would require several dam modifications to make this operation possible, as described in Section 2.3.3.1 for Measure #40. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for the construction of these required modifications at Cougar Dam.

Details on the operation of this measure are provided for each dam in Table 2.2-8, including the target elevation and the duration the reservoir would be held at this elevation. For operation of this measure, beginning February 1, the reservoir would be drafted down as needed to reach the target elevation by May 1. The target elevation would be held until June 15, as hydrology allows, to increase survival of juvenile UWR spring Chinook salmon and UWR winter steelhead during downstream passage.

**Table 2.2-8. Reservoir Drawdown Target Elevations**

| Dam | Target Elevation (feet) (25 feet above top of the outlet)[1] | Duration Held at this Elevation (weeks) |
|---|---|---|
| Detroit | 1,375 | 6 |
| Green Peter | 780 | 3 |
| Lookout Point | 761 | 6 |
| Hills Creek | 1,446 | 6 |
| Cougar RO | 1,517 | 6 |
| Cougar DT | 1,330 | 6 |

[1]These are targets. If a reservoir is lower, it would be filled to the target (inflow allowing) while meeting minimum flows; if higher, it would be drafted without exceeding maximum flows.

### *2.2.3.4 Construct Structural Downstream Fish Passage (#392)*

Under this measure, downstream fish passage structures would be constructed to provide passage for migrating ESA-listed and other native fish. Downstream fish passage structures for anadromous smolts migrating toward the ocean fundamentally differ from upstream fish passage structures for adults travelling upstream to spawn.

Upstream fish passage in the WVS involves adult fish collection facilities located downstream of a dam. Fish are collected and transported via truck to a location above the reservoir.

Downstream fish passage structures either float in the reservoir or are attached to the dam's spillway. For in-reservoir floating structures, juvenile fish are collected near the dam and transported downstream via 'trap and haul' methods like upstream passage methods (Figure 1.6-4). In the case of downstream passage structures attached to the dam, fish are allowed to volitionally swim over the spillway structure and past the dam.

A description of in-reservoir floating structures and a downstream structure attached to the dam is provided below. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for construction of either type of downstream fish passage structure.

#### *2.2.3.4.1 Structural Downstream Fish Passage at Detroit, Green Peter, Cougar, Lookout Point, and Hills Creek Dams*

Under this measure a floating downstream passage structure would be constructed and operated to capture downstream migrating UWR spring Chinook salmon and UWR winter steelhead, as well as other species and life stages. Water flowing into the entrance of the floating structure attracts juvenile fish. The fish enter and are held for transport around the dam by truck or barge or guided into a pipe that safely carries them downstream of the dam.

Capture structures that rely on gravity flows (and may also utilize supplemental pumped flow) are called Floating Screen Structures (FSS). Capture structures that utilize only pumped flow are called Floating Surface Collectors (FSC). Both types floating structures typically consist of large barges attached to vertical tracks on WTC towers that allow the structure to rise and fall with the reservoir (Figure 2.3-11).

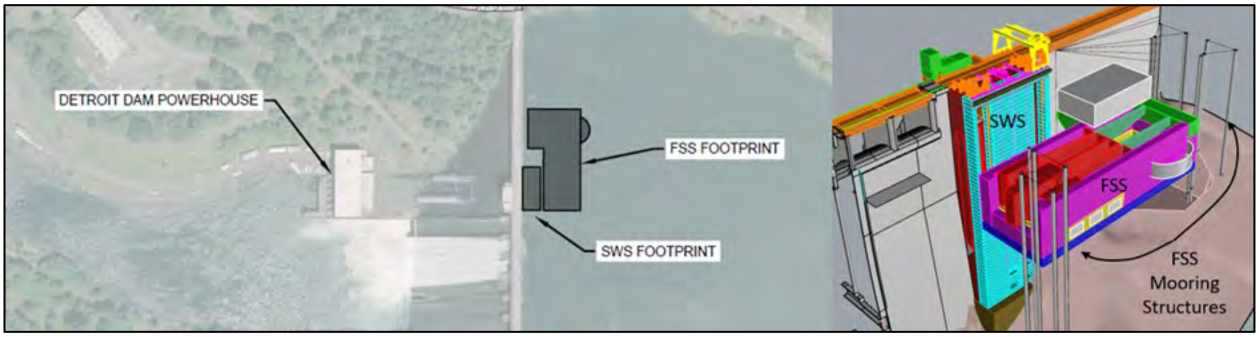

**Figure 2.2-11. Proposed Detroit Water Control Tower with Attached Floating Screen Structure**

The construction approach, feasibility, and design of the FSSs or FSCs would be site-dependent and would be determined during the construction design phase. Existing examples of FSS/FSCs have shown that consistent flows result in higher collection efficiency (Kock et all., 2019).

Adaptive management would be used to inform how to operate for hydropower and collection efficiency at these locations. The proposed Detroit Dam downstream passage facility (documented in the Detroit Downstream Passage Draft EIS [USACE, 2019b]) would be used for modeling and analyzing effects of the measure for Detroit Dam. Available design concepts for other locations, including Detroit and Cougar Dams, would be adapted to model and analyze effects for those locations. The flow range that would attract fish through each passage structure are shown in Table 2.3-9.

**Table 2.2-9. Minimum and Maximum Flows Floating Screen Structure by Project**

| Project | Minimum Flow1 (cfs) | Maximum Flow (cfs)2 |
|---|---|---|
| Detroit | 1,050 | 5,600 |
| Green Peter | 300- 1,000[3] | 5,300 |
| Cougar | 300 | 1,000 |
| Lookout Point | 1,350 | 6,000 |
| Hills Creek | 300 | 1,000 |

[1]Minimum flow is the minimum dam discharge.

[2] cfs = cubic feet per second

[3] At Green Peter Dam, the minimum dam discharge is 300-500 cfs, but can be supplemented with pumped flow up to 1,000 cfs.

### *2.2.3.4.2 Structural Downstream Fish Passage at Foster Dam*

Spillways can be the safest route for juvenile fish to pass a dam, but the spillway may be difficult for the fish to find. Most salmon and steelhead juveniles like to stay in the top 20 feet of the water column. Spillway openings may be as much as 60 feet below the surface, too deep for the fish to use.

At the Foster Dam, the spillway has been equipped with a spillway weir, a movable gate on the upriver side. When juvenile fish are migrating, water flows over the top of the weir and out through the spill gate. Since fish do not have to dive down to find the spillway entrance, more fish could pass with less water spilled. And since the fish quickly find passage, they also may escape predators above the dam. However, currently the Foster Dam spillway weir does not efficiently pass fish downstream.

Under this measure, the Foster Dam fish weir would be modified to improve downstream passage. The approach, feasibility, and design of the structure would be determined during the construction design phase. The design would utilize a flow rate of 500-800 cfs. Table 2.2-10 shows assumptions used for this measure at the Foster Dam.

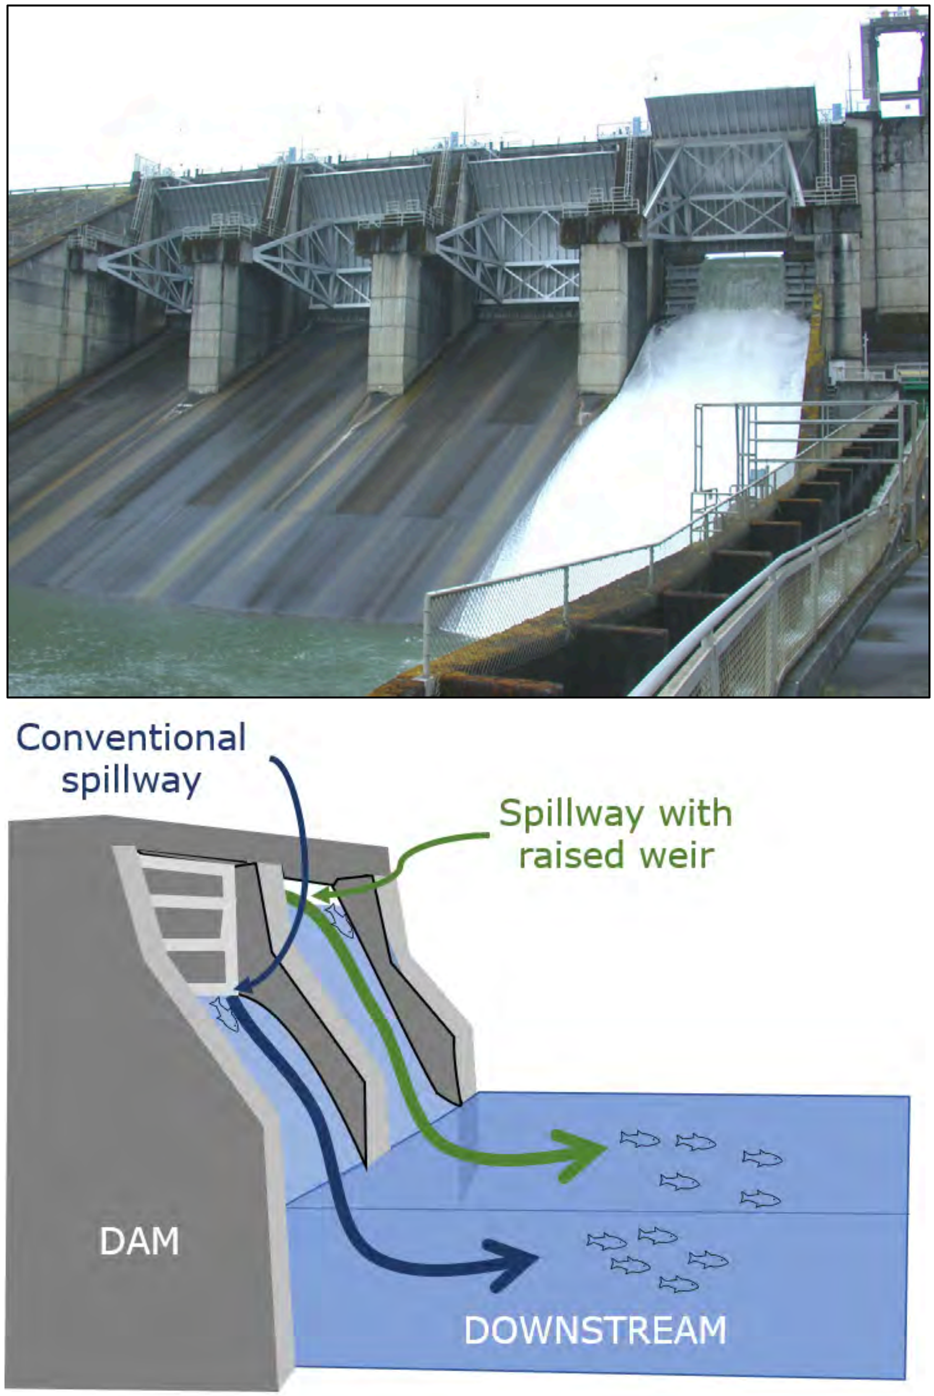

**Figure 2.2-12. Foster Dam's Fish Weir**

**Table 2.2-10. Assumptions used for the Downstream Passage Measure at Foster Dam**

| Category | Description |
|---|---|
| Description of work | Improve structural passage at Foster Dam |
| Duration (hours/days) | Fish structure operates all day, year-round at 600 cfs |
| Estimated Annual Start Date (day/month) | Year-round |
| Recurrence Interval (years) | Annually when the pool is within the operating elevation (winter at 615 feet min and summer at 635 feet max) |
| Pool Elevation (feet) | Foster Spillway: 615 (min elevation) to 635 (max elevation) |
| Restricted Outlet (RO/spillway/etc.) | Turbines restricted between 7:00 p.m. – 7:00 a.m. during fish passage seasons |
| Estimated Day/Month Start | When within operating range |
| Duration of Outlet Restriction (days) | When within operating range |
| Maximum Flow (cfs) | 800 cfs |

cfs = cubic feet per second

### 2.2.4 Upstream Fish Passage Measures

Adult salmon migrate from the ocean to spawn in freshwater, migrating upstream to the river where they were hatched. Dams and other structures across the river, block this upstream migration unless passage is provided.

The most common way for adult fish to get past a dam is to use a fish ladder, a water-filled structure that allows fish to pass up and over in a series of steps. Migrating salmon are attracted to the current at the base of an extended concrete stairway. The fish swim or jump from step to step. However, due to the height of the WVS high-head dams (between 93 feet and 463 feet tall), fish ladders are not practical. Where ladders are not practical, a trap and haul operation can be used to move adult fish upstream.

In trap and haul operations, migrating salmon are attracted to flow at the base of a fish ladder. They climb the ladder to a loading system where they wait in pools or tanks before transfer into specialized tankers or barges. These vehicles release the salmon into the river on the other side of the dam. This section describes the structural and operational measures to address upstream passage. Details specific to each basin/reservoir are provided where appropriate.

#### *2.2.4.1 Provide Pacific Lamprey Passage and Infrastructure (#52)*

Lamprey swim differently than salmon; passage facilities built for salmon present a difficult obstacle for this species. Square corners in the ladders are particularly difficult for lamprey. Lamprey will grab onto a vertical or horizontal surface then release, burst ahead, and grab on again in a near, up-ladder location. As they creep along in this way, they can lose their grip and be washed down the ladder.

Under this measure, structural features and modifications would be made at adult fish passage facilities to improve Pacific lamprey passage. Features and modification could include rounded corners in turning pools, rounded side edges of the ladder opening, replacement of diffuser screens[16] with lamprey-friendly screens, and other nature-based features.

Any new adult fish facilities (see measure #722) or facility modifications and upgrades, including at the drop structures under measures #639 below, would include these types of features to benefit lamprey.

Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared when this measure is implemented.

#### *2.2.4.2 Restore Upstream and Downstream Passage at Drop Structures (#639)*

A drop structure, also known as a low head dam, grade control, sill, or weir, is a manmade structure, typically small and built on minor streams, to pass water to a lower elevation while controlling the energy and velocity of the water as it passes over. Unlike most dams, drop structures are usually not built for water impoundment, diversion or raising the water level. Drop structures are built to control the velocity and energy of water as it flows from higher to lower elevation and can also help control erosion (Figure 2.3-14). However, drop structures are nearly impossible for fish to traverse if they were constructed without fish passage measures.

Under this measure, infrastructure would be improved downstream of the Fern Ridge Dam at Monroe, Stroda, and Cox Butte drop structures to provide improved fish passage. This measure is intended to provide passage for fish, including juvenile UWR spring Chinook salmon and other aquatic organisms, to the mainstem Long Tom River and tributaries between the confluence with the Willamette River and Fern Ridge Dam.

Infrastructure improvements could include installation of fish ladders, notching or other direct modifications to drop structures, installation of bypass channels, or dam removal and replacement with riffle and pool systems. These improvements would include design features to provide Pacific lamprey passage as described in Section 2.3.4.1 under Measure #53. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for construction to restore passage at drop structures.

#### *2.2.4.3 Construct Adult Fish Facility (#722)*

This measure would include the construction of new adult fish facilities, like the one at Cougar Dam (Figure 2.3-15), and at Green Peter, Hills Creek, and Blue River Dams. These facilities would be designed with the flexibility to provide adequate water supply, provide normative

[16] A diffuser is a system of hydraulic components arranged to control water flow rate and convert high-velocity, high-pressure, non-uniform flow into low-energy, uniform flow to attract fish. A diffuser screen or grate also includes one or more panels of narrowly spaced horizontal or vertical bars to prevent fish from passing through the bars and entering the area upstream of the panels.

temperatures in the fish ladder, and attract upstream migrant fish in a timely manner during the spring.

The approach and design of the facility and/or upgrades would be determined during the construction design phase. Site-specific design and environmental compliance documentation would be prepared for construction of each new adult fish facility (Chapter 7).

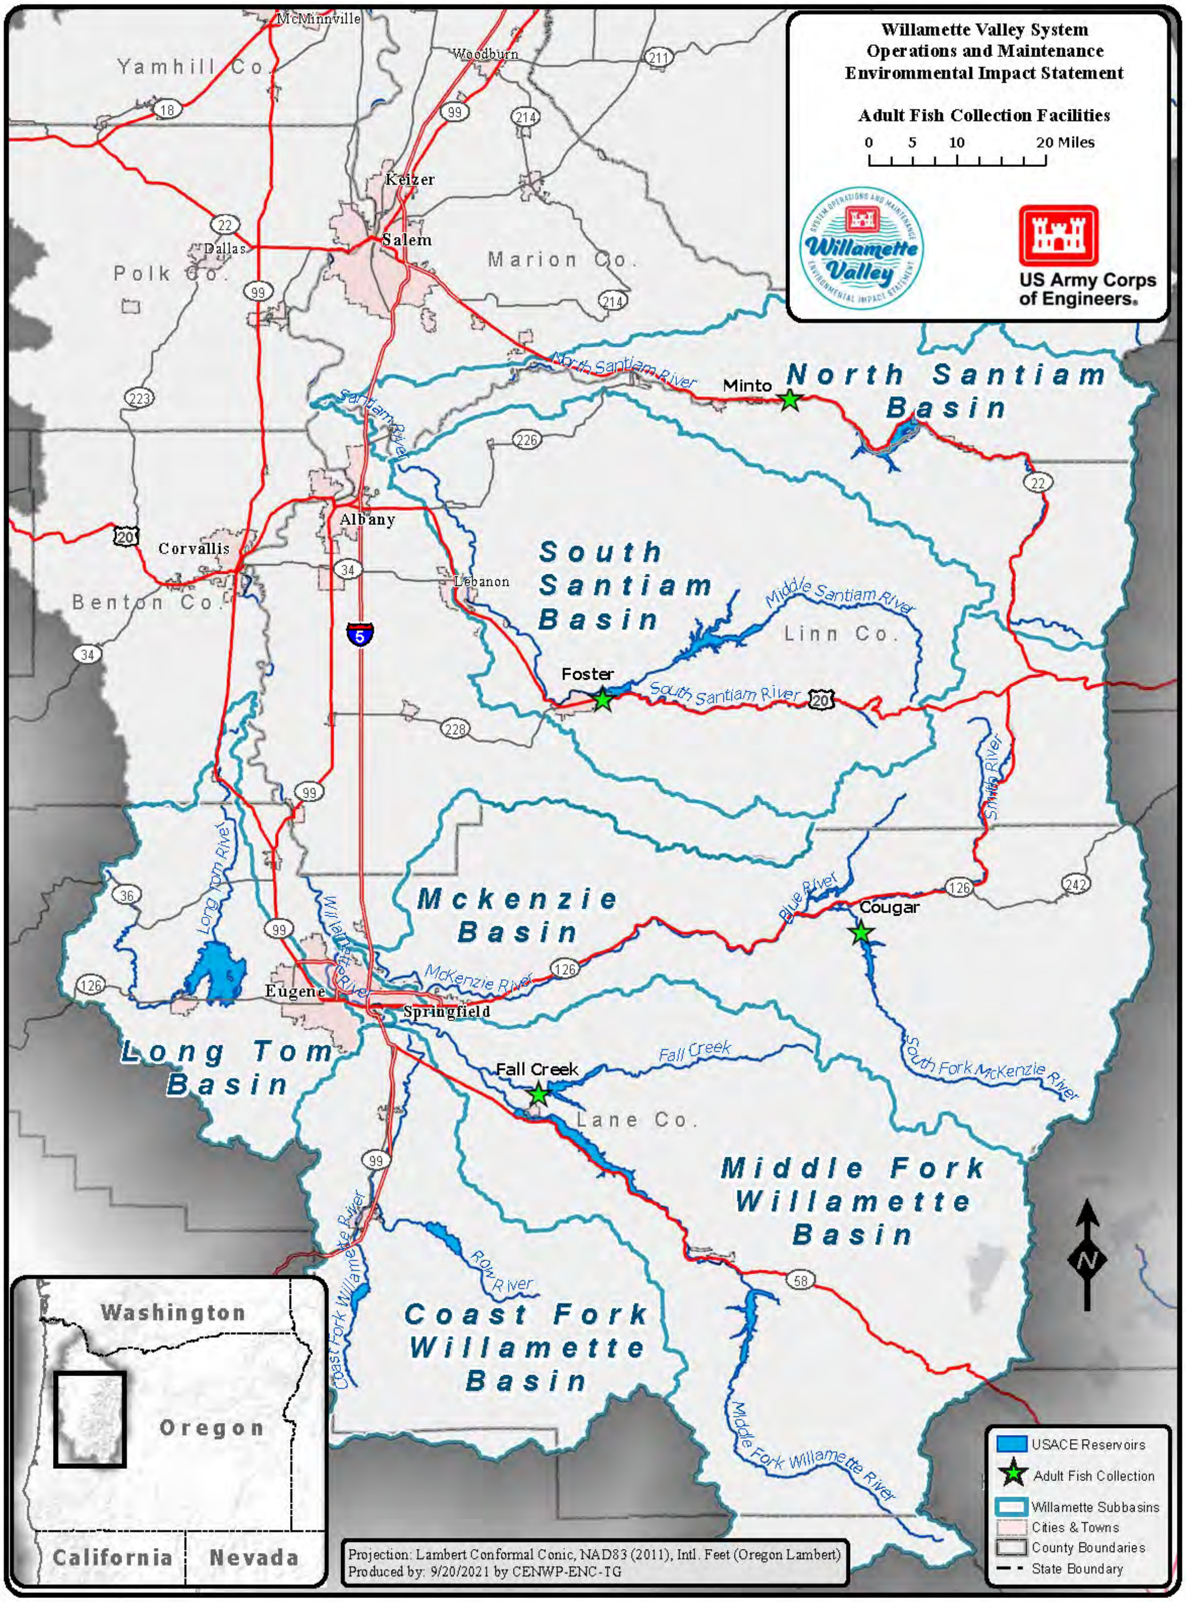

**Figure 2.2-13. USACE Existing Adult Fish Collection Facilities in the WRB**

**Figure 2.2-14. Drop Structure Downstream of the Fern Ridge Dam**

**Figure 2.2-15. Fish Ladder at the Cougar Adult Fish Collection Facility**

### 2.2.5 Suite of Near-term Operations

USACE is evaluating a suite of operations like the injunction operations ordered by the District Court in *Northwest Environmental Defense Center, et al. v. United States Army Corps of Engineers, et al.,* No. 3:18-cv-00437-HZ, (D. Or. September 2021). The operations would be conducted until the structural measures in the selected alternative supersede or replace the operations. The operations, modeled after the injunction, have been slightly refined through adaptive management (AM) during implementation.

A short description of the near-term operations in the measures including location, timing, outlet priorities for use to release flow through the dam, and target elevations of the reservoirs are listed in Table 2.3-11. Details for each of these operations are provided in Appendix A.

**Table 2.2-11. Suite of Near-term Operations**

| Description of Near-term Operations by Location | Duration of Operation | Priority Outlet | Target Elevation |
|---|---|---|---|
| **Detroit** | | | |
| Spring downstream fish passage and operational downstream temperature management | mid-Mar to Fall | Spillway/ Turbines/ ROs | n/a |
| Nighttime RO prioritization for improved downstream fish passage | Winter | Upper ROs/ Lower ROs | Less than 1,500 feet |
| Big Cliff | | | |
| Spread spill across spillbays to reduce downstream TDG exceedances | Year-round | Spillway | Discharges greater than Powerhouse Capacity |
| Green Peter | | | |
| Outplanting plan for reintroduction of adult Chinook salmon above Green Peter Dam | Summer | n/a | n/a |
| Utilize spillway for improved downstream fish passage in the spring; perform spill operation until May 1 or for 30 days, whichever is longer | mid-Mar to May/Jun | Spillway | Greater than 971 feet (spillway crest) |
| Deep drawdown and RO prioritization for improved downstream fish passage | Early Sep to mid-Dec | RO | 780 feet |
| Foster | | | |

These operations are designed to improve fish passage and water quality until the structural measures under an alternative can be implemented. The duration of a near-term operation at a specific location would depend on the implementation order of the structural measures under the alternative.

Structural measures require additional design, site-specific NEPA evaluation, permitting, planning, construction, etc. delaying implementation. The effects of the near-term operations are analyzed for the 30-year temporal span of the WVS PEIS ensuring impacts from the operations are analyzed because duration of an operation at a particular location is uncertain. The implementation timeline for the construction of structural measures under the Preferred Alternative and the duration of these operations under that alternative are described in Chapter 5.

USACE would comply with NEPA and other environmental compliance requirements if operations are modified through the AM process.

### 2.2.6 General Construction Activities Common to All Alternatives

Measures described above in Section 2.2 would be applied programmatically under any alternative. Each would require construction activities; however, details of these activities are largely unknown at this time. Limited analyses and a range of potential effects of general construction activities are included in the effects analysis for each resource in Chapter 3 of this PEIS in the methodology description for each resource area.

Although site-specific design and construction are not yet available, descriptions of general activities that could occur during implementation of the measures under any alternative are summarized below. Measure numbers correspond to measure descriptions above. The following subsections provide a summary of the anticipated construction needed for specific measures.

#### *2.2.6.1 Construct WTC Tower (#105)*

Construction of a WTC tower at a high head dam like Detroit would require an intake tower to be built in the reservoir that can pass water from multiple elevations between the minimum pool and maximum pool. The tower can be constructed out of steel or concrete.

The Cougar Dam temperature control tower was built in dry conditions (i.e., in-the-dry) out of concrete by using the diversion tunnel to lower the reservoir. The concrete tower was then built using traditional concrete construction methods like slip forming.

A WTC tower at Shasta Dam in California was built out of steel in wet conditions (i.e., in-the-wet) by constructing steel modules off site, lowering the modules into position with a crane, and then attaching them to the face of the dam using divers.

A Design Decision Document was complete for Detroit Temperature Control that proposes to build the tower out of concrete in-the-wet using pre-cast concrete modules. This would involve dredging the forebay to make room for the foundation, placing a concrete foundation that is level, and then using a large crane to place the pre-cast concrete modules on top of the foundation. After the concrete is in position, the mechanical and electrical features would be installed, and the tower would be plumbed into the existing dam outlets. Construction of a WTC tower would take 3 to 5 years.

#### *2.2.6.2 Foster Fish Ladder Temperature Improvement (#479)*

Temperature control at Foster Dam is currently targeting a narrow range of forebay elevations so a full height intake tower is not required. A smaller intake structure is being proposed at Foster Dam that would pass warm water during the spring and summer months. Construction would involve boring a hole through Foster Dam, attaching the prefabricated intake structure to the face of the dam using barge mounted cranes, and then installing the mechanical and electrical systems. This is expected to take 3 years to construct.

#### *2.2.6.3 Use Spillways for Surface Spill in Summer (#721) Only at Hills Creek and Blue River Dams*

The spillway at Hills Creek and Blue River Dams would require civil and structural improvements to be used on a regular basis. Hydraulic excavators would be used to excavate and regrade the spillway channel back to the river and then concrete would be placed to armor the channel. A cofferdam may be required at the bottom of the spillway channel to place concrete below ordinary high water. This work is expected to take 1 to 2 years.

#### *2.2.6.4 Structural Improvements to Reduce TDG (#174)*

TDG improvements are at a conceptual design level. A possible method is to place concrete structures in the tail race (e.g., baffle blocks - several identical structures arranged in one or several rows orientated perpendicular to the direction of flow).

Construction would involve building a cofferdam during the summer low flow and in-water-work period, excavating for a foundation, potentially drilling into the bedrock and embedding rebar dowels, placing concrete, and then removing the cofferdam. Construction can only take place during the summer when flows are low. Depending on the quantity of concrete structures to be placed and how far apart they are spaced, it could take multiple seasons to complete all the structures at a dam.

#### *2.2.6.5 Deeper Fall Reservoir Drawdowns for Downstream Fish Passage (#40) Only at Cougar Dam for the Drawdown Operation to the DT*

An intake and access tower would need to be constructed at Cougar Dam to use the diversion tunnel as a routine outlet. Construction of the tower would require an extended deep drawdown of Cougar reservoir and a cofferdam around the diversion tunnel intake so that concrete placement can be completed in-the-dry. The concrete tower would be constructed by equipment staged on barges in the reservoir.

Multiple seasons of deep drawdowns would be required to get the tower to full height. Once the concrete placement is complete, the mechanical and electrical systems would be installed. Construction is expected to take 5 years.

#### *2.2.6.6 Construct Structural Downstream Fish Passage (#392)*

Floating surface collectors (FSCs) and floating screen structures (FSSs) are largely built off-site at a metal fabrication shop in modules that are as large as possible but can still be trucked to the shoreline of a reservoir. A staging area along the shore of the reservoir would be identified, typically at an existing boat ramp. The facility would be assembled at the staging area with as much mechanical testing and commissioning completed as possible prior to launching the facility. Once complete, the facility would be launched into the water by driving, pushing, or rolling it down the hill. It would then be towed into position by tugs and anchored in place. Construction of a downstream passage structure would take 2 to 3 years.

Structural downstream passage at Foster Dam would not be provided by an FSC or FSS. At the Foster Dam, an existing surface route structure (fish weir) would be modified to improve downstream passage. Construction of the gate modification would require taking the gate out of service for several months.

Access platforms would be constructed around the concrete piers and a crane would be staged on top the dam. The road over the dam would have to be closed to for several months. Structural, mechanical, and electrical work would be completed on the gate. All work would be completed in-the-dry. This is expected to take 1 year to complete.

#### *2.2.6.7 Pass Water over Spillway in Spring for Downstream Fish Passage (#714) Only at Hills Creek Dam*

The spillway at Hills Creek Dam would require civil and structural improvements to be used on a regular basis. Hydraulic excavators would be used to excavate and regrade the spillway channel back to the river and then concrete would be placed to armor the channel. A cofferdam may be required at the bottom of the spillway channel to place concrete below ordinary high water. This work is expected to take 1 to 2 years.

#### *2.2.6.8 Spring Reservoir Drawdown for Downstream Fish Passage (#720) Only at Cougar Dam for the Drawdown Operation to the DT*

An intake and access tower would need to be constructed at Cougar Dam to use the diversion tunnel as a routine outlet. Construction of the tower would require an extended deep drawdown of Cougar reservoir and a cofferdam around the diversion tunnel intake so that concrete placement can be completed in-the-dry. The concrete tower would be constructed by equipment staged on barges in the reservoir.

Multiple seasons of deep drawdowns would be required to get the tower to full height. Once the concrete placement is complete, the mechanical and electrical systems would be installed. Construction is expected to take 5 years.

#### *2.2.6.9 Provide Pacific Lamprey Passage and Infrastructure (#52)*

Lamprey passage measures are typically incorporated into an upstream fish passage structure. It would consist of minor modifications that help lamprey navigate up the ladder. For example, metal strips would be welded to diffuser grating, also known as a diffuser screen, so that there is a continuous strip of metal for lamprey suction (Section 2.2.4.1). Construction would require the fish ladder to be dewatered to provide access. It would take a few months to complete the modifications.

#### *2.2.6.10 Restore Upstream and Downstream Passage at Drop Structures (#639)*

There are several versions of fish ladders that can provide passage for fish over drop structures. The simplest version would be to use stones and gravel to create a series of pools for fish navigation. On the robust end of the spectrum, a concrete fish ladder would be constructed. Construction would involve using hydraulic excavators to regrade the ladder area and then placing necessary building materials into the area. These structures typically do not have any mechanical or electrical features. A temporary cofferdam is likely required to dewater the construction area. It would take several months to 1 year to complete.

#### *2.2.6.11 Construct Adult Fish Facility (#722)*

Upstream passage at WVS dams involves building a trap and haul facility similar to those recently built at Cougar, Minto, Foster, and Fall Creek Dams. The facility would be built on the bank of the river immediate downstream of a structure that prevents the fish from swimming upstream.

Construction would involve building a cofferdam along the bank so that the water intake and fish ladder entrance can be built below ordinary high water. The fish ladder would bring the fish upland to a presort pool. Fish would then be processed through the sorting area, post sort pools, and then loaded into trucks and transported above the dam. This would require earthwork, concrete placement, in-water-work, mechanical, and electrical work. Construction of an upstream passage facility would typically take 2 to 3 years.

#### *2.2.6.12 Gravel Augmentation (#384)*

Gravel augmentation would involve use of an existing road to the riverbank, backing a dump truck full of gravel down the bank, and dumping the gravel in the river. Placing a dump truck load of gravel would takes a few hours.

#### *2.2.6.13 Maintain Revetments considering Nature-based Engineering or Alter Revetment for Aquatic Ecosystem Restoration (#9)*

This work would involve using a hydraulic excavator to maintain the revetment using natural materials. The work would not require a cofferdam but would be performed during the in-water-work period.

Maintenance of a revetment would take about 1 week. Altering revetments for aquatic ecosystem restoration could require more extensive work that could take up to several months during the in-water-work period over 1 or more years.

#### *2.2.6.14 Maintenance of Existing and New Fish Release Sites above Dams (#726)*

Some proposed sites may require minor improvements consisting of minor grading or occasion tree removal.

#### *2.2.6.15 Major Maintenance and Rehabilitation Sequencing and Timing*

As discussed in Section 1.8.7.2, the timing, duration, and extent of non-routine major maintenance are unforeseeable. The type of construction activities required would be unique to each maintenance requirement and cannot be predicted. Each action would be routinely assessed for environmental compliance prior to implementation.

## 2.3 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

As noted above, measures were combined to form distinct alternatives with a particular management strategy. A stand-alone hydropower alternative was determined not to be distinctive enough from other action alternatives being considered and was, therefore, eliminated from further consideration. After development of the alternatives and identification of measures to be implemented under each of the alternatives, USACE determined that a stand-alone hydropower alternative was not necessary because measures that would benefit hydropower production were integrated into other action alternatives.

## 2.4 ALTERNATIVES CONSIDERED IN DETAIL

The following sections describe the alternatives evaluated in detail in this PEIS, including the NAA. All the action alternatives described below would meet the USACE proposed action to continue operation and maintenance of the WVS for specific, authorized purposes and in compliance with the ESA and all other applicable treaties, laws, and regulations (Section 1.3).

The measures outlined in Section 2.2 are incorporated under each alternative as applicable. Summary tables of the measures incorporated into an alternative are provided at the end of each alternative description.

A summary table comparing measures under each alternative is provided at the end of this chapter (Table 2.4-14).

### 2.4.1 No Action Alternative

The NAA is required by NEPA (40 CFR §1502.14) to provide the existing condition of the analysis area and O&M for comparison of environmental effects of the action alternatives. The NAA consists of the current projects within the WVS and the conditions that would result from continued O&M and configuration of the WVS under existing management, prior to the initiation of this Draft PEIS, with no change.

All ongoing, scheduled, and routine maintenance actions for the USACE-managed infrastructure in the WRB and all USACE-managed structural features, including those recently constructed or that were reasonably foreseeable at the beginning of this Draft PEIS effort, are included under the NAA. Actions and operations occurring in the WVS include those agreed to in previous ESA consultations between USACE and the Services.

This alternative does not meet the full purpose and need of the project because the current operating conditions of the WVS do not adequately protect ESA-listed fish species, specifically UWR spring Chinook salmon and UWR winter steelhead or designated critical habitat for these species.

The NAA consists of the O&M of the WVS as they stood in April 2019 when USACE issued the Notice of Intent to prepare a Draft PEIS. The hydrology dataset, information on waters within the WVS, was used as input for the Draft PEIS reservoir regulation model and was developed in 2018, the year prior to when modeling of the NAA began. The April 2019 date was selected to provide a clear set of operations to analyze and compare alternatives, given the length of time needed to complete a draft PEIS and several temporary operational changes that were shifting throughout the process due to the temporary dam safety operations and litigation, discussed in Sections 1.9.2 and 1.9.3, respectively.

Each of the 13 dams and reservoirs within the WVS are operated according to a water control manual that is authorized by Engineering Regulation 1110-2-240. These manuals provide specific information to meet the congressionally authorized purposes of FRM, generation of hydropower, water supply, irrigation, navigation, recreation, and fish and wildlife (Section 1.7). The manuals also detail operations, procedures, and rule curves for each project. The operations evaluated in the NAA follow these manuals with minor changes that have been made in response to changes in WRB conditions and new information related to system operations and technology, the affected environment, polices, and regulations such as the ESA.

Measures analyzed as part for of the NAA are described further in this section. **Error! Reference source not found.**Table 2.4-1 lists these measures and identifies the locations where they occur.

#### *2.4.1.1 Stream Flow*

Under the NAA, USACE would continue to use the water control annual planning process described in Section 1.8.3. This planning process would determine how the authorized project purposes would be accomplished during the conservation season based on the water supply forecast and the 2008 NMFS BiOp targets.

Operational flow targets at Salem would continue to be set on April 1, based on a storage forecast (e.g., adequate, insufficient) for mid-May (May 10 to May 20). Mainstem flow targets for adequate and abundant water years are listed in Table 2.4-2, and the tributary flow targets are provided in Table 2.4-3.

Water from the power pool at Green Peter Reservoir would continue to be used on an as needed basis, depending on hydrologic conditions, to augment flow in the South Santiam sub-basin and mainstem Willamette River.

**Table 2.4-2. Mainstem Willamette Flow Objectives**

| Time Period | 7-Day Moving Average 2 Minimum Flow at Salem (cfs) 3 USGS 141910004 | Instantaneous Minimum Flow at Salem (cfs) 3 USGS 141910004 | Minimum Flow at Albany (cfs) 3 USGS 141740005 |
|---|---|---|---|
| April 1 - 30 | 17,800 | 14,300 | – |
| May 1 - 31 | 15,000 | 12,000 | – |

| | Oct 16 – Jan 31 | UWR Chinook salmon | 1,200[3] | – |
| | Feb 1 – Mar 15 | Rearing/adult | 1,000 | – |
| | Mar 16 – May | UWR Steelhead | 1,500 | 3,000 |
| | Jun 1 – Jul 15 | UWR Steelhead | 1,200[3] | – |
| | Jul 16 – Aug | Rearing | 1,000 | |
| Foster | Sep 1 – Oct 15 | UWR Chinook salmon spawning | 1,500 | 3,000 through Sep 30, when possible |
| | Oct 16 – Jan 31 | UWR Chinook salmon | 1,100[3] | – |
| | Feb 1 – Mar 15 | Rearing | 800 | – |
| | Mar 16 – May | UWR Steelhead | 1,500 | 3,000 |
| | May 16 – Jun | UWR Steelhead | 1,100[3] | – |
| | Jul 1 – Aug 31 | Rearing | 800 | – |
| Blue River | Sep 1 – Oct 15 | UWR Chinook salmon spawning | 50 | – |
| | Oct 16 – Jan 31 | UWR Chinook salmon | 50 | – |
| | Feb 1 – Aug 31 | Rearing | 50 | – |
| Cougar | Sep 1 – Oct 15 | UWR Chinook salmon spawning | 300 | 580 through Sep 30, when possible |
| | Oct 16 – Jan 31 | UWR Chinook salmon | 300 | – |
| | Feb 1 – May | Rearing | 300 | – |
| | Jun 1 – Jun 30 | Rearing/adult | 400 | – |
| | Jul 1 – Jul 31 | Rearing | 300 | – |
| | Aug 1 – Aug 30 | Rearing | 300 | – |

[1] When a reservoir is at or below minimum conservation pool elevation, the minimum outflow will equal inflow or the Congressionally authorized minimum flows, whichever is higher.

[2] Maximum flows are intended to minimize the potential for spawning to occur in stream areas that might subsequently be dewatered at the specified minimum flow during incubation.

[3] USACE will attempt to avoid prolonged releases in excess of the recommended maximum spawning season discharge to avoid spawning in areas that would require high incubation flows that would be difficult to achieve and maintain throughout the incubation period. When maximum flow objectives are exceeded for a period of 72 hours or longer, the WATER Flow Management Committee will review available monitoring information (e.g.,

regarding redd deposition in relation to flow rates), projected runoff, and reservoir storage, and will formulate a recommendation for an appropriate and sustainable incubation flow rate prior to the initiation of the subsequent incubation period.

### *2.4.1.2 Water Quality*

Under the NAA, water quality management objectives in the WVS would continue to include control of instream water temperature and reduction in TDG concentrations in river reaches below WVS dams as described below.

#### *2.4.1.2.1 Temperature Control*

There are no water temperature goals set for the WVS at Salem. The focus, instead, would be on in-tributary conditions (directly downstream of USACE dams) where spawning, rearing, and incubation of ESA-listed anadromous fish occurs. Table 2.5-4 shows the operational temperature management strategies that would continue to be implemented under the NAA to improve in-tributary conditions.

**Table 2.4-4. Operational Temperature Management Strategies at Projects**

| Dam | Strategy |
|---|---|
| Cougar | WTC tower operated to aid in meeting downstream water temperature goals for the purpose of ESA-listed species. Cougar Dam is the only project in the WVS with selective withdrawal capabilities to manage downstream water temperatures. |
| Detroit | Downstream temperature control starts June 1 or as soon as reservoir reaches spillway after June 1 by blending flow released over the spillway with flow released through the upper ROs or through turbines. Mixing takes place in Big Cliff Reservoir before water is passed downstream through Big Cliff Dam. |
| Fall Creek | Operational water temperature is informally conducted through a combination of fish horns and ROs. The main objective for the Fall Creek temperature management is to attract adult fish back to the fish facility located at the base of Fall Creek Dam. |
| Foster | The Foster fish weir is used during approximately June 15 through approximately July 30 annually as an operation to pass warm surface water from the reservoir to increase the river temperatures downstream. This operation is conducted to improve adult salmon collection at the Foster Adult Fish Facility. Without this fish weir operation, the river downstream of Foster Dam remains cold and creates a temperature block for returning adult salmon; that is, returning adult salmon remain downstream instead of returning to the Adult Fish Facility. The warm surface flow from the fish weir blends with the river downstream creating ideal water temperatures to attract adult salmon back to the Adult Fish Facility. |

#### *2.4.1.2.2 Total Dissolved Gas*

The amount of TDG generated through dam operations is highly dependent on the amount of water discharged, the dam outlets used to pass water, and the water temperatures observed during a particular operation. To reduce high levels of TDG, the general operating guidance under the NAA would be as follows:

- Discharge water through the powerhouse to reduce/dilute the TDG generated from use of the spillways or ROs.
- Under high flows, distribute the discharge over as many spill bays as possible with a uniform pattern, rather than putting all discharge through one bay.
- TDG generated at the high-head peaking projects would likely decrease before being passed through the downstream re-regulating dam. USACE would focus on using the powerhouse to further reduce/limit TDG from being passed downstream under the NAA.

### ***2.4.1.3 Downstream Fish Passage***

Under the NAA, there are two locations where downstream fish passage operations would occur. Although a surface outlet is available for fish to pass at other dams, the intent of these operations would be for temperature management.

Fall Creek Reservoir would be drawn down to its lowest outlet, elevation 690, for a few weeks in November lasting sometime into December. The actual operation would vary based on when fish are present and are passing. The analyses under the NAA considers this operation as a deep fall drawdown to elevation 690 from November 15th to December.

At Foster Reservoir fish pass downstream via the spillway. The analyses under the NAA considers this operation as releasing half of the flow over the spillway from March 16 through June 16 and then again from October 16 through December 16. Additionally, the NAA includes releasing 300 cfs over the spillway from June 16 through August 16.

### ***2.4.1.4 Upstream Passage (Adult Fish Facilities)***

Under the NAA, the adult fish facilities would continue to be operated and maintained in accordance with the Willamette Fish Operation Plan (WFOP), the operational plan noted in Section 1.8.8. The WFOP is developed annually by USACE in coordination with the BPA as well as regional federal, state, and Tribal fish agencies and other partners through the WFPOM coordination team.

Generally, adult fish collection facilities are operated annually between April and October. However, the WFOP describes year-round O&M activities of the adult fish collection facilities as coordinated through WFPOM to protect and enhance anadromous and resident fish species listed as endangered or threatened under the ESA, as well as non-listed species of concern, including Pacific lamprey. The WFOP guides USACE actions related to fish protection and passage at the 13 WVS projects.

#### *2.4.1.5 Willamette River Basin Bank Protection Program*

Under the NAA, when funding is available, USACE would continue to maintain and repair the USACE-maintained revetment projects in the WRB that were assessed in the 2013 hydraulic, hydrologic, and geomorphic investigation discussed in Section 1.6.1.

#### *2.4.1.6 Hatchery Program*

Under the NAA, the Hatchery Program would continue to be operated as described in Section 1.6.2.

#### *2.4.1.7 Hydropower Generation*

Under the NAA, hydropower generation would occur as described in Sections 1.7.2 and 1.8.4.

#### *2.4.1.8 Municipal and Industrial Water Use*

The NAA uses the 2050 M&I demand as estimated in the WBR (USACE, 2019). An important difference between the M&I values and the AI values is the estimated increase in withdrawals of live flow under existing water rights for M&I use. This PEIS uses estimates of increases in withdrawals of live flow between 2020 and 2050 from the WBR (USACE, 2019).

#### *2.4.1.9 Agricultural Irrigation Water Use*

Irrigation use in the WRB has not increased as initially projected and is not expected to increase in the future at levels near the scope and scale originally envisioned in the authorizing legislation for the projects. As of October 2022, there were 266 BOR Water Service Contracts for 82,815 acre-feet of water per year (approximately 5 percent of the conservation storage), which would be the NAA contract value.

At the current low level of use for water service contracts, USACE does not make special operational adjustments, such as increasing flow releases, to meet contract requirements at most projects, except for Fern Ridge and Detroit Dams. However, in deficit water years, the NMFS RPA requires BOR to curtail water contract diversions. In other years, the RPA requires USACE to release more than minimum flow to ensure the contract users do not take water intended for fish purposes from Fern Ridge and Detroit Dams. These conditions would remain in effect under the NAA.

In “deficit" water years, as defined in the 2008 NMFS BiOp, a partial water supply or no water supply may be available to satisfy some existing and new irrigation contracts. Water deliveries may be ceased or curtailed under these conditions, per RPA 3.4, under the NAA.

#### *2.4.1.10 Maintenance Operations*

Under the NAA, USACE would continue to implement a maintenance program at each WVS facility, consisting of routine inspection and maintenance of both power and non-power assets. USACE utilizes computerized maintenance management systems to plan, schedule, resource, and track this work.

##### *2.4.1.10.1 Scheduled/Routine Maintenance*

Under the NAA, routine maintenance would continue as described in Section 1.8.8.1.

##### *2.4.1.10.2 Major Maintenance and Rehabilitation*

Under the NAA, major maintenance and rehabilitation would occur as described in Section 1.8.7.

### 2.4.2 Measures Common to All Action Alternatives

Measures common to all action alternatives are those that would be implemented regardless of the action alternative selected. Measures common to all action alternatives include both operational measures and structural measures in multiple locations throughout the WVS. They also include new measures, existing operations, and O&M activities that would be carried forward. These measures, whether they are new or existing, and the locations where they would occur are shown in Table 2.5-5.

**Table 2.4-5. Measures and Locations Common to All Action Alternatives**

| Measure | New or Existing Measure | Action Location |
|---|---|---|
| Gravel Augmentation below Dams | New | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River Dams |
| Adapt Hatchery Program | New | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins |
| Maintain Revetments considering Nature-based Engineering or Alter Revetments for Aquatic Ecosystem Restoration | New | Basin-wide |
| Maintenance of Existing and New Fish Release Sites above Dams | New | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins |
| Fall Creek Drawdown | Existing | Fall Creek |

| Measure | New or Existing Measure | Action Location |
|---|---|---|
| Operation and Maintenance of Existing Adult Fish Facilities | Existing | Dexter, Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar Dams |
| Operation, Maintenance, Repair, Replacement, and Rehabilitation | Existing | Basin-wide |

#### *2.4.2.1 Gravel Augmentation below Dams (#384)*

Under all action alternatives, improving downstream streambeds with gravel would occur in the North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River Dams. The WVS is restricting sediment transport and subsequently degrading habitat for ESA-listed and other native fish below its dams.

This measure would first involve surveying below the dams to determine where gravel placement could increase usable spawning areas while considering channel bathymetry, water temperature, hydrology, and hydraulics. Then, clean round river gravel would be added to the areas of wetted streambeds that were identified to best improve river substrate conditions for spawning and rearing of native fish species downstream of WVS dams. Gravel would be sized appropriately for use by spawning UWR spring Chinook salmon and UWR winter steelhead, and to the maximum extent feasible, locally sourced. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for each location prior to implementation of gravel augmentation.

#### *2.4.2.2 Adapt Hatchery Program (#719)*

The overall goal of this measure would be to adjust production of WVS hatcheries for mitigation obligations and conservation needs after demonstrated improvements to fish access to habitat above dams. Congress authorized USACE to mitigate for the construction of the WVS, recognizing that the dams would block habitat access for migratory fish and inundate habitat and existing hatcheries. USACE has historically done this by carrying out a program to produce and release hatchery salmon, steelhead trout, and game fish in the WVB (Figure 2.5-1).

Congress did not define detailed goals for mitigation, including the level of fish production to be achieved. This left USACE discretion to determine how to implement the fish mitigation program in the WVB, whether that be through hatchery programs, passage improvements, or a combination. Current levels of mitigation production are defined in HGMPs prepared by ODFW and USACE as discussed in Section 1.6.2.

If fish passage measures are successful, they would provide access to habitat once blocked by the WVS; so USACE is proposing to reduce the hatchery production amounts needed for mitigation after demonstrated improvement to fish habitat access. Sub-basins where there are

Willamette Hatchery Mitigation Program production goals include the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette. Each sub-basin hatchery program would be considered separately according to the metrics and protocols described in the detailed measure description provided in Appendix A.

**Figure 2.4-1. McKenzie River Fish Hatchery Near Leaburg, Oregon**

#### *2.4.2.3 Maintain Revetments considering Nature-based Engineering or Alter Revetments for Aquatic Ecosystem Restoration (#9)*

As described in Section 1.6.1, the Willamette River Basin Bank Protection Program (WRBBPP) consists of 193 active bank protection structures, 83 of which are maintained by USACE and 105 of which are maintained by a local non-federal sponsor (USACE, 2000). Figure 2.5-2 provides a map of all bank protection structures in the WRBBPP.

Under this measure USACE would continue to implement maintenance of revetments throughout the basin, as funded, to support WRBBPP bank protection structures currently managed by USACE.

Nature-based methods would be included, to the extent the project purpose is maintained, by decreasing hard surfaces (e.g., rock) within the system to provide habitat for various fish and wildlife species in the river margins and riparian zone while maintaining the authorized project purposes.

This measure would be implemented as part of maintenance actions and would include:

- Consideration of nature-based engineering options as part of any USACE maintenance activity for USACE-managed revetments.

- Adherence to standard engineering practices for maintenance such that the revetment would still meet intended authorized purposes.

In addition, USACE would seek opportunities to work with non-federal sponsors to study and work through the process for environmental restoration projects that would substantially alter USACE or non-federally managed WVS revetments. Continuing Authority Program Section 1135, Project Modifications for Improvement of the Environment (WRDA, 1986), is the only authority that allows USACE to alter a federal project for ecosystem restoration purposes.

Under Continuing Authority Program studies, USACE must have a non-federal sponsor to cost share the project, acquire all necessary real estate permissions, and agree to operate and maintain the project in perpetuity. Working with NMFS and USFWS, as well as local agencies and stakeholders, USACE would seek non-federal sponsors for substantial alterations to provide ecological improvements to one or more WRBBPP structures that are determined to be in the federal interest using the Aquatic Ecosystem Restoration metrics (cost per habitat unit).

Project-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for Continuing Authority Program studies. However, it should be noted the requirement to find a sponsor severely limits the ability for USACE to carry out large scale changes under this program.

Existing information would be used to identify projects with the greatest potential for improving habitat without posing an increased FRM risk; however, additional technical analyses would likely be necessary to further evaluate potential effects of the modifications. Post-construction monitoring would also be conducted to ensure that the project performs as intended, both biologically and for bank protection. This information would also be used to investigate the implementation of future substantial alterations to revetments.

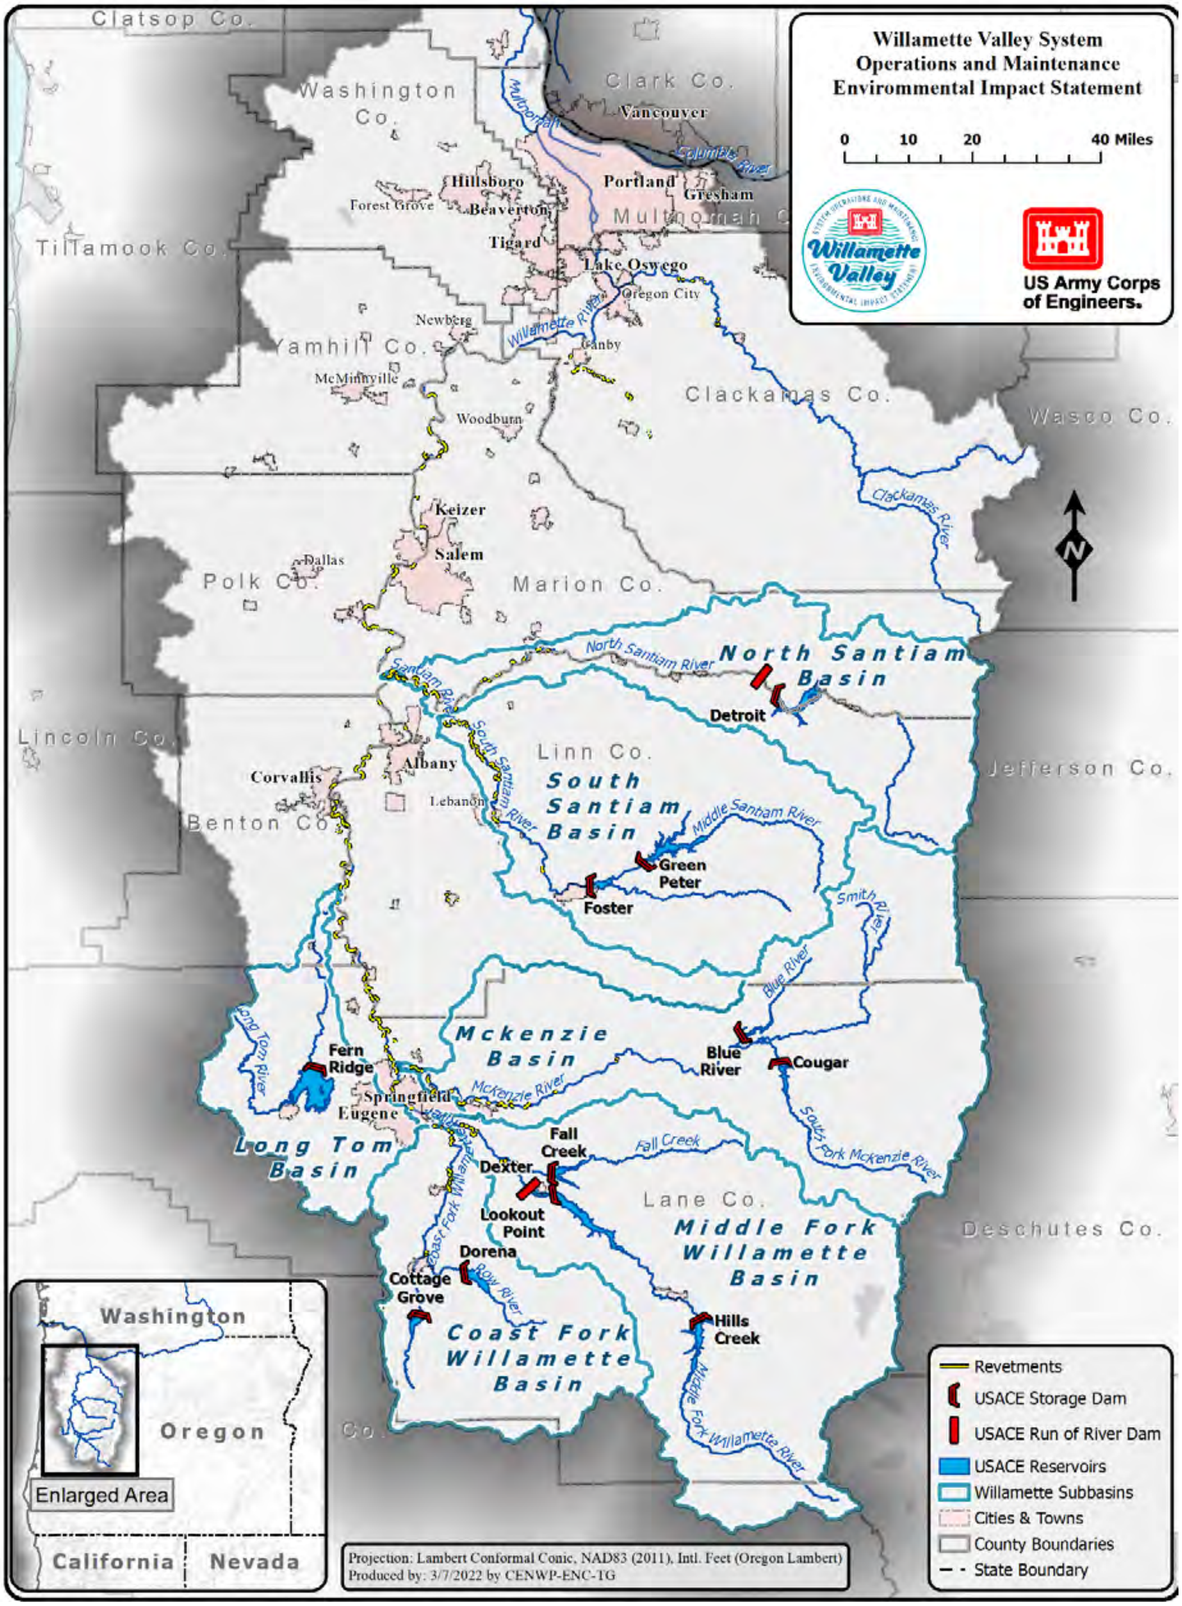

**Figure 2.4-2. Willamette River Basin Bank Protection Program Revetment Locations**

### *2.4.2.4 Maintenance of Existing and New Fish Release Sites above Dams (#726)*

Basin-wide actions would be taken to ensure safe and effective release of outplanted adult fish and to support upstream passage above dams. Outplanting refers to transporting adult UWR spring Chinook salmon and UWR winter steelhead and releasing them in stream reaches above WVS reservoirs.

Specific actions would vary within the WRB by outplant reach, but in general, adult hatchery fish would be outplanted to support salmonid reintroduction with a goal of eventually only outplanting returning adult wild fish to locations upstream of barriers to migration (dams and reservoirs). Several release sites (Table 2.5-6) were evaluated for this measure based on their access to high quality habitat. Some proposed sites may require minor improvements that may require minimal construction. In cases where construction would be required, site-specific designs and environmental compliance (as described in Chapter 7) would be completed, if needed.

**Table 2.4-6. Current and Proposed Outplanting Sites**

| Project | Description | Existing or Proposed |
|---|---|---|
| **Detroit** | Private Site | Proposed |
| | Breitenbush USGS Gage Site (#14179000) | Proposed |
| | Parrish Lake Road (Upper) | Existing |
| | Cooper's Ridge (Lower) | Existing |
| **Minto (Big Cliff)** | North Santiam River upstream of Minto | Existing |
| **Foster** | Gordon Road (Upper) | Existing |
| | River Bend A (Lower) | Existing |
| | Reservoir release | Proposed |
| **Cougar** | Hardrock campground (lower) | Existing |
| | Homestead campground (upper) | Proposed |
| **Lookout Point** | Site 1 (lower) | Existing |
| | Site 3 (upper) | Proposed |
| **Fall Creek** | Gold Creek Confluence (upper) | Existing |
| | Site C (lower) | Existing |
| **Hills Creek** | Construction site (spur road) | Existing |
| | Paddy's Valley | Existing |
| **Blue River** | Lower release site 2-5 miles above head of reservoir | Proposed |
| **Green Peter** | Lower release site 2-5 miles above head of reservoir in Quartzville Creek | Proposed |
| **Green Peter** | Lower release site 2-5 miles above head of reservoir in Middle Santiam | Proposed |

### 2.4.3 Adaptive Management Common to All Action Alternatives

Adaptive management would be applied to any selected action alternative. As described in Section 5.5, an Adaptive Management Plan would be prepared that outlines the governance framework[17] to be used for adaptive decision-making, the annual adaptive management process for engaging with stakeholders, and the process to incorporate new learning into management priorities. The Adaptive Management Plan would also outline the decision criteria relevant to monitoring and evaluating the success of management measures at achieving stated objectives.

### 2.4.4 Existing Operations Common to All Alternatives

This section describes current operations that would continue under all action alternatives.

#### *2.4.4.1 Fall Creek Drawdown*

The annual drawdown at Fall Creek would continue as described under the NAA. Fall Creek Reservoir would continue to be drawn down to its lowest outlet, elevation 690 feet, for a few weeks in November lasting sometime into December. The actual operation would vary based on when the majority of fish are observed to be present and are passing.

#### *2.4.4.2 Continued Operation of Existing Adult Fish Facilities*

USACE would continue to operate and maintain the existing adult fish collection facilities located at Dexter, Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar Dams (Figure 1.6-2) in accordance with the WFOP, the operational plan noted in Section 1.8.8. The WFOP is developed annually by USACE in coordination with the BPA as well as regional federal, state, Tribal fish agencies, and other partners through the WFPOM coordination team. Generally, adult fish collection facilities are operated annually between April and October.

#### *2.4.4.3 Operation, Maintenance, Repair, Replacement, and Rehabilitation*

USACE would continue to implement the operation, maintenance, repair, replacement, and rehabilitation (OMRR&R) program at each WVS facility, consisting of routine inspections and maintenance of both power and non-power assets. USACE utilizes computerized maintenance management systems to plan, schedule, resource, and track this work.

##### *2.4.4.3.1 Scheduled/Routine Maintenance*

Routine maintenance would continue as described in Section 1.8.7.

---

[17] A governance framework as part of the Adaptive Management Plan will specifically describe how USACE will continue to work the WATER to design a robust research, monitoring, and evaluation plan to inform decision-making during implementation of the selected alternative.

###### *2.4.4.3.2 Major Maintenance and Rehabilitation*

Major maintenance and rehabilitation would occur as described in Section 1.8.7.

The following describes each of the alternatives analyzed in the PEIS.

### 2.4.5 Alternative 1. Improve Fish Passage Through Storage-focused Measures (Project Storage Alternative)

Under Alternative 1, also referred to as the Project Storage Alternative, USACE would maximize the refill volumes of conservation pools at WVS reservoirs to meet authorized purposes that depend on full reservoirs, including M&I water supply, AI, recreation, and water quality, and improve fish passage through the WVS dams to increase the survival of ESA-listed fish species.

#### *2.4.5.1 Stream Flow*

Flows would be reduced to the Congressionally authorized minimum flows (Measure #723) to benefit reservoir refill objectives at all project locations, as described in Section 2.3.1.5. This would increase the likelihood of refilling the WVS reservoirs to their maximum conservation pool levels in the spring. However, Alternative 1 would also augment instream flows by using the power pool (Measure #304) at Lookout Point, Hills Creek, Cougar, Green Peter and Detroit Dams, and by using the inactive pools at Cottage Grove, Dorena, Fall Creek, and Blue River Dams (Measure #718), as described in Section 2.3.1.2 and Section 2.3.1.4, respectively. These two measures would augment flows for biological purposes at critical times of the year and reduce temperatures.

#### *2.4.5.2 Water Quality*

Under Alternative 1, many structural improvements would also be implemented for water quality purposes as well as for downstream and upstream fish passage. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for each of these construction measures.

Structural measures for water quality would include structural improvements to reduce TDG (Measure #174) at Dexter, Cougar, and Foster Dams, as described in Section 2.2.2.3. Structural measures in this alternative also include constructing WTC towers (Measure #105 described in Section 2.3.2.1) at Lookout Point, Green Peter, and Detroit dams.

#### *2.4.5.3 Total Dissolved Gas*

The WTC towers at these dams would also be structurally designed to reduce TDG (Measure #174). The WTC towers would be paired with a FSS (Measure #392) to provide downstream passage, as described in Section 2.3.3.4. The towers would have slots that allow the FSS to move up and down with annual reservoir elevation changes. The structures would allow for fish collection over various water levels throughout the year, with the intent of minimizing effects to project storage from operations for fish passage and water quality.

### *2.4.5.4 Fish Passage*

Fish collected at Lookout Point, Green Peter, and Detroit Dams would be transported and released downstream of their reregulation dams (Dexter, Foster, and Big Cliff dams, respectively) so that these fish would not have to find passage over the reregulating dams. At Foster, Alternative 1 includes the Foster Fish Ladder Temperature Improvement (Measure #479 described in Section 2.3.2.4) and modification of the existing surface route structure (fish weir) for improved downstream passage (Measure #392 as described in Section 2.2.3.4).

To address upstream passage needs, an adult fish collection facility would be constructed at the Green Peter Dam (Measure #722 described in Section 2.2.4). Upstream and downstream fish passage would be restored downstream of the Fern Ridge Dam at the Monroe, Stroda, and Cox Butte drop structures (Measure #639 described in Section 2.2.4). The design of the adult fish facility at Green Peter and fish passage restoration at the drop structures below Fern Ridge Dam would include Pacific lamprey passage (Measure #52 described in Section 2.2.4).

All the measures for Alternative 1 and the locations at which they would be implemented are shown in Table 2.5-7.

Note that the following abbreviations for the WVS projects are used in each alternative table:

- FRN – Fern Ridge
- CTG – Cottage Grove
- DOR – Dorena
- DEX – Dexter
- LOP – Lookout Point
- FCR – Fall Creek
- HCR – Hills Creek
- CGR – Cougar
- BLU – Blue River
- FOS – Foster
- GPR – Green Peter
- BCL – Big Cliff
- DET – Detroit

### 2.4.6 Alternative 2A. Integrated Water Management Flexibility and ESA-listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam) (Hybrid Alternative with Cougar Floating Screen Structure)

Alternative 2A was developed to improve fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and meet ESA-listed fish obligations. Alternative 2A is also referred to as the Hybrid Alternative with Cougar Floating Screen Structure.

Alternative 2A was developed after action Alternatives 1, 3A, 3B, and 4 to allow for very cursory modeling results from these alternatives to inform the formulation of Alternative 2A. Prior to this modeling, it was difficult to know which operational measures under Alternatives 3A or 3B would provide suitable downstream passage results when compared to the structure-focused alternative (Alternative 4).

Structural measures require comprehensive design and engineering efforts, additional environmental compliance (such as site-specific NEPA documents), and often long construction timeframes. These requirements can substantially delay a structural measure's implementation and substantially increase the cost of an alternative. Thus, the formulation of Alternative 2A was an effort to identify the combination of structural and operational downstream fish passage measures that could more effectively meet ESA objectives, while balancing the challenges of large-scale structural changes. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for each of the measures requiring construction.

#### *2.4.6.1 Near-term Operations Implementation*

Under Alternative 2A, the near-term operations measure (discussed in Section 2.2.5) would be implemented. The near-term operations measure combines operations at different locations, that can be implemented immediately, into a single measure. The operation at a location would be implemented until the structural measure for that location can be constructed.

If there is not a structure or operation to replace the near-term operation, it would cease upon full implementation of all the measures under the alternative (a detailed analysis of how near-term measures would be replaced by the measures under the Preferred Alternative is provided in Chapter 5). Note that this integration of the near-term operations measure is largely the same for Alternatives 2B, 3A, 3B, 4, and 5 and only differences will be highlighted in those sections.

#### *2.4.6.2 Stream Flow*

Under Alternative 2A, the integrated temperature and habitat flow regime (Measure #30a as described in Section 2.3.1.1) would be utilized at all dams in the WVS. However, this alternative would also augment instream flows by using the power pool (Measure #304) at Lookout Point, Hills Creek, Cougar, Green Peter and Detroit dams, and by using the inactive pools at Fall Creek, and Blue River dams (Measure #718), as described in Section 2.3.1.2 and Section 2.3.1.4, respectively. These two measures would augment flows for biological purposes at critical times of the year and reduce temperatures.

Alternative 2A strikes a balance between implementing operational and structural solutions by incorporating operational downstream fish passage measures at Green Peter Dam, including passing water over the spillway in the spring (Measure #714 as described in Section 2.3.3.2) and a deep fall drawdown (Measure #40 as described in Section 2.3.3.1) with the construction of downstream fish passage structures at Detroit, Lookout Point, Cougar, and Foster Dams as described below in Section 2.4.4.4.

#### *2.4.6.3 Adult Fish Facility and Fish Passage*

Alternative 2A would also include a new adult fish facility for upstream fish passage at Green Peter (Measure #722 as described in Section 2.2.4) that would provide passage for Pacific lamprey (Measure #52 described in Section 2.2.4). Structural downstream passage (Measure #392) is proposed at Lookout Point, Cougar, and Detroit Dams as described in Section 2.2.3.4.1, and at Foster Dam as described in Section 2.2.3.4.2. Fish collected at Lookout Point and Detroit dams would be transported and released downstream of their reregulation dams (Dexter and

Big Cliff dams, respectively) so that these fish would not have to find passage over the reregulating dams.

### *2.4.6.4 Water Quality*

Alternative 2A would also include a combination of structural and operational measures to address water quality. The fish passage structure at Detroit would be integrated with a WTC tower (Measure #105 as described in Section 2.3.2.1). However, a WTC tower at Hills Creek was omitted from this alternative after initial modeling showed an inability to affect temperatures downstream of Dexter Dam.

For temperature control at Green Peter Dam, Alternative 2A would include the following operational measures:

- Using the ROs to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below these dams (Measure #166 as described in Section 2.3.2.2) and;
- Using the spillway for surface spill in summer (Measure #721 as described in Section 2.3.2.5).

At Foster Dam, Alternative 2A would include the Foster fish ladder temperature improvement (Measure #479 described in Section 2.2.2.4) and modification of the existing surface route structure (fish weir) for improved downstream passage (Measure #392 as described in Section 2.2.3.4.1).

All the measures for Alternative 2A and the locations at which they would be implemented are shown in Table 2.5-8.

**Table 2.4-8. Alternative 2A Measures and Locations**

### 2.4.7 Alternative 2B. Integrated Water Management Flexibility and ESA-listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel) (Hybrid Alternative with Cougar Diversion Tunnel Modification)

Actions and measures under Alternative 2B would be the same as under Alternative 2A but would include a modification to the combination of measures at Cougar Dam. Alternative 2B is also referred to as the Hybrid Alternative with Cougar Diversion Tunnel Modification. Only the differences between Alternative 2B and Alternative 2A are discussed below.

Measures under Alternative 2B and Alternative 2A would be identical except for the downstream passage measure via the DT at Cougar Dam as described in Section 2.2.3.1. The use of structural versus operational downstream passage measures has unique environmental and operational implications. By identifying the distinction between Alternative 2A (i.e., structural measure) and Alternative 2B (i.e., operational measure), the unique impacts associated with a structure versus an operation are disclosed. Specifically, this distinction is demonstrated for downstream passage at Cougar Dam. The environmental consequences between structural (Alternative 2A) and operational measures (Alternative 2B) at Cougar Dam are then assessed and compared in Chapter 3.

Specifically, structural downstream fish passage would be constructed at Cougar Dam under Alternative 2A (Measure #392 as described in Section 2.2.3.4). In contrast, under Alternative 2B operations would be changed at Cougar Dam by drafting the reservoir down within 25 feet of the DT, located at the bottom of the reservoir (Figure 2.3-9) so that fish can pass through the DT in the fall and spring (Measures #40 and #720 as described in Sections 2.3.3.1 and 2.3.3.3, respectively). A drawdown to the DT at Cougar Dam would require several dam modifications to make this operation possible and a change in operational authority.

First, dam safety concerns associated with Cougar Reservoir's fluctuating pool levels would need to be addressed. Second, redundant gate structures to allow for safe, remote, routine operation of the DT would need to be designed and constructed. Finally, the DT would need to be made accessible for O&M through the construction of a tower and bridge. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for these required modifications.

Under Alternative 2B, fall and spring deep drawdowns to the DT for fish passage would draft the reservoir below the power pool most of the time, making the power pool inaccessible for flow augmentation (Measure #40 and Measure #720 as described in Section 2.2.3.1 and Section 2.3.3.3, respectively) (Measure #304, Section 2.2.1). Alternative 2B As discussed in Section 2.3.3.1, modifications to the Cougar DT needed to perform this operation would require site-specific construction and environmental compliance (as described in Chapter 7).

The measures for this alternative and the locations at which they would be implemented are shown in Table 2.5-9. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for each of the measures requiring construction.

[1] Draw down to DT. Requires structural modification to the DT

[2] Basin-wide including Willamette River

## 2.4.8 Alternative 3A. Improve Fish Passage Through Operations-focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet) (Operations-focused Fish Passage Alternative)

Alternative 3A was developed to improve fish passage through the WVS dams by modifying operations rather than focusing on storage (as under Alternative 1) or structural measures (as under Alternative 4). Alternative 3A is also referred to as the Operations-focused Fish Passage Alternative.

This alternative includes operational measures that allow for increased survival of ESA-listed fish while maintaining the USACE FRM mission. Operational measures under Alternative 3A are intended to improve downstream fish passage, increase water management flexibility, optimize conservation season draft rates, and reduce impaired water quality below the WVS dams to benefit ESA-listed fish species. Some operational measures may require the modification of existing infrastructure, or the construction of adult fish collection facilities for benefits to be realized from the proposed operational measures.

Under Alternative 3A, as under Alternative 2A and Alternative 2B, the near-term operations measure would be implemented (Section 2.2.5 and Section 2.2.6). The operations in the near-term operations measure would be replaced immediately at the locations where the long-term operation in Alternative 3a is proposed.

### *2.4.8.1 Stream Flow*

Under Alternative 3A, the integrated temperature and habitat flow regime (Measure #30a, Section 2.3.1.1) would be applied the same as under Alternative 2A and Alternative 2B. Instream flows would also be augmented by using the power pool (Measure #304, Section 2.2.1), but would utilize the inactive pools at additional dams: Cottage Grove, Dorena, Fall Creek, and Blue River Dams. These measures would augment flows for biological purposes at critical times of the year and would reduce temperatures.

### *2.4.8.2 Water Quality*

Under Alternative 3A, ROs would be used to discharge colder water during drawdown operations in fall and winter to reduce water temperatures (Measure #166, Section 2.3.2.2) below Lookout Point, Green Peter, and Detroit dams. Also at these dams, and at Hills Creek, Blue River, and Foster Dams, the spillways would be used for surface spill in summer (Measure #721, Section 2.3.2.5). The spillways at Hills Creek and Blue River Dams and the fish weir at Foster Dam would be modified for this measure, requiring site-specific construction and environmental compliance (as described in Chapter 7), which would be prepared for each of the measures requiring construction.

### *2.4.8.3 Adult Fish Facility and Fish Passage*

Alternative 3A proposes new adult fish facilities for upstream fish passage (Measure #722, Section 2.2.4) at Hills Creek, Blue River, and Green Peter Dams. These facilities would also provide Pacific lamprey passage and infrastructure (Measure #52, Section 2.2.4). Additional upstream fish passage would be provided by means of existing trap and haul facilities.

No structural downstream fish passage measures are included under Alternative 3A. Operations-based fish passage measures include:

- Deeper fall season reservoir drawdowns at Lookout Point, Hills Creek, Green Peter, Detroit, Blue River, and Cougar (to the RO) dams (Measure #40, Section 2.2.3.1) as compared to the NAA.
- Spring drawdowns (Measure #720, Section 2.3.3.3) at Lookout Point, Detroit, and Cougar (to the RO) dams.
- The use of spillways (Measure #714, Section 2.3.3.2) to facilitate downstream fish passage at Dexter, Fall Creek, Hills Creek, Green Peter, and Big Cliff dams.

The measures for Alternative 3A and the locations at which they would be implemented are shown in Table 2.5-10.

### 2.4.9 Alternative 3B. Improve Fish Passage Through Operations-focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel) (Operations-Focused Fish Passage Alternative)

Actions and measures under Alternative 3B would be the same as under Alternative 3A but would include a modification to the combination of operational measures for downstream fish passage. The description for Alternative 3B addresses only the distinction with Alternative 3A.

Measures under Alternative 3B and Alternative 3A would be identical except for operational measures for downstream fish passage. Variations in operational measures result in unique environmental and operational implications. By identifying the downstream fish passage operational distinctions between Alternative 3A and Alternative 3B, the unique impacts associated with downstream fish passage operational differences are disclosed. The environmental consequences between downstream fish passage measures under Alternative 3A and operational measures under Alternative 3B are then assessed and compared in Chapter 3.

Specifically, Alternative 3A includes downstream fish passage elements at a different combination of projects than under Alternative 3B. Alternative 3A also includes drawdown drafting to 10 feet over the top of the Cougar Dam RO for deep fall and spring drawdown measures. Conversely, Alternative 3B includes drawdown drafting to the DT at Cougar Dam for both drawdown measures, a much deeper drawdown than proposed under Alternative 3A.

As under Alternative 3A, Alternative 3B includes the two measures that augment flows for biological purposes at critical times of the year and to reduce temperatures. Instream flows would be augmented under both Alternative 3A and Alternative 3B by using the inactive pools at Cottage Grove, Dorena, Fall Creek, and Blue River dams (Measure #718, Section 2.3.1.4). However, under Alternative 3B, instream flows would only be augmented by using the power pool (Measure #304, Section 2.2.1) at Lookout Point, Hills Creek, Green Peter, and Detroit dams (Section 2.3.1.2).

Unlike Alternative 3A, Alternative 3B includes the deep fall and spring drawdowns to the DT for downstream fish passage (Measure #40, Section 2.2.3.1 and Measure #720, Section 2.3.3.3) that would draft the reservoir below the power pool most of the time and result in the power pool becoming inaccessible for flow augmentation (Measure #304, Section 2.2.1). As discussed in Section 2.3.3.1, needed modifications to the Cougar DT to perform this operation would require site-specific construction and environmental compliance (as described in Chapter 7).

The other downstream passage measures proposed under Alternative 3B include:

- Deeper fall season reservoir drawdowns than under current conditions identical to Alternative 3A.
- Spring drawdowns at Hills Creek and Green Peter dams (as compared to spring drawdowns at Lookout Point and Detroit dams under Alternative 3A) (Measure #720, Section 2.3.3.3).

- The use of spillways to facilitate downstream fish passage at four dams: Dexter, Lookout Point, Big Cliff, and Detroit Dams (Measure #714, Section 2.3.3.2). This differs from Alternative 3A where spillway use would occur at five dams: Dexter, Big Cliff, Fall Creek, Hills Creek, and Green Peter Dams.

The measures for this alternative and the locations at which they would be implemented are shown in Table 2.4-11.

**Table 2.4-11. Alternative 3B Measures and Locations**

### 2.4.10 Alternative 4. Improve Fish Passage with Structures-based Approach (Structures-based Fish Passage Alternative)

Alternative 4 is a structures-based approach to improve fish passage through the WVS dams to increase the survival of ESA-listed fish. It also contains operational measures, such as adjusting conservation season draft rates. Alternative 4 is also referred to as the Structures-based Fish Passage Alternative.

#### *2.4.10.1 Near-term Operations Measure*

Under Alternative 4, as under Alternatives 2A, 2B, 3A, and 3B, the near-term operations measure would be implemented (Section 2.2.5 and Section 2.2.6).

#### *2.4.10.2 Stream Flow*

Under Alternative 4, the integrated temperature and habitat flow regime (Measure #30a, Section 2.3.1.1) would be utilized at all dams in the WVS. However, Alternative 4 would also augment instream flows by using the power pool (Measure #304, Section 2.2.1) at Lookout Point, Hills Creek, Cougar, Green Peter and Detroit dams, and by using the inactive pools at Cottage Grove, Dorena, Fall Creek, and Blue River dams (Measure #718, Section 2.3.1.4). These two measures would augment flows for biological purposes at critical times of the year and reduce temperatures.

#### *2.4.10.3 Water Quality*

Under Alternative 4, structural improvements would also be implemented for water quality purposes as well as for downstream and upstream passage. Site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for each of these construction measures.

Structural measures for water quality include structural improvements to reduce TDG at Dexter, Cougar, Foster, and Green Peter dams (Measure #174, Section 2.2.2.3). Structural measures also include constructing WTC towers at Lookout Point, Hills Creek, and Detroit dams (Measure #105, Section 2.3.2.1). The WTC towers at Lookout Point and Detroit dams would also be designed to reduce TDG (Measure #174, Section 2.2.2.3).

#### *2.4.10.4 Adult Fish Facility and Fish Passage*

To address upstream passage needs, an adult fish collection facility would be constructed at Hills Creek Dam (Measure #722, Section 2.2.4). Upstream and downstream fish passage would be restored downstream of the Fern Ridge Dam at the Monroe, Stroda, and Cox Butte drop structures (Measure #639, Section 2.2.4.). The design of the adult fish facility at Hills Creek and fish passage restoration at the drop structures below Fern Ridge Dam would include Pacific lamprey passage (Measure #52, Section 2.2.4).

All three WTC towers would be paired with a FSS attached to provide downstream passage (Measure #392, Section 2.3.3.4). The structures would allow for fish collection over various water levels throughout the year, with the intent of minimizing effects to project storage from operations for fish passage and water quality.

Fish collected at Lookout Point and Detroit dams would be transported and released downstream of their reregulation dams (Dexter and Big Cliff dams, respectively) so that these fish would not have to find passage over the reregulating dams. Alternative 4 includes the construction of a FSS at Cougar Dam attached to the existing WTC tower.

At Foster, Alternative 4 includes Foster fish ladder temperature improvement (Measure #479, Section 2.2.2.4) and modification of the existing surface route structure (fish weir) for improved downstream passage (Measure #392, Section 2.2.3.4).

The measures for this alternative and the locations at which they would be implemented are shown in Table 2.4-12.

**Table 2.4-12. Alternative 4 Measures and Locations**

### 2.4.11 Alternative 5. Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-listed Fish Alternative (Refined Hybrid Alternative - Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)

Alternative 5 is the USACE Preferred Alternative. This alternative is also called the Refined Hybrid Alternative with Cougar Diversion Tunnel Modification because it is the same as Alternative 2B except that the integrated temperature and habitat flow regime (Measure #30a, Section 2.3.1.1) has been replaced by the refined integrated temperature and habitat flow regime (Measure #30b, Section 2.3.1.2, and Appendix A).

The Preferred Alternative was developed to improve fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and meet ESA-listed fish obligations (Chapter 5).

The Preferred Alternative was developed after the formulation and analyses of all other action alternatives. Alternative 2B was initially proposed as the Preferred Alternative. However, after engaging with BPA, NMFS, and USFWS, USACE determined that the integrated temperature and habitat flow regime proposed under Alternative 2B should be refined to improve outcomes for ESA species (Measure #30a, Section 2.3.1.1).

Consequently, the Preferred Alternative, Alternative 5, is the same as Alternative 2B except that the integrated temperature and habitat flow regime (Measure #30a, Section 2.3.1.1) has been replaced by the refined integrated temperature and habitat flow regime (Measure #30b, Section 2.3.1.2 and Appendix A). Because of this development history, comparisons with Alternative 2B are provided rather than highlighting only differences between the two alternatives.

As with all the action alternatives, site-specific design and environmental compliance documentation (as described in Chapter 7) would be prepared for each of the measures requiring construction.

#### *2.4.11.1 Near-term Operations Measure*

Under the Preferred Alternative, as under Alternatives 2A, 2B, 3A, 3B, and 4, the near-term operations measure would be implemented (Section 2.2.5 and Section 2.2.6). Chapter 5 and Appendix N provides a more detailed analysis of how near-term measures would be replaced by the measures under this alternative.

#### *2.4.11.2 Stream Flow*

Unique to the Preferred Alternative, the refined integrated temperature and habitat flow regime (Measure #30b, Section 2.3.1.2 ) would be utilized at all dams in the WVS. Identical to Alternative 2B, the Preferred Alternative would augment instream flows using the power pool (Measure #304, Section 2.2.1.3) at Lookout Point, Hills Creek, Green Peter and Detroit dams, and by using the inactive pools at Fall Creek, and Blue River dams (Measure #718, Section 2.2.1.4). These two measures would augment flows for biological purposes at critical times of the year and reduce temperatures.

#### *2.4.11.3 Water Quality*

As under Alternative 2B, the Preferred Alternative includes a combination of structural and operational measures to address water quality. The fish passage structure at Detroit Dam would be integrated with a WTC tower (Measure #105, Section 2.3.2.1). A WTC tower at Hills Creek Dam was omitted from this alternative after initial modeling showed an inability to affect temperatures downstream of Dexter Dam.

For temperature control at Green Peter Dam, the Preferred Alternative proposes the following operational measures, which would be the same as Alternative 2B:

- Using the ROs to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below these dams (Measure #166, Section 2.3.2.2).
- Using the spillway for surface spill in summer (Measure #721, Section 2.3.2.5).

Identically to Alternative 2B, the Preferred Alternative includes the Foster fish ladder temperature improvement (Measure #479 described in Section 2.2.2.4) and modification of the existing surface route structure (fish weir) for improved downstream passage (Measure #392 as described in Section 2.2.3.4.2).

Operations at Cougar Dam would be changed by drafting the reservoir down so that fish can pass through the DT in the fall and spring, as under Alternative 2B (Measures #40, Section 2.2.3.1 and #720, Section 2.3.3.3). These deep fall and spring drawdowns to the DT for fish passage would draft the reservoir below the power pool most of the time, making the power pool inaccessible for flow augmentation under the Preferred Alternative (Measure #304, Section 2.2.1.3). As discussed in Section 2.3.3.1, modifications to the Cougar DT needed to perform this operation would require site-specific construction and environmental compliance (as described in Chapter 7).

#### *2.4.11.4 Adult Fish Facility and Fish Passage*

The Preferred Alternative includes a new adult fish facility for upstream fish passage at Green Peter (Measure #722, Section 2.2.4) that would provide passage for Pacific lamprey (Measure #52, Section 2.2.4). As under Alternative 2A and Alternative 2B, the Preferred Alternative includes operational downstream fish passage measures at Green Peter Dam, including passing water over the spillway in the spring (Measure #714, Section 2.3.3.2) and a deep fall drawdown (Measure #40, Section 2.3.3.1). Structural downstream passage measures (Measure #392, Section 2.2.3.4) were proposed only at Lookout Point and Detroit Dams (Section 2.2.3.4.1) and at Foster Dam (Section 2.2.3.4.2).

The measures for the Preferred Alternative and the locations at which they would be implemented are shown in Table 2.5-13.

# CHAPTER 3 - AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES

This chapter presents both the affected environment and environmental consequences for resources that could be affected by the Proposed Action and alternatives. The following resources were not analyzed and are dismissed from further analysis for the following reasons.

- Flood Risk – the U.S. Army Corps of Engineers (USACE) considered but dismissed flood risk from the analysis after development of the final array of alternatives when USACE confirmed that each alternative carried forward in the analysis would have not increase the levels of flood risk when compared to current operations and management levels of flood risk.
- Navigation and River Transportation – USACE considered but dismissed navigation and river transportation from the analysis because authorized flows for navigation serve the dual purpose of also meeting water quality standards; therefore, impacts to navigation, due to the availability or lack thereof of water to support these flows, are analyzed in the water quality analysis. Further analysis of impacts to navigation would be redundant.
- Transportation – USACE considered but dismissed ground transportation from the analysis because that effects on traffic would be negligible to minor throughout and could only be discussed very generically due to the programmatic level of analysis and lack of specifics. Ground transportation impacts for actions requiring construction will be assessed under subsequent tiered analysis.

## 3.1 METHODOLOGY

Sections 3.2 through 3.24 discuss the resources analyzed. The affected environment section for each of these resources defines the bounds of the area of analysis that could be affected by the Proposed Action and alternatives; it also summarizes the current physical, biological, social, and economic conditions for that resource area. The affected environment describes the elements or components of the resource that may be potentially affected by the Proposed Action and alternatives.

The environmental consequences section for each resource area considers how the condition of a resource would change as a result of implementing each of the alternatives. These potential effects are described in terms of types (direct, indirect, beneficial, adverse). These types of effects are further described using evaluation criteria or significance criteria including context and intensity, as well as effect factors including magnitude (how much), duration (how long), and extent (how big or how far). The types of effects are defined in Section 3.1.2and the development of evaluation criteria is described in Section 3.1.3 below. For each resource, the effects analysis is performed using a framework that follows the logical sequence of analytical steps below.

1. **Types of Effects –** Determine the types of effects that could occur with the implementation of individual measures or the suite of measures under each alternative. These could include direct, indirect, beneficial, and adverse effects.

2. **Evaluation Criteria** – Apply the evaluation criteria to determine the effect factors and scale from all effect-causing measures. The evaluation criteria, including significance, are defined for each resource in the respective methodology section.

3. **Effects Analysis by Alternative –** Combine the types of effects, effect factors (magnitude, extent, duration), and scale for each effect factor under each alternative. Compare effects between alternatives.

### 3.1.1 Types of Effects

According to the Council on Environmental Quality's (CEQ) National Environmental Policy Act (NEPA) Regulations at 40 Code of Federal Regulations (CFR) §§ 1500-1508 (1978), direct and indirect effects are defined as:

**Direct effects:** Effects that are caused by the action and occur at the same time and place (1508.8[a]). Examples include filling a wetland or digging up an archaeological site.

**Indirect effects:** Effects that are caused by the action and occur later in time or are farther removed in distance but are still reasonably foreseeable. Indirect effects also include "induced changes" in the human and natural environments (1508.8[b]). Examples of an indirect effects include causing economic change in a community that changes the environment over the long run (through development, increased taxes, etc.) or causing turbidity (a direct effect on water quality) in spawning grounds which in turn increases sedimentation which may damage next year's hatch of salmonids (an indirect biological effect).

Identified effects may be either adverse or beneficial. The CEQ Guidelines that govern NEPA implementation describe the need for identifying and differentiating between adverse and beneficial effects, but do not offer a definition of these terms. This Draft PEIS considers both adverse and beneficial effects as defined below:

**Adverse effects:** Those effects having a negative and harmful effect on the analyzed resource. An adverse impact causes a change that moves the resource away from a desired condition or detracts from its appearance or condition.

**Beneficial effects:** Those effects having a positive and supportive effect on the analyzed resource. A beneficial impact constitutes a positive change in the condition or appearance of the resource or a change that moves the resource toward a desired condition.

### 3.1.2 Evaluation Criteria for Potential Effects

Evaluation criteria (or significance criteria) provide a structured framework for assessing effects, supporting conclusions regarding the significance of effects, and comparing effects between alternatives.

#### *3.1.2.1 Context and Intensity*

As defined in 40 CFR 1508.27, determining the significance of effects requires a consideration of both context and intensity. Context means that the significance of an action must be analyzed in several contexts such as society as a whole (human, national), the affected region, the affected interests, and the locality. Short-, medium- and long-term effects are all relevant. Intensity refers to the severity or magnitude of the effect. See 40 CFR 1508.27 for the list of factors that can contribute to the intensity of an impact.

The primary purpose of significance ratings in the NEPA process is to ascertain whether a lead agency should prepare an Environmental Impact Statement (EIS) (or Programmatic EIS [PEIS]) and Record of Decision (ROD), as opposed to a less time-consuming and less in-depth Environmental Assessment (EA) and Finding of No Significant Impact (FONSI). In the present case, USACE has already determined that a PEIS will be prepared because of the high potential for significant or major effects. This PEIS details where significant (and non-significant) effects would occur.

#### *3.1.2.2 Effect Factors and Scale*

For this Draft PEIS, USACE developed evaluation criteria for each resource by defining effect factors and the scale of these effect factors. The effect factors considered include the magnitude (how much), extent (how big or how far), and duration (how long or how often). The scale for the magnitude of effects includes negligible, minor, moderate, and major or significant. The scale for extent includes small, medium, and large or local, regional, and state-wide. The scale for duration includes short term, medium term, and long-term (permanent, continuous, or recurring).

While magnitude and extent vary for each resource, the duration of measures do not.

Short-, medium-, and long-term are defined below.

**Short-term:** Alteration lasts for the duration of the small construction project and can be temporary or is continuous for less than 2 years.

**Medium-term:** Alteration is limited to the duration of large construction projects and is continuous for a period of 2-5 years.

**Long-term:** Alteration is permanent or lasts continuously beyond operation changes or the completion of all construction projects; the alteration recurs at regular intervals (e.g., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently over the long term.

The duration(s) for each measure is shown in the below table, and the measures that could have effects on specific resources are discussed in the appropriate section. Note that the following abbreviations for the WVS projects are used in the table:

- FRN – Fern Ridge;
- CTG – Cottage Grove;
- DOR – Dorena;
- DEX – Dexter;
- LOP – Lookout Point;
- FCR – Fall Creek;
- HCR – Hills Creek;
- CGR – Cougar;
- BLU – Blue River;
- FOS – Foster;
- GPR – Green Peter;
- BCL – Big Cliff; and
- DET – Detroit.

**Table 3.1-1. Duration(s) of Measures**

| Alternative and Action Location | Duration of Construction Activity | Duration of Operational Activity |
|---|---|---|
| **Measures common to all action alternatives** | **–** | **–** |
| 384. Gravel augmentation below dams | – | – |
| North Santiam, South Santiam, and McKenzie River sub-basins below BCL, FOS, BLU, and CGR dams | Short term | N/A |
| 719. Adapt hatchery program | – | – |
| North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins, including BCL, DET, GPR, FOS, BLU, CGR, DEX, LOP, FCR, and HCR | N/A | Long-term permanent |

Each section begins by presenting the methodology used to characterize potential effects. For each resource, the definitions of types of impacts that could occur (direct, indirect, beneficial, adverse), consideration of both context and intensity (as defined in 40 CFR 1508.27), and the evaluation criteria (including magnitude, geographic extent, and duration) used to arrive at an overall conclusion of effects are explained.

### 3.1.3 Structure of the Effects Analysis by Resource

The analysis for each resource follows one of two different approaches based on whether it was more logical to discuss effects by measure(s) on a smaller scale, or effects by geographic region (basin-wide and/or sub-basins) on a larger scale. Regardless of the approach taken, each environmental consequences section begins with a detailed description of the methodology used for that resource.

The first approach, and the method that most of the resources use, analyzes the combined effects of all the measures under each alternative by geographic region, both by sub-basin and basin wide. The macroscopic approach was more applicable to resources that would have broader system-wide effects, such as hydrologic processes, river mechanics and geomorphology, and geology and soils. Analyses only discuss effects for relevant geographic regions (e.g., water supply only considers the Santiam and McKenzie sub-basins rather than all sub-basins).

The second approach analyzes the effects from each measure and groups analyses by measures that would have similar effects. The analysis under each action alternative refers up to the discussion of effects by measure(s) subsection but discusses effects by dam/reservoir as applicable. The analysis by measure(s) was more applicable to resources that would have smaller and more discrete effects that were not logical to discuss by geographic region, such as noise, visual resources, and hazardous materials. The approach used for each resource topic is shown below in Table 3.1-2.

**Table 3.1-2. Structure of the Effects Analysis by Resource**

### 3.1.4 Level of analysis in this PEIS

Programmatic analysis of the resources in this chapter is at a broad and macroscopic scale and scope. This analysis of the resources focuses on the effects that are relevant at the broad scale and would factor into the decision to select the suite of measures to include in the preferred alternative. These broad effects of the proposed action serve as a starting point for further site-specific evaluation of direct, indirect, and cumulative effects – effectively laying the groundwork for subsequent tiered analyses. Tiering means taking general, preliminary analyses from a programmatic document and adding to them in a subsequent EA or EIS when more detail and specifics about the project are known.

The level of analysis in this PEIS depends on the amount of information currently available and whether detailed design and construction will be needed. The PEIS fully assesses the effects of most operational measures that do not require detailed design and construction to implement immediately. Some operational measures would eventually require dam modifications to address operational and dam safety concerns and may thus need further analysis. These measures are listed in Tables 3.1-3 and 3.1-4, respectively, and discussed below in Section 3.1.5.1 (Operational Measures). If USACE determines that this PEIS has not sufficiently evaluated the potential environmental effects of an action, then tiered NEPA analysis will be required – probably for some but not all resources. For measures that would require site-specific construction, USACE would perform subsequent NEPA evaluations tiered to this PEIS, as applicable. During this subsequent NEPA phase, the effects analysis would be informed by the site-specific designs prepared at that time for measures requiring construction. Subsequent analysis would include appurtenant or ancillary implementation features or activities, such as use of construction equipment, site preparation, access, staging, and material storage and transfer facilities. These measures are listed in Table 3.1-5 and discussed below in Section 3.1.5.2 (Structural Measures). Typical descriptions of several activities that could occur during implementation of the measures are summarized in Section 2.2.6. Subsequent NEPA analysis tiered to this PEIS will include public review and comment opportunities.

#### *3.1.4.1 Operational Measures*

This Draft PEIS fully assesses the effects of most operational measures that do not require detailed design and construction to implement immediately. The PEIS has taken the required “hard look” at the potential environmental effects of these measures, and further NEPA evaluation will not be necessary. These measures are shown below in Table 3.1-3. If USACE determines that this PEIS has not sufficiently evaluated the potential environmental effects of an action, then tiered NEPA analysis will be required – probably for some but not all resources.

**Table 3.1-2. Operational measures with no further site- or project- specific NEPA analysis required**

| Measures | Locations[1] |
|---|---|
| **Flow Measures** | – |
| 30b. Refined Integrated temperature and habitat flow regime | FRN, CTG, DOR, DEX, LOP, FCR, HCR, CGR, BLU, FOS, GPR, BCL, DET |
| 304. Augment instream flows by using the power pool | LOP, HCR, CGR, GPR, DET |
| 718. Augment instream flows by using inactive pool | CTG, DOR, FCR, BLU |
| 723. Reduce minimum flows to Congressionally authorized minimum flow requirements | FRN, CTG, DOR, DEX, LOP, FCR, HCR, CGR, BLU, FOS, GPR, BCL, DET |
| **Water Quality Measures** | – |
| 166. Use Regulating Outlets for Temperature Management | LOP, GPR |
| 721. Use spillway for surface spill in summer | LOP, GPR, DET |
| **Downstream Passage Measures** | – |
| 40. Deeper fall reservoir drawdowns for downstream fish passage for the drawdown operation to the Regulating Outlet | LOP, HCR, CGR, BLU, GPR, DET |
| 714. Pass water over spillway in spring for downstream fish passage | DEX, LOP, FCR, GPR, BCL, DET |
| 720. Spring reservoir drawdown for downstream fish passage | LOP, CGR, DET |
| **Measures Common to All Alternatives** | – |
| 719. Adapt Hatchery Program | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins |
| Fall Creek Drawdown | FCR |
| Continued Operation of Existing Adult Fish Facilities | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins |
| Scheduled/Routine Maintenance of WVS Facilities | Basin-wide |

[1]: Dam Abbreviations

BCL – Big Cliff; BLU – Blue River; CGR – Cougar; CTG – Cottage Grove
DET – Detroit; DEX – Dexter; DOR – Dorena; FCR – Fall Creek
FOS – Foster; FRN – Fern Ridge; GPR – Green Peter; HCR – Hills Creek
LOP – Lookout Point

It is assumed that routine Operations and Maintenance (O&M, as described in Section 1.8.2 and Appendix A) will not result in impacts to the environment, as they are mostly sited within existing structural facilities. Therefore, impacts associated with these actions are not analyzed further in the effects analysis (Chapter 3). However, each action is routinely assessed for environmental compliance prior to implementation, and any action that may result in impacts to the human environment will undergo additional analysis under the tiered NEPA process described in Chapter 7.

Some operational measures would eventually require dam modifications to address operational and dam safety concerns and may need further analysis. If USACE determines that this PEIS has not sufficiently evaluated the potential environmental effects of an action, then tiered NEPA analysis will be required – probably for some but not all resources. These measures are shown in Table 3.1-4.

**Table 3.1-3. Operational measures that would require site- or project- specific NEPA analysis**

| Measures | Locations |
| --- | --- |
| **Water Quality** | **–** |
| 721. Use spillway for surface spill in summer | HCR, BLU |
| **Downstream Passage Measures** | – |
| 40. Deeper fall reservoir drawdowns for downstream fish passage for the drawdown operation to the DT | CGR |
| 714. Pass water over spillway in spring for downstream fish passage | HCR, BLU |
| 720. Spring reservoir drawdown for downstream fish passage for the drawdown operation to the DT | CGR |
| **Measures Common to All Alternatives** | – |
| 726. Maintenance of existing and new fish release sites above dams | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins |
| Major Maintenance and Rehabilitation of WVS Facilities | Basin-wide |

### *3.1.4.2 Structural Measures*

For structural measures that would require site-specific construction, limited analysis and a range of potential effects of the potential site-specific implementation of the general construction activities are included in the effects analysis for each resource in this PEIS. Site-specific alternatives development and evaluation will determine the actual features and activities included during a subsequent analysis tiered to this PEIS, when site-specific design objectives and constraints will be addressed. During this subsequent NEPA phase, the effects analysis would be informed by the site-specific designs performed at that time for measures requiring construction. Subsequent analysis would include appurtenant or ancillary implementation features or activities, such as construction equipment, site preparation, access, staging, and material storage and transfer facilities. Typical descriptions of several activities that could occur during implementation of the measures are summarized in Appendix A and 7.2.2.3 (Structural measures with subsequent tiered NEPA analysis).

The following measures in Table 3.1-5, discussed in Chapter 2 and in Appendix A, are analyzed generally in this PEIS, but would require site-specific design and construction and therefore would be analyzed in more detail in the tiered EA or EIS.

**Table 3.1-4. Structural measures that would require site- or project- specific NEPA analysis**

| Measures | Locations |
|---|---|
| **Water Quality Measures** | – |
| 105. Construct water temperature control tower | LOP, HCR, DET |
| 479. Foster Fish Ladder Temperature Improvement | FOS |
| 174. Structural improvements to reduce TDG | DEX, LOP, CGR, FOS, GPR, DET |
| **Downstream Passage Measures** | – |
| 639. Restore upstream and downstream passage at drop structures | FRN |
| 392. Construct structural downstream fish passage | LOP, HCR, CGR, FOS, DET |
| **Upstream Passage Measures** | **–** |
| 52. Provide Pacific lamprey passage and infrastructure | FRN, HCR, BLU, GPR |
| 722. Construct adult fish facility | HCR, BLU, GPR |
| **Measures Common to All Alternatives** | – |
| 384. Gravel Augmentation | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River dams |
| 9. Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration | Basin-wide |

### 3.1.5 Climate Change

USACE developed a list of climate factors that were relevant to the WVS PEIS climate change assessment. These climate factors are discussed in more depth in Appendix F. The list of relevant climate change factors is summarized below:

1. Ambient air temperature change;
2. Water temperature change;
3. Precipitation changes;
4. Seasonal timing of flow peaks and volumes;
5. Low summer flow- shortage/volume/frequency;
6. Change in snowpack accumulation and spring freshet timing;
7. Reservoir evaporation/ reach evapotranspiration effects;
8. Wildfire intensity/frequency change; and
9. Wildfire impacts to water quality.

Each resource area topic qualitative determination, use the climate change assessment information provided in Appendix F as shown in Table 3.1-5.

**Table 3.1-5. Relevant climate factors analyzed in resource topics**

| Section | Resource Topic | Ambient temp (1) | Water temp (2) | Precipitation (3) | Flow peak and timing (4) | Summer low flow (5) | Spring snow melt (6) | Evapotranspiration (7) | Wildfire (8) | Wildfire effects (9) |

#### *3.1.5.1 Near-term operational measure analysis*

The Near-term Operations Measure is evaluated qualitatively for effects over the period of analysis for this Draft PEIS (30 years) with an intent to capture the maximum range of impacts. The Near-term Operations Measure is not included in the No Action Alternative (NAA) because its initiation occurs after the period of record that defines the NAA. The Near-term Operations Measure is not included in Alternative 1 as these operations are counter to the objective of the alternative to maximize storage; however, this measure is included in Alternatives 2A, 2B, 3A, 3B, 4, and 5. The analysis of effects is discussed in each resource area under Alternative 2A and then referenced under each subsequent alternative as the maximum range of effects would be the same across all other action alternatives.

Similarly, projected climate change effects to/of the Near-term Operations Measure are not analyzed quantitively. The future projections of relevant climate change variables are the same for the Near-Term Operations Measure and the action alternatives. The Near-term Operations Measure is not likely to be any more sensitive to expected climate change factors than the other alternatives or measures. The future hydrologic and hydro-climate trends that are likely to impact the range of the Draft PEIS alternatives in the WVS, including Near-term Operations Measure, are contained in Appendix F. Though unlikely, specific operations in the Near-term Operations Measure could conceivably be in effect from 2024 through 2050. The climate change factor trends cited in Section 3.1.5 would be experienced over the period of implementation.

Climate change effects associated with the Near-term Operations Measure are not analyzed because the projected near-term climate change effects experienced under the Near-term Operations Measure are the same as for other Draft PEIS alternatives. Alternatives would be executed at different times for different sites, depending upon individual implementation plans. Near term operations at a certain location may be in place for a relatively short amount of time, up to a maximum duration of 30 years. The Near-term Operations Measure may therefore experience changing climate over different time frames (e.g., 15 years versus 30). Additionally, the response to near-term climate change would be inherently a monitor centric based approach. From that standpoint, Near-term Operations Measure operational changes are inherently adaptable. Monitoring of climate change factor trends can inform adjustment, within the permissible constraints, of the Near-term Operations Measure parameters.

### 3.1.6 Summary of Environmental Consequences

A summary comparing the effects of each alternative by resource area is provided in Table 3.1-6. The categories of effects (i.e., minor adverse and major beneficial) shown in Table 3.1-7 are defined for each resource area in their associated detailed environmental consequences section in the methodology description.

**Table 3.1-6. Summary of overall indirect and direct effects to resources compared to the No Action Alternative**

| Resource Topic | NAA | Alternative 1 | Alternative 2A | Alternative 2B | Alternative 3A | Alternative 3B | Alternative 4 | Alternative 5 |
|---|---|---|---|---|---|---|---|---|
| 3.2 Hydrologic Processes and River Infrastructure | None/Negligible Effects<br><br>Maintains hydrology of WRB consistent with existing conditions, with the addition of increased releases for M&I water storage agreements. | Major Effects<br><br>Would have limited effects during an average or wet year in the WRB. Summer flows would sometimes be a bit higher than NAA but flow differences are minimal. Would alter storage in drier than average years, shifting flow releases from April to June into July through October. Would miss the current BiOp flow requirements more often, but those misses would occur earlier in the year during the April to June period. Later flow targets from July to October are met more frequently. | Major Effects<br><br>Lower spring flows in dry years and higher summer flows in nearly all years would have long term effects across the WRB. Reservoir elevations would be somewhat higher than the NAA.<br>Green Peter reservoir would have a fall drawdown resulting in more flow in the late summer and early fall in the South Santiam, Santiam, and Willamette downstream of the confluence with the Santiam. The WVS would also meet the mainstem Willamette River flow targets more often with higher Cougar storage levels, as compared to the NAA. | Major Effects<br><br>Lower spring flows in dry years and higher summer flows in nearly all years would have long term effects across the WRB. Flows would be lower than NAA flows in the year during the April to June period. Later flow targets from July to October would be met more frequently due to the additional accumulated stored water. Compared to NAA, the spring and early flows would be similar or somewhat lower across the WVS, so reservoir elevations would be somewhat higher than the NAA throughout the conservation season. Storage at Cougar is reduced resulting additional water released at other WVS reservoirs, notably in the Middle Fork of the Willamette River subbasin, to meet mainstem Willamette River flow targets. The flow target at Albany is missed more often in dry years as the larger WVS reservoirs reach their minimum elevations earlier in the year. | Major Effects<br><br>NAA flow targets and the lower Integrated Flow Regime flow targets would not be met across the WRB during an average flow year. These notably lower flows would have long term consequences across the WRB. Spring drawdowns at Detroit, Lookout Point and Cougar (to the regulating outlet) and the fall drawdown operations at Blue River, Hills Creek, Green Peter, Detroit, Lookout Point and Cougar are typically to the lowest level possible. The spring drawdown can inhibit refill of the reservoirs into the late winter and spring, limiting available water to augment flows downstream during the summer and fall. Releases during the during the spring can lower flows in the summer, especially during drier years. An average flow year would see Detroit and Cougar unable to contribute meaningfully to flow targets downstream. | Major Effects<br><br>Santiam subbasin summer flow would be well below the baseline and the adaptability of the WVS would be constrained by a reduced ability to refill during conservation season. All changes to the WRB would be long term. Spring drawdown operations are at Hills Creek, Green Peter and Cougar (to the diversion tunnel) and fall drawdown operations at Blue River, Hills Creek, Green Peter, Detroit, Lookout Point and Cougar are typically to lowest level possible. Both the spring and fall drawdowns at Cougar make use of the diversion tunnel leading to a much lower drawdown. The spring drawdown can inhibit refill of the reservoirs into the late winter and spring making less water available to augment flows downstream during the summer and fall. | Major Effects<br><br>The shift in releases of stored water to a different season would be very noticeable throughout the basin and would bring long term changes to the WRB. Would have limited effects during an average or wet year. Summer flows are sometimes a bit higher Would alter storage in drier than average years, shifting flow releases from April to June into July through October. Would result in less flow compared to the NAA earlier in the year during the April to June period. Later flow targets from July to October would be met more frequently Compared to Alternative 1, the flows are similar or higher across the WVS, so reservoir elevations would be somewhat lower than Alternative 1. | Major Effects<br><br>Lower spring flows in dry years and higher summer flows in nearly all years would have long term effects across the WRB. Flows would be lower than NAA flows in the year during the April to June period. Later flow targets from July to October would be met more frequently due to the additional accumulated stored water. Compared to NAA, the spring and early flows would be similar or somewhat lower across the WVS, so reservoir elevations would be somewhat higher than the NAA throughout the conservation season. Storage at Cougar is reduced resulting additional water released at other WVS reservoirs, notably in the Middle Fork of the Willamette River subbasin, to meet mainstem Willamette River flow targets. The flow target at Albany is missed more often in dry years as the larger WVS reservoirs reach their minimum elevations earlier in the year. |

| 3.8 Fish, Aquatic Invertebrates, and Aquatic Habitat (including ESA/sensitive species and critical habitat) – *bull trout* | Minor adverse effects for bull trout. Bull trout above Cougar have been stable for several years and have been increasing above Hills Creek. Habitat scores for bull trout are reasonable, with 100% of the available spawning habitat available, and 70% of the rearing habitat available. Passage conditions at dams limit bull trout access to below dam rearing habitat.<br><br>Climate change is predicted to further degrade habitat for bull trout below dams | Minor adverse effects for bull trout. The EDT output indicates that Alternative 1 is somewhat resilient to different hydrology year types with respect to life history diversity. Scores and risks for bull trout would be ranked similar to the NAA with MINOR effects<br>predicted. Habitat scoring for bull trout is only marginally better than in the NAA with rearing habitat increases for North Santiam bull trout below Detroit. | Minor adverse effects for bull trout. EDT results shows resiliency with respect to recruits per spawner. Bull trout habitat scores and risks are comparable to Alternative 1, with a fish passage addition providing access to habitat below Cougar Dam. | Minor adverse effects for bull trout. EDT results shows resiliency with respect to recruits per spawner. Bull trout habitat scores and risks are comparable to Alternative 1, with a fish passage addition providing access to habitat below Cougar Dam.<br><br>McKenzie: increased adverse effects to bull trout compared to Alternative 2A (still moderate) | Major adverse effects for Bull trout. Reservoir rearing area is significantly reduced in both Detroit and Cougar reservoirs and expected to result in increased movement into more degraded rearing habitat below Detroit and Hills Creek dams where spawning habitat does not exist, and human disturbance is high.<br><br>Climate change is predicted to further degrade habitat for bull trout below dams. | Moderate to Major adverse effects for bull trout. Reservoir rearing area is significantly reduced in Cougar Reservoir, and passage will result in increased movement into more degraded rearing habitat below Detroit and Hills Creek dams where spawning habitat does not exist, and human disturbance is high.<br><br>Climate change is predicted to further degrade habitat for bull trout below dams. | Moderate adverse effects for bull trout. The EDT output also indicates Alternative 4 is somewhat resilient to different hydrology year types with respect to life history diversity. Habitat scoring for bull trout is improved in all three sub-basins due to passage actions, however access to below dam habitat increases demographic risks especially below Hills Creek and secondarily below Detroit where spawning habitat does not exist, and human disturbance is high. | Minor adverse effects for bull trout. EDT results shows resiliency with respect to recruits per spawner. Bull trout habitat scores and risks are comparable to Alternative 1, with a fish passage addition providing access to habitat below Cougar Dam.<br><br>McKenzie: increased adverse effects to bull trout compared to Alternative 2A (still moderate) |

| 3.12 Power and Transmission - *Regional Power System Reliability Effects* | No/Negligible Effect. WVS Projects 73-Year Average Generation is estimated to be 171 aMW (roughly the amount of power used by 136,416 Northwest homes or used by residential customers in a city slightly more populated than Gresham, Oregon). Loss of Load Probability (LOLP) is 6.5%, which is within the range of the Pacific Northwest Power System LOLP in recent years, and the risk of blackouts or power shortages is about once every 15 years. | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would increase by 8 aMW (roughly enough to power 6,371 households annually). LOLP only decreases by 0.1 percent and the risk of blackouts or power shortages remains the same resulting in no detectable change to regional power system reliability. | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would decrease by 4 aMW (roughly enough to power 3,185 households annually). LOLP and the risk of blackouts or power shortages remain the same as the NAA. | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would decrease by 18 aMW (roughly enough to power 14,334 households annually). LOLP only increases by 0.1 percent and the risk of blackouts or power shortages remains the same resulting in no detectable change to regional power system reliability. | Negligible Impact on power system reliability. Hydropower generation from the WVS projects would decrease by 87 aMW (roughly enough to power 69,283 households annually). LOLP only increases by 0.5 percent and the risk of blackouts or power shortages remains the same resulting in no detectable change to regional power system reliability. | Negligible Impact on power system reliability. Hydropower generation from the WVS projects would decrease by 79 aMW (roughly enough to power 62,912 households annually). LOLP only decreases by 0.5 percent and the risk of blackouts or power shortages remains the same resulting in no detectable change to regional power system reliability. | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would increase by 1 aMW (roughly enough to power 796 households annually). LOLP and the risk of blackouts or power shortages remain the same. | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would decrease by 18 aMW (roughly enough to power 14,334 households annually). LOLP only increases by 0.1 percent and the risk of blackouts or power shortages remains the same resulting in no detectable change to regional power system reliability. |
| 3.12 Power and Transmission - *Transmission System Effects* | No/Negligible Effect. The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires. | Long-term, minor, adverse effects on the transmission system. Less than 10MW increased loading on congested paths all seasons (CCS and SOA). Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) similar to the NAA. Construction projects at Cougar Dam are not anticipated to impact local transmission services to Blue River provided generation is not affected. | Long-term, moderate, adverse effects on the transmission system. Increased loading in winter on CCS path (18.4MW) and in spring on both CCS (61.3MW) and SOA (11.8MW) paths. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated), providing transmission services to Oakridge and Blue River, respectively, similar to the NAA. Construction projects at Cougar Dam are not anticipated to impact local transmission services to Blue River provided | Long-term, moderate, adverse effects on the transmission system. Increased loading in winter on CCS path (21.9MW) and in spring on both CCS (25.1MW) and SOA (5.1MW) paths. Generation at Hills Creek Dam would remain able to operate islanded (isolated), providing transmission services to Oakridge, similar to the NAA. Infrequent, temporary major adverse effects on transmission services to Blue River. Deep fall and spring drawdowns would compromise Cougar Dam's ability to operate islanded and | Long-term, moderate, adverse effects on the transmission system. Increased loading on CCS and SOA paths in winter (37.2MW and 13.6MW, respectively) and spring (113.7 MW and 22.3 MW, respectively). Infrequent, temporary major adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to operate islanded and serve these communities under temporary storm or fire related outage conditions. | Long-term, moderate, adverse effects on the transmission system. Increased loading on CCS path all seasons (winter: 41.4MW, spring: 94.8 MW, and summer: 25.6MW) and on SOA path in winter (15.2MW) and spring (18.7 MW). Infrequent, temporary major adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to operate islanded and serve these communities under temporary | Long-term, minor, adverse effects on the transmission system. Less than 10MW increased loading on congested paths (CCS and SOA) all seasons with exception of a slightly greater increase on the CCS path in spring (15MW). Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) similar to the NAA. Construction projects at Hills Creek and Cougar dams are not anticipated to impact local transmission services to Oakridge and Blue River, respectively, provided | Long-term, moderate, adverse effects on the transmission system. Increased loading in winter on CCS path (21.9MW) and in spring on both CCS (25.1MW) and SOA (5.1MW) paths. |---|---|---|---|---|---|---|---|---|
| | | drawdowns. Adverse effects would be less severe than all other action alternatives because Alternative 1 includes only one recurring drawdown and does not include the suite of near-term operations. Alternative 1 is the only action alternative that would result in direct benefits to recreation by promoting reservoir storage (i.e., from reducing minimum flows to congressionally authorized minimum flows). All other alternatives would only result in indirect benefits to recreation over time by improving recreational fishing. | drawdowns. Adverse effects would be more severe than Alternative 1 but less severe than Alternatives 2B, 3A, 3B, 4, and 5 due to the number of recurring drawdowns. | drawdowns. Adverse effects would be the same as Alternative 5, more severe than Alternatives 1 and 2A, but less severe than Alternatives 3A, 3B, or 4 due to the number of recurring drawdowns. | drawdowns. Adverse effects would be less severe than Alternative 3B but more severe than Alternatives 1, 2A, 2B, 4, and 5 due to the number of recurring drawdowns. | drawdowns. Adverse effects would be more severe than any other action alternative because it would involve the most recurring drawdowns, including the deeper drawdown to Cougar's DT. Alternative 3B would only be slightly more adverse than Alternative 3A as they would involve the same number of recurring drawdowns, but Alternative 3B would also require the construction of the tower and bridge in order to draw-down Cougar Reservoir to the DT. | drawdowns. Adverse effects would be more severe than Alternatives 1, 2A, 2B and 5, but less severe than Alternatives 3A and 3B due to the number of recurring drawdowns, inclusion of the near-term operations, and number of medium-term construction measures. | drawdowns. Adverse effects would be the same as Alternative 2B, more severe than Alternatives 1, and 2A, but less severe than Alternatives 3A, 3B, or 4 due to the number of recurring drawdowns. |
| 3.15 Land Use | Effects would be moderate in magnitude, local in extent, and long-term recurring at Fall Creek due to the drawdowns. There would be no other effects. | Effects would be minor in magnitude, local in extent, and long-term in duration due to restoring upstream and downstream passage at drop structures and maintaining revetments using nature-based engineering methods. Moderate, local, and long-term recurring effects would continue due to the drawdowns. ## 3.2 HYDROLOGIC PROCESSES

### 3.2.1 Affected Environment

With a watershed of approximately 11,500 square miles, the Willamette River is located entirely within the state of Oregon, beginning south of Cottage Grove and extending approximately 187 miles to the north where it flows into the Columbia River. The Willamette River is the 13th largest river in the coterminous U.S. in terms of streamflow (annual discharge) and produces more runoff per unit area than any of the 12 larger rivers (EPA 2013b). The basin averages 75 miles in width and encompasses approximately 12 percent of the total area of the state. The Willamette Valley System (WVS) PEIS covers the basin from the reservoirs on the Willamette River and its tributaries to the Willamette Falls in Oregon City.

#### *3.2.1.1 Basin layout*

The basin is bounded by three mountain ranges: the Cascade Range to the east, the Coast Range to the west, and the Calapooya Mountains to the south. Maximum elevations exceed 10,000 feet in the Cascade Range, 4,000 feet in the Coast Range, and 6,000 feet in the Calapooya Mountains. In the upper reaches, Willamette River tributaries flow in narrow valleys with steep gradients.

Major Cascade Range tributaries include the Santiam, McKenzie, Middle Fork of the Willamette, Molalla, and Clackamas rivers. The Willamette River is also fed by major tributaries from the Coast Range, including the Long Tom, Marys, Luckiamute, Yamhill, and Tualatin rivers. At the south end of the basin, the Coast Fork of the Willamette River emerges from the Calapooya Mountains and joins the mainstem Willamette River near the City of Springfield. The average annual flow at Salem (river mile [RM] 84, drainage area of 7,280 square miles) for the water years 1910-2020 was about 24,200 cubic feet per second (cfs) or about 17.5 million acre-feet annually per USGS gage data.

Within the watershed are most of the state's population, larger cities, and major industries. The basin also contains much of Oregon's most productive agricultural lands and supports nationally and regionally important fish and wildlife species and populations. Thirteen of Oregon's 36 counties (Benton, Clackamas, Columbia, Douglas, Klamath, Lane, Linn, Marion, Multnomah, Polk, Tillamook, Washington, Yamhill) intersect or lie within the boundary of the WRB, where nearly 70 percent of Oregon's population lives.

#### *3.2.1.2 Basin climate*

Topography, proximity to the Pacific Ocean, and exposure to middle latitude westerly winds are the principal climate controls for the WRB. The basin climate ranges from warm dry summers and cool wet winters in the center of the basin to extreme alpine conditions in the highest Cascade Mountain reaches. Rainfall ranges from 40 inches per year in most of the basin to over 200 inches per year in the highest Cascade Mountain reaches. For the entire basin, average annual precipitation totals approximately 63 inches, with 60 percent falling during November through March based on rain gage and snow depth data (USACE 2015b).

During the winter months, high-pressure centers are characteristically to the south so that winds consistently come from the relatively warm and humid ocean surface and bring precipitation into the basin. In contrast, summer conditions typically have high-pressure centers near the west coast, which often forces the flow of air over the basin from a northerly direction. This pattern decreases relative humidity and reduces the amount of cloud cover and precipitation over the entire area during summer months. Thunderstorms can occur during the summer but are not a major source of precipitation in the basin. During spring and autumn, intermediate conditions occur causing alternating wet and dry periods (USACE 2015b).

#### *3.2.1.3 River System*

There are approximately 465 RM along the Willamette River and its regulated subbasins below USACE's WVS. The approximate regulated river length in each subbasin is:

- Mainstem Willamette River – 187 RM
- Mainstem Santiam River – 11 RM
- North Santiam River – 46 RM
- South Santiam River – 44 RM
- Long Tom River – 25 RM
- McKenzie River (including South Fork) – 60 RM
- Blue River – 2 RM
- Coast Fork of Willamette River – 30 RM
- Middle Fork of the Willamette River – 45 RM
- Fall Creek – 7 RM
- Row River – 8 RM

Most of the drainage area in the WRB is located downstream of the WVS dams and reservoirs. For example, although more than 90 percent of Middle Fork of the Willamette drainage passes through USACE reservoirs upstream of Eugene, only about 27 percent of the drainage area is above a reservoir at the Willamette's confluence with the Columbia River. The relative volume of water in the Willamette River from USACE reservoirs varies significantly throughout the year depending on the primary seasonal flow management goal.

#### *3.2.1.4 Flow Management Goals*

During each year there are overarching three reservoir control periods: flood risk management (FRM) (fall/winter), conservation storage (spring), and conservation holding and release (summer). The transition date between seasons varies slightly at each reservoir (USACE 2014a).

Operation of each project is guided by its water control diagram, including the rule curve, which establishes the elevation at which the pool is to be maintained at or below during various seasons and during seasonal transitions unless regulating a flood event. Figure 3.2-1 depicts a typical WVS water control diagram, including the rule curve, with the three overarching regulation seasons across the top. The main features of the water control diagram are annotated.

From September to November (or December at some projects), the reservoirs are drawn down to minimum flood pool elevations to reserve space to detain and release winter flood flows as necessary. In February (depending on the project), reservoirs begin to accumulate water in conservation storage by releasing less water than flows in. By about the end of May or June, WVS reservoirs are as full as possible for the summer season (USACE 2015b).

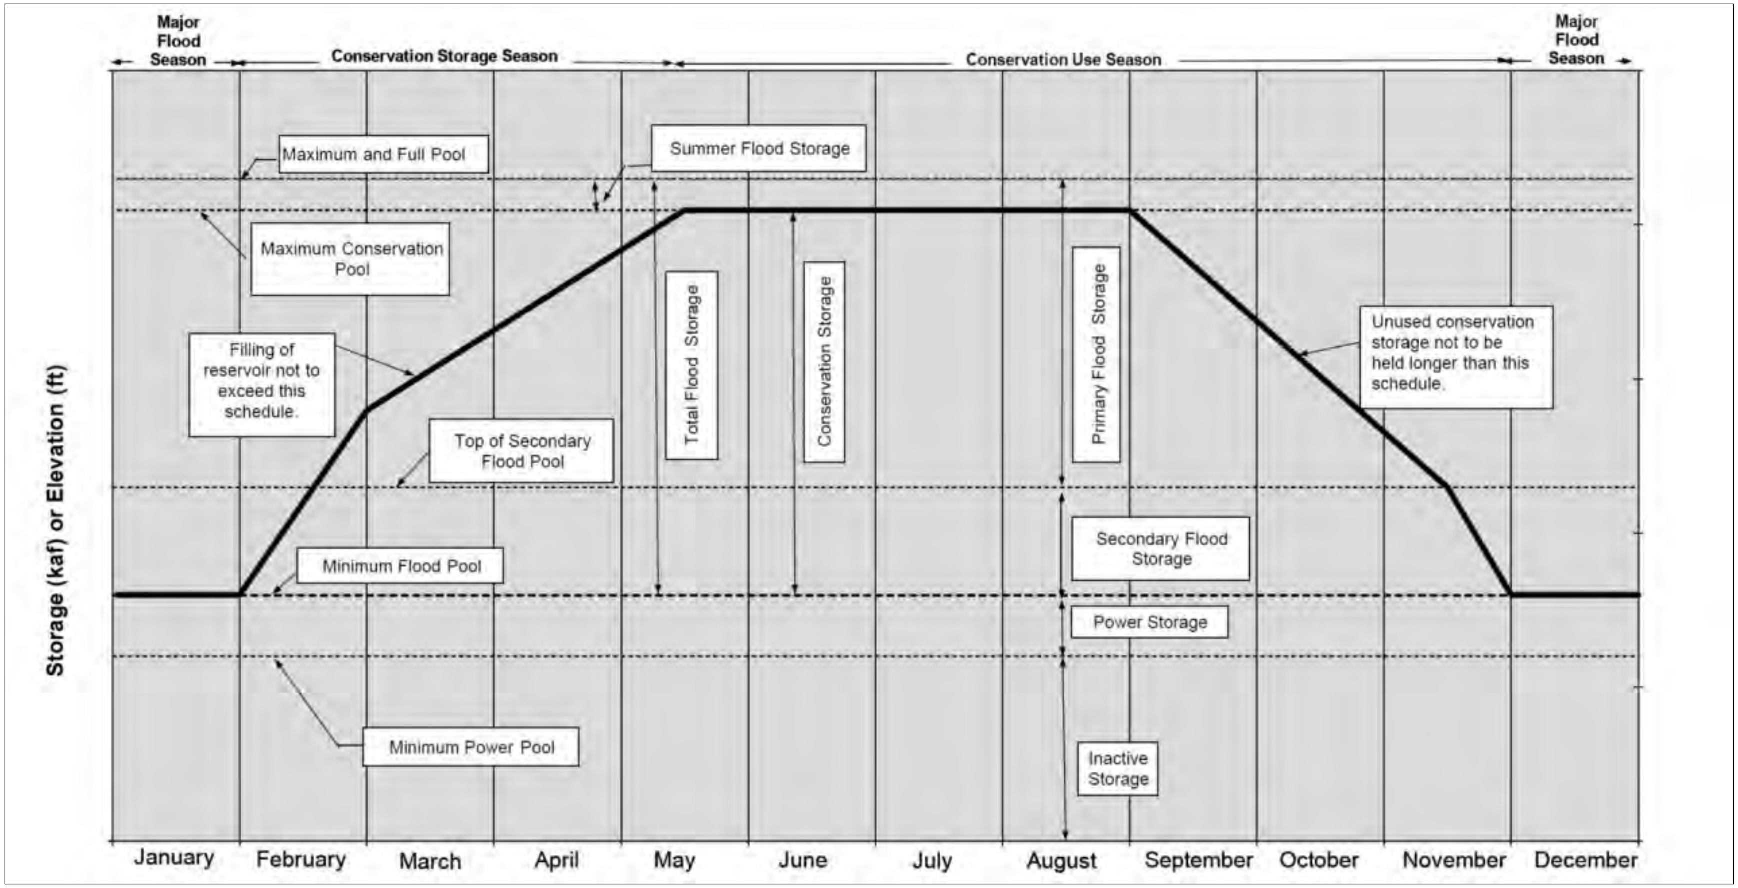

**Figure 3.2-1 Typical Willamette Basin Project Dam and Reservoir Water Control Diagram and Rule Curve**

As required by Congress, USACE manages the WVS to meet multiple responsibilities or purposes, including flood control or flood risk management (FRM), hydropower, water quality, fish and wildlife, recreation, irrigation, navigation, and municipal and industrial water supply. In some years, inflow to WVS reservoirs are not sufficient to fully meet all the demands on the system.

The goal of spring and summer flow management planning is to develop a strategy for the release of stored water using the National Oceanic and Atmospheric Administration Regional Forecast Center's (NOAA RFC) anticipated precipitation and runoff patterns. Each year, the Willamette Action Team for Ecosystem Restoration (WATER), made up of the US Fish and Wildlife Service, National Marine Fisheries Service, USACE, Bureau of Reclamation, Bonneville Power Administration, Oregon Water Resources Department, and Oregon Department of Fish and Wildlife, works cooperatively and adaptively before and during the conservation storage and release season to plan WVS operations to meet flow objectives for ESA-listed fish and management for other project purposes. Since each water year is different, this coordination is preferable to establishing fixed operating criteria. Adaptive management is necessary as it is not possible for USACE to forecast, describe, model, and implement a comprehensive release program that addresses potential management scenarios and contingencies without frequent coordination.

The Conservation Plan developed in cooperation with WATER describes individual reservoir and system flow objectives, reservoir release priorities, minimum and maximum flows, and balances the multipurpose needs given the forecasted availability of water. The general operational goal – assuming sufficient inflow of water – is to maintain each reservoir above minimum conservation pool ("Minimum Flood Pool" level in Figure 3.2-1) through October 31 while attempting to meet the other project purposes. Operational flow objectives at Salem begin on April 1, before the reservoir refill period ends in May, so WVS releases may be adjusted through the conservation season. The availability of water is reassessed as necessary (monthly, at a minimum) through October, and changes in the WVS management strategy are made in coordination with the representatives from WATER throughout the conservation season (USACE 2015b).

During the winter months, WVS reservoirs are primarily operated for FRM. There is a notable history of flooding in the Willamette Valley, with large floods occurring in 1861, 1964 and 1996. The largest historical flow at Salem was during 1861, peaking at an estimated 500,000 cfs. The 1964 and 1996 floods peaked at 308,000 cfs and 244,000 cfs respectively. Both more modern events were reduced by the WVS winter storage capacity. If the WVS had not existed during these events, the peak flows would have been much higher: approximately 472,000 cfs and 381,000 cfs (USACE 1997).

Each WVS reservoir is managed for targets at control points downstream, shown in Figure 3.2-2. These targets can apply only to an individual USACE project or to the entire system. For example, Fern Ridge flood season flow decisions are immediately evaluated at its nearest control point at Monroe on the Long Tom River and no other WVS reservoir can influence water levels at this location. Continuing downstream, the control point at Salem on the mainstem Willamette is influenced by all the WVS reservoirs. Section 3.2.1.5, Basin Description and Reservoir System, contains a more detailed explanation and maps of each subbasin.

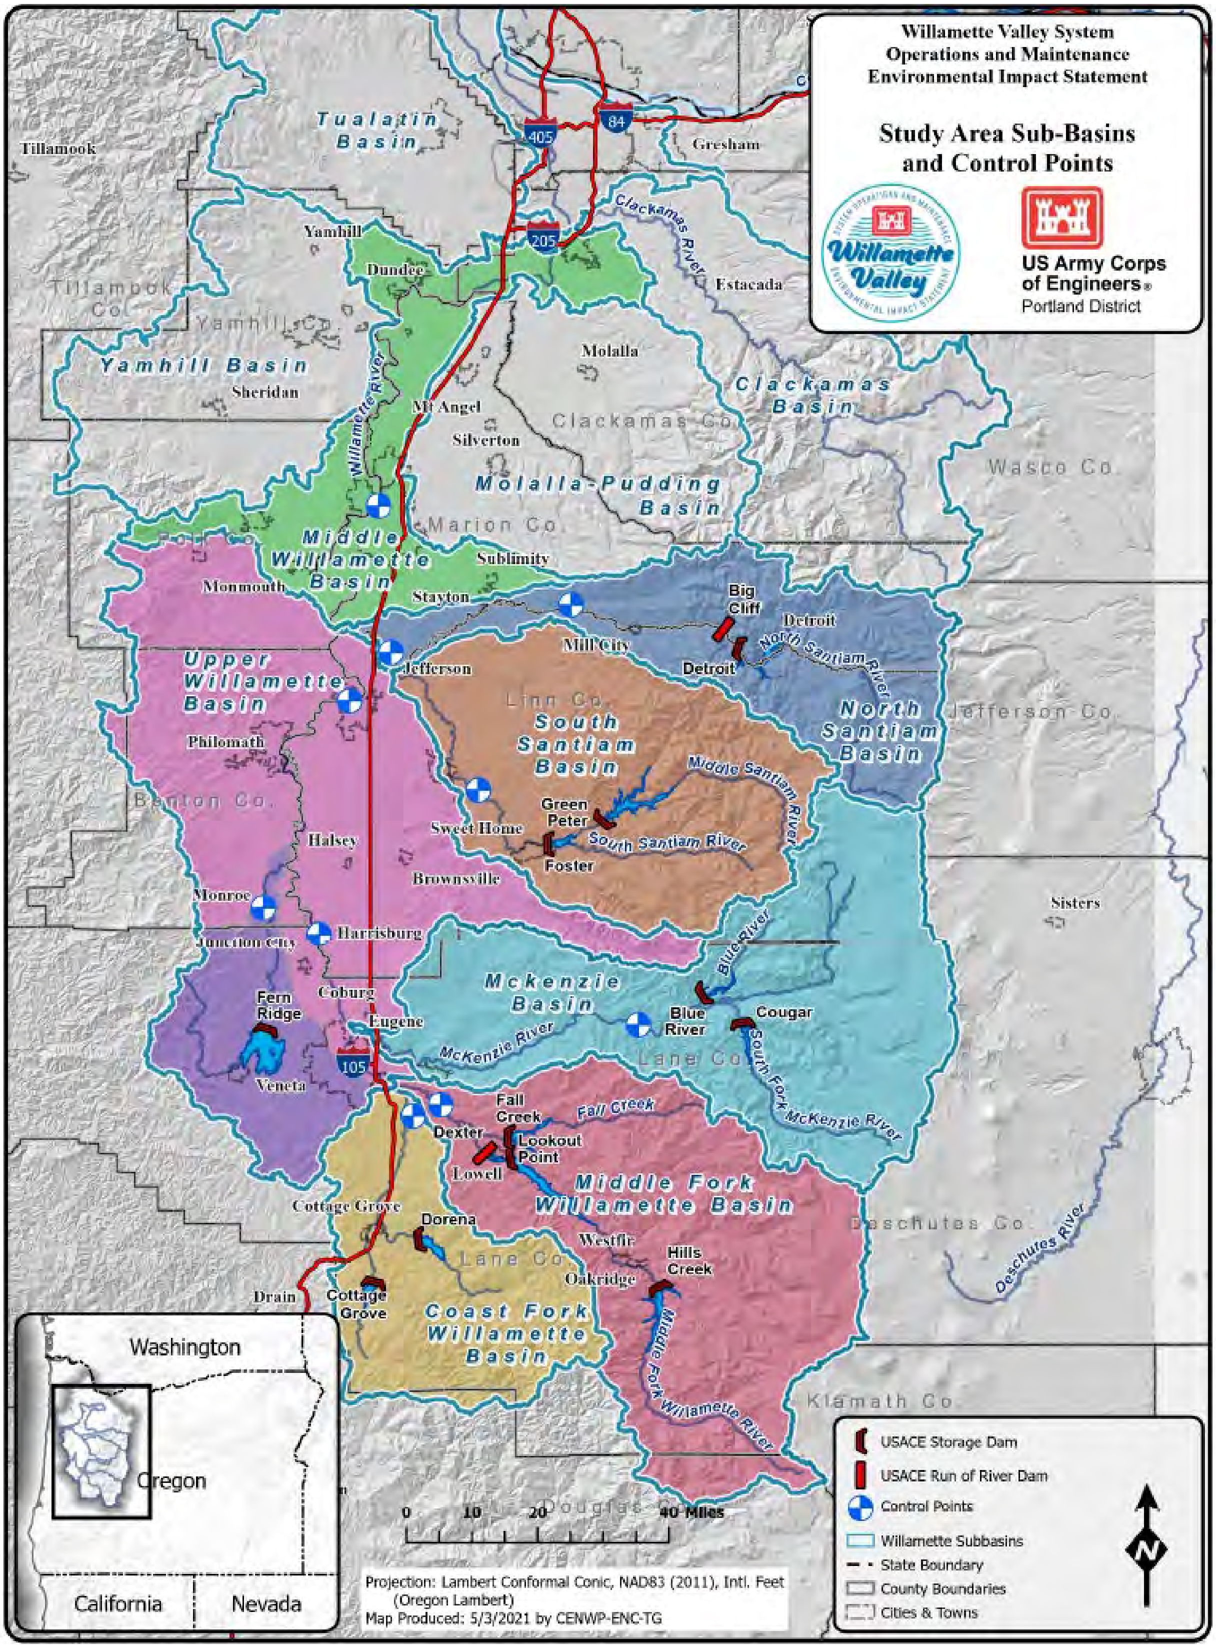

**Figure 3.2-2. Willamette River Basin subbasins and WVS layout**

Major flood season runs from the middle of November through early February in the WRB. Floods result principally from rainfall, augmented by snowmelt. House Document 531 (HD531) established the guidelines for flood season operation for the WVS and established two types of flood storage. Primary flood storage provides risk management for floods of record except for the 1861 flood, while secondary flood storage provides risk management for flows to the 1861 level. Secondary flood storage can be used jointly for FRM and hydropower purposes. The document mandates that the maximum amount of flood storage space (i.e., the bottom of secondary flood storage) at the non-power projects must be available at the start of each flood season. Current practice is to lower the water level in all projects, regardless of power generating capability and excluding the smaller reregulating projects Big Cliff and Dexter, to minimum flood storage prior to the beginning of the flood season.

As flood waters allow downstream, USACE lowers reservoir levels to the minimum flood pool elevation, which is the bottom of secondary flood storage pool. Timelines are dictated by project limitations such as flow change limits and outlet capacities, which vary at each WVS dam, but the bottom of flood storage is typically achieved in seven to ten days.

#### *3.2.1.5 Basin Description and Reservoir System*

The WVS was constructed over approximately 30 years starting with Fern Ridge (completed 1942) on the Long Tom River, west of Eugene. The complete WVS is authorized for flood control, hydropower, pollution abatement, fish and wildlife conservation, navigation (removed in 1986), recreation, irrigation, municipal and industrial water supply, and water quality. Based on the hydrologic dataset from 1935-2019, the total average annual basin flow volume is 17.2 million acre-ft (Maf) at Salem, OR and 22.7 Maf at Willamette Falls, or an annual average of 23,700 cfs and 31,300 cfs, respectively. Approximately 6.1 Maf, or an average of 8,350 cfs (35 and 27 percent of the flow at Salem and Willamette Falls, respectively), flowed through the WVS, compared to a total conservation storage volume of 1.59 Maf. Annual variability accounts for slightly different flow measurements when using different time periods for the analysis.

Construction of the 13 USACE dams and reservoirs in the WRB fundamentally changed the character of the flow regime in the watershed. The WVS moderates floods during the winter by storing and releasing water to manage flood risk. Outside of flood season, the WVS releases stored water to maintain downstream flows throughout the summer, supplementing downstream basin inflows. With ResSim and other models, USACE can calculate the effects on reducing and increasing flows at various points in the WRB. An unregulated flow refers to a natural flow regime without the influence of the WVS and an observed flow refers to the basin with the WVS in place, managing flow in the system.

Figure 3.2-3 shows a comparison between the observed and unregulated flow for the 1996 water year at Salem, OR and the daily minimum, average and maximum unregulated flow as calculated by the USGS for 1928 to 2008 (Lind and Stonewall 2018). Note the reduced peaks during the winter and increased flow during the summer and fall. Similar patterns are present across most years; 1996 was a wetter than average year and both the unregulated and regulated flows are above the median flow for most of the winter months.

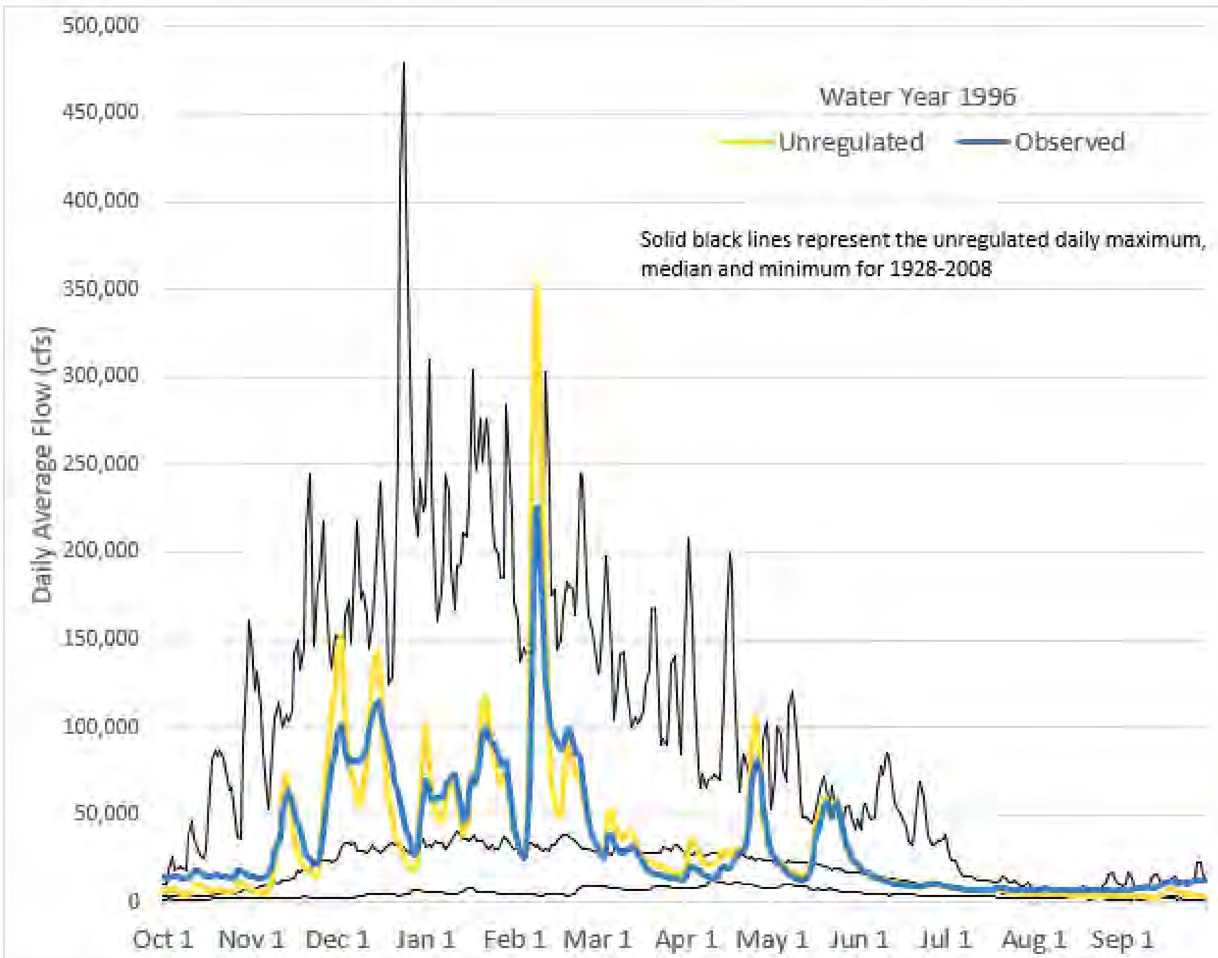

**Figure 3.2-3. Willamette River stream flows at Salem, Oregon for October 1995 to September 1996 (WY1996)**

The WVS stores water in its reservoirs and some of this water evaporates. Except at Fern Ridge, the evaporation is a relatively minor component of the total reservoir inflow – WVS reservoirs have a large volume compared to their surface area. Since inflow is calculated with the change in storage and the measured outflow, the evaporated water is already accounted for in the input dataset as a slightly lower inflow. At Fern Ridge, since it is shallower than the other WVS reservoirs and has the largest surface area, evaporation is estimated and removed from the reservoir in the ResSim model. Appendix B, Hydrologic Processes Technical Information, has additional information on the hydrologic dataset development.

WVS has target flows at the mainstem control points during the summer. The goal is to augment the natural downstream flows with stored water for fish and irrigation withdrawals. This actual target flow varies with the conditions set out in the 2008 NMFS BiOp (NMFS 2008), based on the projected amount of stored water each spring.

The hydrologic study area ends at the Willamette Falls in Oregon City, Oregon. The portion of the Willamette River flowing through Portland, Oregon, is downstream of Willamette Falls and is not included in the reservoir model, and neither is any flow coming into the river downstream of the Falls. The Willamette River below the Falls has a tidal influence that cannot be modeled in ResSim. See the Columbia River System Operations EIS for information on the tidally influenced portion of the river (USACE, et al., 2020).

###### *3.2.1.5.1 Basin Flow*

Total basin-wide inflow is not evenly distributed throughout the WRB. In general, larger size and higher elevation subbasins contribute more flow. Most of the flow from the WRB originates from areas that are not upstream of a WVS dam. For example, 1.5 percent and 2.8 percent of the total basin flow comes into Blue River and Cougar reservoirs, respectively. Much more water (8.8 percent of the total) flows into the control point at Vida below those two reservoirs without having passed through the reservoirs upstream. Moreover, about 24 percent of annual flow of the Willamette at its confluence with the Columbia enters the river from tributaries downstream of Salem, the most downstream control point for current operational targets. Figure 3.2-4 shows the origin of basin flows on an average annual basis. The values represent the additional accumulated inflow as compared to the next upstream point under natural conditions with no dams present.

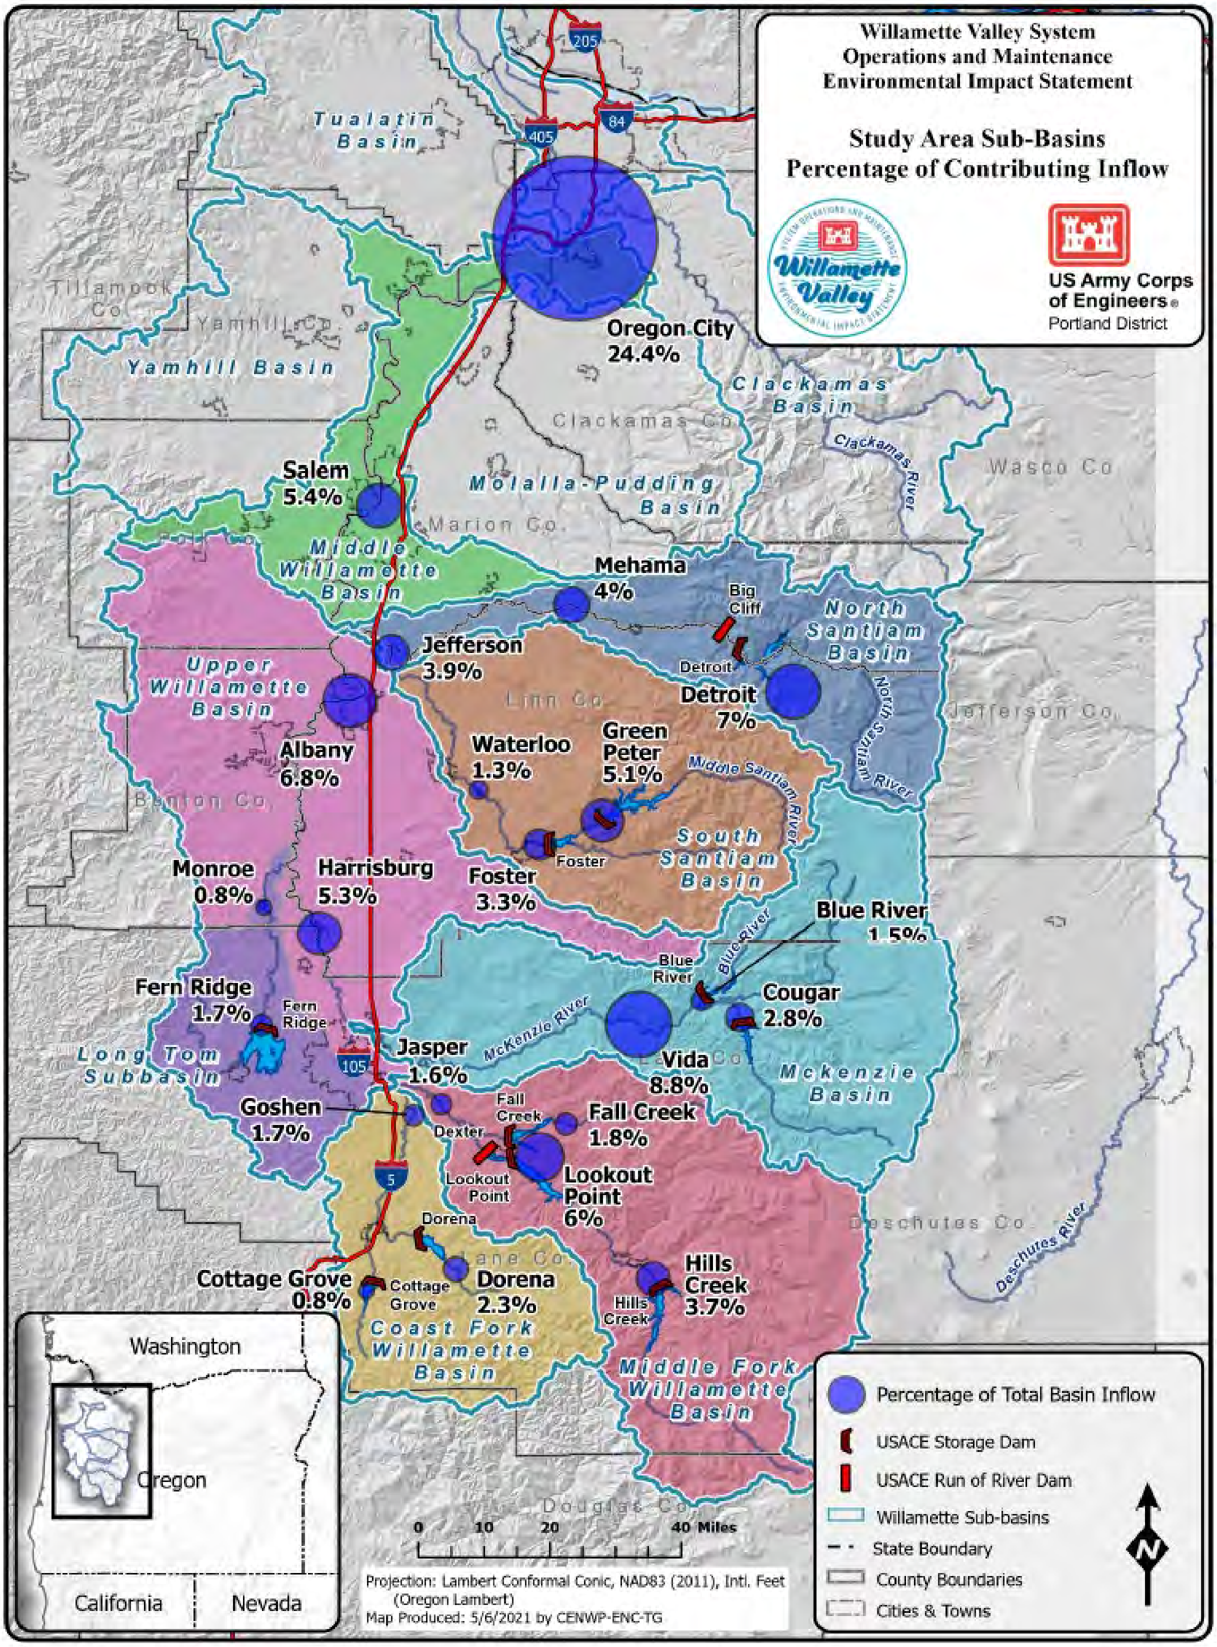

**Figure 3.2-4. Basin inflow origin by WVS and Control point location**

### *3.2.1.5.2 Unregulated and Observed Flow*

As discussed in Flow Management Goals, the primary objectives of the WVS change throughout the year based on the season. During the winter, the primary objective is FRM with a goal to reduce flows, and hence flood stages, downstream of the WVS. During the spring, the WVS holds water to fill and release the stored water through the summer and fall.

A comparison of the observed (USGS gage records after the construction of WVS) and unregulated (Lind and Stonewall 2018) flows show the effects of WVS operations. The example figures below show a reduction in peaks (the 5 percent non-exceedance line – 5 percent of years are above that threshold on that calendar day) and increased median flows from December to February. The median is higher because the water volume stored during large inflows is generally released over 7-14 days, increasing the flow of a larger number of days than peak reduction over 2-3 days. In the spring, the median observed flows go below the unregulated flow as the WVS reservoirs store water and high peaks are reduced. Later into the summer, flow augmentation from the reservoirs means that observed flow is higher than unregulated flow. In fall, the reservoirs release any remaining water to return to minimum elevation in preparation for major flood season.

Figures 3.2-5 and 3.2-6 show the water year flows at Jasper (the control point for Lookout Point and Hills Creek) and Albany, respectively. The difference in observed and unregulated flows is greater at Jasper than Albany because a much higher percentage of the drainage basin flows through a WVS dam and reservoir upstream of Jasper. Similar figures for the remaining WRB control points are available in Appendix B, Hydrologic Processes Technical Information.

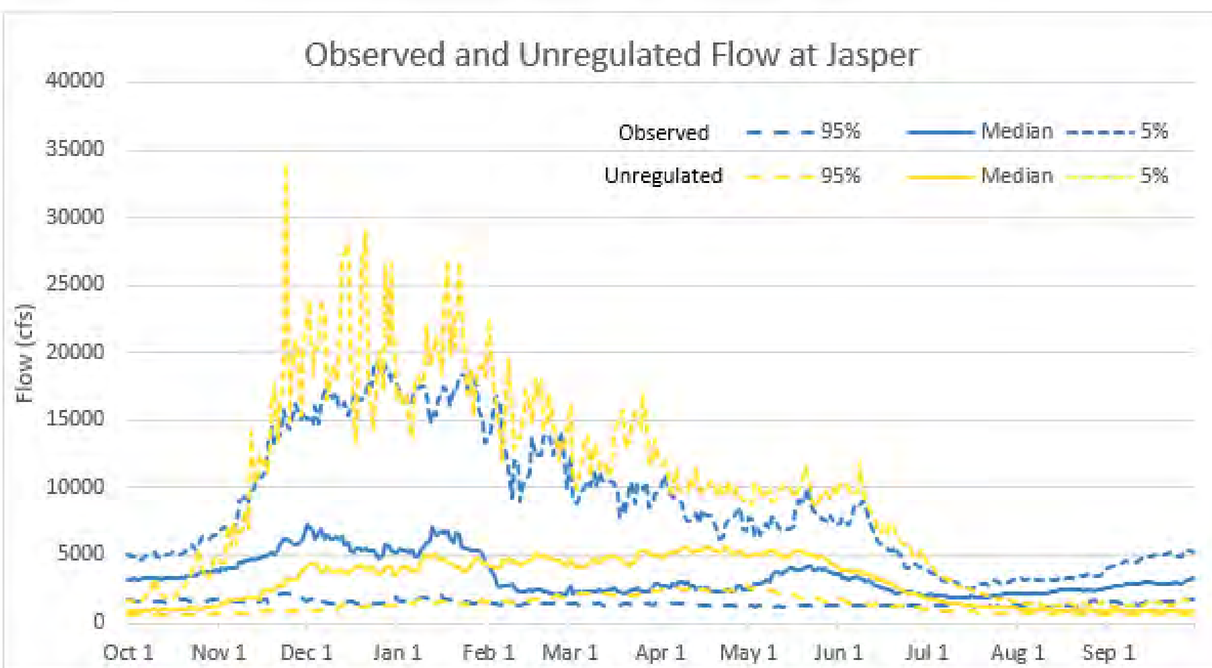

**Figure 3.2-5. Middle Fork of the Willamette River at Jasper, OR. Flows across the water year**

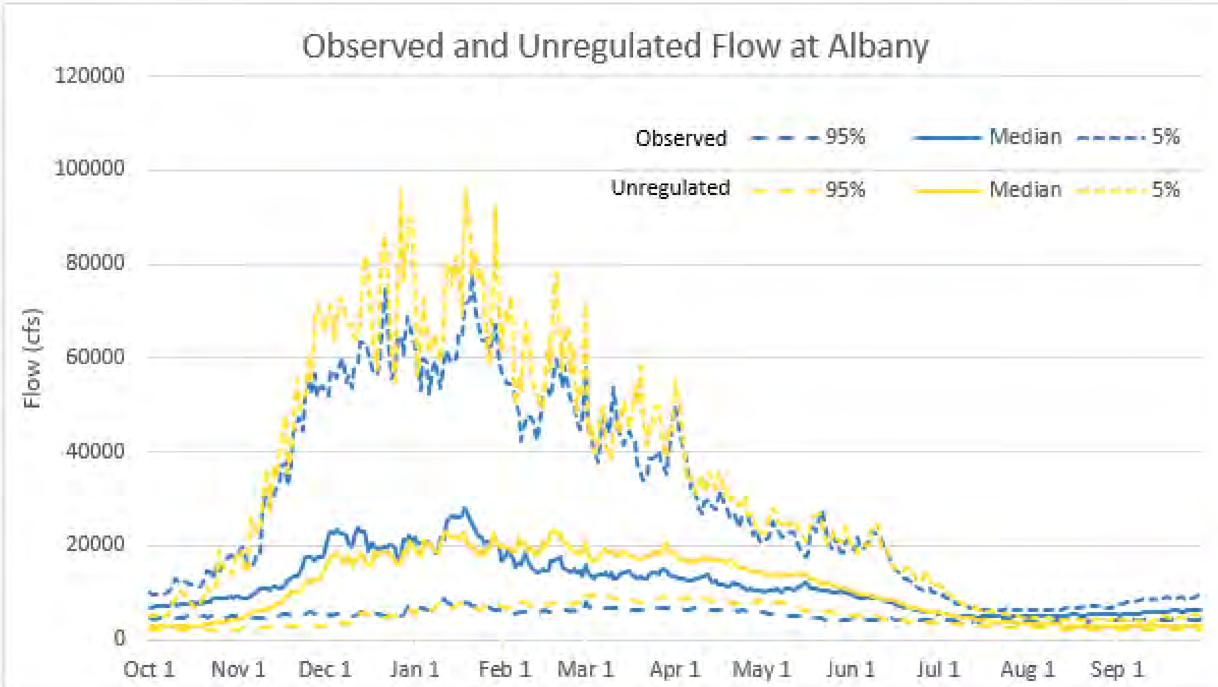

**Figure 3.2-6. Willamette River at Albany, OR. Flows across the water year**

*3.2.1.5.3 Reservoir Pool Operations*

During April and May, the WATER partners assign a rating of abundant, adequate, insufficient or deficit for the upcoming conservation storage season based on the forecasted refill volume of the WVS reservoirs. The insufficient and deficit designations change the mainstem flow targets at Albany and Salem and allowable withdrawals from the Willamette River. Water Quality (Section 3.5) used three recent prototypical years to show the range of the designations: 2011, abundant; 2015, deficit; and 2016, insufficient.

The figures below are of actual operations, not model results, for illustration purposes. WVS reservoirs were nearly full during the 2011 conservation season and stayed at or near rule curve until they were drafted (i.e., lowered) in preparation for a major flood season. Detroit reservoir (Figure 3.2-7) is operated for downstream temperature control in insufficient years, so levels stayed relatively high in 2016; maintaining the pool above the spillway crest (elevation 1541 ft) makes these operations more effective. In contrast, Green Peter (Figure 3.2-8) and Lookout Point (Figure 3.2-9) were drafted down as USACE used its stored water to meet the biological opinion mainstem flow requirements. 2015 was a deficit year, so the reservoirs did not reach the rule curve during the spring and released the stored water, going below minimum conservation pool into the power pool. Similar figures of the remaining storage reservoirs are available in Appendix B, Hydrologic Processes Technical Information.

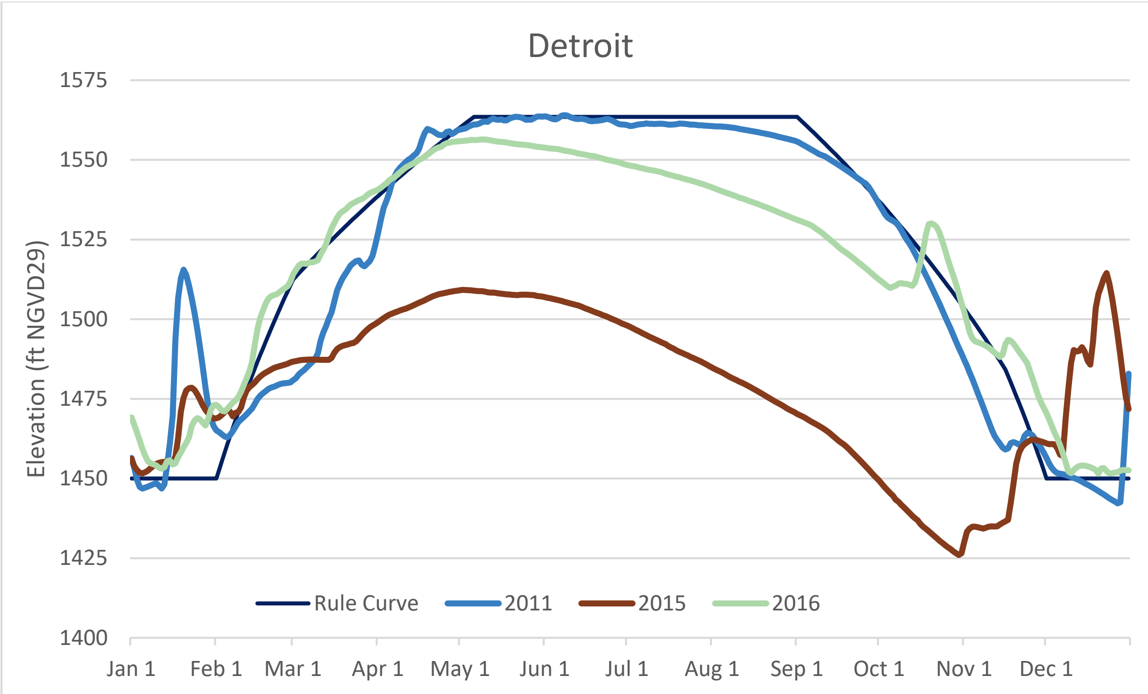

**Figure 3.2-7. Detroit reservoir water surface elevation across 2011, 2015 and 2016**

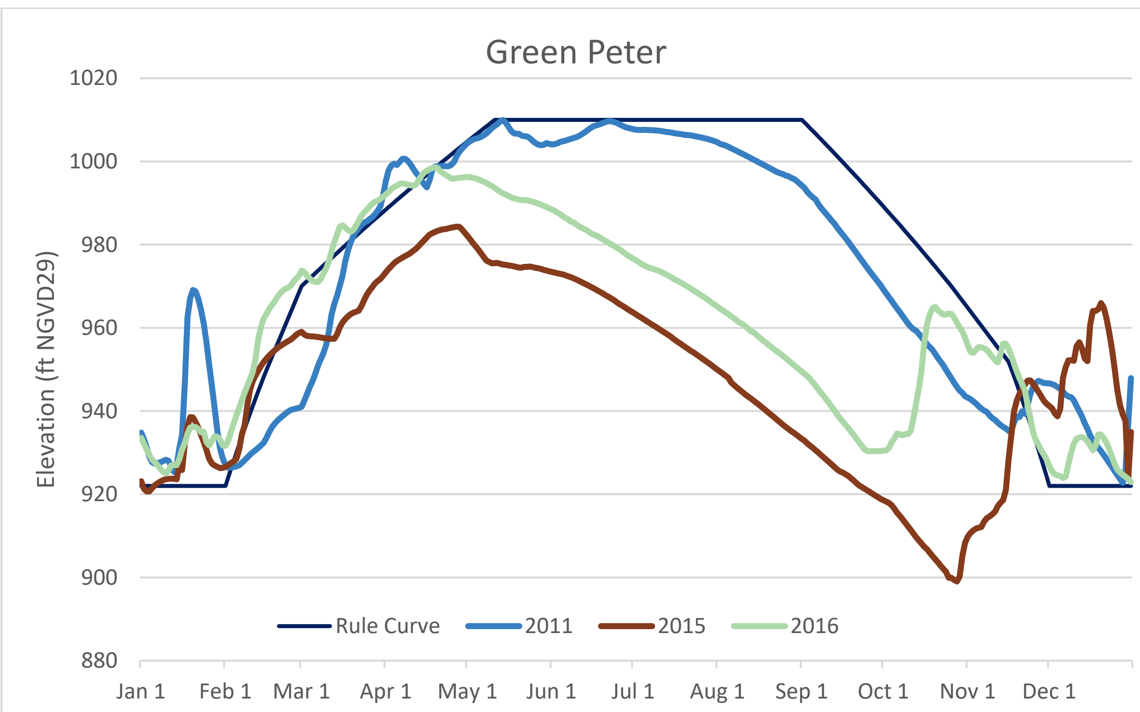

**Figure 3.2-8. Green Peter reservoir water surface elevation across 2011, 2015 and 2016**

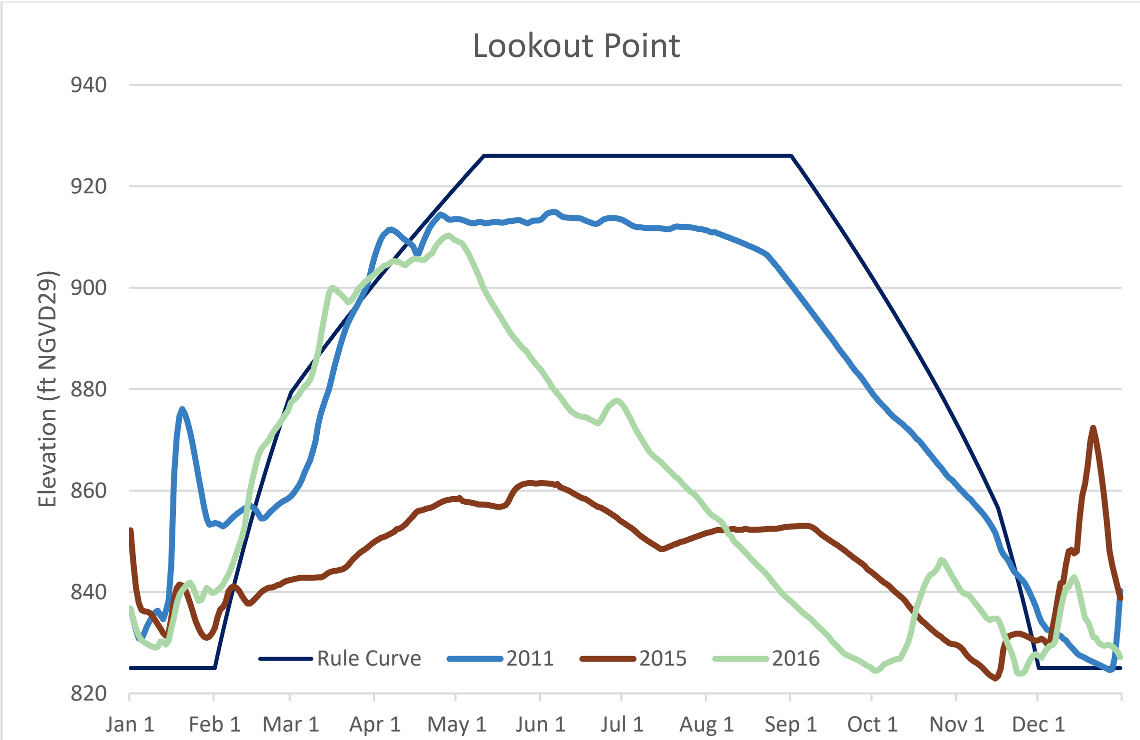

**Figure 3.2-9. Lookout Point reservoir water surface elevation across 2011, 2015 and 2016**

### *3.2.1.5.4 Mainstem Willamette*

The mainstem Willamette River subbasins are divided into three main sections. The upper portion of the mainstem Willamette River starts at the confluence between the Middle and Coast Forks and continues up to the Santiam River. The extent of the Middle Willamette stretches from the Santiam River to Willamette Falls at Oregon City. The Lower Willamette below Willamette Falls is the tidal portion of the river to the Columbia River and is not part of this study. Including the Clackamas River, which is the largest drainage basin downstream of the Falls, the Lower Willamette River is about 12 percent of WRB at its confluence with the Columbia River.

The Middle Willamette subbasin (Figure 3.2-10) is characterized by a braided meandering channel upstream of the mouth of the Yamhill River. From the Yamhill River to Willamette Falls, the river is characterized by a well-defined channel with comparatively narrow floodplain, most of which is located on its right bank. In the 5 miles above Oregon City, the river flows through a gorge upstream of the Tualatin River confluence to Willamette Falls. Above the falls, a fixed-crest hydropower dam (Thomas A. Sullivan Dam) was built and during low flows, the backwater effects of this dam extend upstream nearly 23 miles to Newberg.

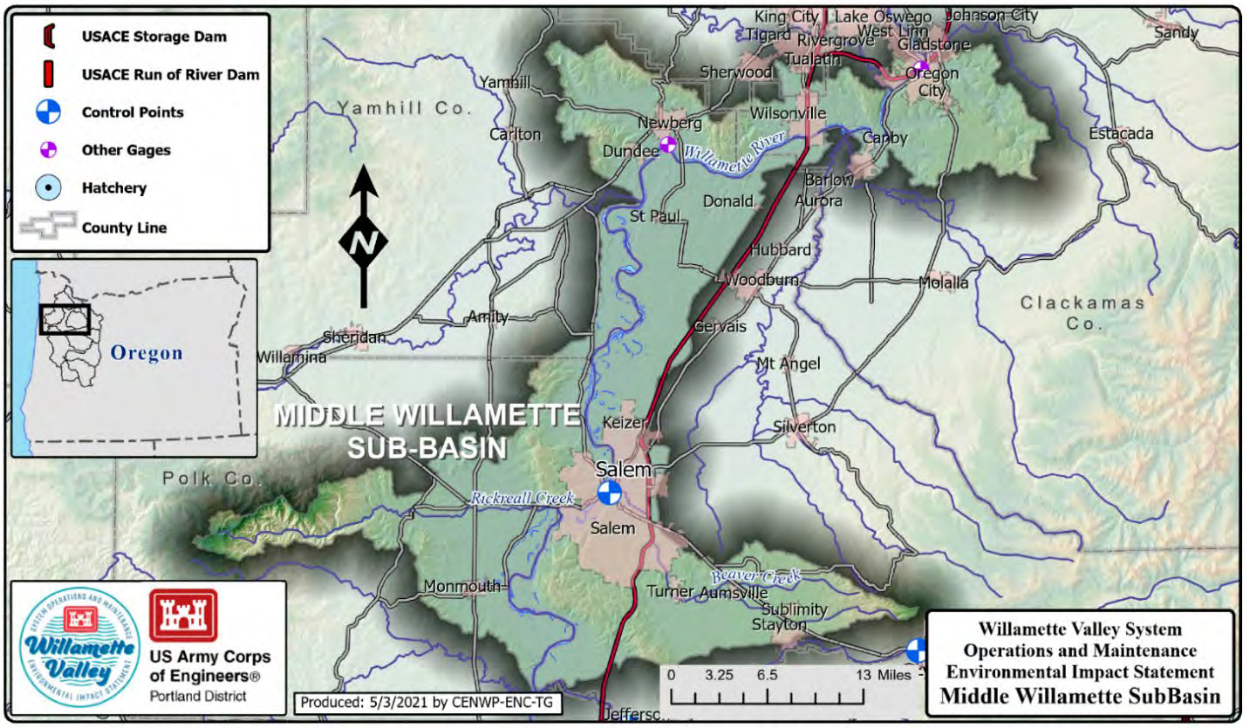

**Figure 3.2-10. Middle Willamette Basin subbasin**

Major population centers downstream of Salem include Newberg, Wilsonville, Canby, Oregon City, and Portland. The percentage of developed area in this reach of the Willamette is much greater than the other reaches. This most downstream control point for WVS is at Salem (USGS gage 14191000) and all projects affect flows at this location. The total drainage area of the Middle Willamette (including inflows from Yamhill, Tualatin, Molalla-Pudding Basins) makes up about 27 percent of the WRB.

The upper Willamette mainstem reach (Figure 3.2-11) flows north from just south of Eugene in a braided meandering channel to the Santiam River confluence. The floodplain in this approximately 130-mile reach is flat and wide. This reach was shaped through natural patterns of erosion and avulsion (abandonment of an existing channel and formation of a new one) as the Willamette River wandered laterally in a swath two to three miles wide. Many secondary channels, dead-end sloughs, and oxbow lakes remain as a result. Development activity near the river, mainly for agriculture and city growth, compelled the disconnection of the Willamette River from its floodplain by cutting it off from these secondary channels. The historic wandering of the Willamette River is now prevented with the application of levees and bank revetments.

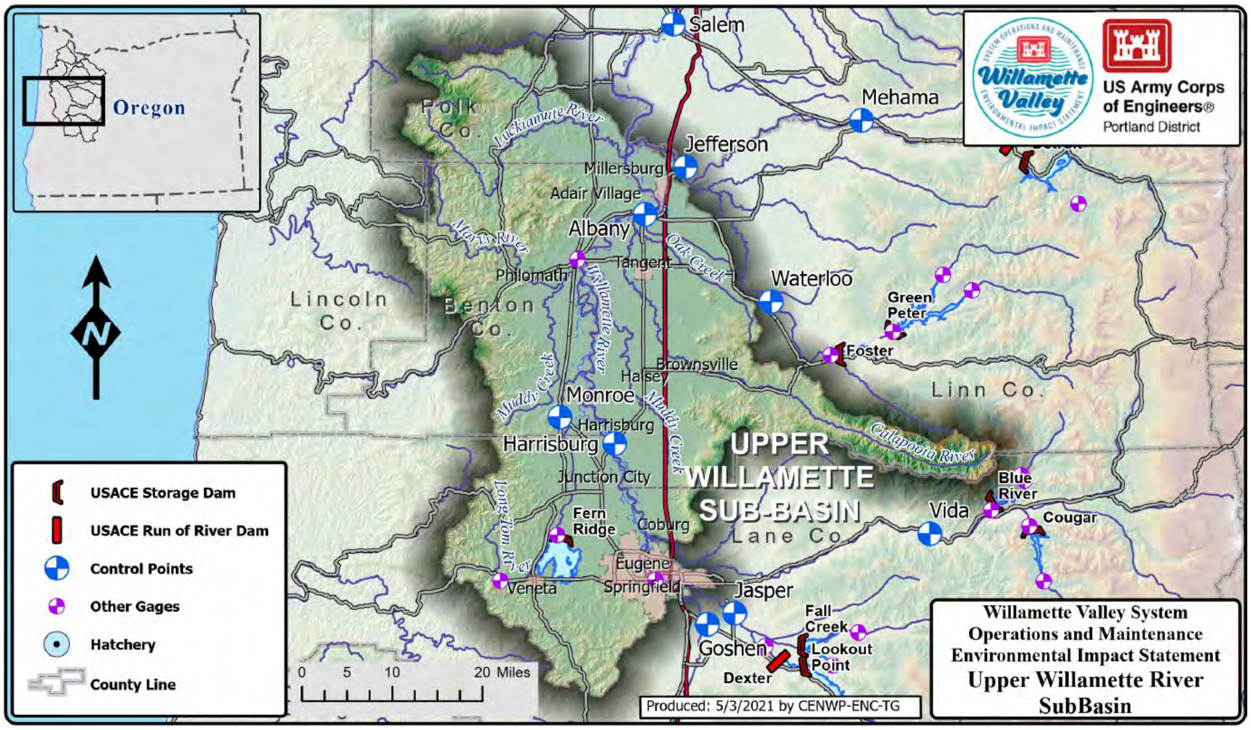

**Figure 3.2-11. Upper Willamette Basin subbasin**

Major population centers along the mainstem Willamette include Eugene-Springfield, Harrisburg, Corvallis, and Albany. Areas within the urban growth boundaries (UGB) of these cities are primarily developed. Outside the UGBs, the land is primarily used for agricultural purposes and state and national forests fringe the valley. The two control points in this reach are at Harrisburg (USGS gage 14166000) and Albany (USGS gage 14174000). As they are upstream of the Santiam confluence, the Santiam Basin WVS are not able to affect flows at these locations. This reach, west-to east from the Coast Range to the Cascade Range and south-to-north from Eugene to the Santiam River, encompasses approximately 16 percent of the WRB, including the Long Tom River.

#### *3.2.1.5.5 Santiam Basin*

The Santiam River subbasin has a drainage area of approximately 1,827 square miles, or about 16 percent of the entire WRB, divided between the North (Figure 3.2-12) and South (Figure 3.2-13) Santiam Rivers. Santiam River subbasin elevations range between 200 and 10,495 feet and average 2,040 feet msl. The Middle and South Santiam Rivers meet in Foster reservoir and the South Santiam River flows north to near Jefferson where it joins the North Santiam River. The North and South Santiam River form the mainstem Santiam River 11.7 miles upstream from the confluence of the Santiam and Willamette Rivers.

The North Santiam River is about 92 miles long and drains an area of approximately 655 square miles. The subbasin features heavily forested watersheds and high plateaus containing scattered volcanic peaks and rugged slopes. The Middle Santiam River also flows through steep, heavily forested mountain terrain, draining an area of 287 square miles. Stream gradients upstream of Green Peter Dam are exceptionally steep, dropping several hundred feet per mile in places. The South Santiam River, roughly 66 miles long, drains an area of approximately 1,040 square miles in geologically older terrain. The South and Middle Santiam Rivers join within Foster reservoir.

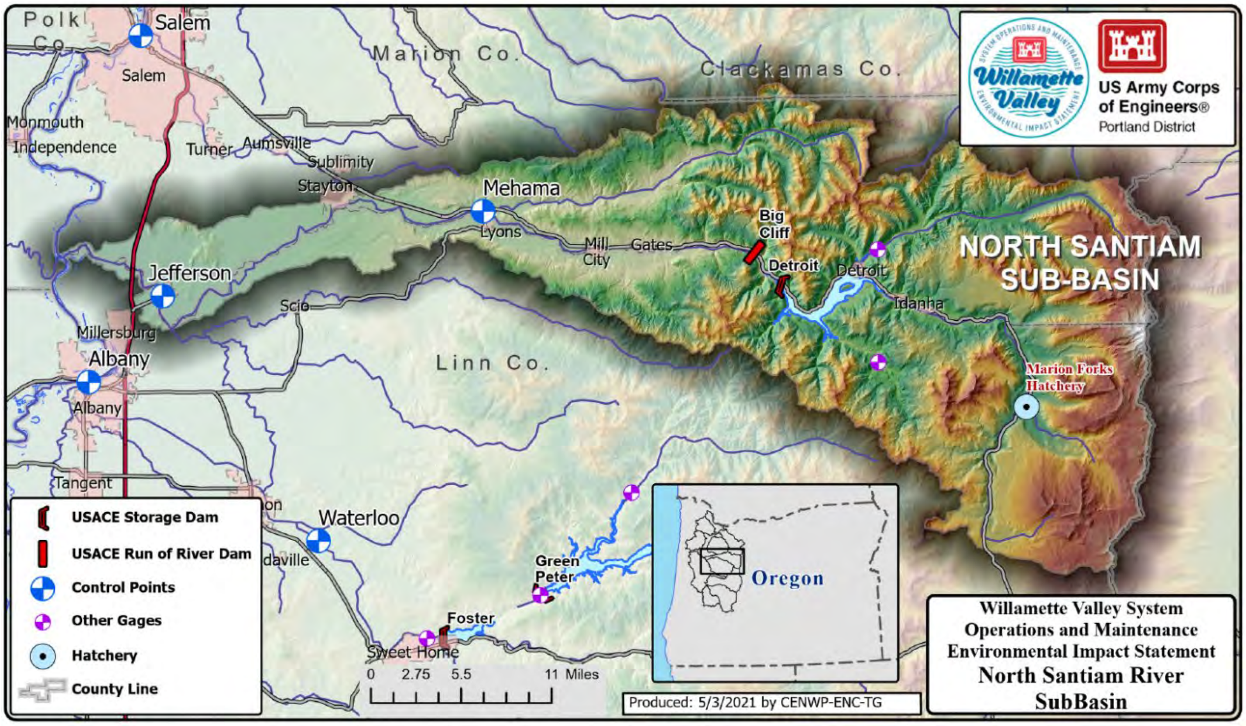

**Figure 3.2-12. North Santiam River subbasin**

There are two USACE dams in the North Santiam Basin. Detroit is a 450-foot-high concrete gravity dam and main storage reservoir with a usable volume of 321 thousand acre-ft (Kaf) and total storage of 455.1 Kaf. Big Cliff is the 172-foot-high reregulating dam directly downstream of Detroit. This enables Detroit to supply power at peak times and not cut off flow to the North Santiam River downstream. In other words, the Big Cliff pool elevation varies throughout the day as it supplies a constant daily flow and Detroit switches on and off. Total storage at Big Cliff is 6.5 Kaf. Both Detroit and Big Cliff have powerhouses rated at 100 MW and 18 MW, respectively (USACE 2015a).

The control points downstream of Detroit and Big Cliff are the North Santiam at Mehama (USGS gage 14183000) and the Santiam at Jefferson (UGSG gage 14189000) on the mainstem, which they share with the South Santiam WVS.

**Figure 3.2-13. South Santiam River subbasin**

There are two USACE dams in the South Santiam Basin, Foster and Green Peter. Green Peter impounds the Middle Santiam and receives a greater share of the total flow, as compared to the South Santiam above Foster. Green Peter is a 327-foot-high concrete gravity dam and has usable storage of 312.5 Kaf and total volume of 430 Kaf. Foster is a rock fill dam, 126 feet high, with usable storage of 28.3 Kaf and total storage of 60.7 Kaf. Foster reregulates Green Peter, but also has some flood storage of its own. Green Peter and Foster have powerhouses rated at 80 MW and 20 MW, respectively (USACE 2015a).

The control points downstream of Foster and Green Peter are the South Santiam at Waterloo (USGS gage 14187500) and the Santiam at Jefferson (UGSG gage 14189000) on the mainstem, which they share with the North Santiam WVS.

#### *3.2.1.5.6 Long Tom Subbasin*

The Long Tom River and Coyote Creek are the two principal rivers entering Fern Ridge Lake, with a combined drainage area of about 2 percent of the entire WRB. A portion of Amazon Creek in Eugene is also diverted into the lake, thus adding an additional 23 square miles to the lake's drainage area.

The Long Tom Basin (Figure 3.2-14) is relatively low, with a maximum elevation of 2,125 feet. Mean elevation of the Fern Ridge's entire subbasin, including the Amazon Creek drainage, is 670 feet and 99 percent of the entire subbasin is below 1,500 feet.

Below Fern Ridge Dam, the Long Tom River meanders for 24 miles before joining the mainstem Willamette River north of Monroe, Fern Ridge's control point (USGS gage 14170000). Portions of the Long Tom River are channelized with embankments to increase the maximum allowable release from Fern Ridge. Three smaller streams, Amazon, Bear, and Ferguson join the Long Tom River between the dam and the Long Tom-mainstem Willamette River confluence.

Fern Ridge Dam is an earth-fill dam with a concrete outlet works. It is 49 feet high with usable storage is 101.1 Kaf and total capacity of 101.2 Kaf. The lake is much shallower than the other WVS reservoirs and evaporation is a significant factor. Fern Ridge does not have a powerhouse (USACE 2015a).

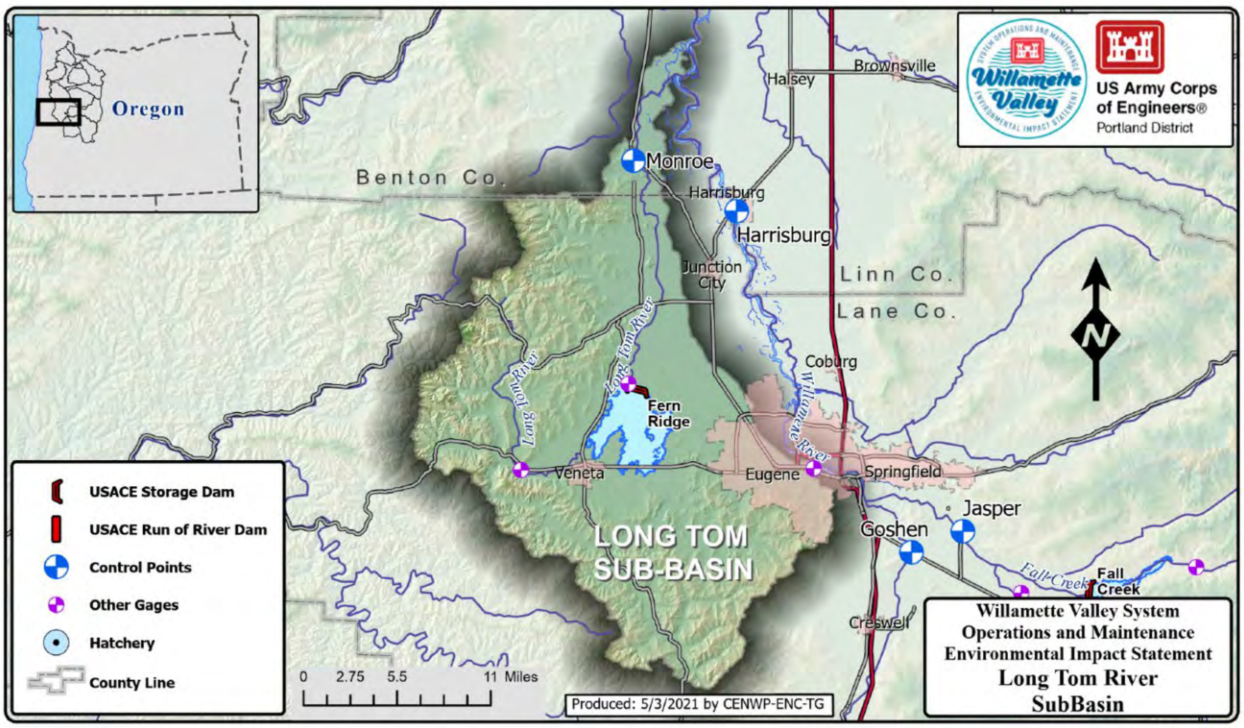

**Figure 3.2-14. Long Tom River subbasin**

### *3.2.1.5.7 McKenzie Subbasin*

The McKenzie subbasin has a drainage area of approximately 1,300 square miles, or about 12 percent of the entire WRB (Figure 3.2-15). The McKenzie River is roughly 90 miles long, joining the mainstem Willamette River a few miles north of Eugene. Elevations range from 350 feet to 6,650 feet. The highest elevations in the headwaters are rugged and heavily forested. There are two non-federal projects in the McKenzie River basin: Carmen-Smith Hydroelectric Project in the upper McKenzie River and Leaburg-Walterville Hydroelectric Project in the lower McKenzie River.

Blue River Dam is on the Blue River about 2 miles upstream of its confluence with the McKenzie River, near Blue River, Oregon. It is a 270-foot-high earth fill dam, with a usable storage of 82.8 Kaf and total storage of 89.5 Kaf. Blue River does not have a powerhouse. Cougar impounds the

South Fork of the McKenzie River, which joins the mainstem McKenzie about 3 miles upstream of the Blue River confluence. The earth-fill dam is 452 feet high and has an installed power capacity of 25 MW. A WTC tower was constructed in 2005, enabling water to be withdrawn from a greater variety of depths in the reservoir. The usable storage capacity is 165.1 Kaf and total storage is 219.3 Kaf (USACE 2015a). Mean basin elevations above Blue River and Cougar are higher than 3,500 feet and both dams control more than 95 percent of their respective watersheds.

Blue River and Cougar share a control point on the McKenzie River at Vida (USGS gage 14162500). Further downstream, the first common control point with WVS outside the subbasin is on the mainstem Willamette at Harrisburg (USGS gage 14166000).

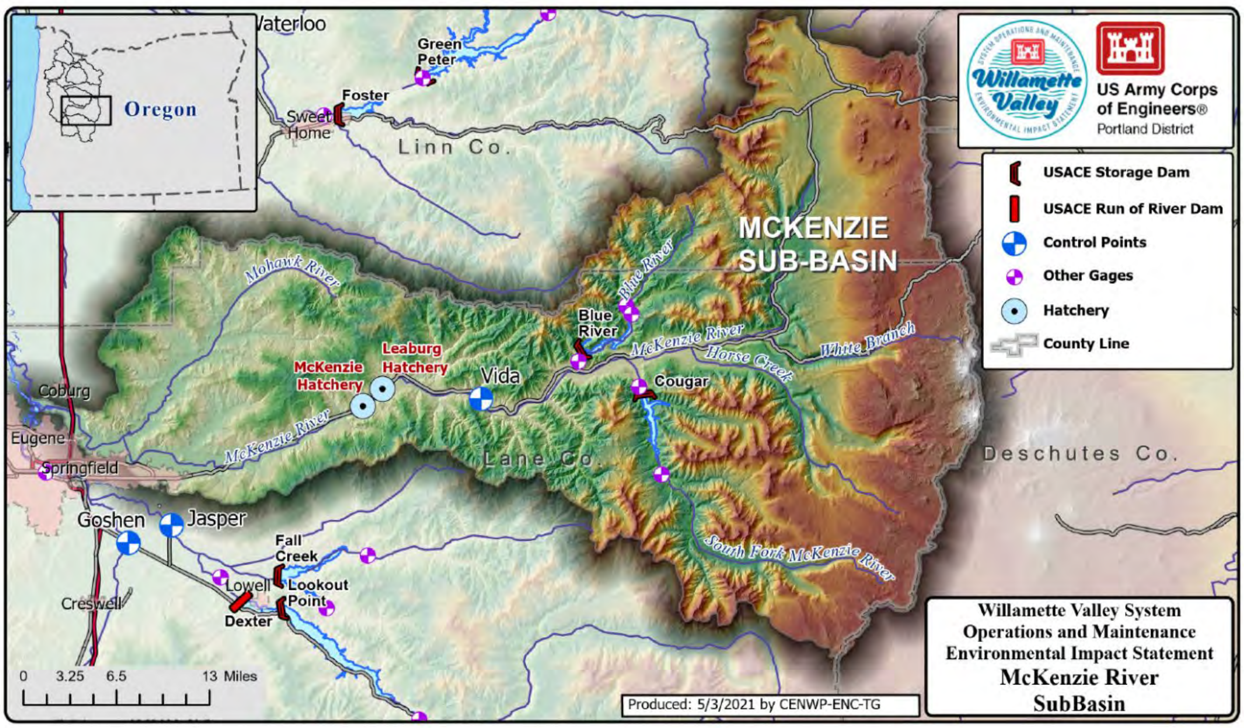

**Figure 3.2-15. McKenzie River subbasin**

### *3.2.1.5.8 Middle Fork of the Willamette Subbasin*

The Middle Fork of the Willamette subbasin (Figure 3.2-16) has a drainage area of approximately 1,569 square miles, or about 14 percent of the entire WRB, ranging from 450 feet at Eugene to 8,790 feet at Diamond Peak, located on the eastern boundary of the subbasin. Most of the subbasin is within the Willamette and Umpqua National Forests.

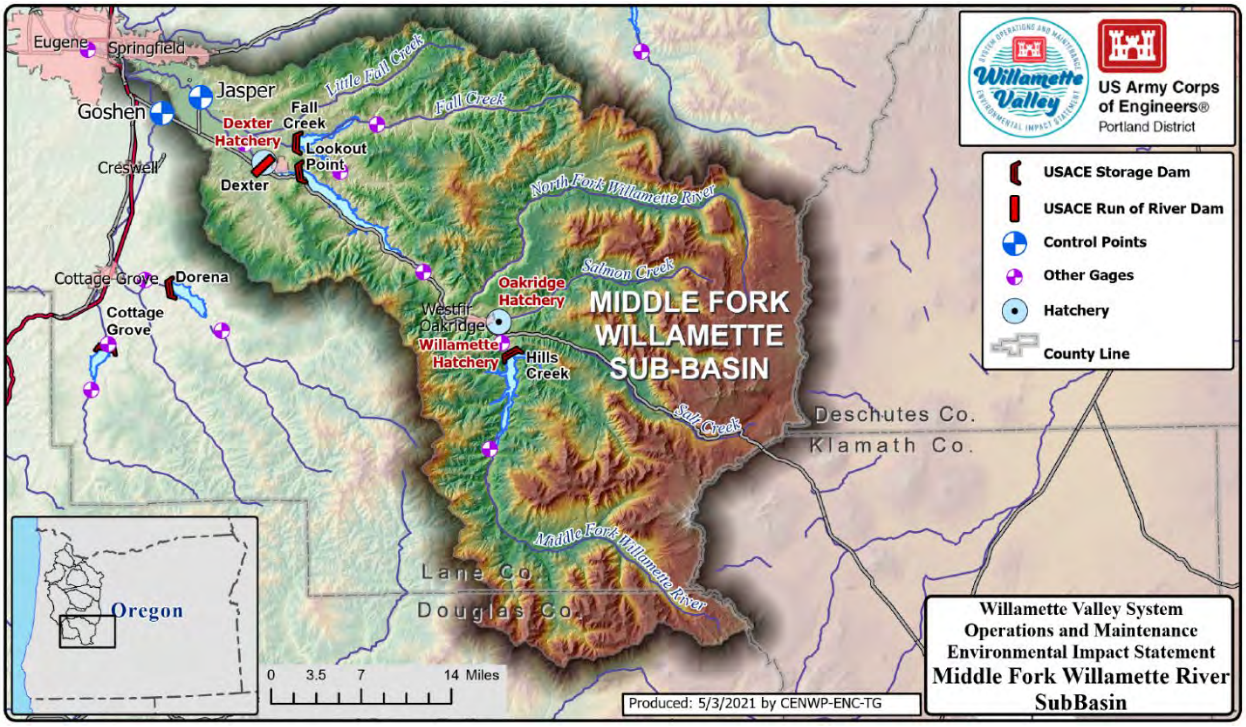

**Figure 3.2-16. Middle Fork of the Willamette River subbasin**

Water originating from the headwaters of the Middle Fork pass through three reservoirs before Eugene, in Hills Creek, Lookout Point and Dexter. Salt Creek, Salmon Creek and the North Fork of the Willamette River also join the Middle Fork between Hills Creek and Lookout Point. Downstream of Lookout Point, Dexter reregulates Lookout Point to enable power peaking operations. Fall Creek Dam impounds Fall Creek and Winberry Creek. The confluence between Fall Creek and the Middle Fork is about 2 miles east of Jasper and 6 miles west of Lowell, on the northern bank of Dexter reservoir.

Hills Creek is a 304-foot-high earth and gravel fill embankment dam. The usable storage of the reservoir is 234.3 Kaf and total storage is 356 Kaf. Lookout Point is a 246-foot-high earth fill dam with concrete outlet works flowing directly into Dexter reservoir. The usable storage is 336.4 Kaf and total storage is 455.8 Kaf. The earth-fill Dexter dam is much smaller, with a total storage capacity of 27.5 Kaf. Hills Creek, Lookout Point and Dexter have powerhouse capacities of 30 MW, 120 MW and 15 MW, respectively. Fall Creek does not have power generating capacity (USACE 2015a).

The shared control point for all four WVS projects in the Middle Fork basin is at Jasper (USGS gage 14152000). The Middle and Coast Forks join to become the mainstem Willamette River south of Springfield. Further downstream, the first common control point with WVS outside the subbasin is on the mainstem Willamette at Harrisburg (USGS gage 14166000).

### *3.2.1.5.9 Coast Fork of the Willamette Subbasin*

The Coast Fork of Willamette (Figure 3.2-17) has a drainage area of 669 square miles, or about 6 percent of the entire WRB. Elevations in the Coast Fork drainage subbasin range from about 450 at Eugene to 6,000 feet at the headwaters. The drainage headwaters consist largely of steep, rugged, mountainous terrain dissected by narrow river valleys. Much of the land is heavily forested. Downstream of Cottage Grove, the Coast Fork runs through a relatively wide and flat river valley, before becoming confined by the hills south of Eugene just upstream of the confluence with the Middle Fork. The Coast Fork subbasin is lower in elevation than the other Willamette headwater basins and so contributes less flow as compared to its drainage area.

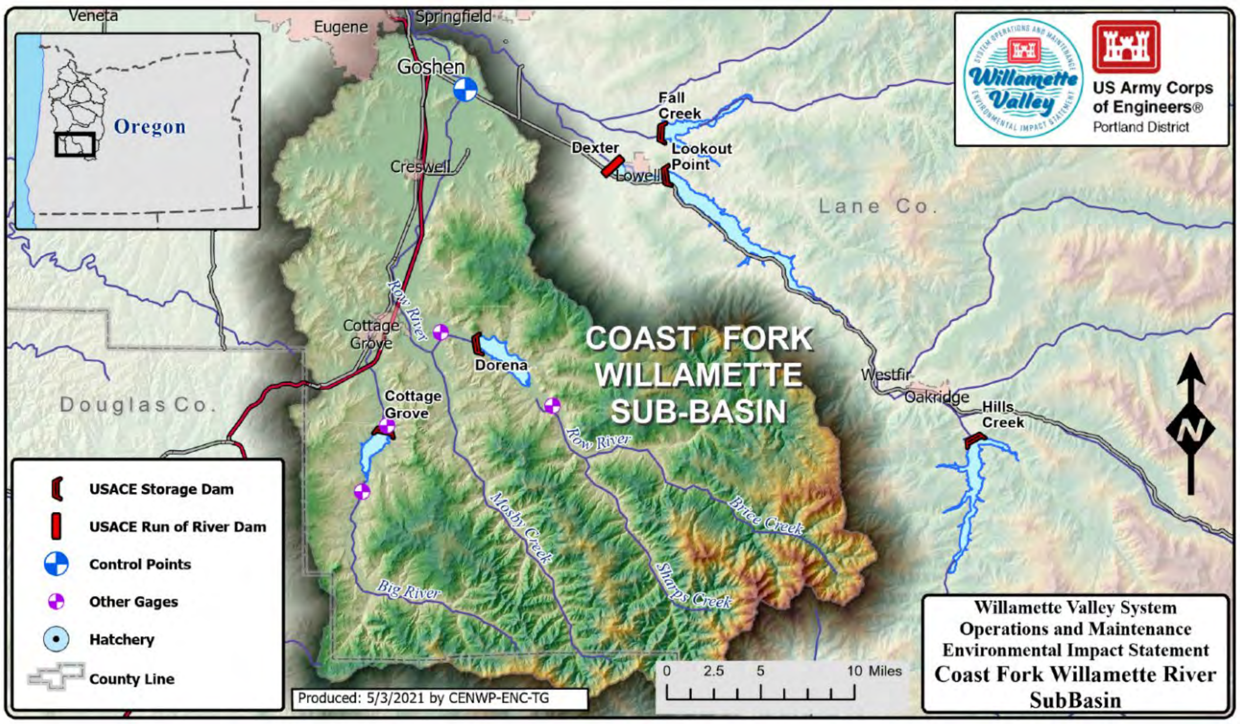

**Figure 3.2-17. Coast Fork Willamette River subbasin**

Cottage Grove and Dorena are the WVS dams on the Coast Fork and Row Rivers, respectively. Both dams are earth fill with concrete outlet works. Dorena is the larger of the two, with a height of 145 feet, usable storage capacity of 72.1 Kaf and total capacity of 77.6 Kaf, compared with Cottage Grove at 114 feet high and usable and total capacities at 31.8 and 33.5 Kaf. Dorena hosts a non-federal powerhouse with a capacity of 7.5 MW and Cottage Grove does not have generating capacity (USACE 2015a).

Cottage Grove and Dorena share a control point on the Coast Fork at Goshen (USGS gage 14157500). The Coast and Middle Forks join to become the mainstem Willamette River south of Springfield. Further downstream, the first common control point with WVS outside the subbasin is on the mainstem Willamette at Harrisburg (USGS gage 14166000).

### 3.2.2 Environmental Consequences

#### *3.2.2.1 Methodology*

USACE and others commonly use the term hydrology and hydraulics (H&H) to discuss the quantity, movement, or behavior of water. The WVS PEIS models the NAA and seven action alternatives over the observed period of record to show how water would move through the system, both within and downstream of the WVS dams and reservoirs, given a specific set of operational measures. Since hydrologic processes describes the flow of water through the system, only measures that would affect the volume or timing of flow are analyzed in this section. For example, structural measures that alter the water temperature would not affect hydrologic processes overall, and therefore, are not included in this analysis.

##### *3.2.2.1.1 Reservoir Operations Model*

The primary method to model basin flow and WVS reservoir operations for the PEIS is the Hydrologic Engineering Center Reservoir Simulation System (HEC-ResSim). ResSim simulates reservoir operations for flood management, low flow augmentation and water supply for planning studies, detailed reservoir regulation plan investigations, and real-time decision support. The input flow data, both for inflows to the reservoirs and flows from river systems downstream, are daily average flow for the period of record (1935 to 2019). This dataset is an extended version of the Willamette Flood Insurance Study (USACE 2011a; USACE 2013a) and 2010 Level Modified Streamflows (BPA 2011). Appendix B, Hydrologic Processes Technical Information, has additional information on the development of the hydrologic dataset. The outputs for each alternative are compared to the NAA to determine the alternative's effect on the system. The details of the flows modeled by ResSim model are also taken for analysis and use by other technical teams.

The period of record analysis provides a wide range of historical meteorological variability. The ResSim model can use the flow information to show how the system operates with a variety of goals across a long period. The longer period enables the model to compute probability based on the historical record. For example, the model can estimate the chance in any given year that a reservoir will fill to capacity during the spring or exhaust the available stored water prior the major flood season. The period of record analysis also allows USACE to study how the system behaves under conditions that did not exist, like running inflows from before the WVS dams were constructed.

A computer reservoir regulation model, such as ResSim, requires fixed operational scenarios, or rules, tested over many years of data. Each alternative alters the rule set to show differences in operation under the same inputs – the flow data – without human interference or preferences. Real-world reservoir operation is complex: different information is available to the water manager for decision making, and decisions are shaped by an individual water manager's experience and risk tolerance. Water managers also adapt operations as is possible within constraints to meet goals responding to the unique conditions of a specific water year. Operational changes of this nature to match the observed record are not possible nor desirable to represent in a planning model like the

PEIS. They would make comparing different alternatives substantially more challenging and likely skew the results towards the actions already undertaken in real-world reservoir operations.

##### *3.2.2.1.2 Presentation of Results*

Summary hydrographs are produced to describe the changes to the flow and water surface elevation with the implementation in each of the alternatives. A hydrograph is a chart showing an indicator of water flow (such as stage or discharge) over time, typically over a water year. A summary hydrograph is an especially useful way to display information because it shows the expected range and likelihood of water levels (or flow) at a given location for each day of the water year. The curves on a summary hydrograph do not represent a single water year. Rather, each curve represents the percentage chance of not exceeding the corresponding water level (or flow) on a given day. Five non-exceedance levels are shown: 5, 25, 50, 75 and 95 percent, representing the percentile (P##) of data below the line. In Figure 3.2-18, the color series for one alternative is compared against the base greyscale background to show differences between the presented alternative and the NAA. For example, the 25 percent curve on the summary hydrograph of reservoir elevation is about 1500 feet on April 1 as in the chart, which means there is 75 percent chance the water surface elevation would be above 1500 feet and a 25 percent chance it would be below 1500 feet on April 1 across all water years. Only selected charts are presented in the narrative analysis of this section. A complete set of charts across all WVS dams and reservoirs and control points is available in Appendix B, Hydrologic Processes Technical Information.

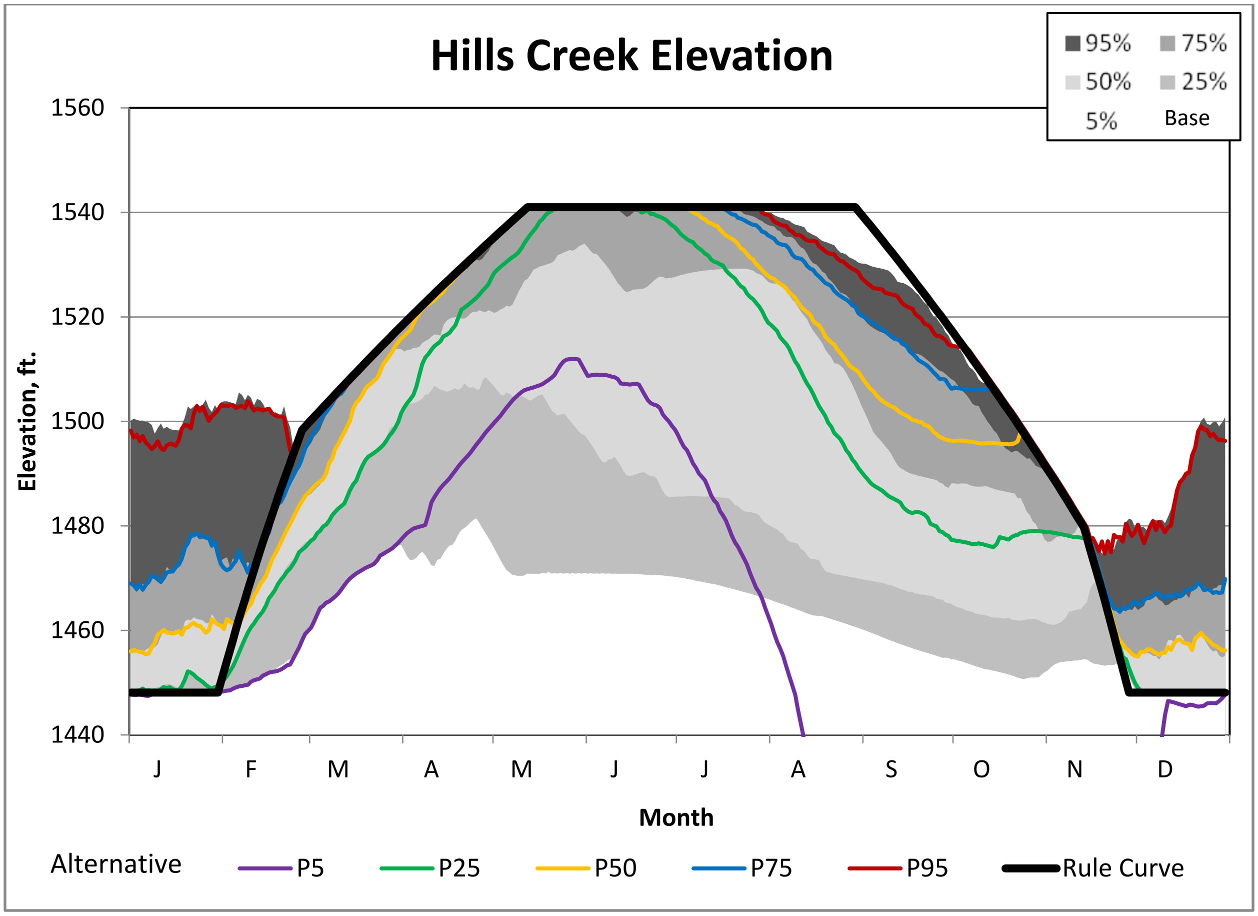

**Figure 3.2-18. Example of non-exceedance chart at Hill Creek Reservoir**

Certain other reservoir operational constraints can also limit the level of the drawdowns in each year. Apart from high inflow, the primary limiter of the drawdowns in the WVS reservoirs is the general drafting guideline of no more than 3 feet of water surface elevation per day. This guideline is used during non-emergency situations to reduce the probability of landslides around the reservoir rim, upstream embankment settlement, and slope stability issues. In practice, this draft limit would cause the reservoir to be above the drawdown target elevation for extended periods as both the reservoir water surface elevation and the target descend at the same 3 ft/day. Figure 3.2-19 shows the fall reservoir drawdown at Green Peter with average reservoir elevation across all years (P50 line) and the year 1993 as an example year, where the reservoir moved parallel to the target for several months. While there would be enough outlet capacity to quickly reach the target, the drafting limit of 3 ft/day prevents achieving the target elevation more quickly. More broadly, this shows an instance where operating a reservoir is a matter of competing goals and a specific target may not always be possible due to other constraints within the reservoir or larger WVS.

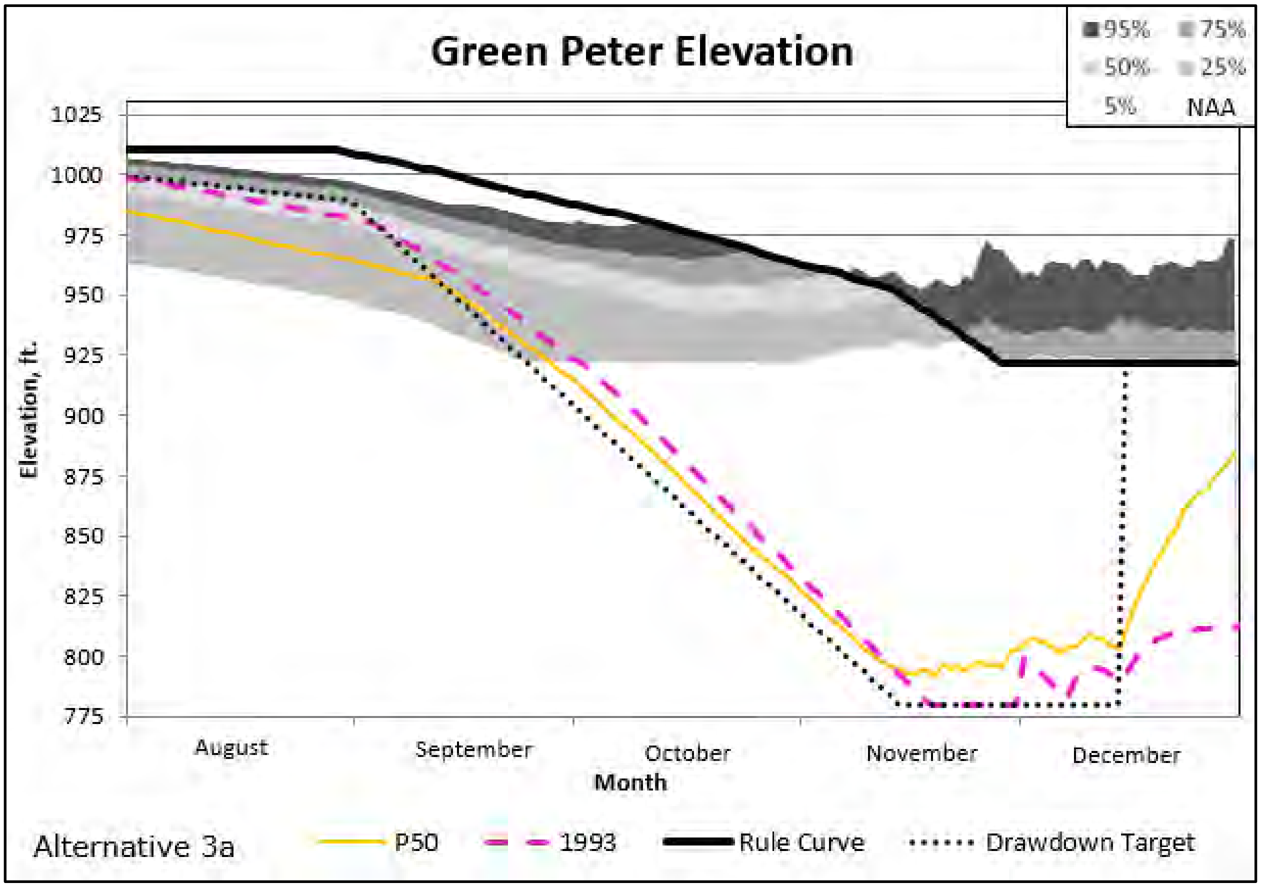

**Figure 3.2-19. Alternative 3A Green Peter reservoir drawdown with the year 1993 as an example of drafting limits preventing the reservoir from reaching the target elevation.**

*3.2.2.1.3 Flood Risk Management*

Across all alternatives, USACE used a screening criterion of "No Increase in Flood Risk" to exclude measures with the potential to increase flood risk during the development phase of the WVS PEIS. Specifically, these are measures that increase the frequency, duration, or magnitude of flow at control points during flood season above threshold stages along tributaries and the mainstem of the Willamette River, increasing flood risk. Operations that increase flood risk can include increased maximum releases from WVS dams or reduced flood storage, leading to higher pool elevations and higher releases to mitigate the risk of overtopping. For the WVS PEIS, operations that increase maximum releases or reduce seasonal flood storage were removed from consideration. Refer to Appendix B for additional discussion on these operations.

*3.2.2.1.4 Evaluation Criteria*

Table 3.2-1 explains the hydrologic criteria for potential effects across the WRB for the alternatives.

**Table 3.2-1. Evaluation Criteria for Potential Hydrologic Effects**

| Effect Scale | Criteria |
|---|---|
| None/negligible | Willamette Basin regulated hydrology would not be changed, would be nondetectable, or changes to water level, discharge, volume, or timing would be slight and localized. The area extent of effects would be small (limited) and would not require additional consideration or adaptive management. |
| Minor | Changes to the Willamette Basin regulated hydrology would be measurable, although the change in water level, discharge, volume, or timing would be small and localized at the watershed level. The need for adaptive management measures would be evaluated to reduce or minimize any potential changes. |
| Moderate | Changes to the Willamette Basin regulated hydrology would be measurable and have either sub-basin or basin-wide differences in water surface elevation, discharge, volume, or timing. The regulated hydrology would be within current regulatory standards[1], but potentially differ from historic condition. The need for adaptive management or mitigation measures would be evaluated and would likely be able to reduce the magnitude of potential changes. |
| Major | Changes to the Willamette Basin regulated hydrology would be readily measurable and would have substantial differences in water level, discharge, volume, or timing on a regional level. The regulated hydrology may not meet existing regulatory standards[1]. The need for adaptive management and mitigation measures would be evaluated to reduce changes in the system, though hydrologic changes would be expected regardless of the actions implemented. |

[1] Applicable regulatory standards can include minimum target flows that the WVS intends to exceed, flow ramping rate limitations (how fast the flow can change in a given time period) and maximum flowrate at a given point (flood operations or physical limits).

The effects in the hydrologic processes are inherently long-term as they would last for the duration of the project (2050) and potentially have lasting effects beyond the project. The WVS dams and reservoirs alter the hydrology of the WRB and the imposed hydrology will continue to affect lasting change on many other areas discussed in this PEIS. Since all WVS regulation actions discussed across all alternatives would be long-term for hydrologic processes, duration is not evaluated or discussed further in this section. These effects are determined by comparing to the NAA throughout these sections unless specifically call out.

Hydrologic effects are evaluated with an integrated reservoir regulation model. The extent of every alternative is basin-wide, or regional. For example, even a seemingly small change to water storage at one reservoir can and does alter the operation of any other, or several reservoirs, within the WRB. While dams and reservoirs closer to each other are more likely to affect each other's operations, shared river control points and flow targets require that the

WVS dams and reservoirs operate together. Since all WVS regulation actions discussed across all alternatives would be regional for hydrologic processes, extents are not evaluated or discussed further in this section.

The changes to hydrologic processes are not characterized in this PEIS as adverse or beneficial. Such a determination would be arbitrary without some other criteria to judge the changes in hydrologic processes, such as fish survival or recreation. Furthermore, some potential changes to hydrologic processes could reasonably be both adverse and beneficial depending on the criteria and perspective applied. Since the results of hydrologic processes are some of the inputs to the other analysis in this PEIS, the determination of adverse or beneficial effects is properly placed within each of those effects analyses.

###### *3.2.2.1.5 Construction Effects on Hydrologic Processes*

This PEIS discusses general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects during the implementation phase. Most of the construction activities associated with the measures within each alternative would only locally affect the hydrology of the river reaches, with the notable exception of the construction of WTC towers. For example, water routed through a different outlet for construction activities at a fish facility would alter the reservoir regulation outlet choice, but not the total flow out of the dam.

Depending on construction methods, construction of the WTC towers at Detroit, Lookout Point, Green Peter, and Hills Creek may require reservoir drawdowns and pool restrictions over several years. A long drawdown may also be necessary at Cougar to construct the outlet works for the routine use of the diversion tunnel. If there are drawdowns in the site-specific plans, water would be drafted out of the reservoir prior to construction, increasing the instream flow downstream of the reservoir until it reaches the necessary elevation. During the construction activities, a lower pool at each of these reservoirs would mean notably reduced conservation season water storage. This could also impact other reservoirs, lowering their stored water volume as they release more water to meet shared downstream flow targets, potentially inducing systemwide effects for construction at selected locations. In the winter, each reservoir could be subject to pool restrictions over the construction period, which may impact FRM operations.

Since the timing, duration, and extent of non-routine major maintenance are unforeseeable (Section 1.8.2, Operation, Maintenance, Repair, Replacement and Rehabilitation), the hydrologic effects of those actions are unforeseeable as well. The hydrologic effects for these actions, along with all other types of effects, would be the subject of additional analysis under the tiered NEPA process described in Chapter 7.

#### *3.2.2.1.6 Climate Change*

Appendix F1, Willamette Basin Climate Change Qualitative Assessment, and Appendix F2, Supplemental Climate Change Information, describe projected climate change trends likely to be experienced in the WVS. The supplemental appendix also identifies changing climate factors and hydrology that could have a consequential impact to the PEIS resource areas. The climate change factors most important to the hydrologic processes are projected future changes in precipitation (rainfall and snow), changing rates in peak and average streamflow, change in snowpack and flow volumes. These climate change factors are described in the technical appendices and USACE qualitatively assesses the expected effects to the system under NAA and each alternative.

USACE expects climate change to impact the WVS in several ways. Temperatures in the WRB are expected to warm relative to the historic period 1970-1999 by another 1.5 to 3°F by about mid-century and 2 to 5°F by end-of-century. Winter snowpack is likely to decline over time as more winter precipitation falls as rain instead of snow. Future precipitation is projected to trend upward for the rest of the century, particularly in the winter and early spring. Later spring months become drier, effectively starting already dry summers earlier. Decreasing baseflow could become drier, primarily further reducing summer flow. USACE used these impacts to qualitatively assess expected changes to reservoir storage and flow, mapped onto the operations each alternative would implement.

### ***3.2.2.2 Environmental Consequences Summary***

The NAA would represent the current management direction of the WVS and as described in Section 2.4.1, No Action Alternative. Each of the action alternatives would change the seasonal flow and use of stored water in the system. In comparison to the NAA, Alternatives 1 and 4 would store more water in the spring and release it during the summer and fall, though how flow is stored and released is different between Alternatives 1 and 4. Alternatives 2A and 2B would store somewhat less water for release in the summer and fall, while incorporating selected drawdowns. Alternatives 3A and 3B include spring reservoir drawdowns at different selected projects and deeper fall reservoir drawdowns at WVS reservoirs in the Santiam, McKenzie, and Middle Fork subbasins – excluding Foster and the reregulating dams. Alternative 5 would be similar to Alternative 2B but release more water in the spring of dry years.

See Tables 3.2-2 to 3.2-7 for a summary of hydrologic effects organized by location across the WRB. All elevations in the hydrologic processes Environmental Consequences are in USACE WVS project datums unless otherwise noted.

### *3.2.2.3 No Action Alternative*

The NAA would represent the current management direction. For this analysis, the No Action Alternative may be thought of in terms of continuing with the present course of actions with respect to how USACE manages the WVS until that action is changed. With respect to the NAA, the following assumptions can be made:

- Rule curves across the WVS would remain as they currently operate. Relatively recent changes such as the Fall Creek fall draw down are simulated across the complete period of record.
- Currently in-progress projects are included, even if they are not fully implemented at time of analysis. Regulation operations intended to be temporary, even if currently active, are not included.
- USACE would continue to operate the WVS to meet mainstem and tributary flow objectives to the maximum extent possible as described in the 2008 NMFS BiOp (NMFS 2008) and implemented per the Willamette Fish Operations Plan (USACE 2017a).
- Additional releases and downstream withdrawals to satisfy anticipated municipal and industrial (M&I) water storage agreements.
- Only those measures that affect the amount of flow through a dam and reservoir or change the flow of an outlet are modeled in reservoir regulation model (HEC-ResSim). Actions that change other variables, such as a WTC tower, are not included in the HEC-ResSim and these changes will not be reflected in the charts in this section.

The primary purpose of the NAA is to compare the existing WVS management with each of the alternatives. Comparisons with the baseline will show meaningful differences in flow and reservoir water surface elevations across the basin rather than only looking at each alternative in isolation.

As explained in the Methodology section, the NAA does not attempt to reproduce observed past operations. In this way, the set of changes in each alternative can be compared to the NAA without the influence of other factors, such as reservoir regulator preferences. Also, all charts below show the calculated value for that date and do not reflect a specific year or sequence of flows or reservoir elevations. As an example, the average, or P50, line is the mean flow on that date across all years of the simulation; even a ‘typical’ year is very unlikely to exactly follow that sequence.

The NAA is designed to continue the current management practices of the WVS, with the addition of increased releases for M&I water storage agreements. Effects from the NAA to hydrologic processes: None/Negligible.

### *3.2.2.3.1 Santiam Subbasin*

Detroit reservoir (Figure 3.2-20) would reach the maximum conservation pool elevation more than 50 percent of years (blue P50) and would stay near the top of conservation pool for more than half the summer provided it does reach maximum pool. Even in the driest years (green P05), the pool would remain above the minimum conservation pool until September.

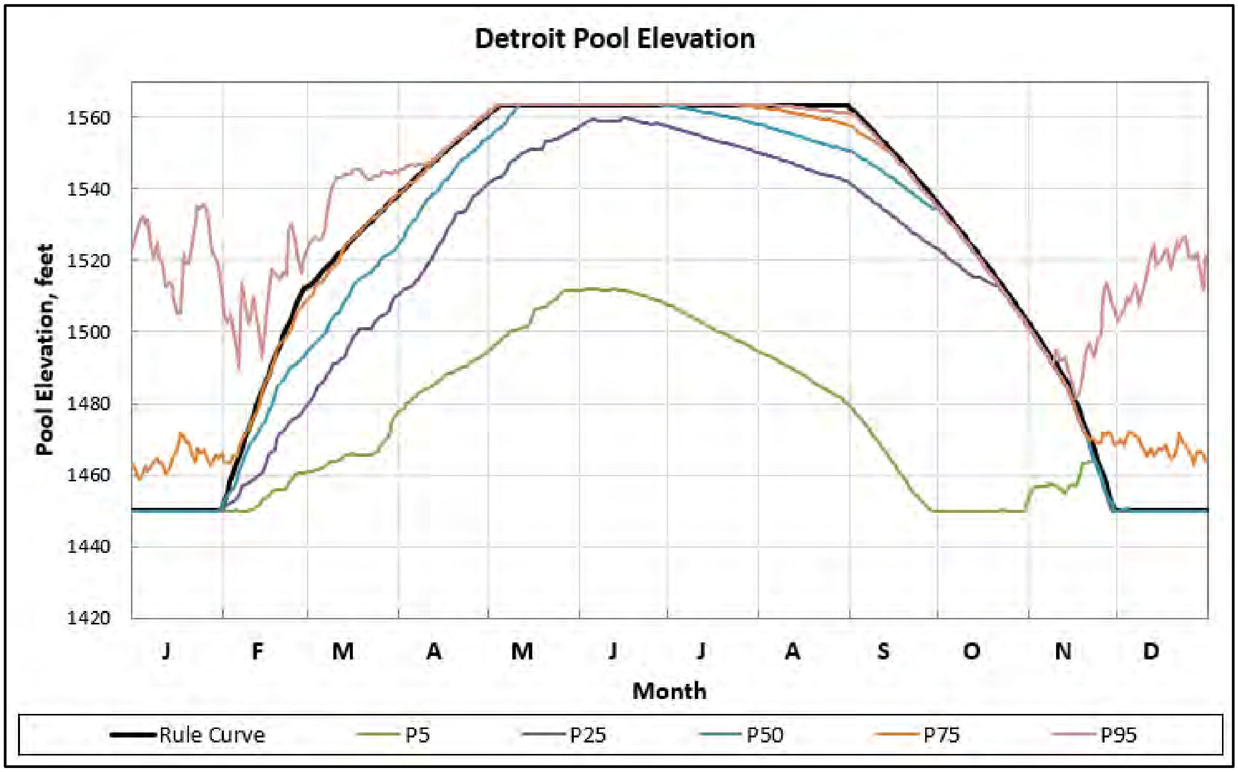

**Figure 3.2-20. NAA Detroit water surface elevation non-exceedance**

On the South Santiam, Green Peter (Figure 3.2-21) would also fill more than half the time (blue P50), but drafts below the rule curve earlier in the season. The Green Peter reservoir releases are an important component to meet 2008 NMFS BiOp (NMFS 2008) flow targets in the mainstem Willamette prior to drafting Detroit. Since all the stored water in both reservoirs is needed to meet downstream flow demands during the driest years, the green P05 line would reach minimum conservation pool at about the same time.

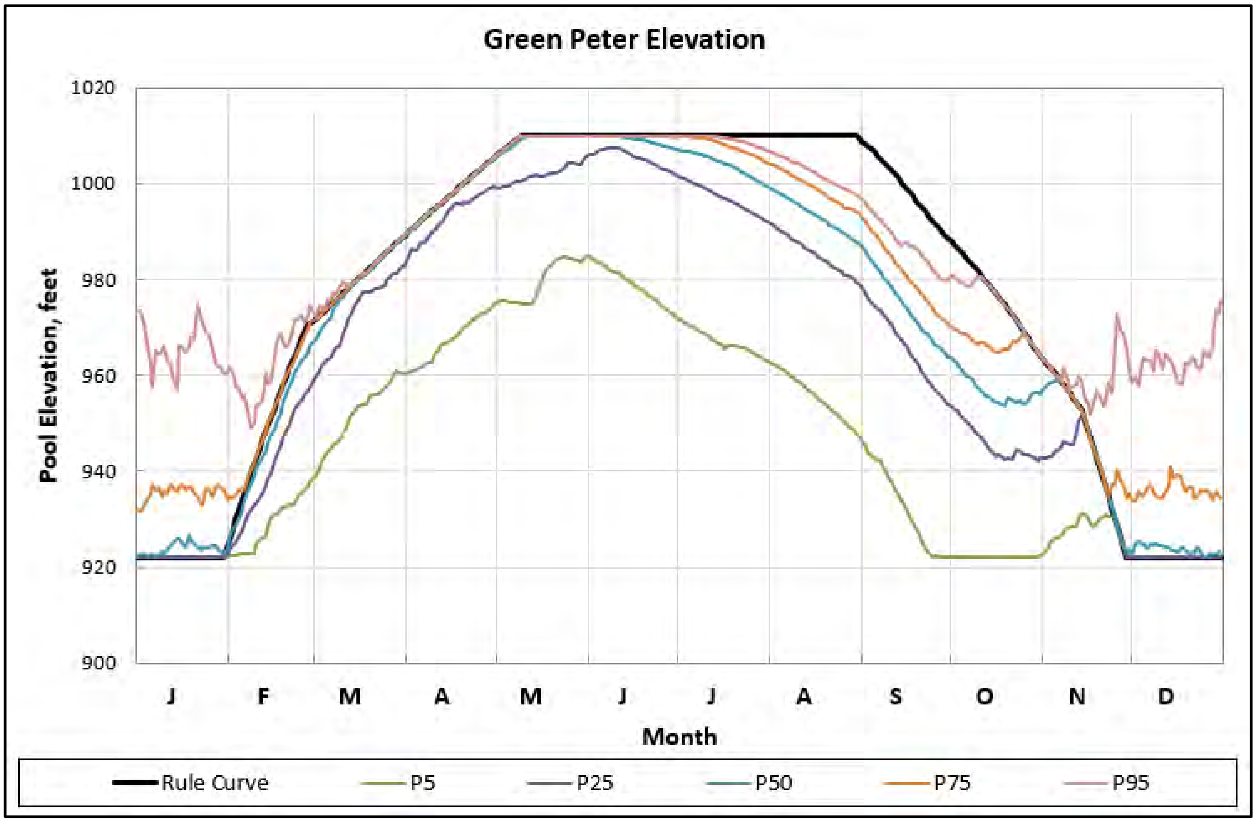

**Figure 3.2-21. NAA Green Peter water surface elevation non-exceedance**

Big Cliff and Foster are not shown as they primarily reregulate Detroit and Green Peter during conservation season, smoothing power peaking flow from the upstream dam, and therefore would follow the rule curve very closely in all years under the NAA.

Figure 3.2-22 shows the results of the regulation model for the Santiam River at Jefferson, a couple miles downstream of the confluence between the North and South Santiam Rivers. The figure combines the flow from the dams and the 'local' flows into the Santiam River from tributaries downstream of the WVS dams. The maximum flow reflects the high flows from high water events and floods. As the chart shows the maximum flow across the NAA, this shows that flows at or above bankfull (35,000 cfs) have occurred at Jefferson in every month except July, August, and September.

Mean and minimum flows would show much greater consistency throughout the year, reflecting 'typical' flows in the river and the minimum flows reached during an abnormally dry period. The dry periods do not reflect a single year but show that these dry periods that reduce flow can happen at any time during the year.

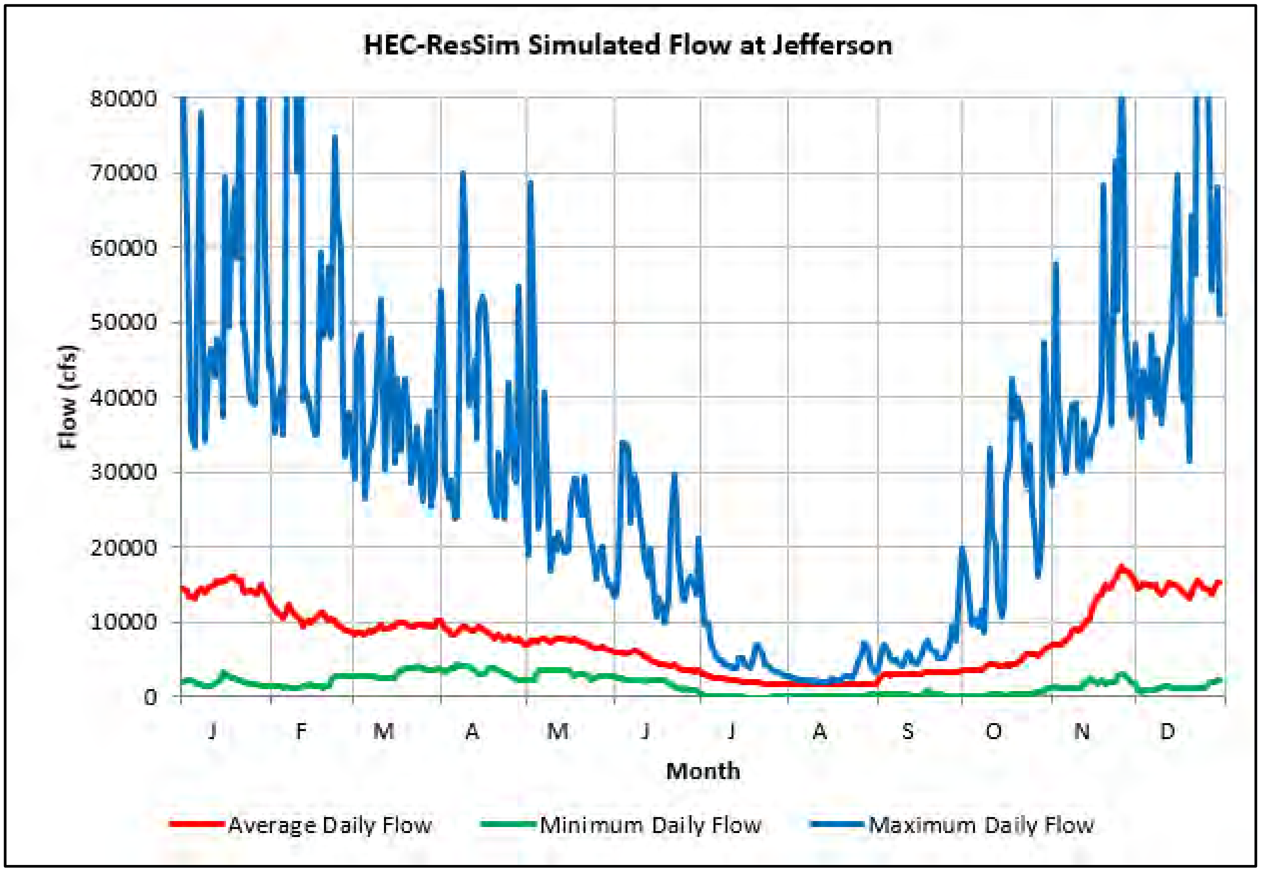

**Figure 3.2-22. NAA Santiam River at Jefferson daily minimum, average, and maximum flows**

#### *3.2.2.3.2 Long Tom Subbasin*

Fern Ridge reservoir (Figure 2.2-23) is relatively small in volume and shallow as compared to the other reservoirs in the WVS. Fern Ridge would reach within 6 feet of its maximum conservation pool in 95 percent of years (green P05 non-exceedance line) and USACE manages water levels to maintain the highest pool elevation possible until the rule curve falls starting in September. Fern Ridge has a small volume relative to other WVS reservoirs. Recreation and fish and wildlife habitat are a high priority at Fern Ridge, and other WVS reservoirs are drafted to meet downstream requirements prior to using the relatively limited water stored in Fern Ridge. Therefore, it is very rare for Fern Ridge to empty during the summer months.

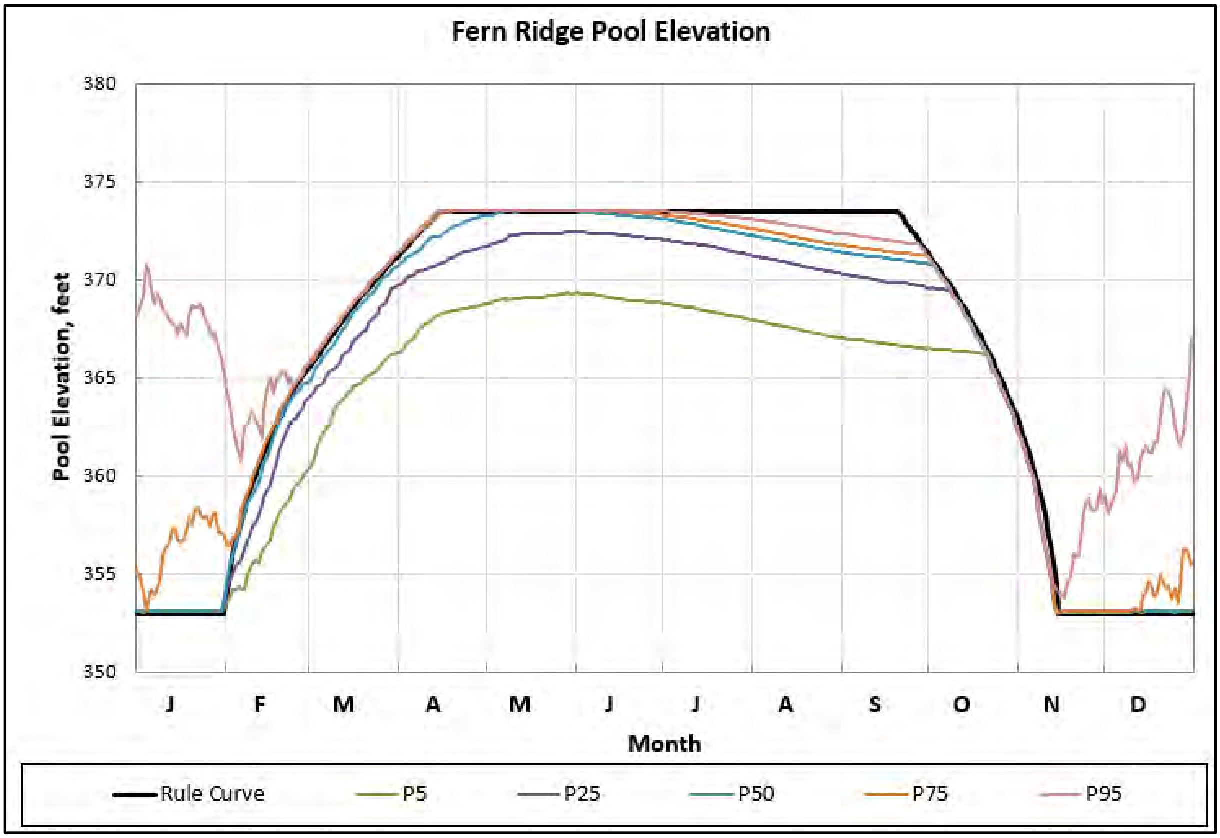

**Figure 3.2-23. NAA Fern Ridge water surface elevation non-exceedance**

Flow in the Long Tom River (Figure 3.2-24) downstream of Fern Ridge dam shows typical seasonal variation in the WRB. The high minimum flow in November is the flow out of the reservoir in preparation for winter flood season. Since USACE prioritizes keeping this reservoir relatively high through the fall in support of recreation and fish and wildlife habitat, there are no years in which the water has already left the pool (for a counterexample, see Green Peter in the Santiam Basin). Therefore, there is always an elevated November flow to return the reservoir to minimum pool.

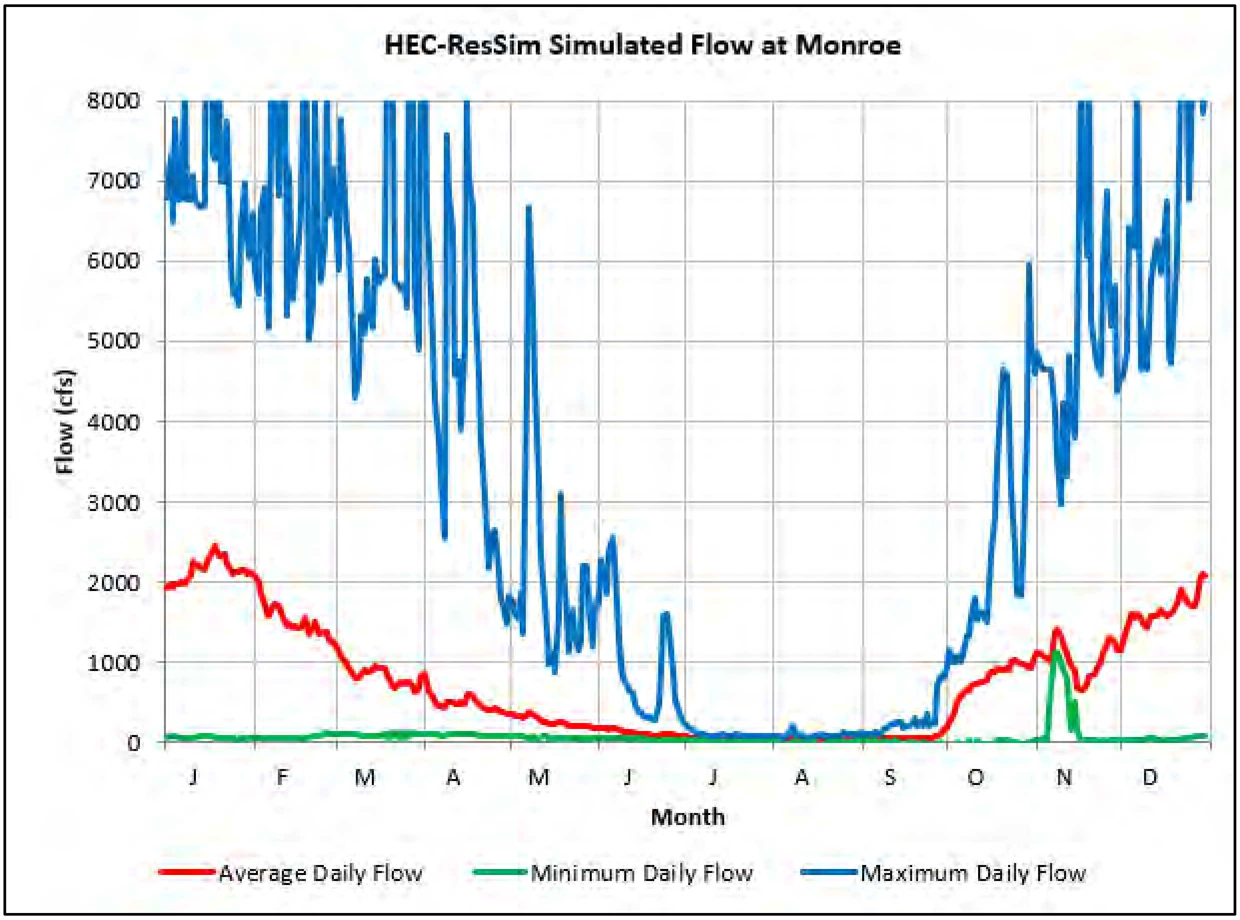

**Figure 3.2-24. NAA Long Tom River at Monroe daily minimum, average, and maximum flows**

*3.2.2.3.3 McKenzie Subbasin*

Cougar (Figure 3.2-25) and Blue River (Figure 3.2-26) would behave similarly with respect to their rule curves during average and wetter years. During drier years (the green P05 and purple P25), Cougar would draft toward its minimum conservation elevation more frequently than Blue River despite its larger capacity. This is because Cougar has hydropower turbines, dictating a higher minimum flow when running, and the reservoir's storage is more often used to meet minimum flows on the mainstem Willamette River at Albany and Salem.

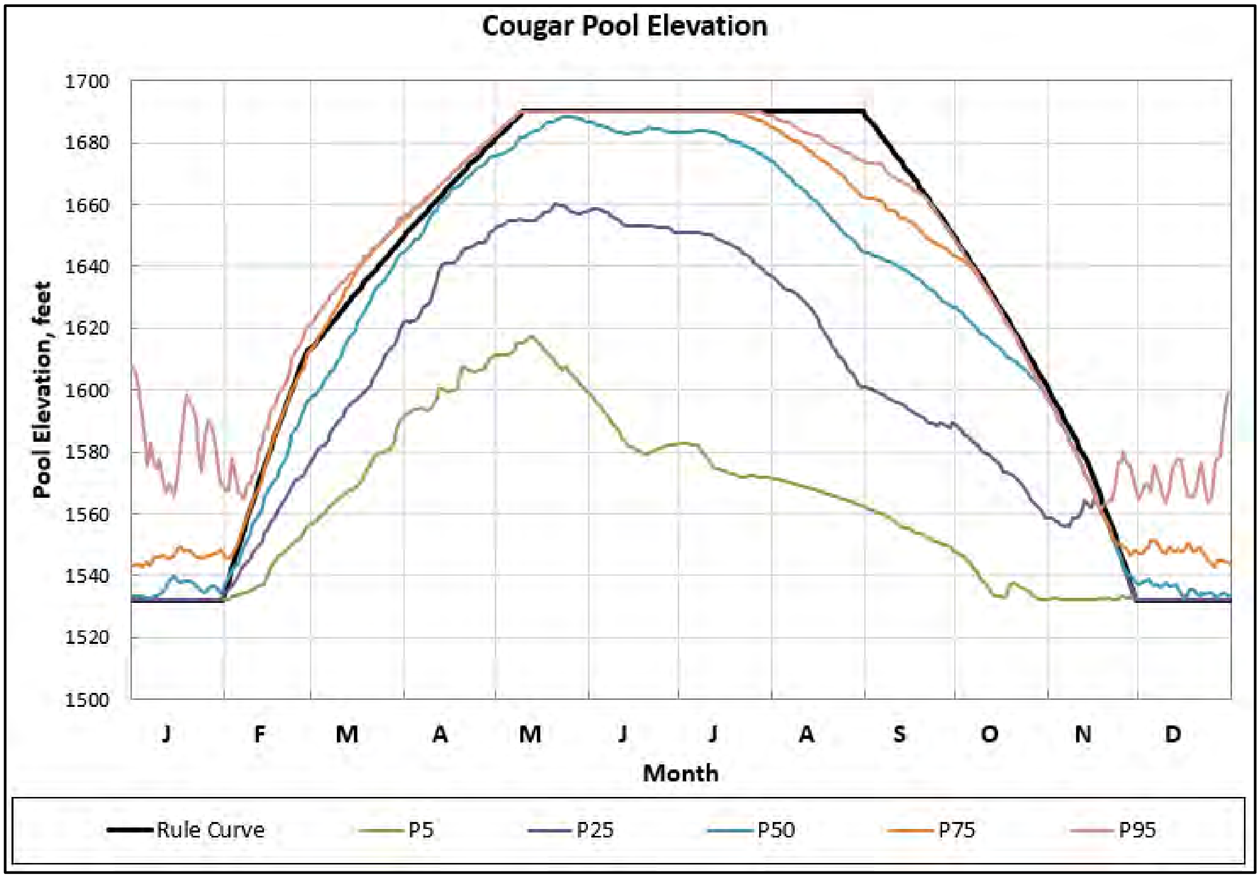

**Figure 3.2-25. NAA Cougar water surface elevation non-exceedance**

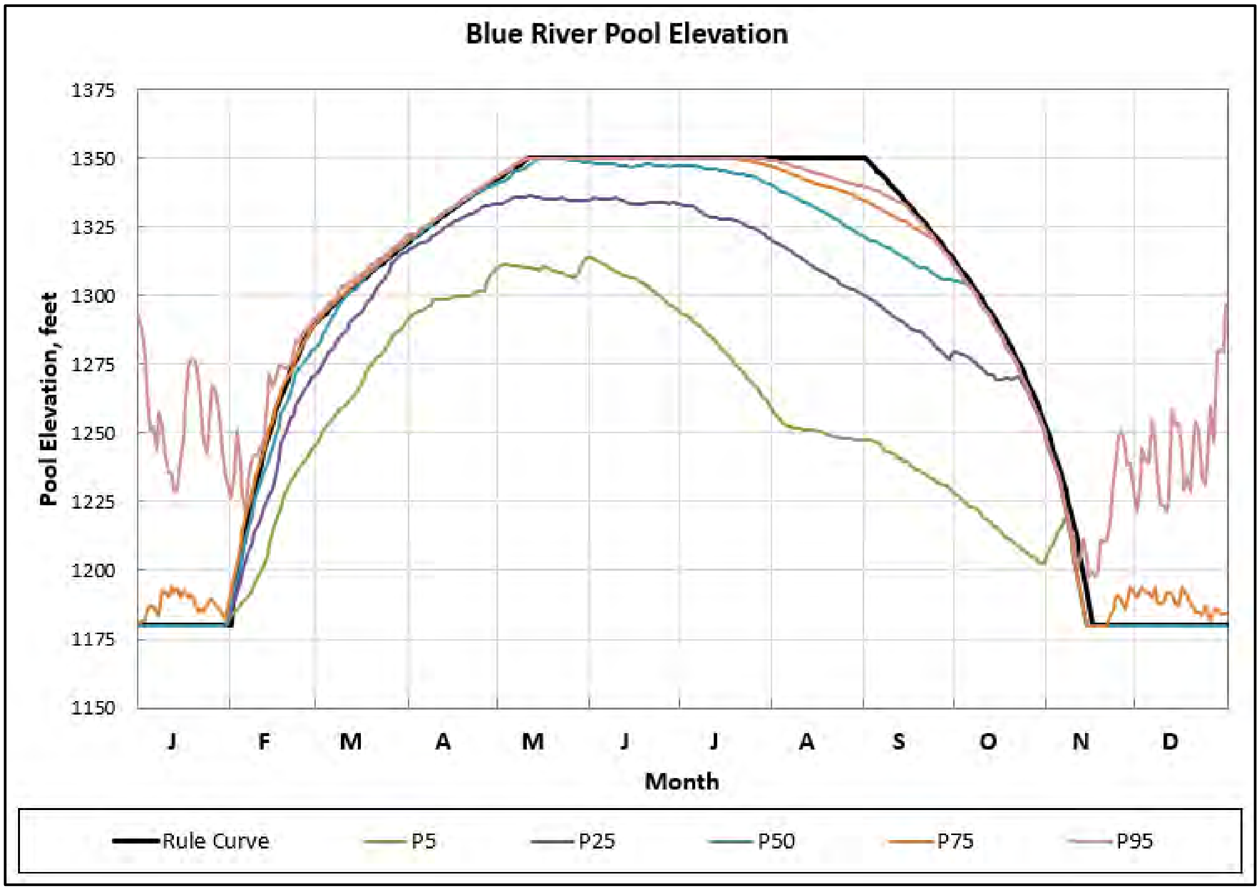

**Figure 3.2-26. NAA Blue River water surface elevation non-exceedance**

The minimum flow across the period of record at The McKenzie River at Vida (Figure 3.2-27) is higher relative to the average flow as compared to other Willamette Valley subbasins due to the geology in the upstream watershed. The control point for Blue River and Cougar is also downstream of the relatively large uncontrolled basin from the mainstem McKenzie River headwaters.

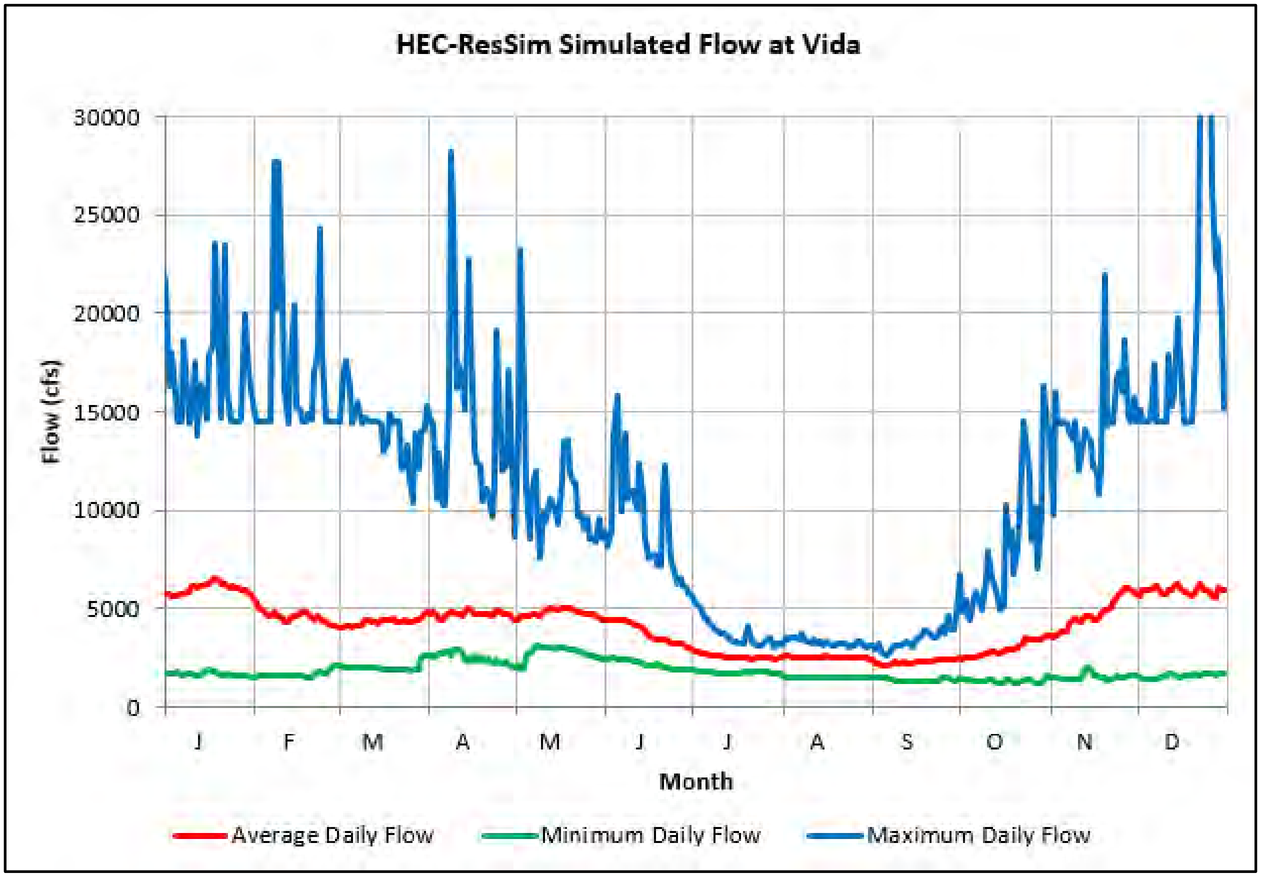

**Figure 3.2-27. NAA McKenzie River at Vida daily minimum, average, and maximum flows**

### *3.2.2.3.4 Middle Fork of the Willamette Subbasin*

Fall Creek reservoir (Figure 3.2-28) is fully drained each year by late November and early December to facilitate downstream passage of juvenile spring Chinook salmon. This deeper fall reservoir drawdown is implemented in the NAA. Although this is a relatively recent operation (the first one was in 2011), this operation is run throughout the period of record to reflect the current USACE management of the WVS. During the deeper fall reservoir drawdown period, there are still periods of higher water due to flood operations and Fall Creek has always been able to return to the minimum conservation pool elevation prior to the start of refill in February.

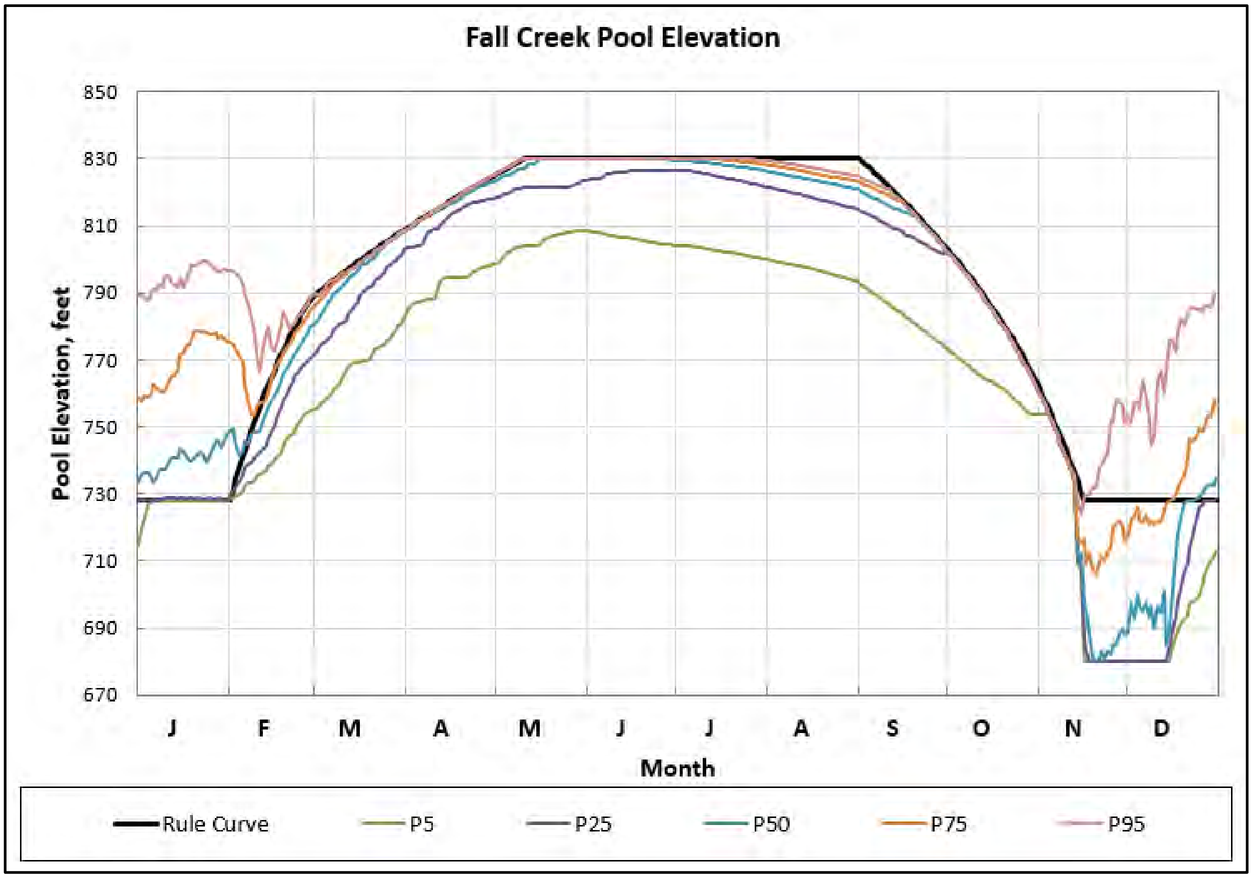

**Figure 3.2-28. NAA Fall Creek water surface elevation non-exceedance**

Hills Creek (Figure 3.2-29) is upstream of Lookout Point (Figure 3.2-30) and under the NAA, these projects would continue to be operated to balance water storage between them. Therefore, they would tend to follow a similar path in average to wet years. During drier years (purple P25 and green P05), flow leaving Hills Creek can be stored in Lookout Point so Lookout Point can remain higher for longer. The 'twice stored' water is required in the fall to meet downstream flow targets, so this effect only lasts through about early September. For example, the Lookout Point P25 line falls in September and October, whereas the Hills Creek line is already nearing its minimum annual level.

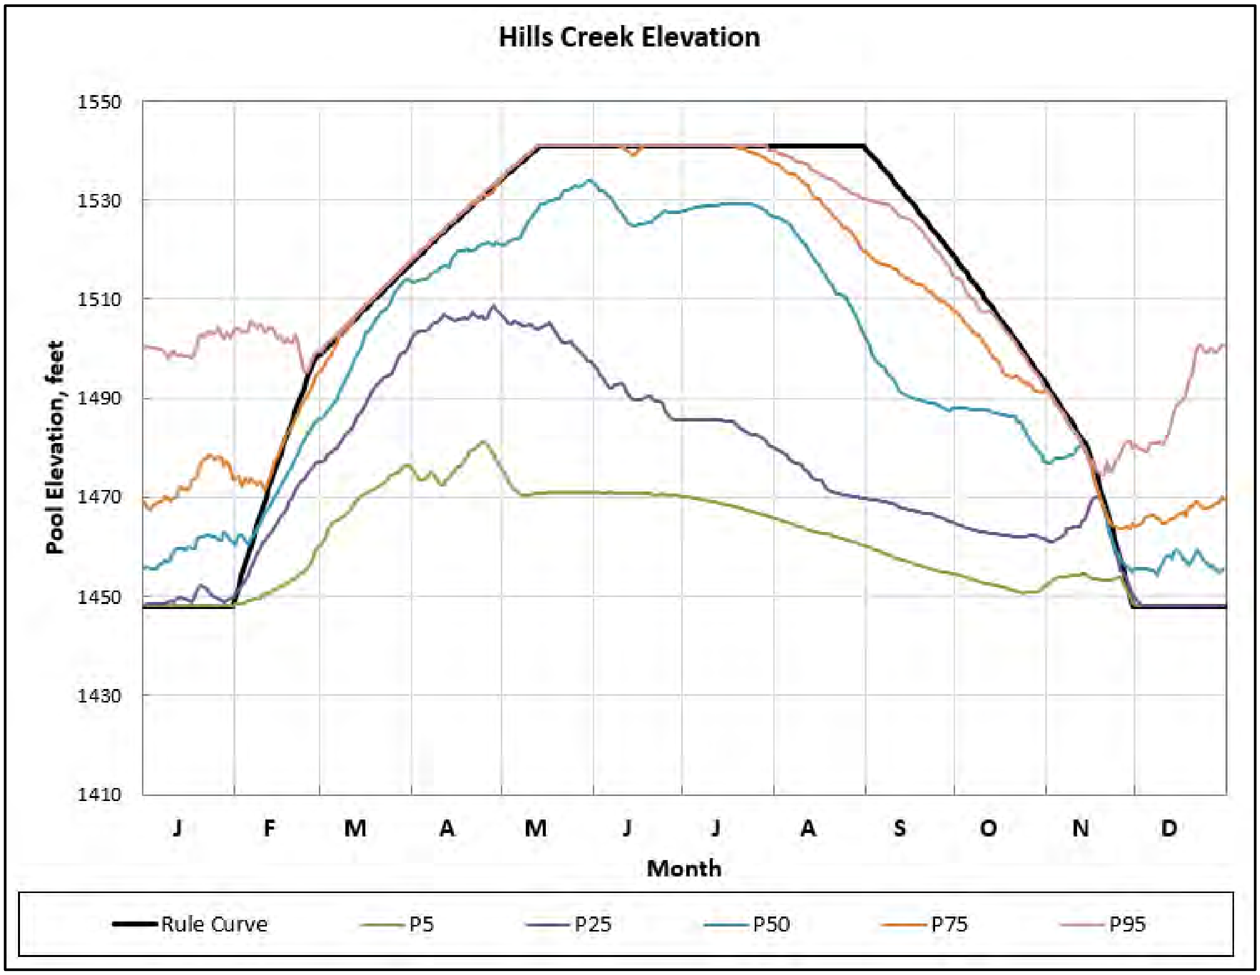

**Figure 3.2-29. NAA Hills Creek water surface elevation non-exceedance**

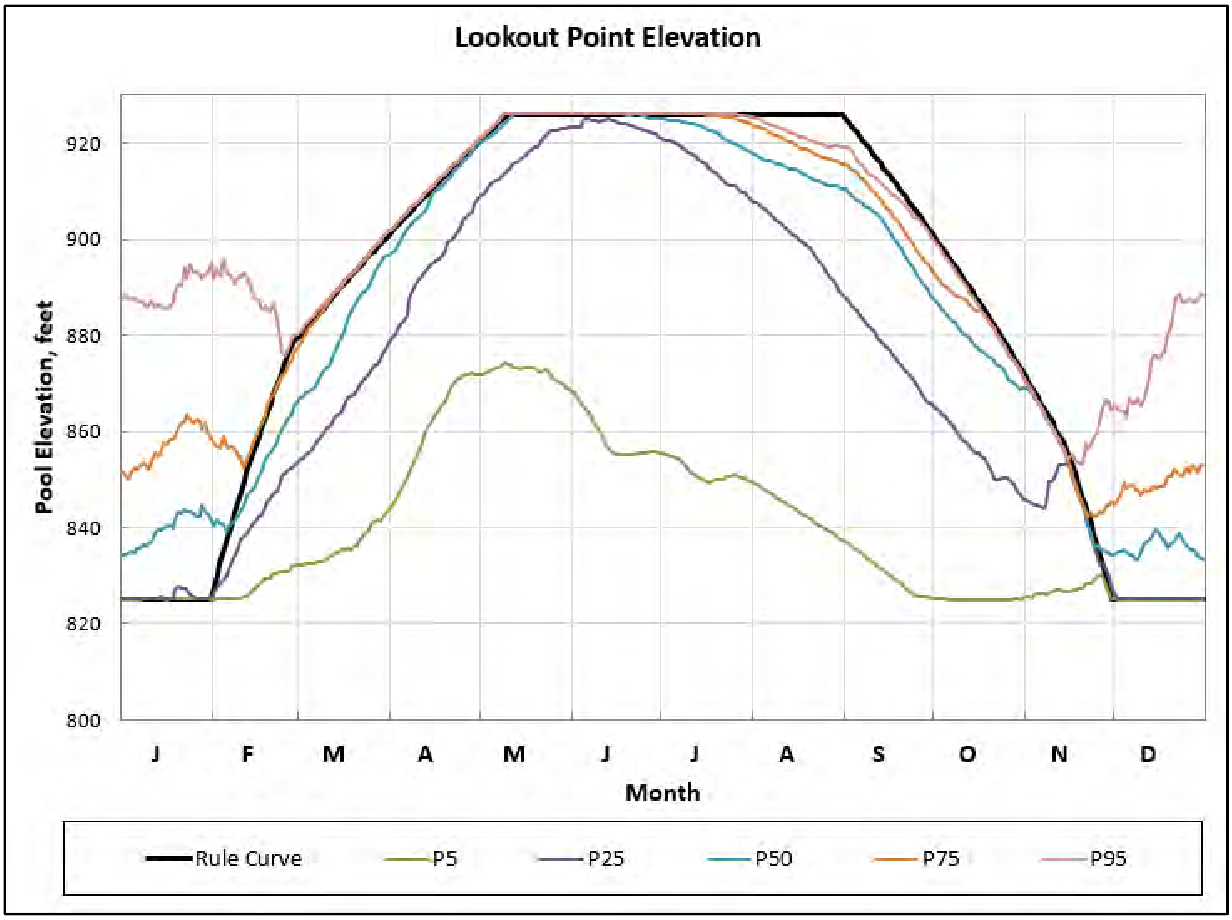

**Figure 3.2-30. NAA Lookout Point water surface elevation non-exceedance**

Dexter is not shown as it reregulates Lookout Point, smoothing power peaking flow. It follows its flat rule curve very closely in all years.

The downstream control point for Middle Fork of the Willamette at Jasper (Figure 3.2-31) shows a typical regulated shape for the Willamette. Flood season from November to April sees regular higher flows with a possibility of low flow at any time during the winter. The most consistently low flow is July through early September. The bankfull regulation target at Jasper is 20,000 cfs, so the maximum flows congregate around there during early winter as USACE drafts the reservoir in preparation for storing water during winter storm events. Since this is the maximum daily flow across all years, each individual year will reach bankfull for a much shorter time to draft the reservoir.

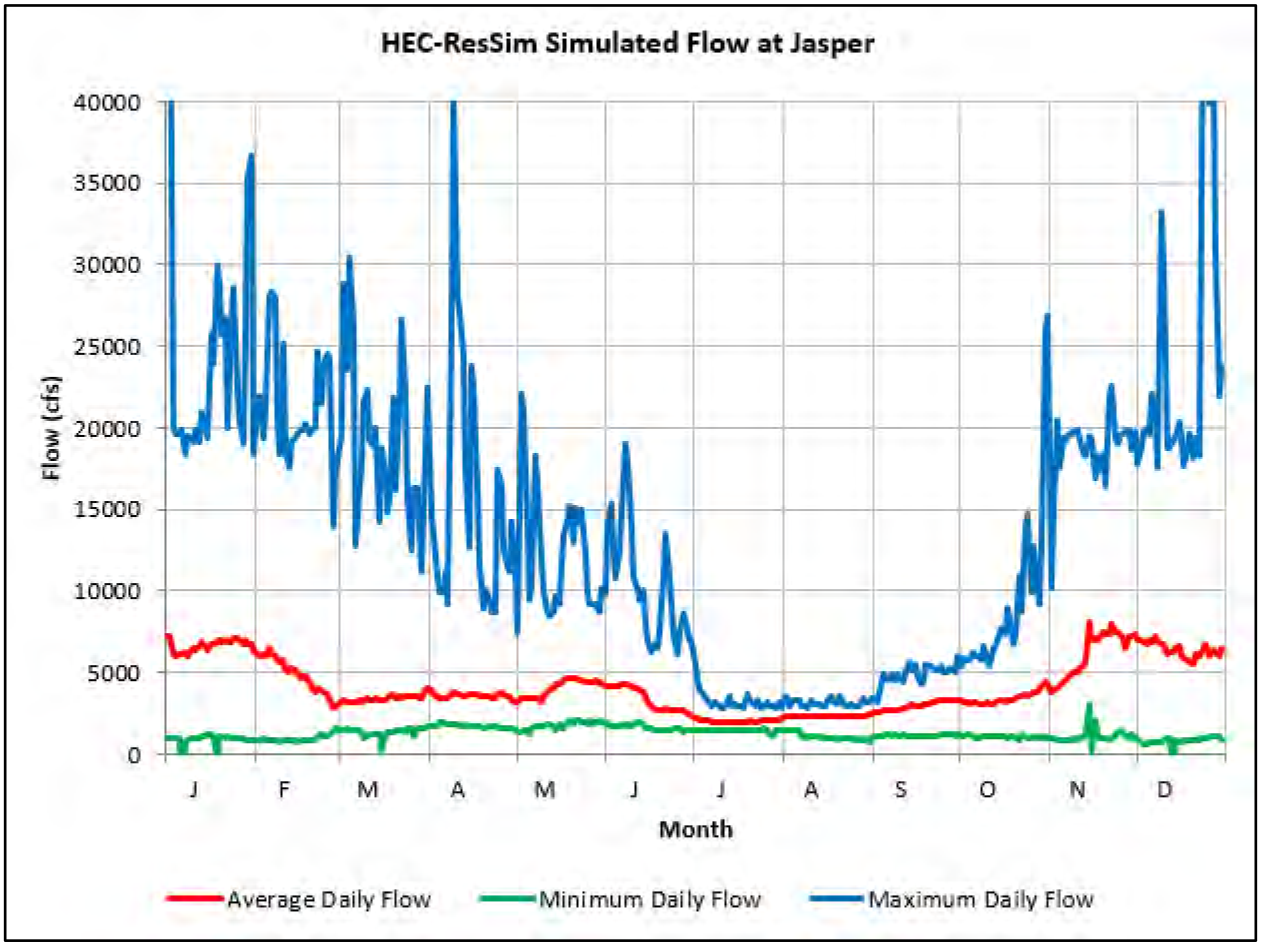

**Figure 3.2-31. NAA Middle Fork of the Willamette at Jasper daily minimum, average, and maximum flows**

*3.2.2.3.5 Coast Fork of the Willamette Subbasin*

Cottage Grove (Figure 3.2-32) and Dorena (Figure 3.2-33) operate very similarly in that they have the same control point and regulation goals. Although Dorena is a bit more than twice as large by volume, its drainage is also a little more than twice as large as Cottage Grove's drainage area. Dorena's drainage area is somewhat higher in average elevation, so the inflow to Dorena is more variable throughout the winter flood season. Summer storage season is very similar between the two reservoirs.

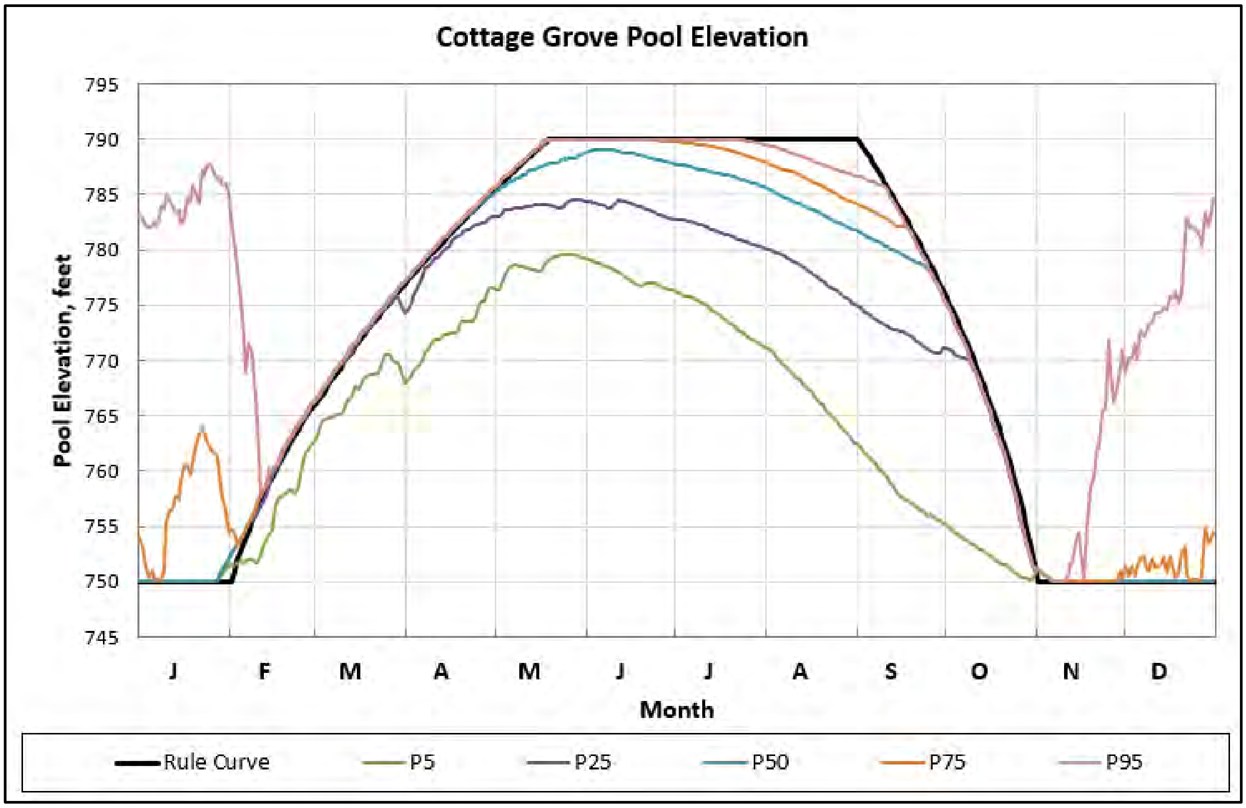

**Figure 3.2-32. NAA Cottage Grove water surface elevation non-exceedance**

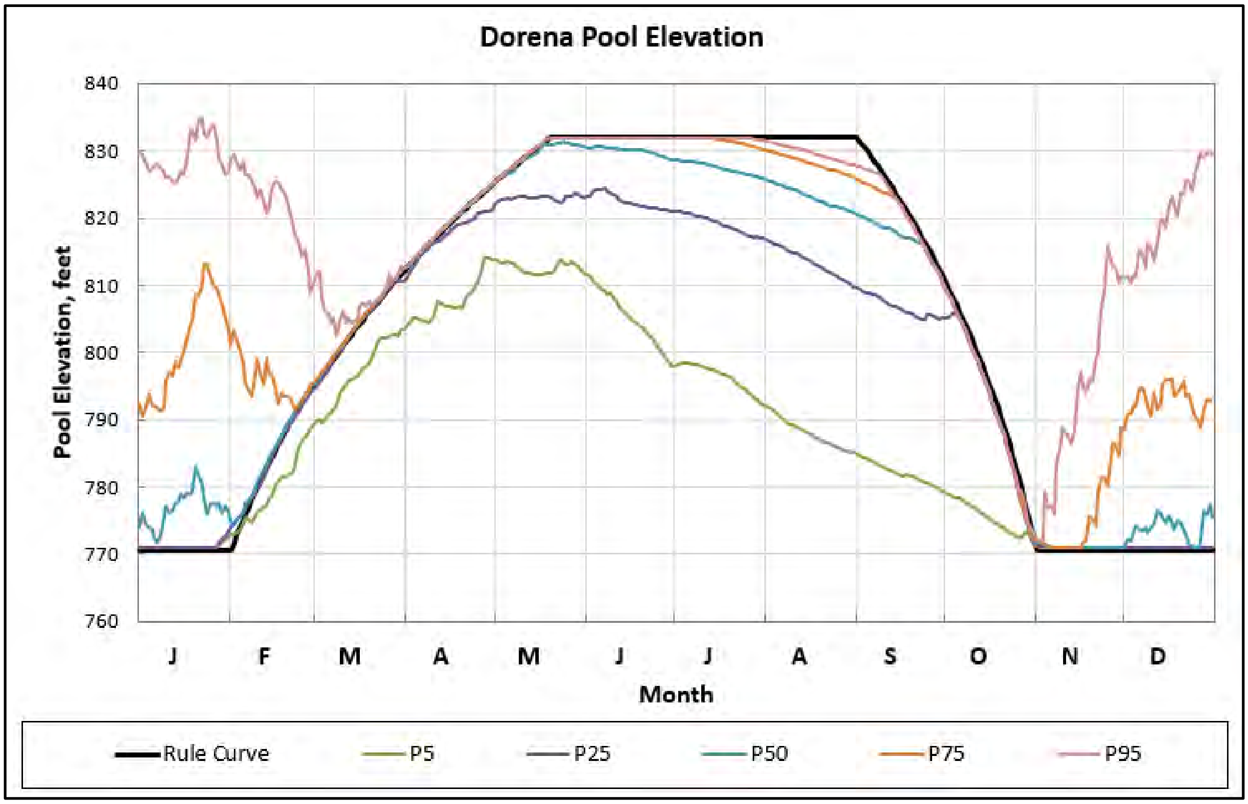

**Figure 3.2-33. NAA Dorena water surface elevation non-exceedance**

The control point for the Coast Fork of the Willamette River is at Goshen (Figure 3.2-34). Since the Coast Fork is lower in elevation and smaller than the Middle Fork, under the NAA, flows would be lower and minimum base flows much lower as a percentage of the average flow. The rise in average flows in October is a function of the reservoirs releasing water in anticipation of flood season. Average flows would drop at the beginning of November as Cottage Grove and Dorena generally get to minimum conservation pool at that time and stop releasing accumulated storage.

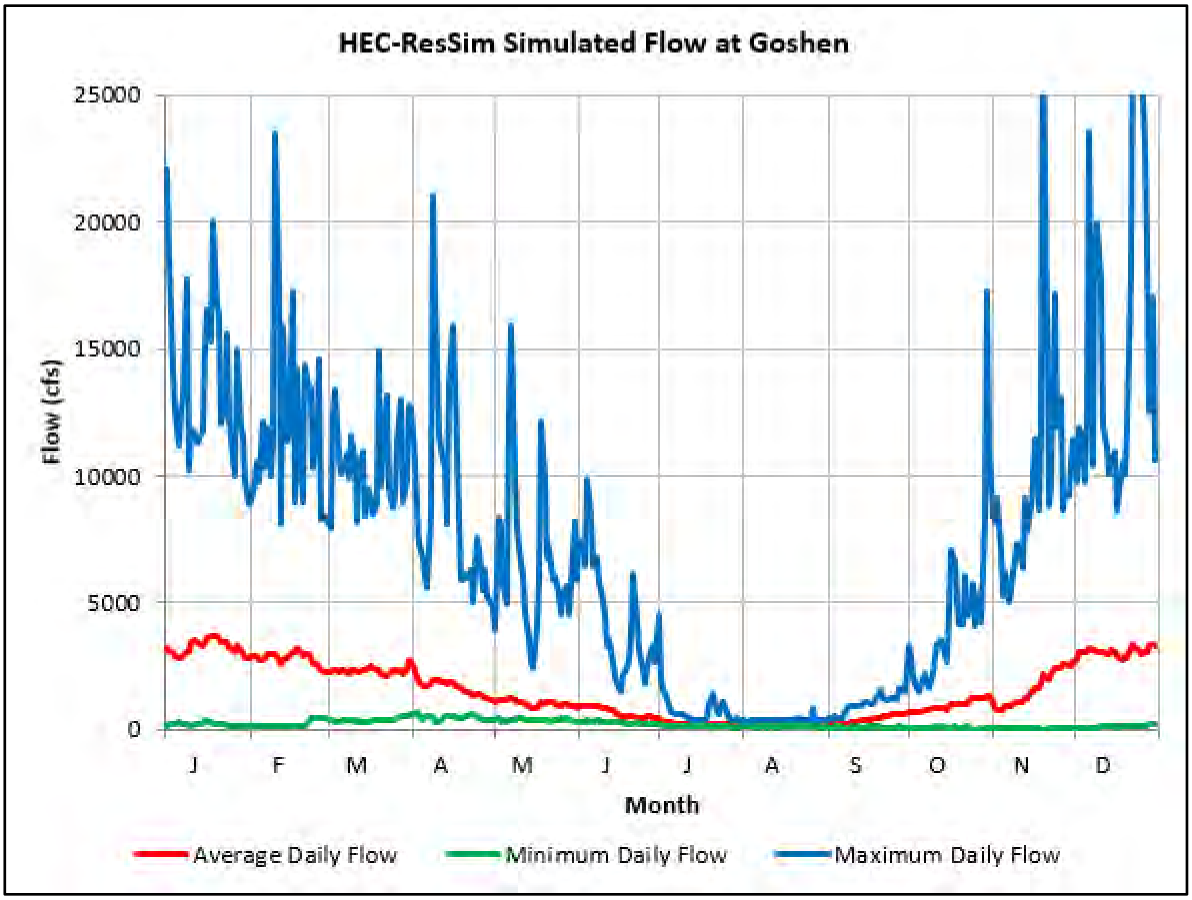

**Figure 3.2-34. NAA Coast Fork of the Willamette at Goshen daily minimum, average, and maximum flows**

*3.2.2.3.6 Mainstem Willamette River*

The 2008 NMFS BiOp set minimum flow targets for the Willamette River at Albany (Figure 3.2-35) and Salem (Figure 3.2-36). The targets shown on both charts are the values set in Abundant and Adequate water years. Deficit years have lower flow targets – shown in the Salem figure – and insufficient years are a sliding scale in between. Flow target determination is set in cooperation with the WATER committee as set forth in the BiOp criteria. Across the inflow dataset's 1935 to 2019 period of record there are:

- 45 Abundant water years
- 26 Adequate water years
- 7 Insufficient water years
- 6 Deficit water years

Since USACE seeks to meet the BiOp targets during summer and fall conservation season as long as possible, the average flow in these months under the NAA would be very close to this minimum flow. Releasing flows above the target would increase the risk of falling below the target later in each water year.

Both the Albany and Salem figures exclude the maximum flood season flows due to show more detail in the lower flow summer season.

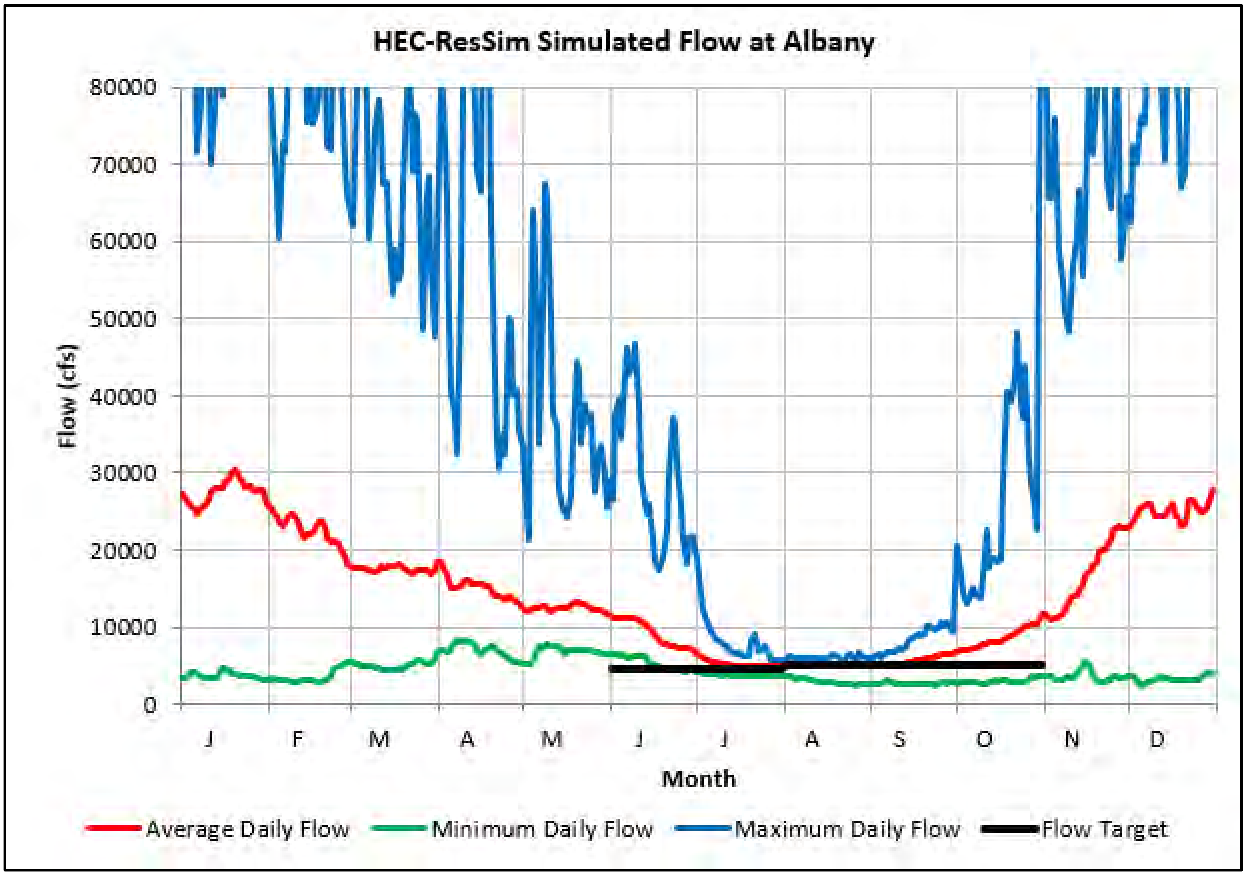

**Figure 3.2-35. NAA Willamette River at Albany daily minimum, average, maximum and BiOp target flows**

The minimum flow line would be well below the target at both Salem and Albany. Since this line represents the minimum on that date across all water years, no single water year is below the BiOp targets for as long. The NAA is below the baseline BiOp target during the driest years for most of the summer and fall as the WATER committee revises these targets lower based on available storage. There is not adequate stored water to fully supplement basin-wide low flows and therefore mainstem flows would not meet the baseline target at either Albany or Salem during dry years. Refer to the biological model section for more information on the flow regime's effect on fish survival.

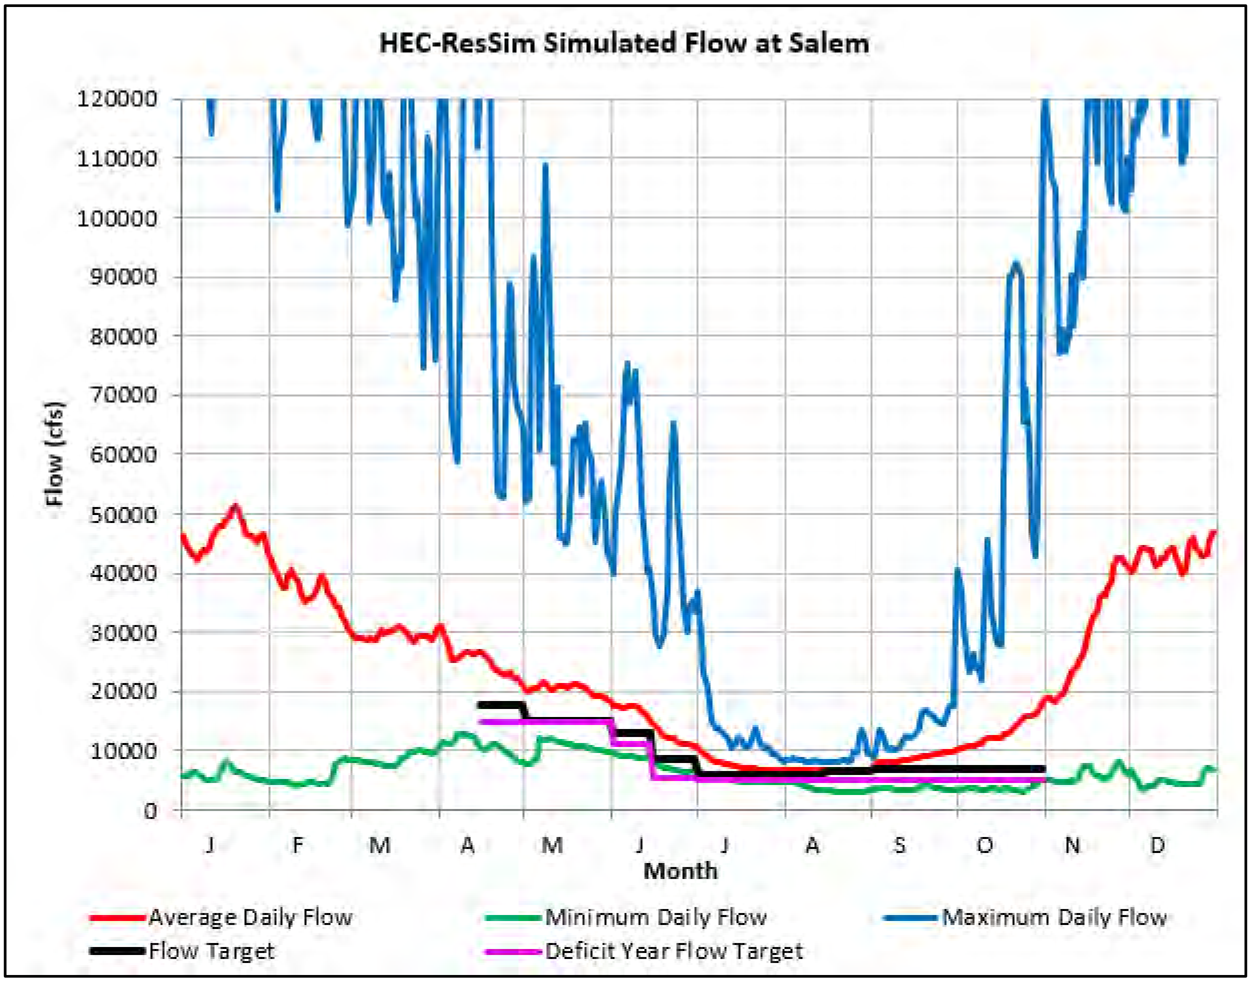

**Figure 3.2-36. NAA Willamette River at Salem daily minimum, average, maximum and BiOp target flows**

### *3.2.2.3.7 Climate Change*

The WVS will likely experience increasing wintertime flow volumes in the future. Some flood magnification (increased severity during flood season) is also likely. Because the WVS system storage will remain about the same, it's likely that FRM operations will face future challenges. An upward shift in median future project inflows may increase both the average reservoir water surface elevation as well as outflows downstream of the WVS dams. Reservoirs located within higher elevation subbasins, such as Detroit and Cougar, are likely to see higher rainfall and runoff volumes in the winter. Higher projected temperatures in the future would mean less snowpack than currently experienced. A lower snowpack would also contribute less to overall spring flows as the snowpack melts. Lower elevation subbasin projects such as Fern Ridge and Cottage Grove, with little or no snowpack, are projected to experience higher wintertime flow volumes, but similar peak runoff timing compared to historical baselines.

Increased variability in the spring shoulder months, drier hotter summers, and lower summer baseflow are the most impactful climate change factors affecting conservation season operations. Decreasing spring inflow may result in less reliable refill. Moreover, increased winter and early spring flows may complicate WVS ability to initiate refill earlier.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently. Water surface elevations may decline more rapidly to meet downstream minimum flow targets. The Santiam and Middle Fork subbasins may be drafted more than other WVS reservoirs. With decreasing summer and fall flows, mainstem Willamette flow targets may not be met as often if the larger WVS reservoirs empty more frequently in the future.

#### *3.2.2.4 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 is designed to accumulate water in the WVS reservoirs as much as congressionally authorized and use a greater portion of the total reservoir volume for conservation storage, including portions of pool currently designated as the inactive and power pools. There are changes in regulated hydrology throughout the conservation season, as the goal of Alternative 1 is to fill the reservoirs as often as possible and supply water from storage as long as possible late into the conservation season.

The BiOp outlines minimum releases from WVS dams and sets targets at the downstream control points in the NAA. In Alternative 1, these releases and targets would be reduced to Congressionally authorized minimum flows or a physical operating limit, whichever is greater. The minimum Congressionally authorized flows are lower at Albany and Salem than the BiOp mainstem targets, generally lower across the WVS, and show less seasonal variability. They are also not adaptive, in contrast to the lower-than-baseline flow targets set by the WATER committee in ‘deficit’ and ‘insufficient’ years.

In general, Alternative 1 would have limited effects during an average or wet year in the WRB. The reservoirs would fill during these years while meeting downstream flow targets. Summer flows would sometimes be a bit higher due to the reservoir reaching maximum pool somewhat earlier than normal and therefore passing inflow sooner, but flow differences are minimal compared to the NAA.

Alternative 1 would alter storage in drier than average years, and especially the 25 percent non-exceedance (P25 in the elevation and flow figures) and below years, shifting flow releases from April to June into July through October compared to the NAA. This would miss the current BiOp flow requirements modeled in the NAA more often, but those misses would occur earlier in the year during the April to June period. Later flow targets from July to October are met more frequently due to the additional accumulated stored water.

A more detailed analysis of Alternative 1 by subbasin follows. The reservoir regulation model only considers those measures that affect the water flow volume, location, and timing. Measures that would not affect flow values, such as WTC towers, are not included in this model or the hydrologic processes results.

The shift of stored water releases to a different season would be very noticeable throughout the basin and would bring long term changes to the WRB. Effects from Alternative 1 to hydrologic processes: Major compared to the NAA.

#### *3.2.2.4.1 Santiam Subbasin*

Detroit reservoir (Figure 3.2-37) would fill more often and earlier in the conservation season under Alternative 1. It would also stay higher later in the year throughout water year types. The effect would be most noticeable in the driest years. The P25 line reaches the maximum pool whereas it did not in the NAA. Also, the P05 line does would not reach minimum pool in the fall, whereas in the NAA, higher minimum flows depleted storage and Detroit was forced to only pass inflow when the reservoir reached minimum conservation pool.

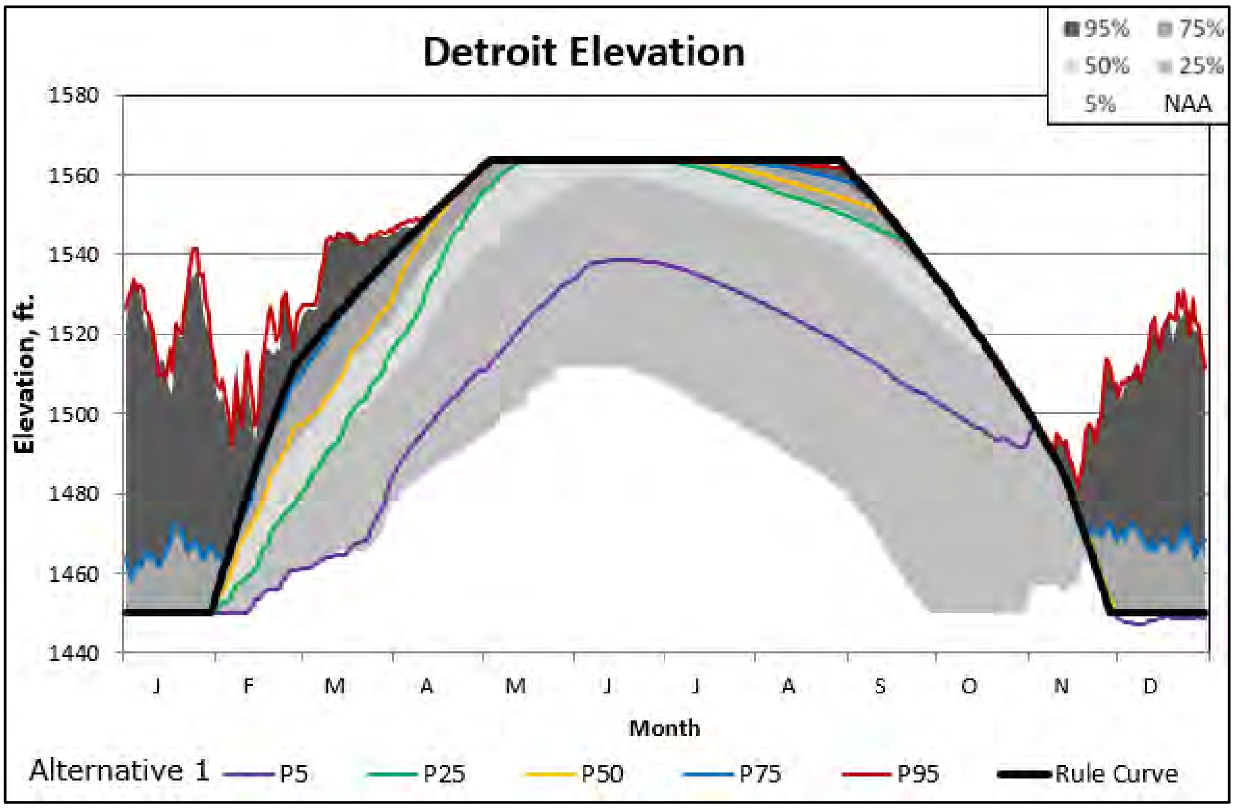

**Figure 3.2-37. Alternative 1 Detroit water surface elevation non-exceedance compared with NAA**

Detroit fills more often and stays higher throughout the summer because the springtime Congressionally authorized minimum flows would be reduced to 1,050 cfs from a variable schedule of 1,000 to 1,500 cfs. Figure 3.2-38 shows this difference starting in March through June. The fall drawdown from a higher typical pool elevation in preparation for winter flood season would drive the increase in flows in September and October. In other words, more remaining stored water would have to be released in the fall to get to minimum conservation elevation compared to the NAA.

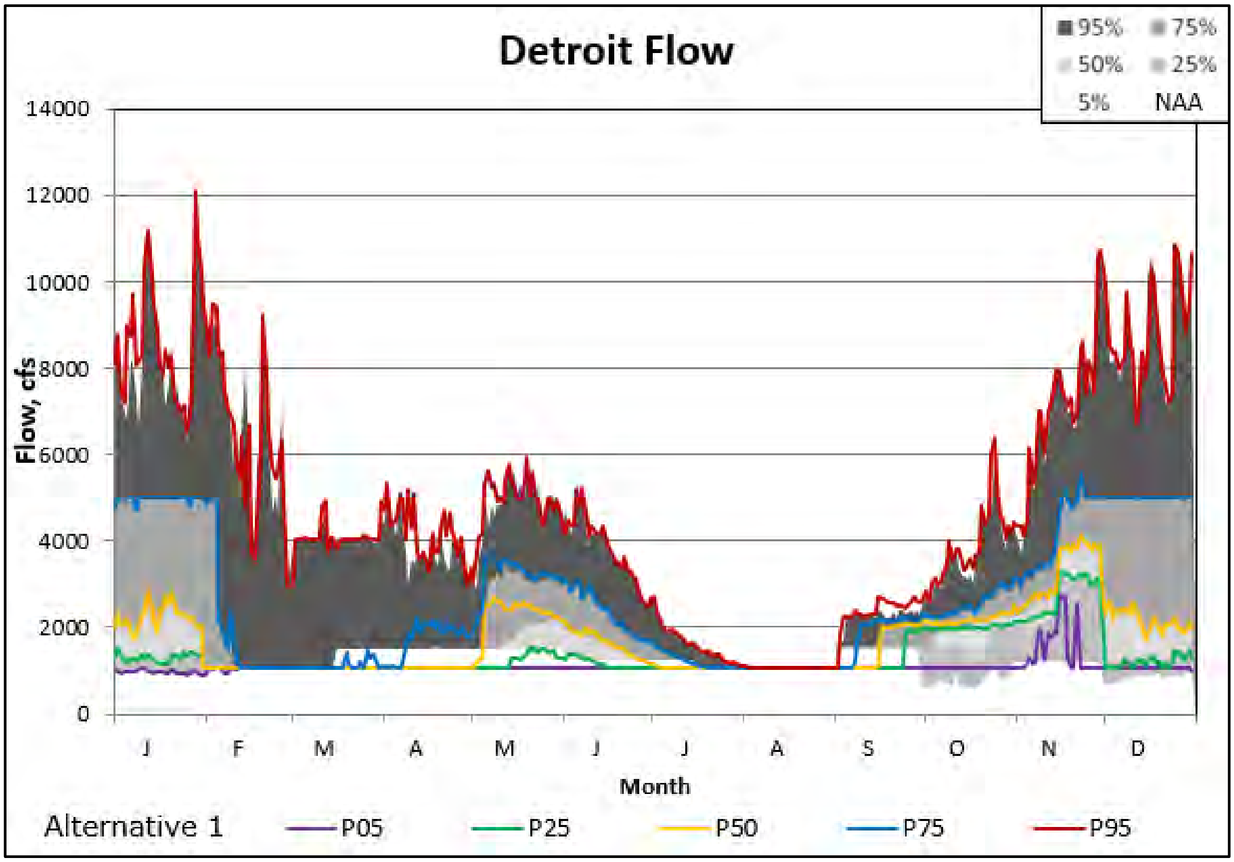

**Figure 3.2-38. Alternative 1 Detroit outflow non-exceedance compared with NAA**

Alternative 1 would have similar effects at Green Peter as it does at Detroit. Figure 3.2-39 shows that the reservoir would stay higher throughout the year and nearly would fill every year – the P05 line comes much closer to the maximum pool than in the NAA. However, this is only a practical difference in the driest years since Green Peter fills in the NAA most of the time. The reduction in these flow minimums means that Green Peter would stay much fuller for longer, able to supply water much later in the year than in the NAA.

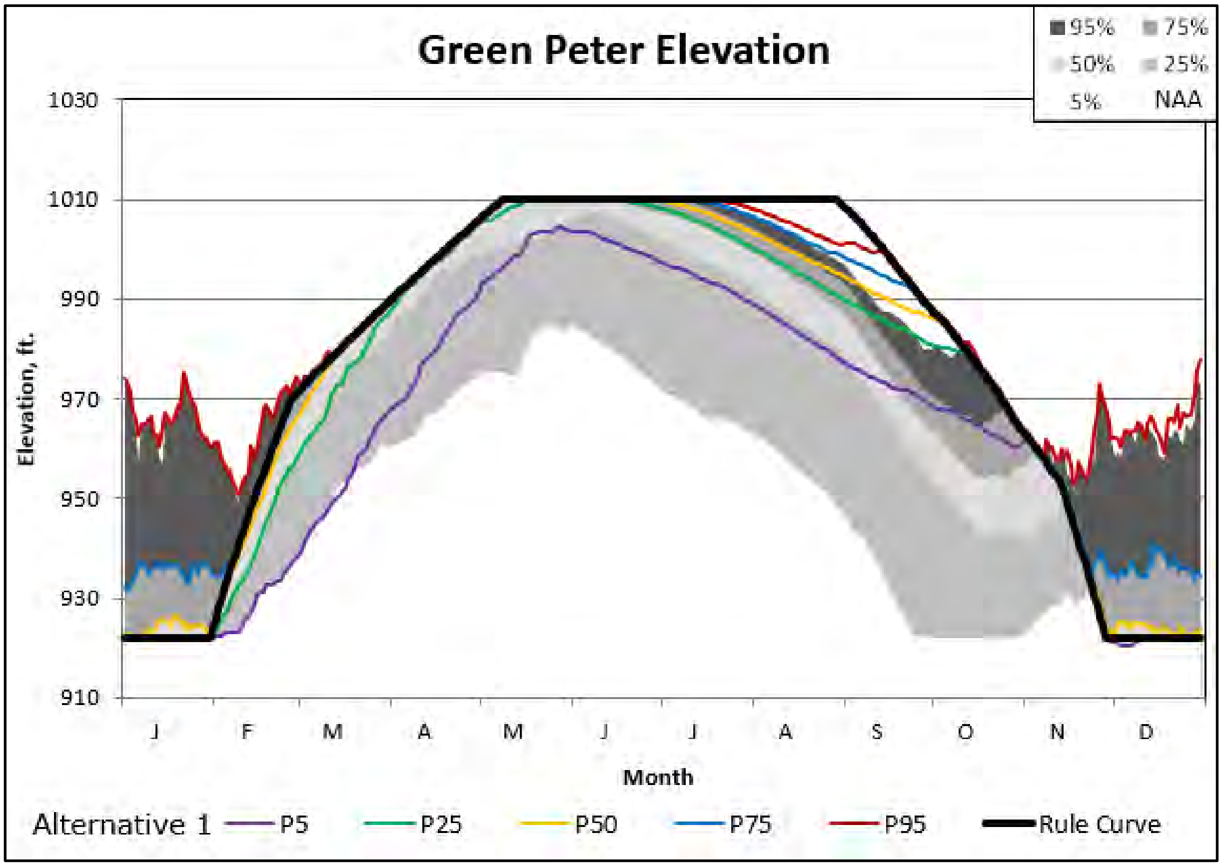

**Figure 3.2-39. Alternative 1 Green Peter water surface elevation non-exceedance compared with NAA**

Downstream of Foster (Figure 3.2-40), which reregulates Green Peter, spring flows would be lower in drier years with the removal of the BiOp targets and about the same in average to wet years. The reduction in target flow on the mainstem would account for the lower flow in September. As Green Peter and Foster draft in preparation for flood season, flows would be higher than in the NAA, as the typical reservoir elevation is higher entering October.

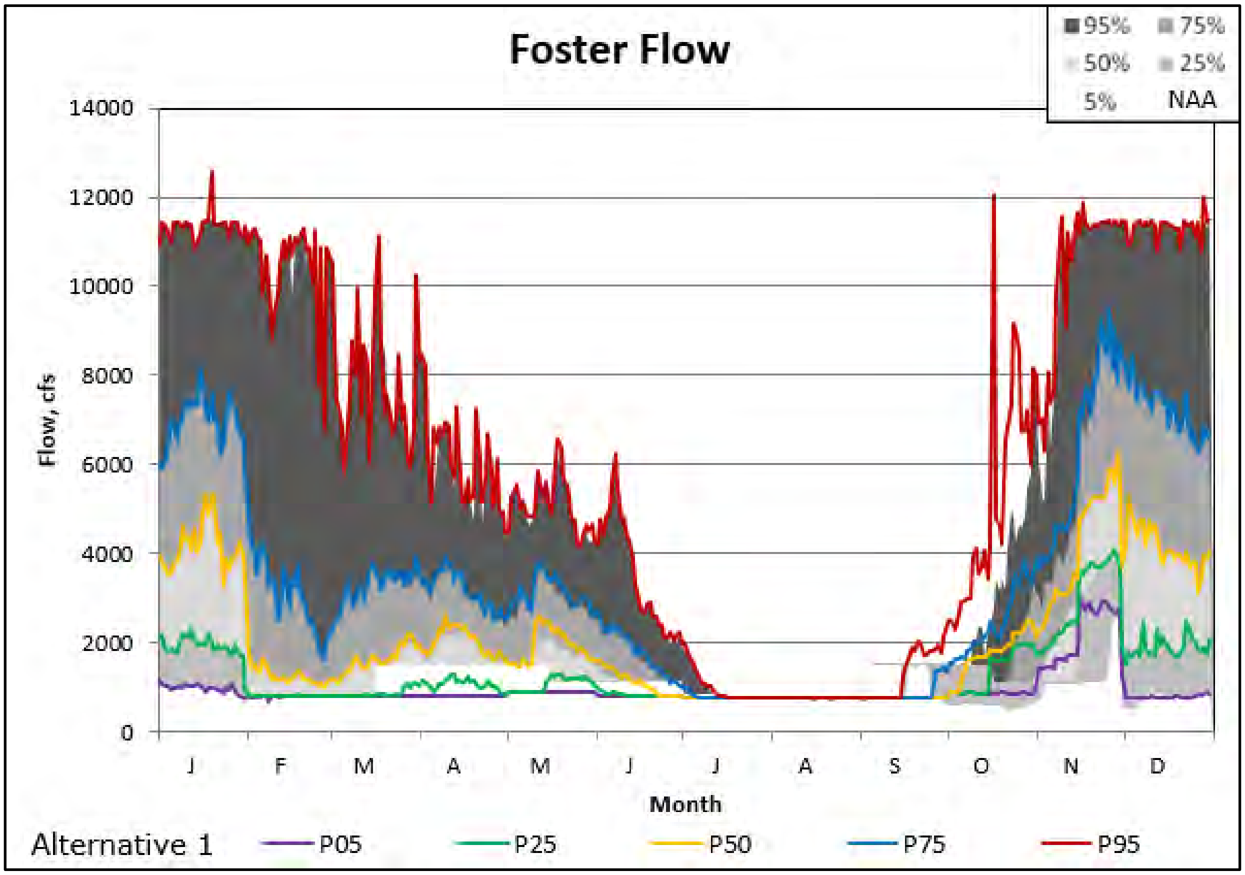

**Figure 3.2-40. Alternative 1 Foster outflow non-exceedance compared with NAA**

At the control point for the Santiam River at Jefferson (Figure 3.2-41), Alternative 1 shows the shift of release of stored water during drier years, while wetter years would remain similar to the NAA. The P05 and P25 lines are below the NAA from March through June with lower minimum flows at Salem. This additional water is stored in the reservoir until the fall drawdown, resulting in higher flows in October.

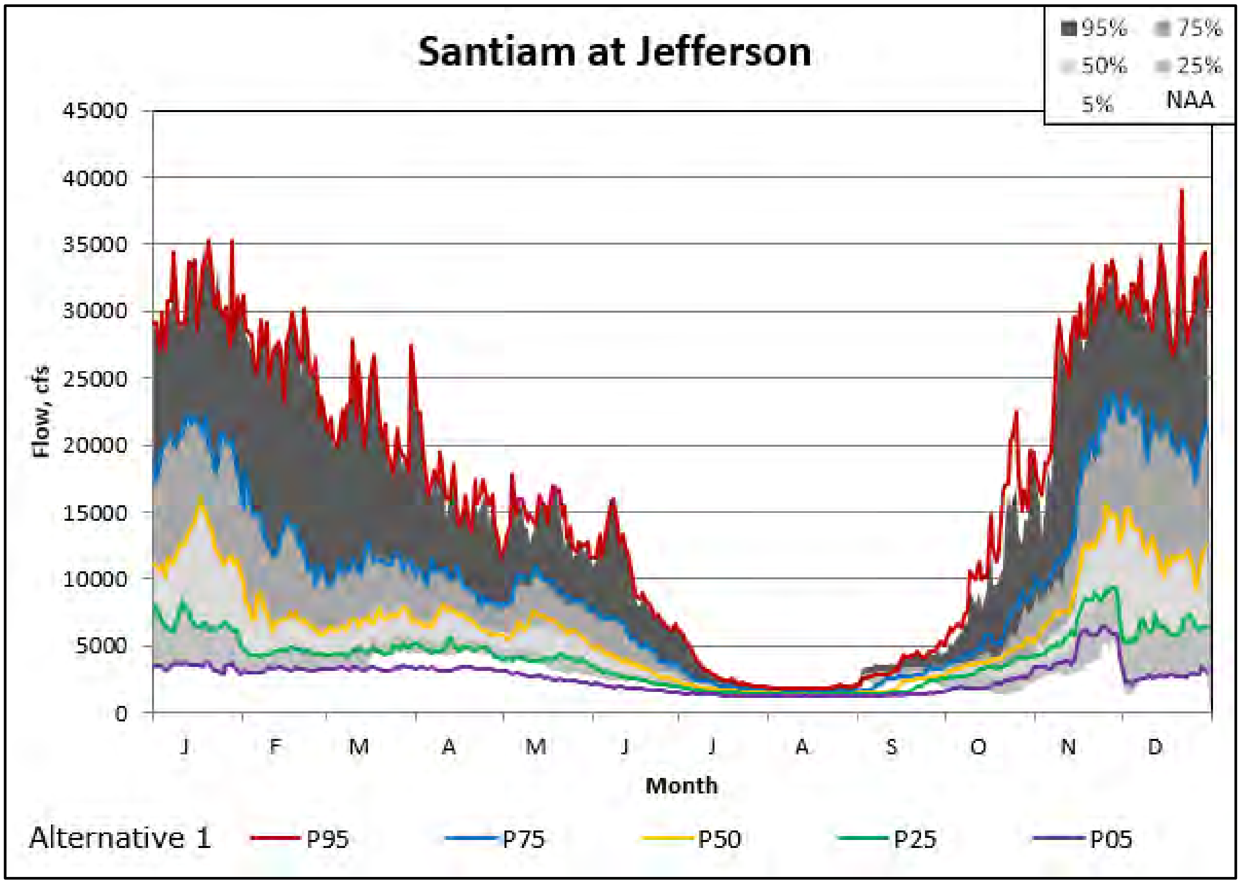

**Figure 3.2-41. Alternative 1 Santiam River at Jefferson flow non-exceedance compared with NAA**

*3.2.2.4.2 Long Tom Subbasin*

As explained in the NAA, Fern Ridge reservoir is operated for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. Alternative 1 would not appreciably change this goal nor the minimum flow targets and the hydrologic patterns would be nearly the same as the NAA, as shown in Figure 3.2-42. The Alternative 1 downstream control point flows at Monroe show a similar lack of change from the NAA.

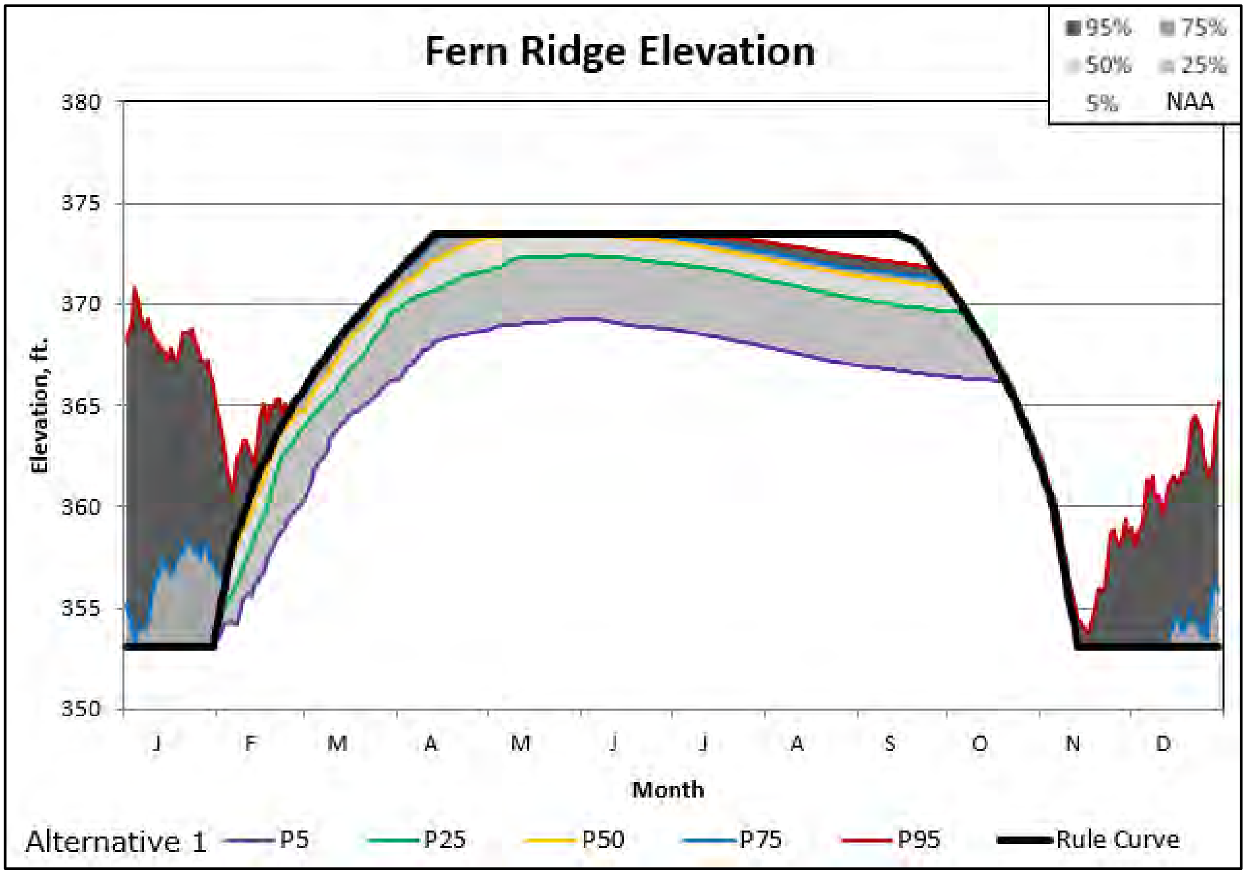

**Figure 3.2-42. Alternative 1 Fern Ridge water surface elevation non-exceedance compared with NAA**

### *3.2.2.4.3 McKenzie Subbasin*

Cougar reservoir would fill more than 75 percent of years with the reduced flow requirements on the mainstem Willamette compared with about 50 percent of years in the NAA, as shown in Figure 3.2-43. There would be more stored water into the summer in all years. Cougar would be able to augment instream flows by using the power pool into the fall of drier years. Blue River reservoir elevations would be similar to the NAA in wetter years and somewhat higher in dry years across Alternative 1.

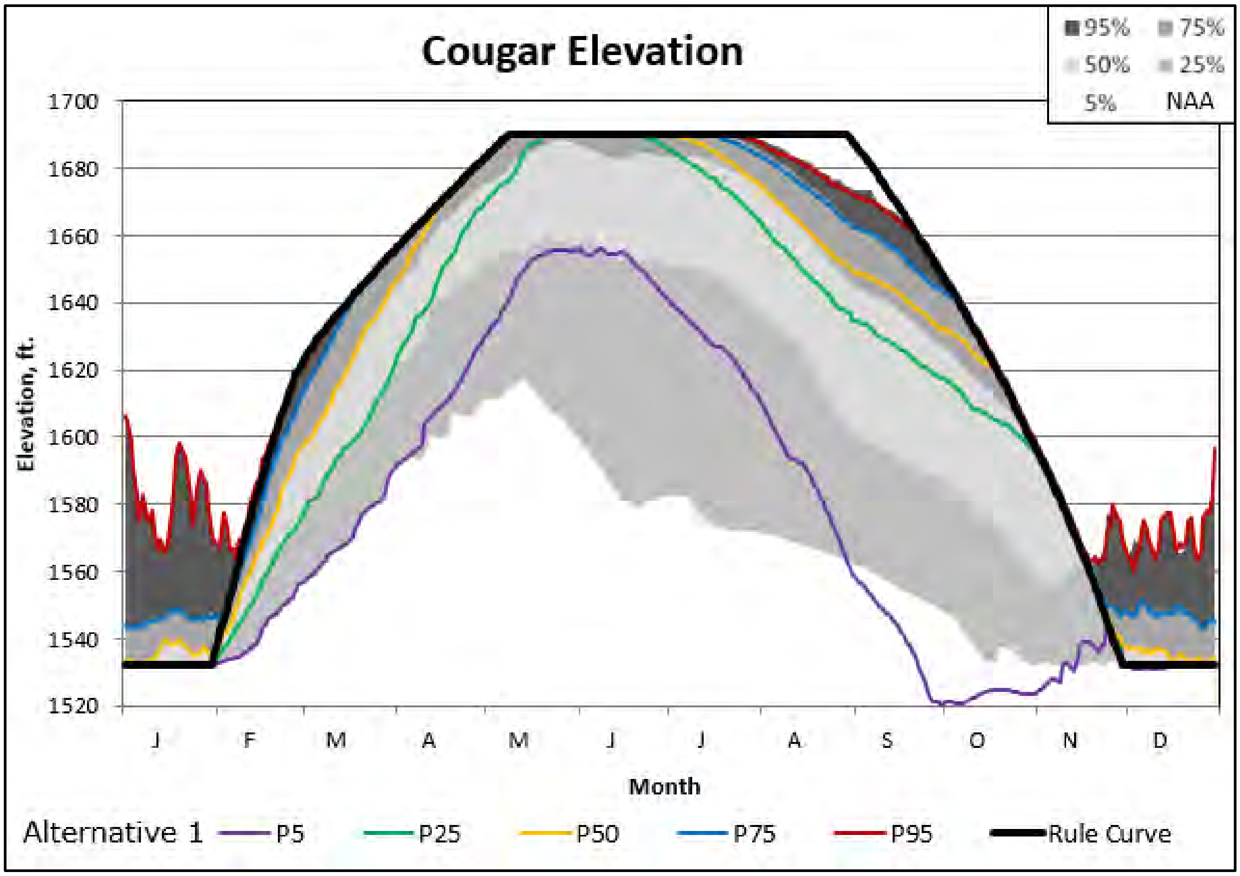

**Figure 3.2-43. Alternative 1 Cougar water surface elevation non-exceedance compared with NAA**

The McKenzie River at Vida (Figure 3.2-44), like other control points, would show a shift of stored water releases from the spring to the summer and fall in the dry years and limited differences in wet years as compared to the NAA. The P05 line would dip below the NAA in October due to the low reservoir elevation at Cougar.

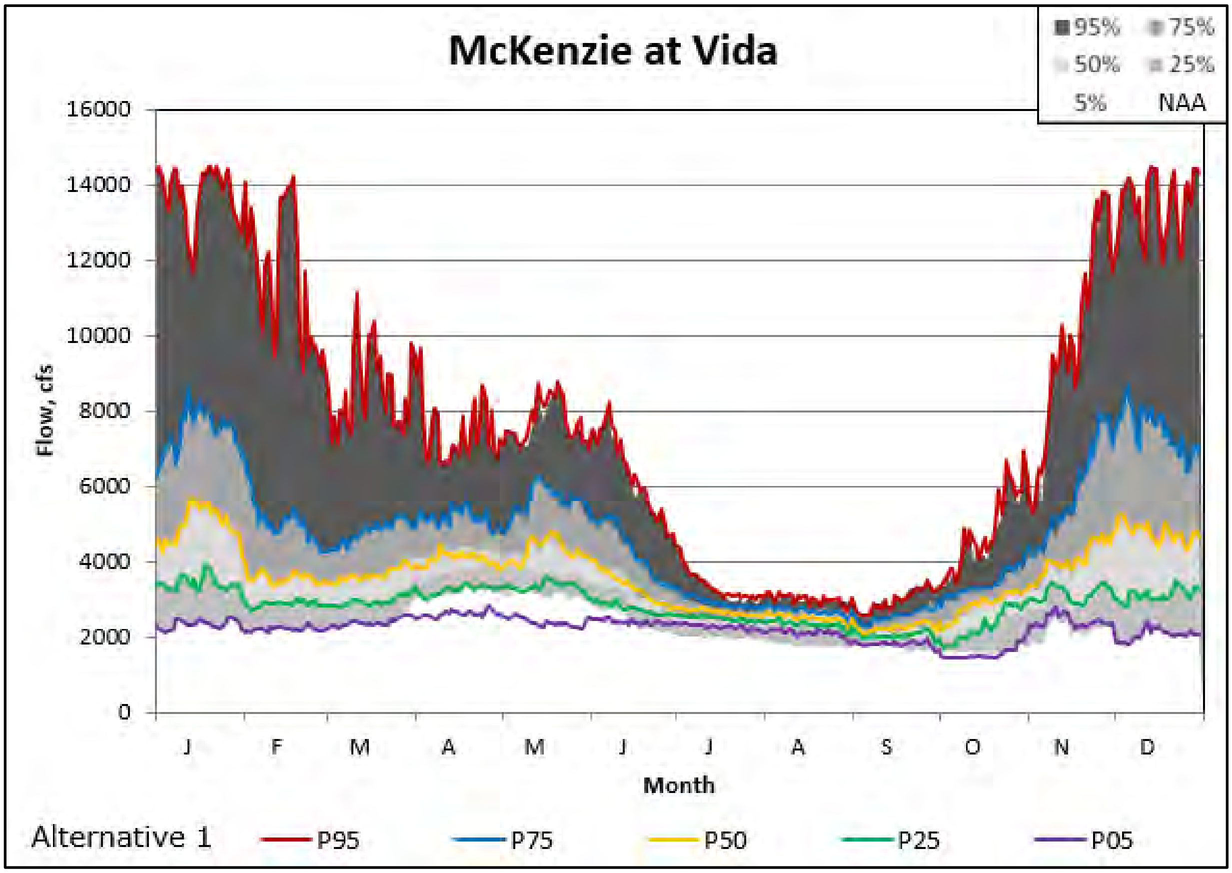

**Figure 3.2-44. Alternative 1 McKenzie River at Vida flow non-exceedance compared with NAA**

### *3.2.2.4.4 Middle Fork of the Willamette Subbasin*

Hills Creek initially would fill more quickly due to the lower downstream flow targets and would stay at similar elevations during wet years (Figure 3.2-45). During dry years, the reservoir would augment instream flows by using the power pool, releasing more water to meet the flow target at Albany. Its capacity would be exhausted in the driest years (P05 line), at which point Lookout Point would supply additional water until it too reaches its minimum power pool elevation in Figure 3.2-46. At the downstream control point at Jasper (Figure 3.2-47), the dry year water shift would be evident, with lower flows in the spring and higher flows in the summer compared to the NAA.

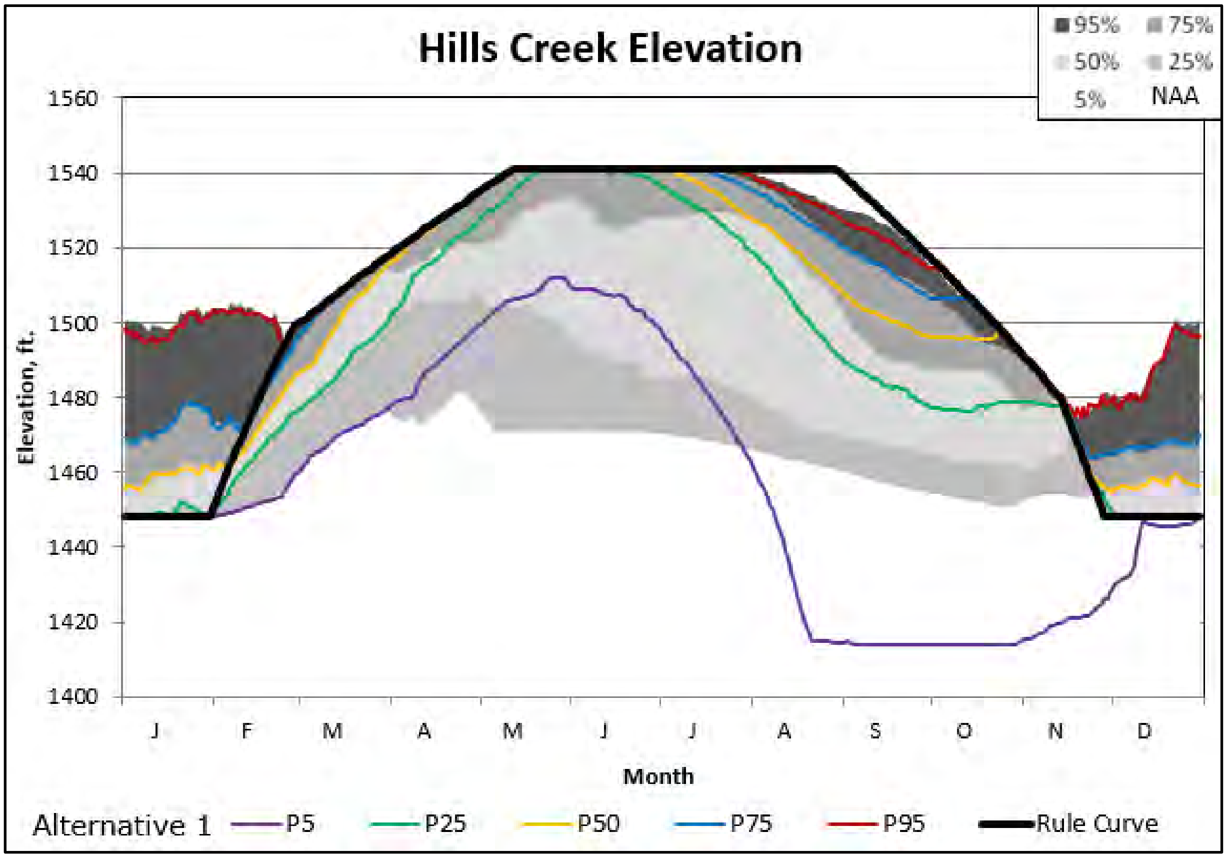

**Figure 3.2-45. Alternative 1 Hills Creek water surface elevation non-exceedance compared with NAA**

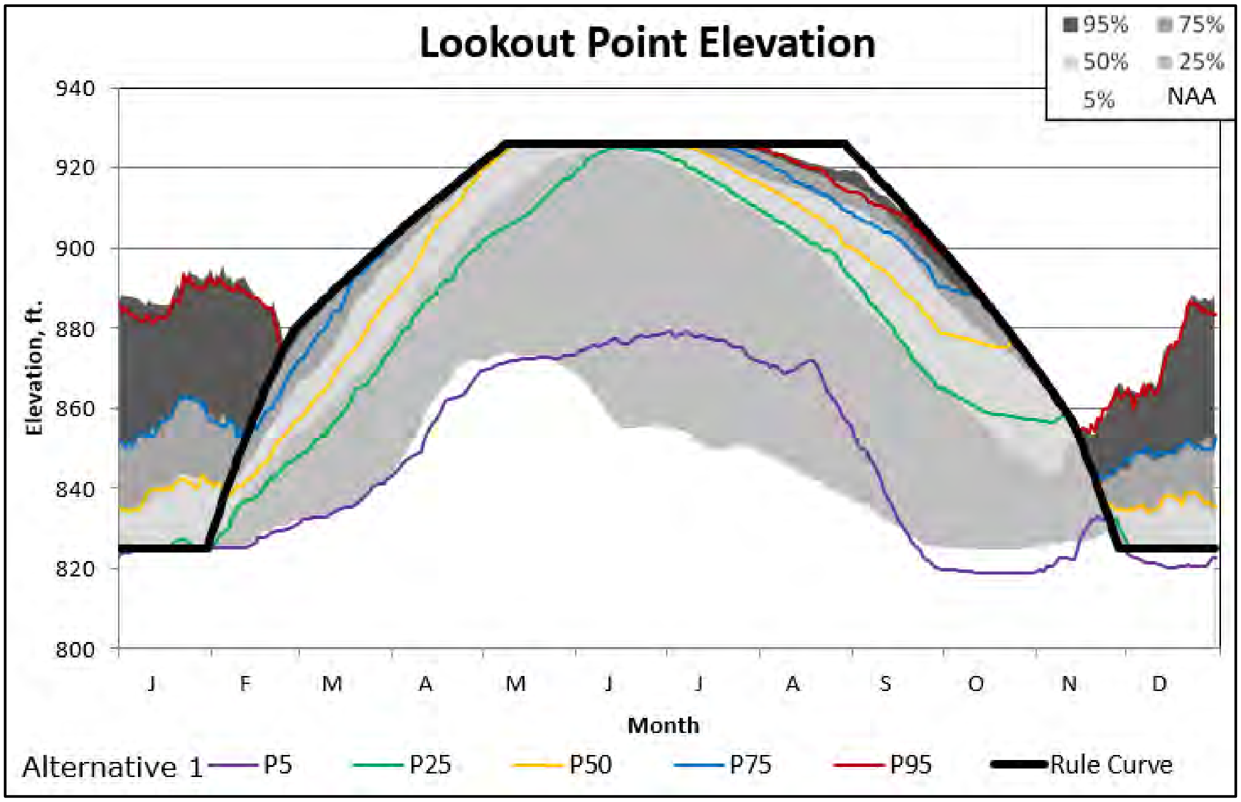

**Figure 3.2-46. Alternative 1 Lookout Point water surface elevation non-exceedance compared with NAA**

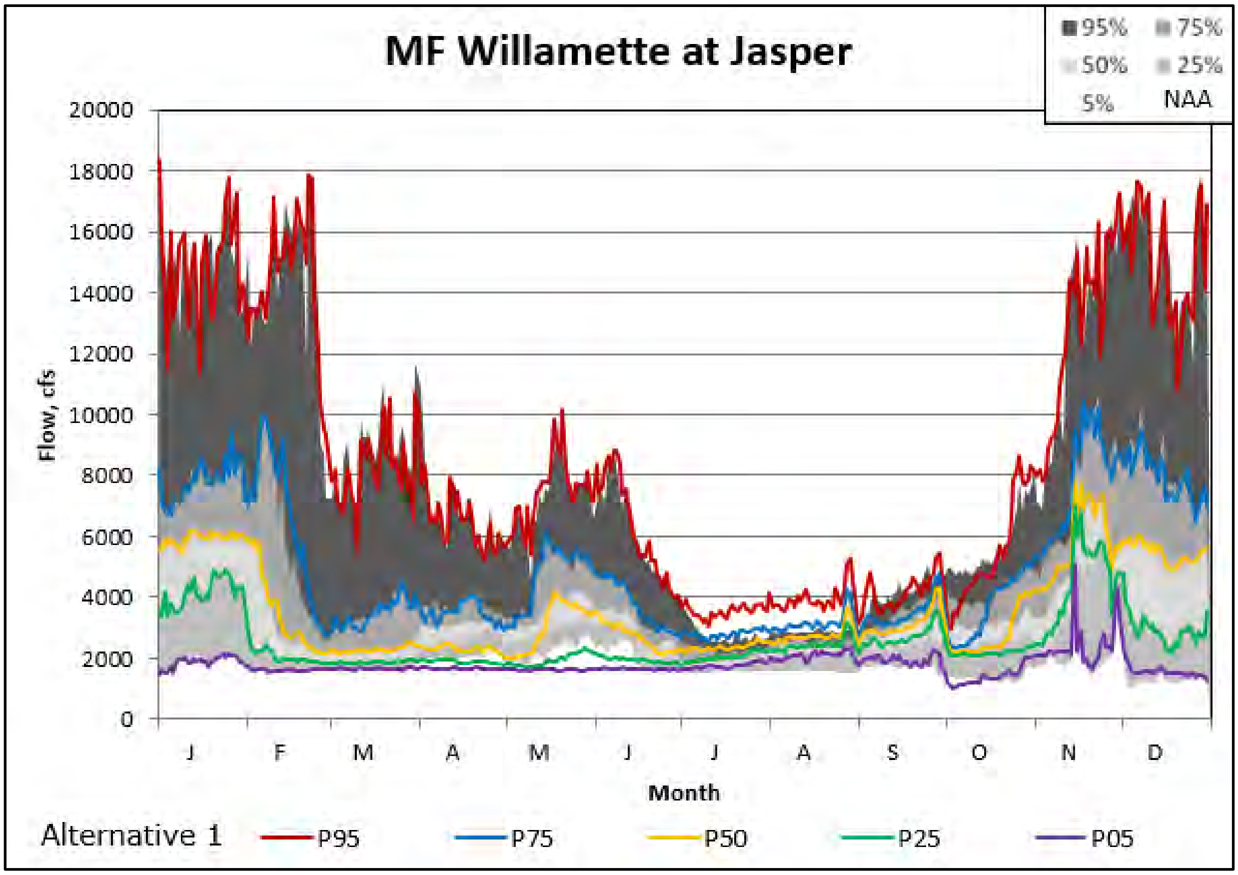

**Figure 3.2-47. Alternative 1 Middle Fork of the Willamette River at Jasper flow non-exceedance compared with NAA**

Fall Creek reservoir elevations (Figure 3.2-48) would be higher and similar for drier and wetter years, respectively, in Alternative 1 as compared to the NAA.

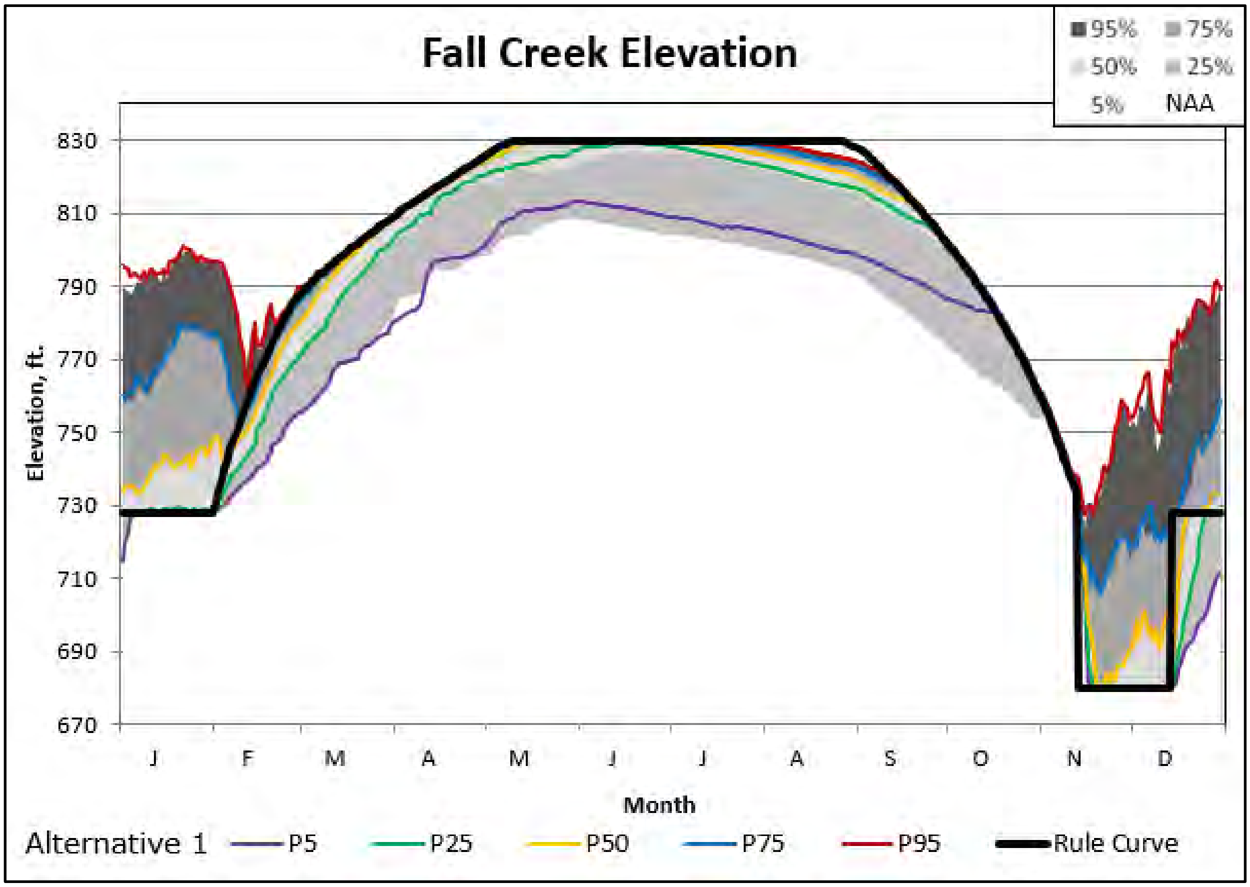

**Figure 3.2-48. Alternative 1 Fall Creek water surface elevation non-exceedance compared with NAA**

### *3.2.2.4.5 Coast Fork of the Willamette Subbasin*

For Alternative 1, the Coast Fork subbasin would also store more water in the spring and release it during the summer and fall during dry years and would be generally similar to the NAA in wet years. Reservoir elevations would be higher at both Dorena (Figure 3.2-49) and Cottage Grove (Figure 3.2-50) for Alternative 1, except in November and December of the driest years when the reservoirs would be augment instream flows by using the inactive pool. Figure 3.2-51 shows the control point at Goshen. Since the pools would stay higher throughout the summer, more water would be released during September and October compared to the NAA.

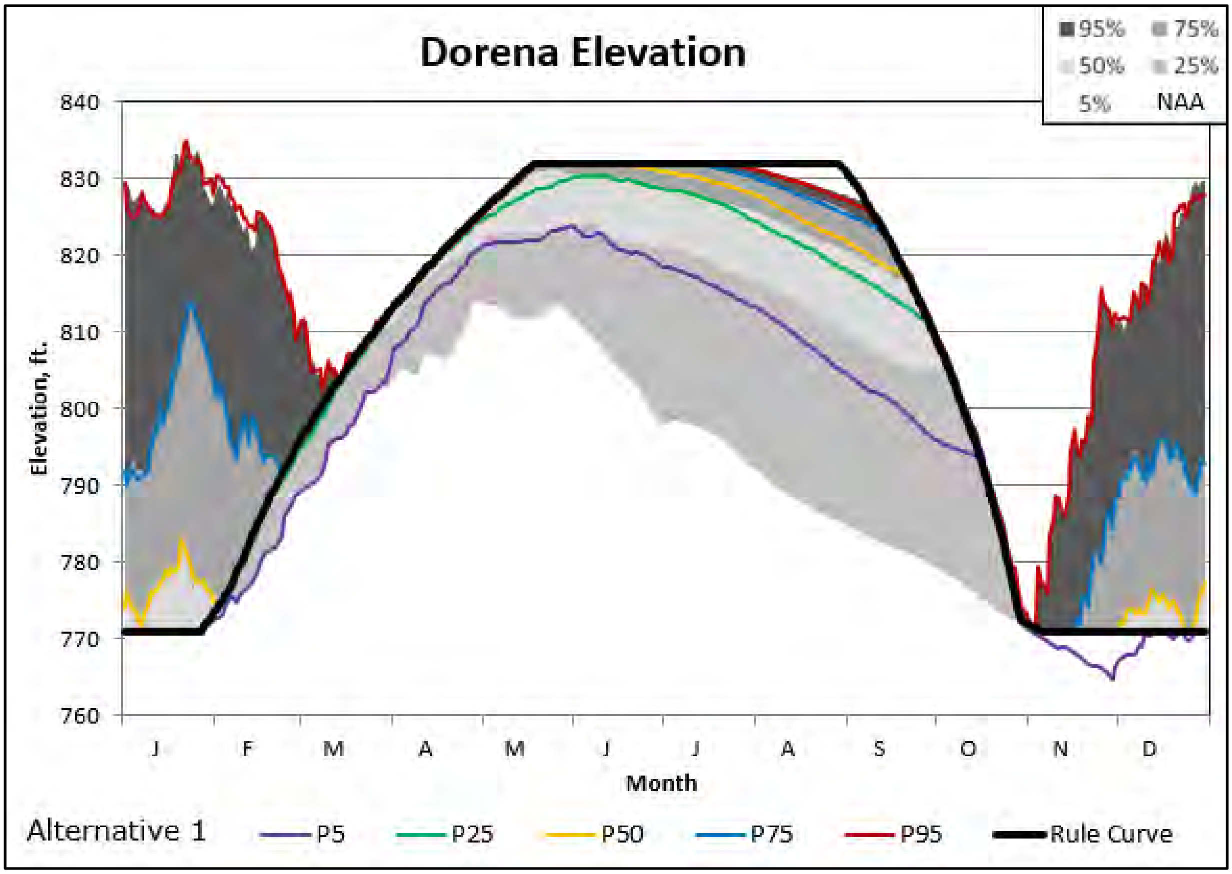

**Figure 3.2-49. Alternative 1 Dorena water surface elevation non-exceedance compared with NAA**

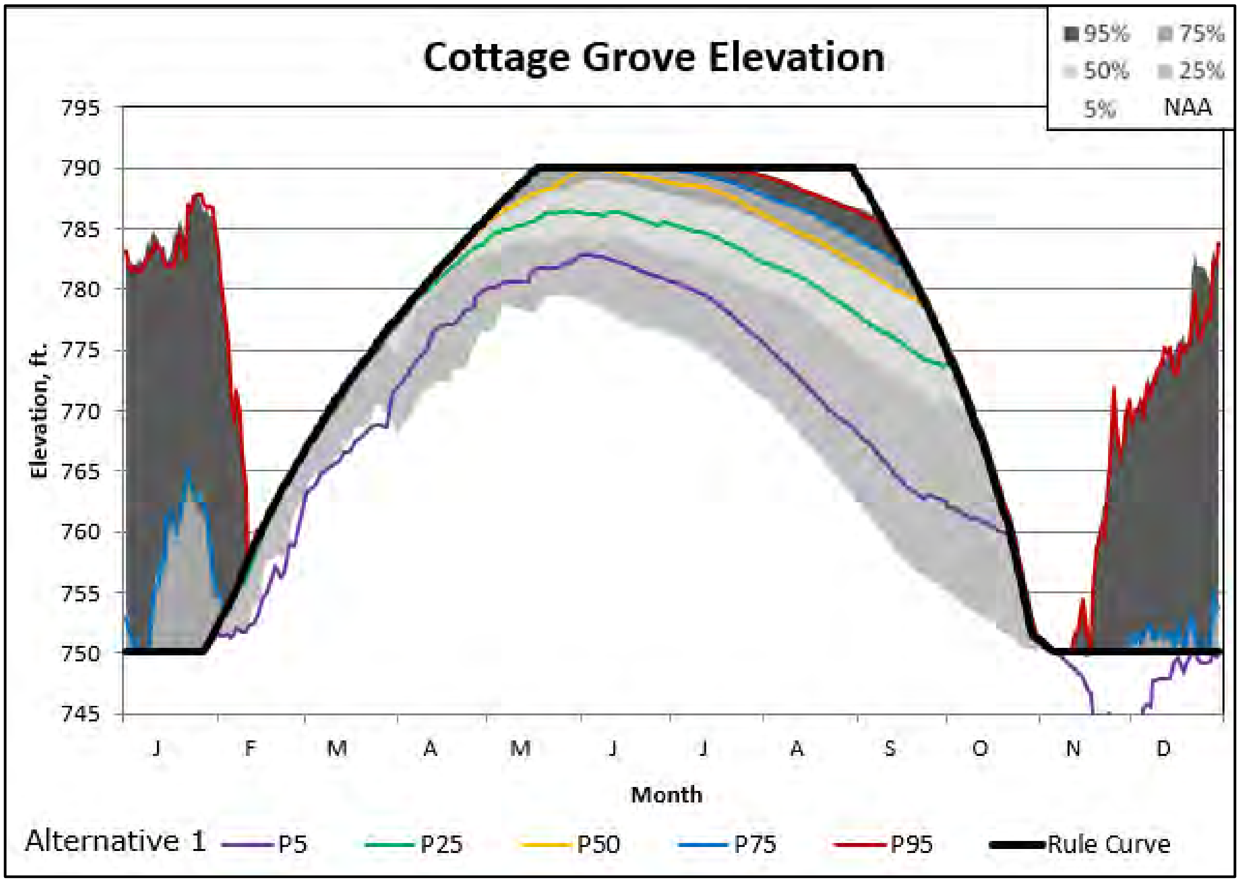

**Figure 3.2-50. Alternative 1 Cottage Grove water surface elevation non-exceedance compared with NAA**

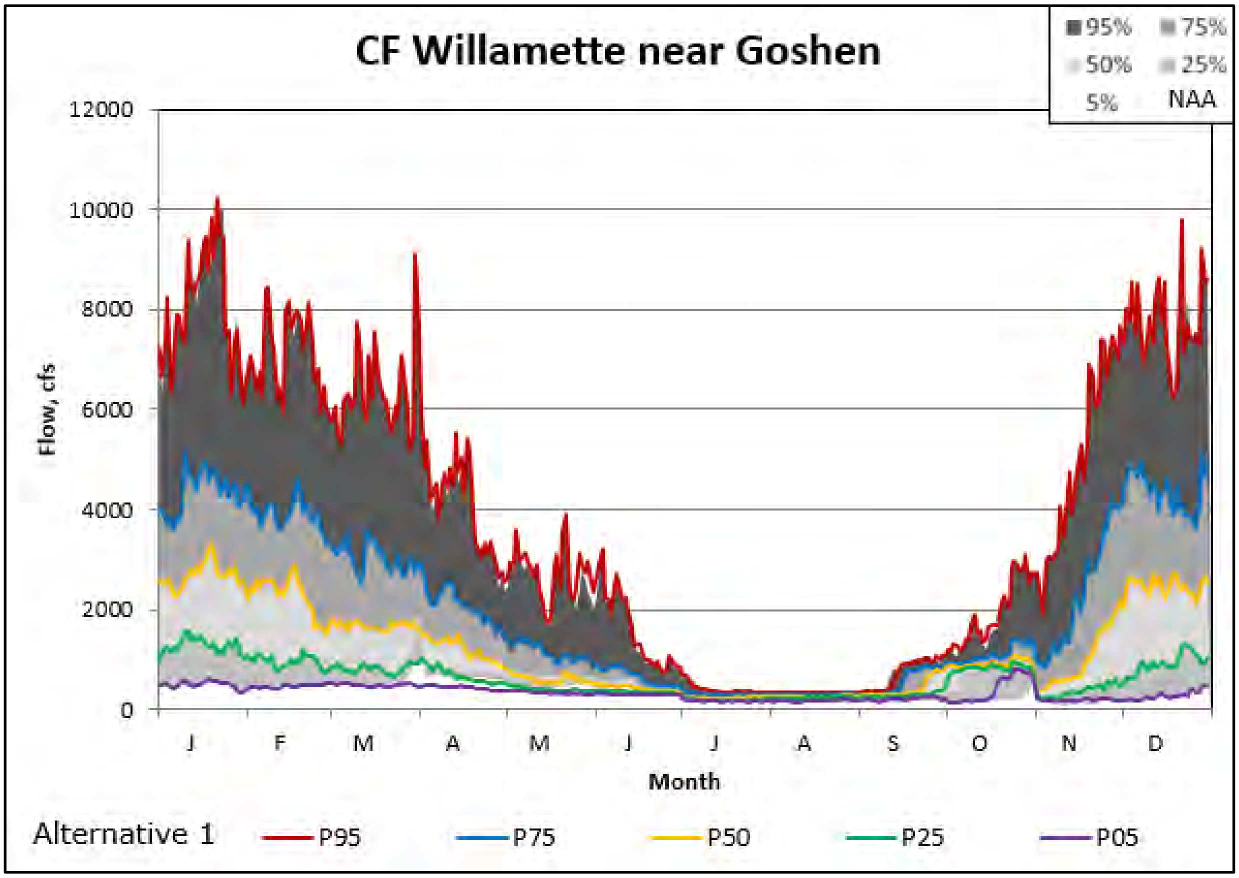

**Figure 3.2-51. Alternative 1 Middle Fork of the Willamette River at Goshen flow non-exceedance compared with NAA**

### *3.2.2.4.6 Mainstem Willamette River*

Alternative 1 would alter the regulated hydrology of the mainstem Willamette River control points during the drier years through the reducing minimum flows to the Congressionally authorized minimum flows. Since higher flows would be generally above these minimums as a matter of course, there would be limited impact to the average and wet years. The P05 and P25 lines would be well below their NAA counterparts from April to June at both Albany and Salem (Figures 3.2-52 and 3.2-53, respectively), with the Congressionally authorized minimum flows lower than the NAA BiOp targets at Salem much more frequently. During dry years, the summer and fall flows would be above the NAA BiOp targets until the driest Octobers, when the Middle Fork reservoirs would exhaust their stored water. The Congressionally authorized minimum flows in Alternative 1 have a lower total volume than the baseline BiOp requirements from the NAA but are not flexible based on expected annual water supply.

Increased flows during the wettest summers, the P95 line, would be due to the reservoirs filling earlier in the year and passing more inflow while at the top of the rule curve compared to the NAA.

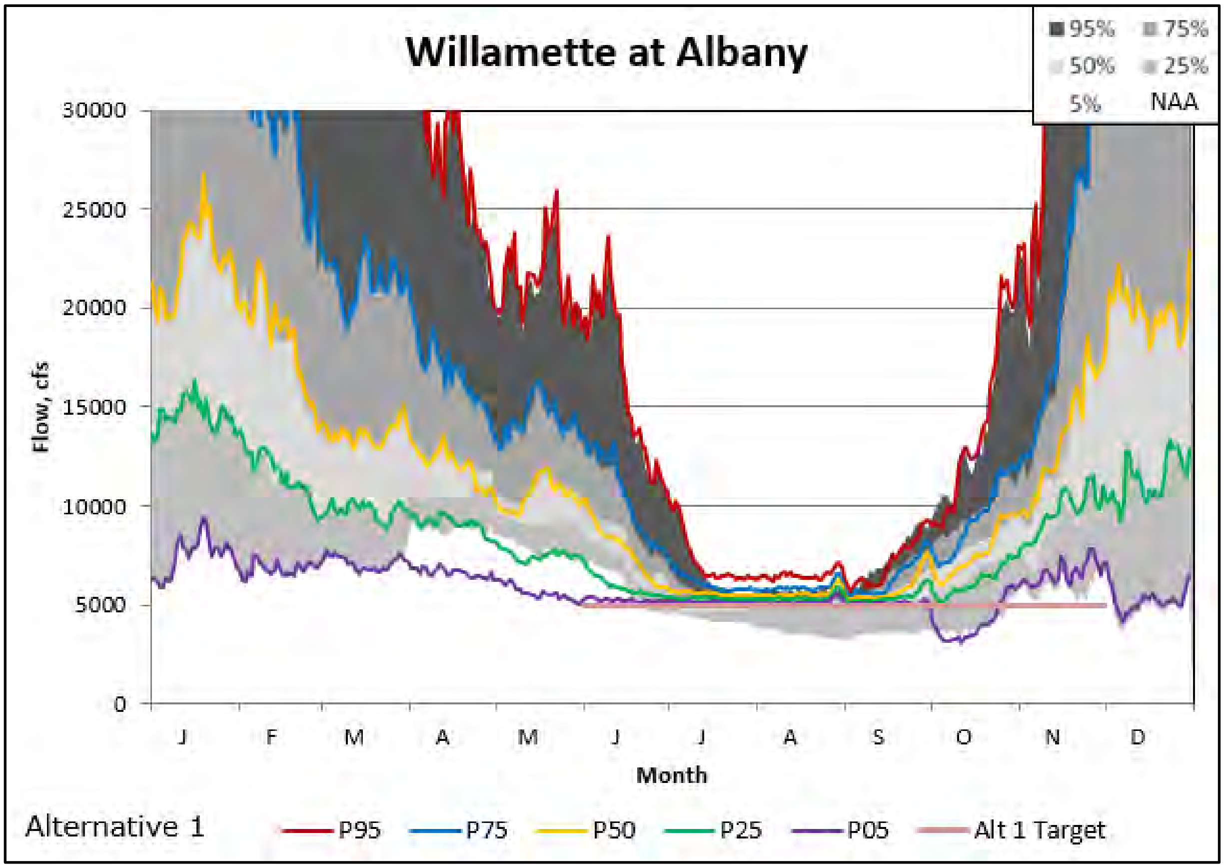

**Figure 3.2-52. Alternative 1 Willamette River at Albany flow non-exceedance compared with NAA**

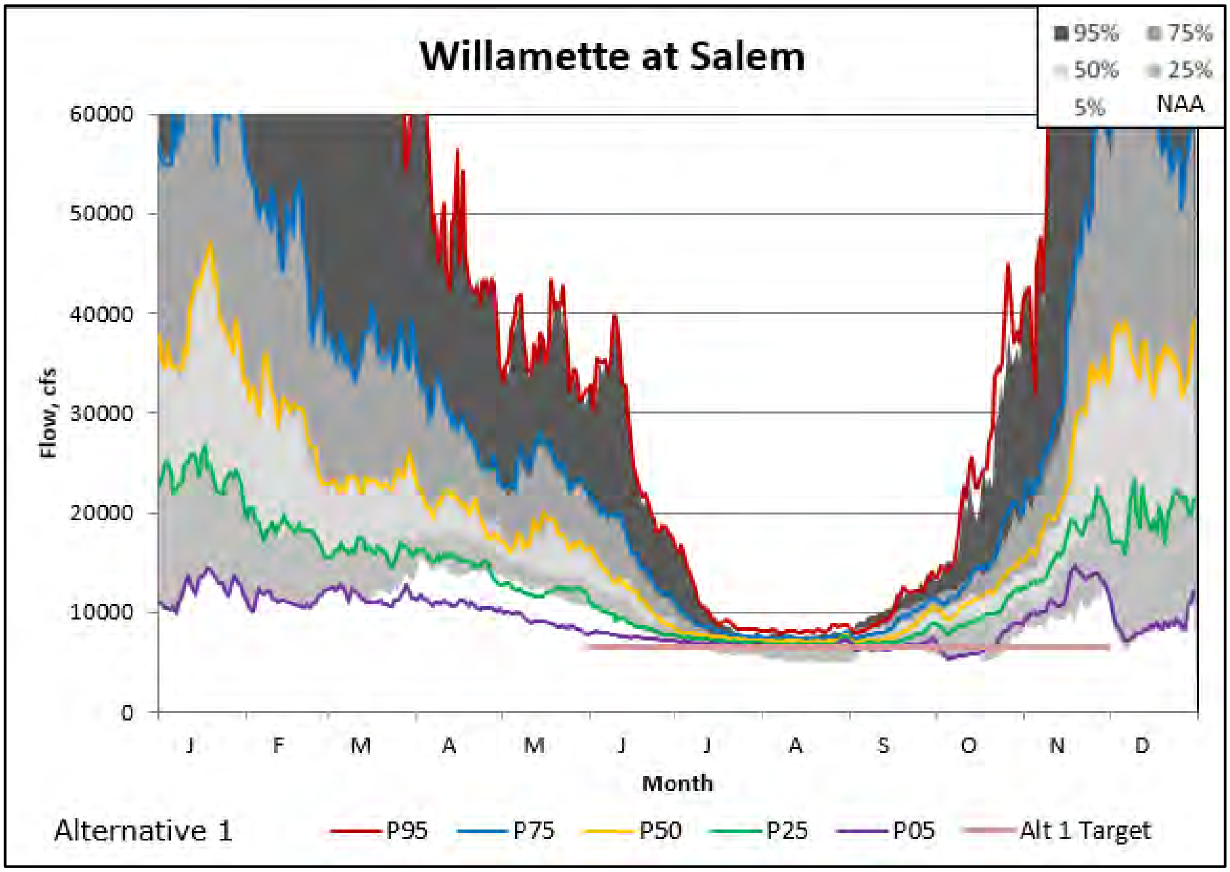

**Figure 3.2-53. Alternative 1 Willamette River at Salem flow non-exceedance compared with NAA**

### *3.2.2.4.7 Climate Change*

The WVS will likely experience increasing wintertime flow volumes in the future. Some flood magnification (increased severity during flood season) is also likely. Because the WVS system storage will remain about the same, it's likely that FRM operations will face future challenges. An upward shift in median future project inflows may increase both the average reservoir water surface elevation as well as outflows downstream of the WVS dams. Reservoirs located within higher elevation subbasins, such as Detroit and Cougar, are likely to see higher rainfall and runoff volumes in the winter. Higher projected temperatures in the future would mean less snowpack than currently experienced. Lower snowpack would also reduce spring volume as the snow melts. Lower elevation subbasin projects such as Fern Ridge and Cottage Grove, with little or no snowpack, are projected to experience higher wintertime flow volumes, but similar peak runoff timing compared to historical baselines.

Since the Congressionally authorized minimum flows are lower, the reservoirs can store more water during conservation season as compared to the NAA. However, reservoirs will have to use more of this stored water to meet downstream flow targets with projected increased variability in the spring shoulder months, drier hotter summers, and lower summer baseflow. Therefore, reservoirs are projected to have lower water surface elevations compared to the baseline. Most reservoirs in Alternative 1 baseline only rarely reach minimum elevation in the fall, meaning they have additional water to continue to augment downstream flows as compared to the NAA. As projected late spring, summer, and fall flows decrease in the future, the WVS could supply more of the additional stored water to augment stream flows. The lowest reservoir water surface elevations will occur in the driest years, which would be drier than the WVS currently encounters, as the reservoirs are drafted more to meet downstream flow targets. Climate change effects, and potential implications as discussed above, draw on the climate change projection and trend information provided in the climate change appendices.

#### *3.2.2.5 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Alternative 2A would shift the release of stored water from the spring to the summer and fall, most prominently in dry years. The "Integrated Temperature and Habitat Flow Regime" would replace the 2008 NMFS BiOp in the NAA. Briefly, this would modify the base flow targets at a WVS reservoir if it is at more or less than 90 percent of rule curve elevation. Flows would be reduced within a range down to minimums needed for fish survival when reservoirs are under the 90 percent threshold. While these minimums would be less the BiOp targets in the NAA, these would be adaptive within a water year and could return to levels that are actually higher than the BiOp flows if reservoir levels are high.

At the mainstem Willamette control points – Albany and Salem – flow targets would be reduced to 4,500 and 5,000 cfs, respectively. The higher BiOp targets, particularly in the spring and early summer, are designed to help migrating fish and keep the river from getting too hot, so substantially more water would be added in the spring. As a replacement, the integrated temperature and habitat flow regime would require additional flow based on the air temperature, with total flow minimum at Salem ranging from 5,900 cfs to 19,800 cfs. This would allow the WVS to store additional water when it is not needed to keep the river, and the fish in the river, cool.

Alternative 2A would alter storage in drier than average years, and especially the 25 and 5 percent non-exceedance (P25 and P05 in the figures) years, shifting flow releases from April to June into July through October. This would result in lower flows than the NAA earlier in the year during the April to June period. Flows later in the summer and fall, from July to October, would be higher than the NAA due to the additional accumulated stored water. Compared to the NAA, the flow targets would be similar or somewhat lower across the WVS, so reservoir elevations would be somewhat higher than the NAA.

Green Peter reservoir would have a deeper fall reservoir drawdown in Alternative 2A and the model shows the consequences of it at all downstream control points. Specifically, the deeper fall reservoir drawdown means there would be more flow in the late summer and early fall in the South Santiam, Santiam, and Willamette downstream of the confluence with the Santiam. Refilling the reservoir to minimum conservation pool would also reduce downstream flows by a relatively small amount through about the middle of January in a typical year compared to the NAA.

USACE would construct structural downstream fish passage in Cougar reservoir in Alternative 2A and therefore the spring and fall reservoir drawdowns would not be as deep in Alternative 2B (and Alternative 3B). The maintenance of storage at Cougar would mean that it can supply water downstream similar to the NAA (or Alternatives 1 and 4). Other reservoirs, most notably in the Middle Fork of the Willamette subbasin, would also maintain higher water surface elevations without the need for additional releases to meet downstream flow targets. The WVS would also meet the mainstem Willamette River flow targets more often with higher Cougar storage levels, as compared to the NAA.

Although there are structural actions in Alternative 2A at the WVS dams to aid fish survival, many of these would not affect the flow out of any WVS dam. These would not appear in the reservoir flow model. An example of this is the WTC tower at Detroit, which would allow for greater control of the temperature of the water released from the dam but would not alter the flowrate or outlet used for dam operations. A more detailed analysis of Alternative 2A by subbasin follows.

Lower spring flows in dry years and higher summer flows in nearly all years would have long term effects across the WRB. Effects from Alternative 2A to hydrologic processes: Major compared to the NAA.

#### *3.2.2.5.1 Santiam Subbasin*

Alternative 2A would fill Detroit reservoir more often and narrow the range of reservoir elevations prior to drafting the reservoir for flood season (Figure 3.2-54). The lowest minimum flow of the integrated temperature and habitat flow regime would be smaller downstream of Detroit so the reservoir would be able to fill more often. These lower flow requirements would only apply when the reservoir is below 90 percent full, so would only come into use during drier years. During wetter years, storage would be near the rule curve regardless of the higher flow requirements downstream. Detroit has more volume to supply to downstream targets later in the year, meeting all its immediate downstream flow targets across all years compared to the NAA.

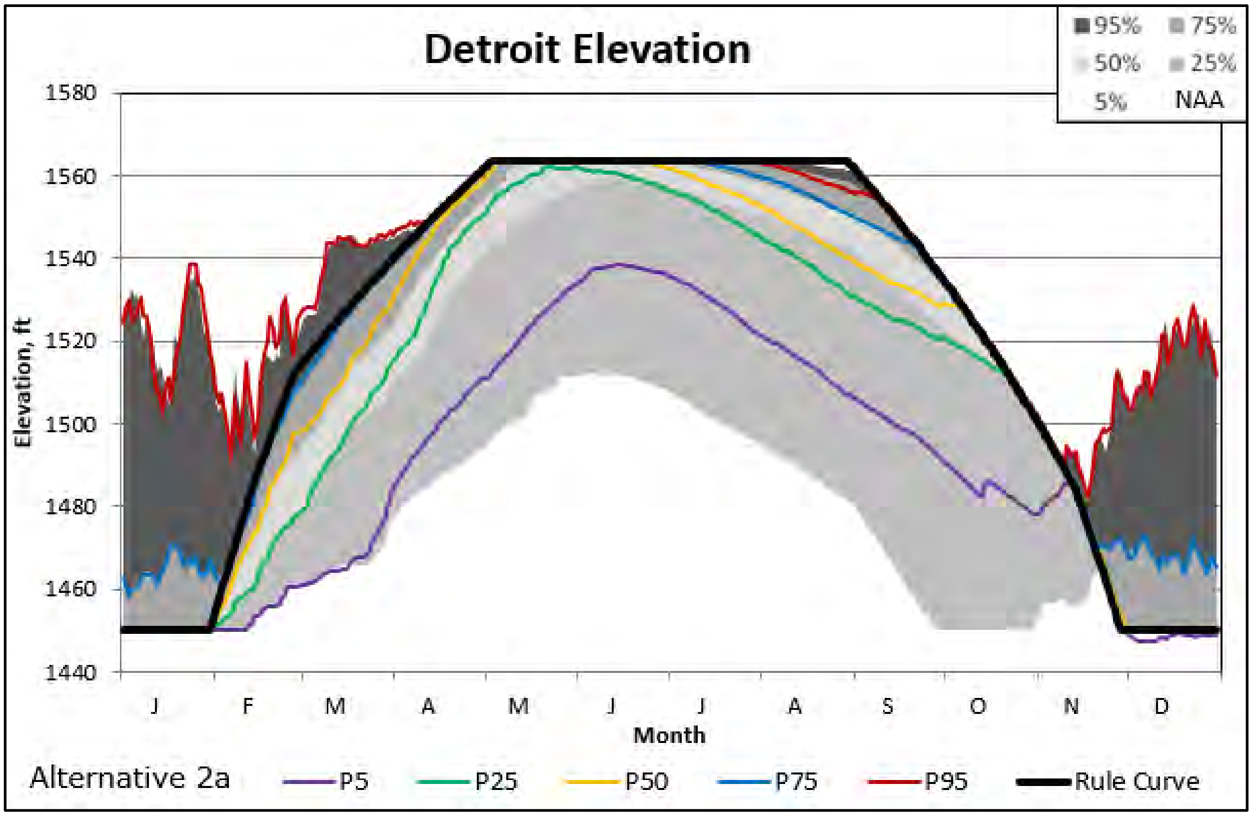

**Figure 3.2-54. Alternative 2A Detroit water surface elevation non-exceedance compared with NAA**

Green Peter reservoir (Figure 3.2-55) would also fill more often during conservation season in Alternative 2A as compared to the NAA, despite implementation of a deeper fall reservoir drawdown. In very dry years, the reservoir elevation would be well below the rule curve through the winter but it would recover to higher levels than the NAA by summer due to the lower integrated temperature and habitat flow regime targets. However, the percentage of time that Green Peter reaches top of conservation storage would remain about the same since all inflow above that level would be released from the reservoir. Lower reservoir levels would be expected throughout the winter flood season, even during the wettest years.

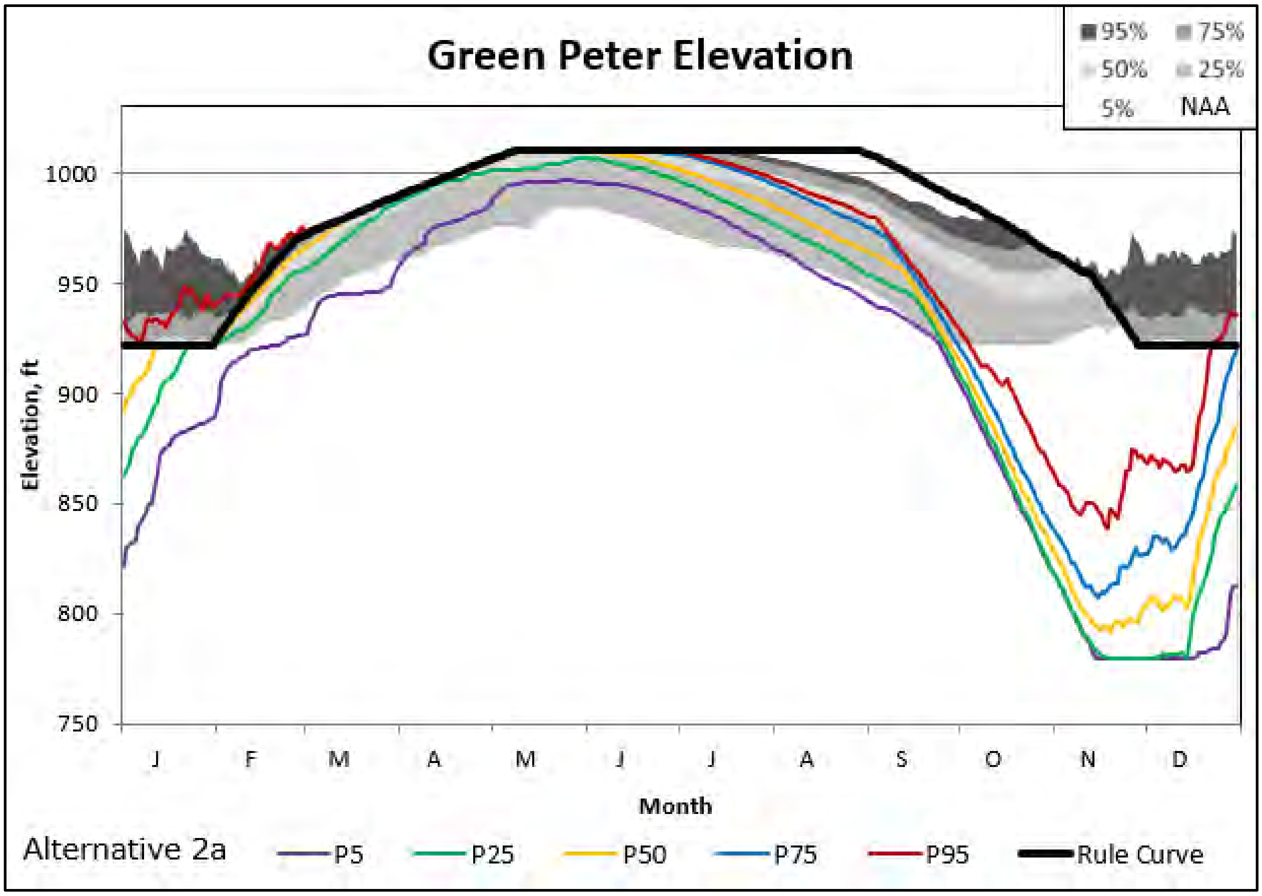

**Figure 3.2-55. Alternative 2A Green Peter water surface elevation non-exceedance compared with NAA**

Outflow from Foster Dam (Figure 3.2-56) would meet the integrated temperature and habitat flow regime targets except in November of very dry years when Green Peter would have already reached the minimum deeper fall reservoir drawdown elevation. The increased flows in September are the result of Green Peter releasing water for the deeper fall reservoir drawdown which does not occur under the NAA. Immediately downstream, winter flows across all but very wet years would be lower. This is also due the Green Peter deeper fall reservoir drawdown, as it holds back water to get back up to minimum conservation pool. Foster Reservoir would seldom deviate from the rule curve for Alternative 2A.

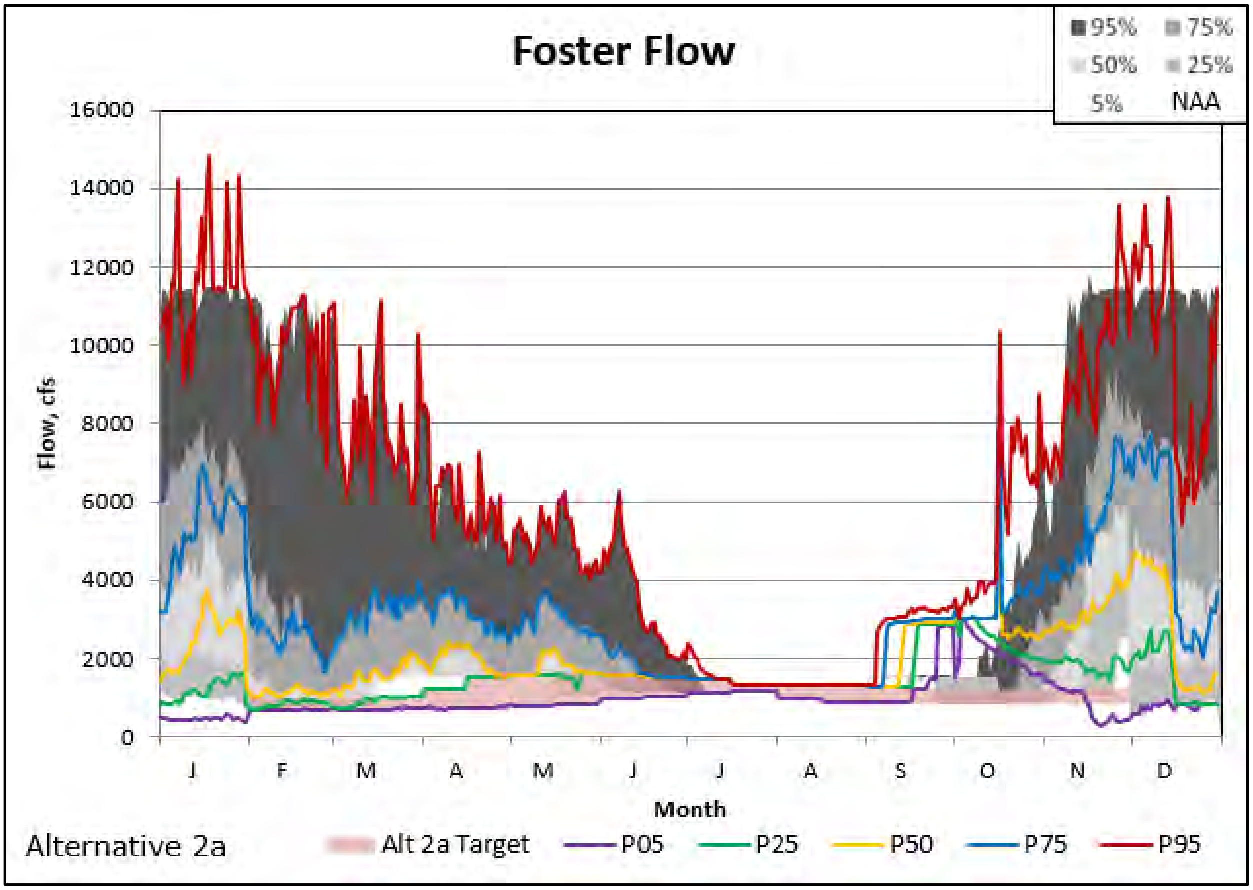

**Figure 3.2-56. Alternative 2A Foster flow non-exceedance compared with NAA**

The Santiam at Jefferson (Figure 3.2-57) would show some of the flow changes at Foster but any potential winter flood management benefits from the deeper fall reservoir drawdown at Green Peter would no longer present. Wet weather flows would be very similar to the NAA during the winter and lower flows are only slightly lower, though these flows would already be well below flood stage. In the spring, lower flows in the driest years would be due to the lower requirements of the integrated temperature and habitat flow regime, both directly downstream of the dams and mainstem flow targets. Detroit, with its higher storage volumes, can supply water throughout the summer, resulting in higher flows than the NAA. The increased flows in September from the Green Peter deeper fall reservoir drawdown would be evident at Jefferson.

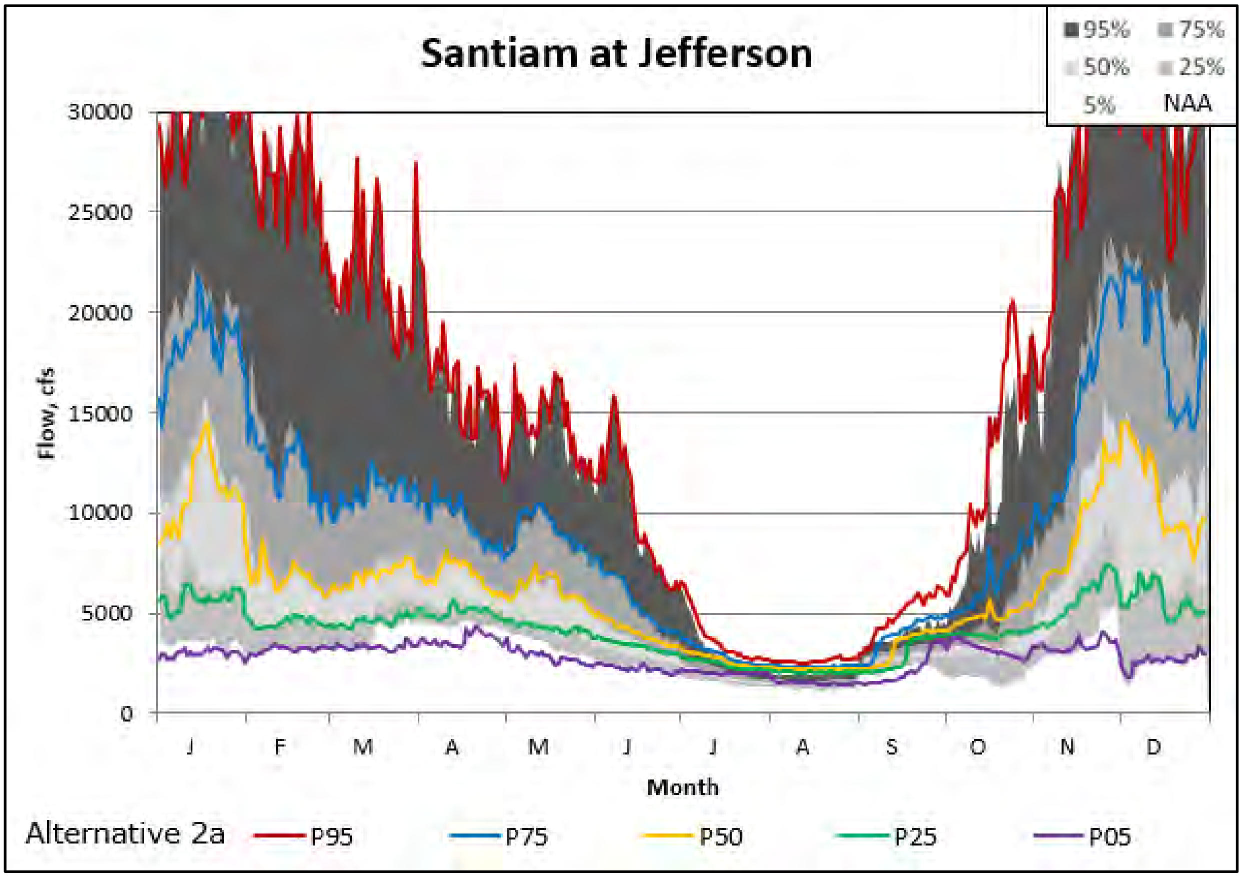

**Figure 3.2-57. Alternative 2A Santiam at Jefferson flow non-exceedance compared with NAA**

### *3.2.2.5.2 Long Tom Subbasin*

As explained in the NAA, Fern Ridge reservoir (Figure 3.2-58) is prioritized for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. Since Fern Ridge has a large surface area and small volume compared to the other WVS reservoirs, there is limited scope to change its operation and the water surface elevations within Fern Ridge remain nearly the same as the NAA. Downstream flows at Monroe would remain similarly unchanged for Alternative 2A.

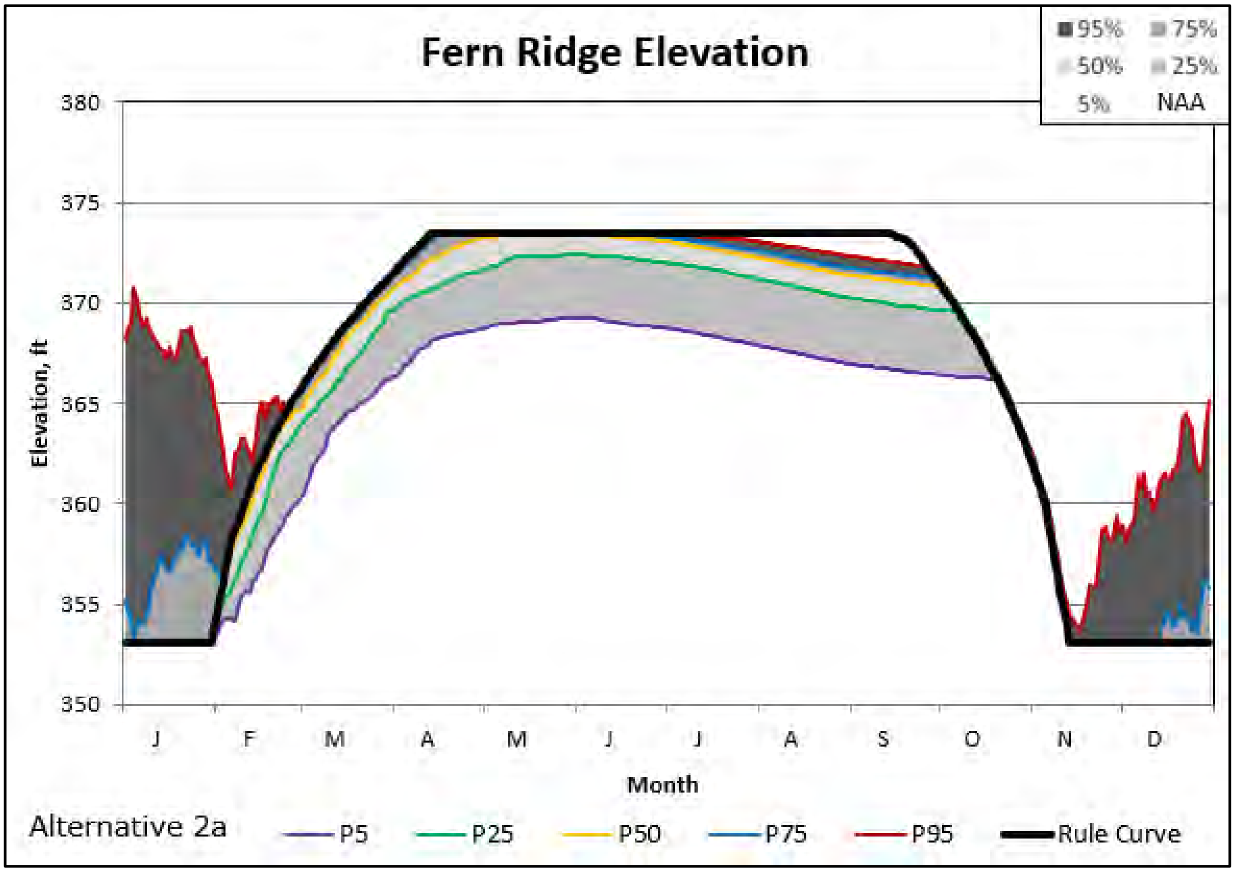

**Figure 3.2-58. Alternative 2A Fern Ridge water surface elevation non-exceedance compared with NAA**

### *3.2.2.5.3 McKenzie Subbasin*

Cougar reservoir (Figure 3.2-59) would fill more often in Alternative 2A and would stay higher in conservation season except in the driest years (P05 line) compared to the NAA. The additional allowance to augment instream flows by using the power pool below minimum conservation storage elevation means that Cougar would be able to meet its integrated temperature and habitat flow regime target directly downstream of the dam even in those driest years.

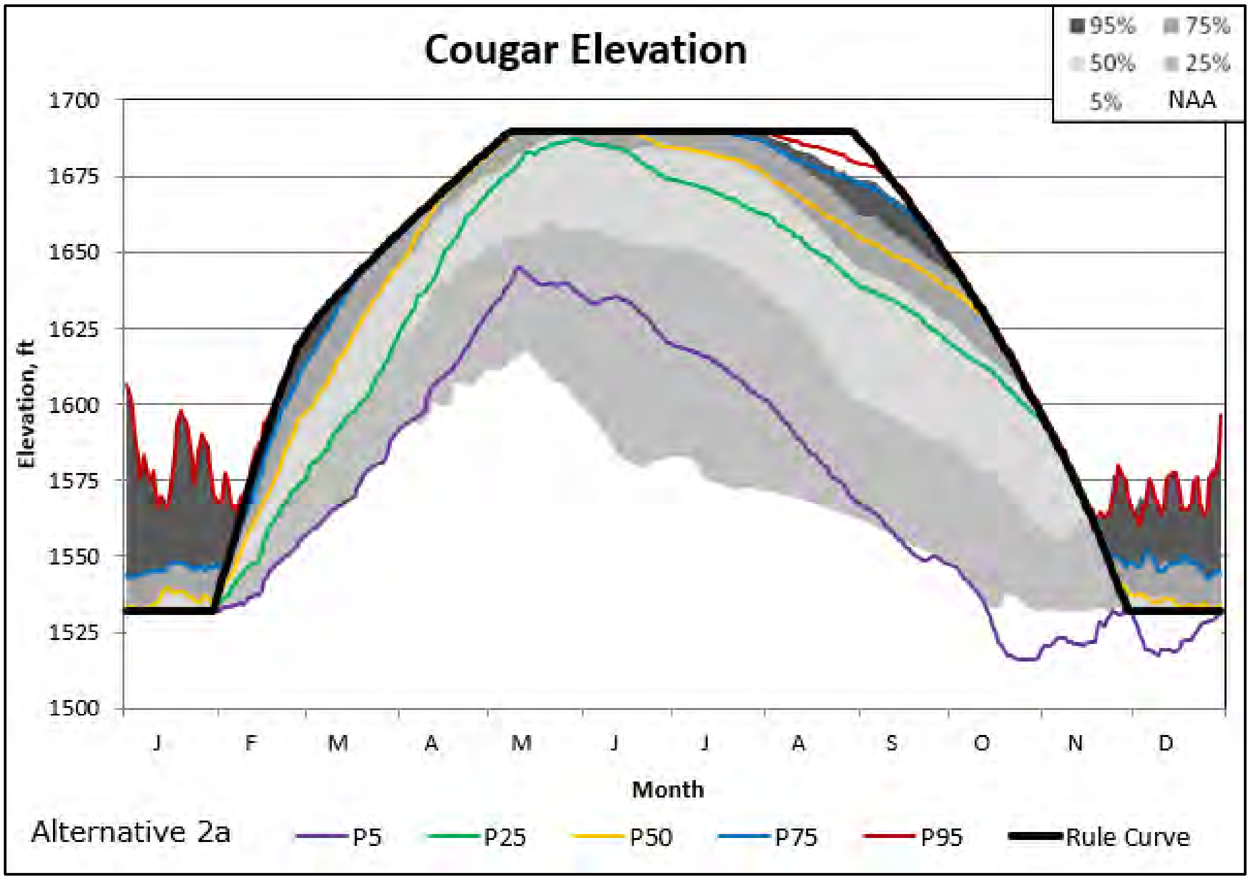

**Figure 3.2-59. Alternative 2A Cougar water surface elevation non-exceedance compared with NAA**

Blue River reservoir (Figure 3.2-60) would also fill more often as compared to the NAA and would augment instream flows by using the inactive pool only after reaching its minimum conservation storage elevation. Moving downstream to the control point for both Cougar and Blue River, the McKenzie River at Vida (Figure 3.2-61) would show the effect of the lower downstream integrated temperature and habitat flow regime targets during spring of dry years. The driest years (P05 line) would be below the NAA from March to June, but above the NAA from July to October. Summer flow would be less variable in the summer across all years and winter flow would remain the same as the NAA.

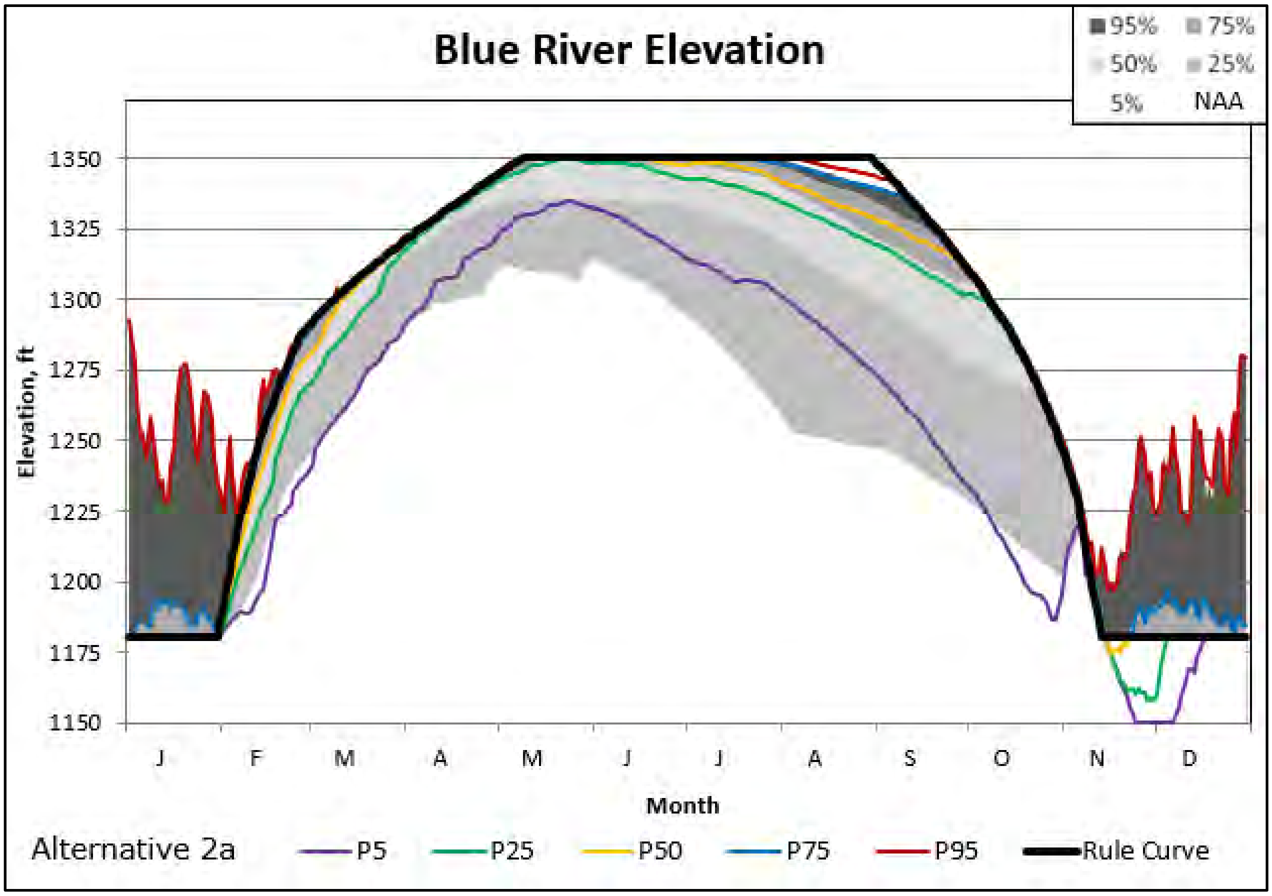

**Figure 3.2-60. Alternative 2A Blue River water surface elevation non-exceedance compared with NAA**

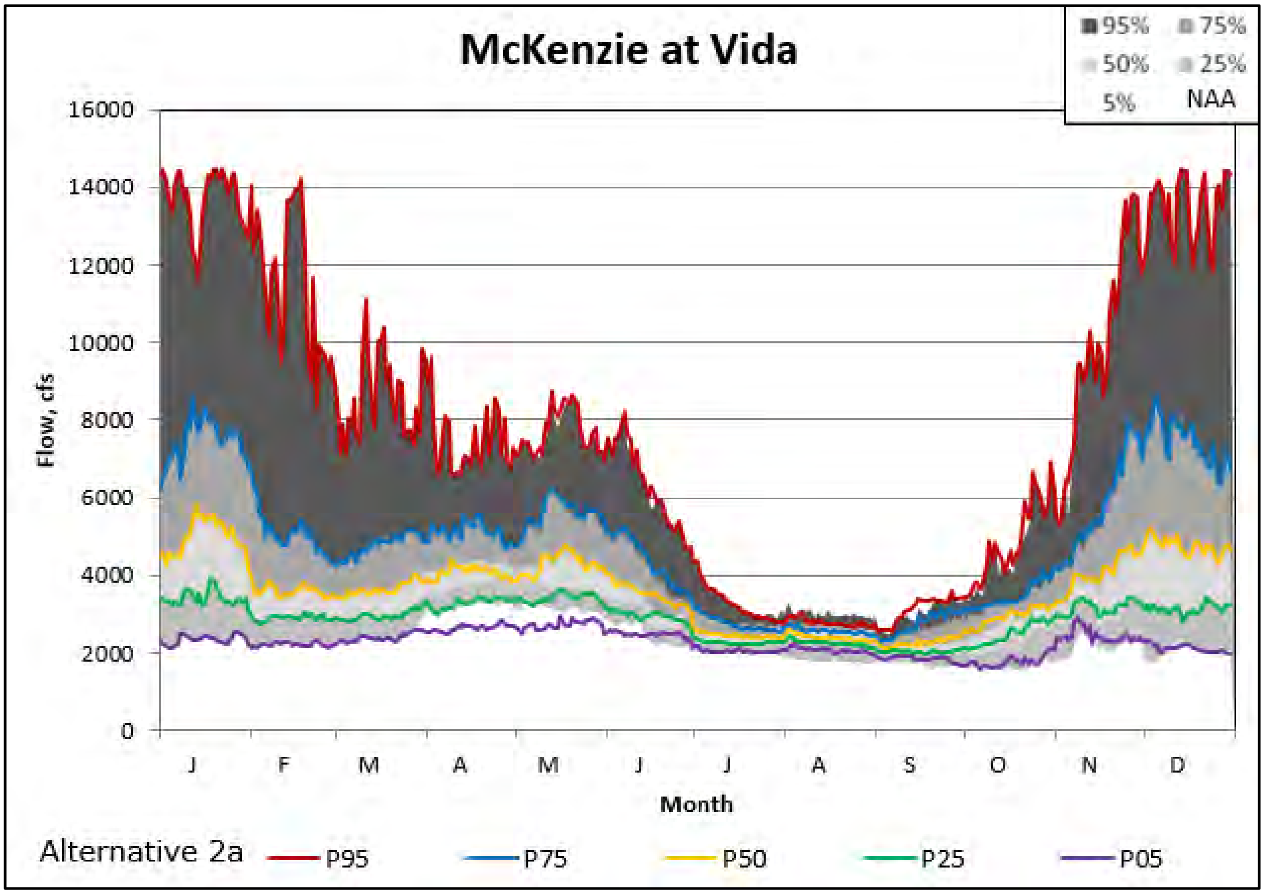

**Figure 3.2-61. Alternative 2A McKenzie River at Vida flow non-exceedance compared with NAA**

### *3.2.2.5.4 Middle Fork of the Willamette Subbasin*

Hills Creek (Figure 3.2-62) would initially fill more quickly due to the lower integrated temperature and habitat flow regime targets when the reservoir is less than 90 percent full and would stay at similar or higher elevations during wet year compared to the NAA s. During dry years, the reservoir would augment instream flows by using the power pool, releasing more water to meet the flow target at Albany. Its capacity would be exhausted in the driest years (P05 line), at which point Lookout Point would supply additional water, reaching its Alternative 2A minimum in late October in Figure 3.2-63. Alternative 2A would miss the integrated temperature and habitat flow regime target below Dexter when Lookout Point is at its minimum power pool. As compared to Alternative 2B, storage elevations for both Hills Creek and Lookout Point would be slightly higher across all years compared to the NAA. Since Cougar has much more storage in Alternative 2A, it would be able to contribute more to downstream flow targets, meaning the Middle Fork reservoirs would not have to make up for this deficit.

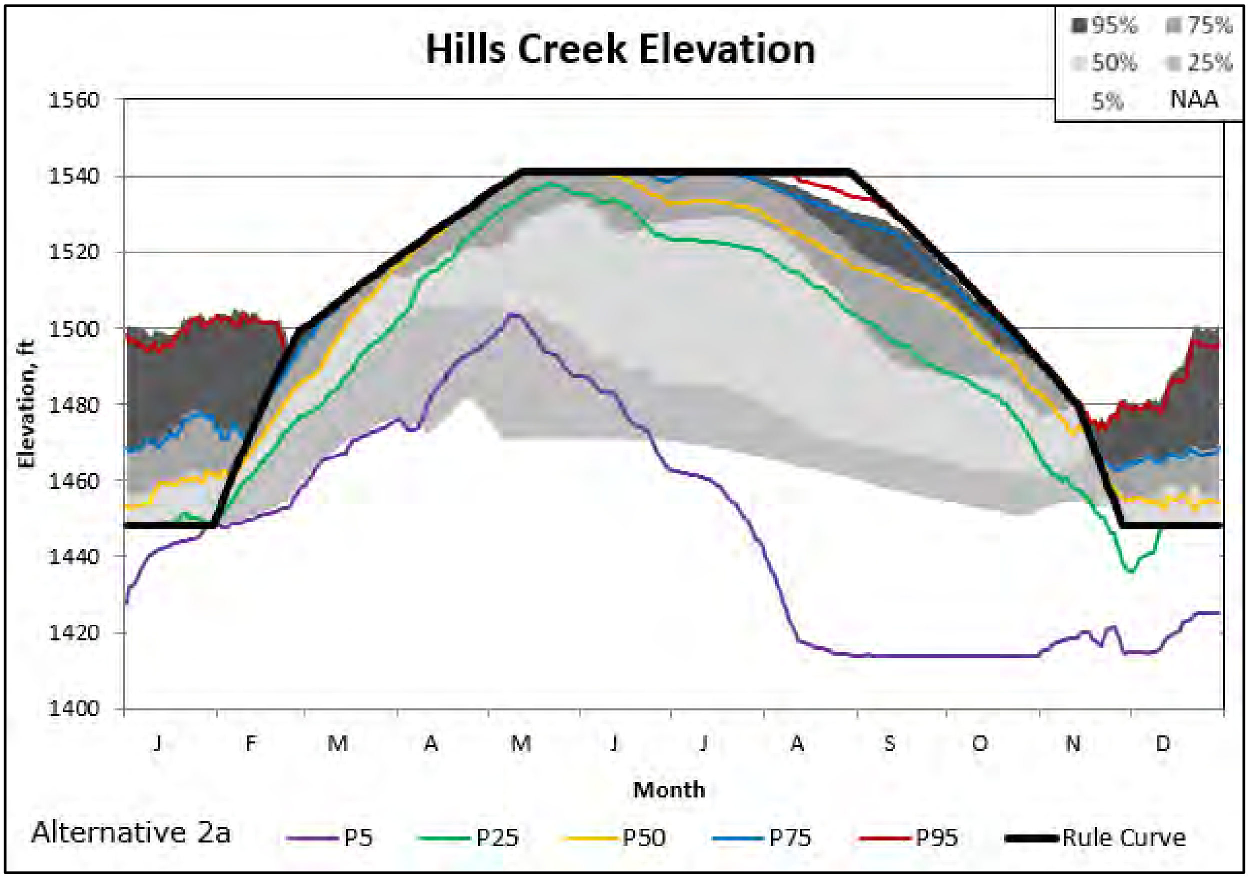

**Figure 3.2-62. Alternative 2A Hills Creek water surface elevation non-exceedance compared with NAA**

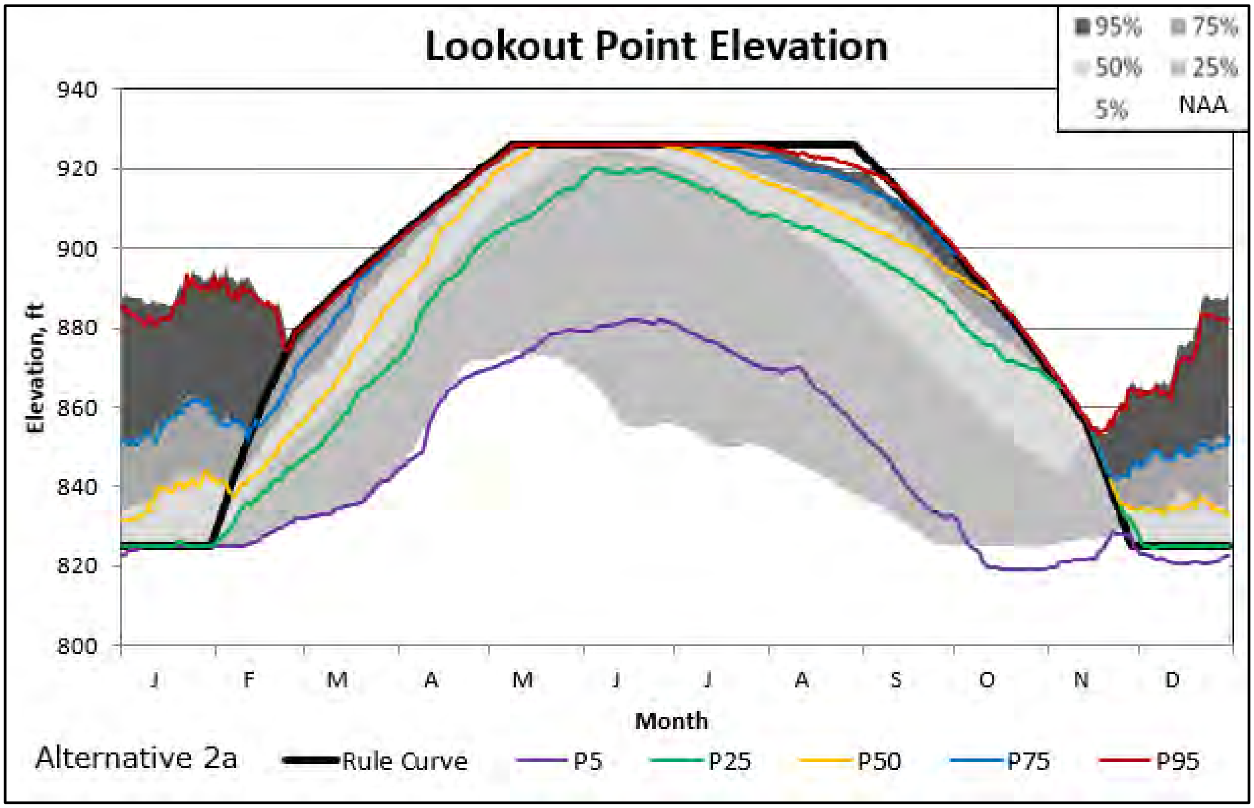

**Figure 3.2-63. Alternative 2A Lookout Point water surface elevation non-exceedance compared with NAA**

Fall Creek reservoir would show only marginal differences from the NAA in Alternative 2A (Figure 3.2-64).

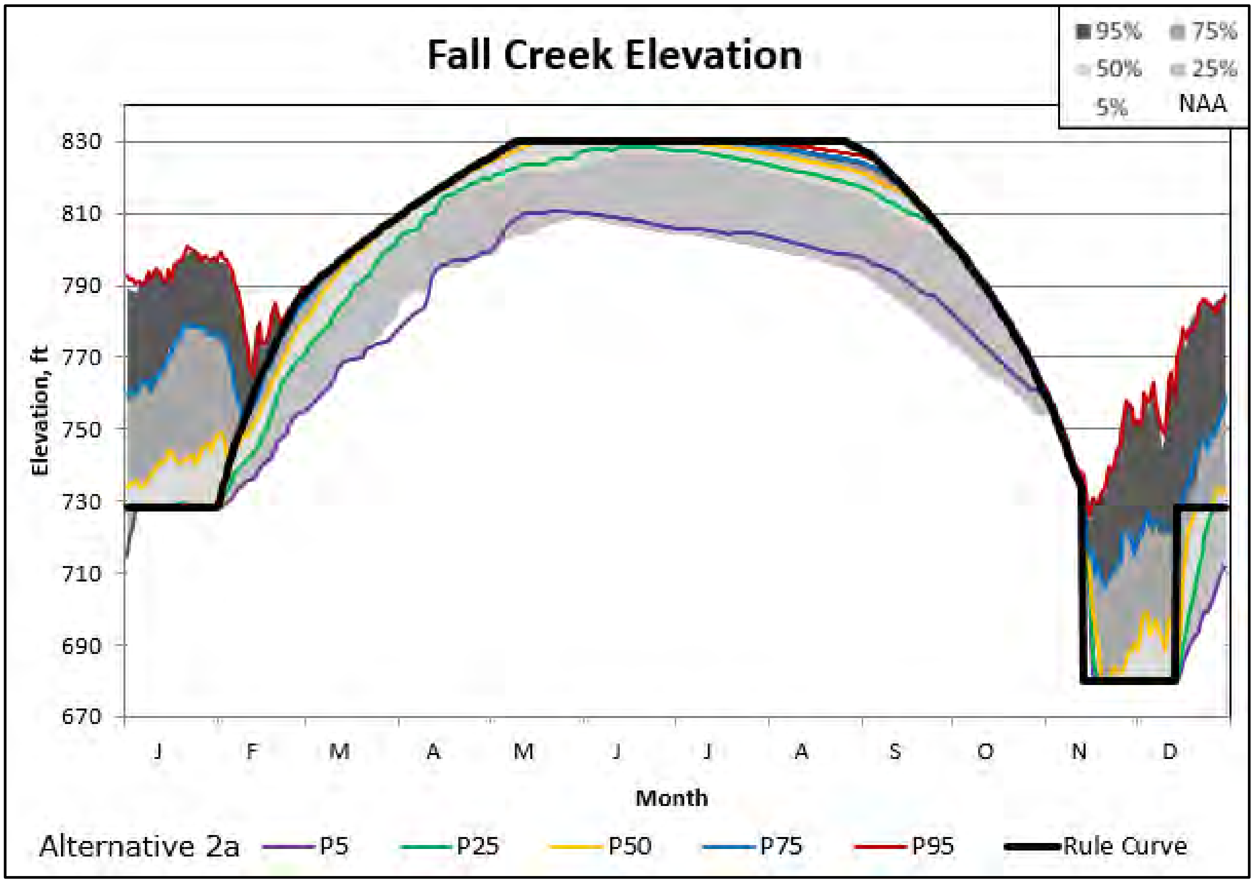

**Figure 3.2-64. Alternative 2A Fall Creek water surface elevation non-exceedance compared with NAA**

At the downstream control point at Jasper (Figure 3.2-65), the shift in release of stored water in dry years would evident, with lower flows in the spring and higher flows in the summer and fall. The increased fall flows during wet years are due to the reservoirs starting at a higher elevation prior to drafting for flood season. There would be more water to release from the reservoirs so there is higher flow downstream of them compared to the NAA.

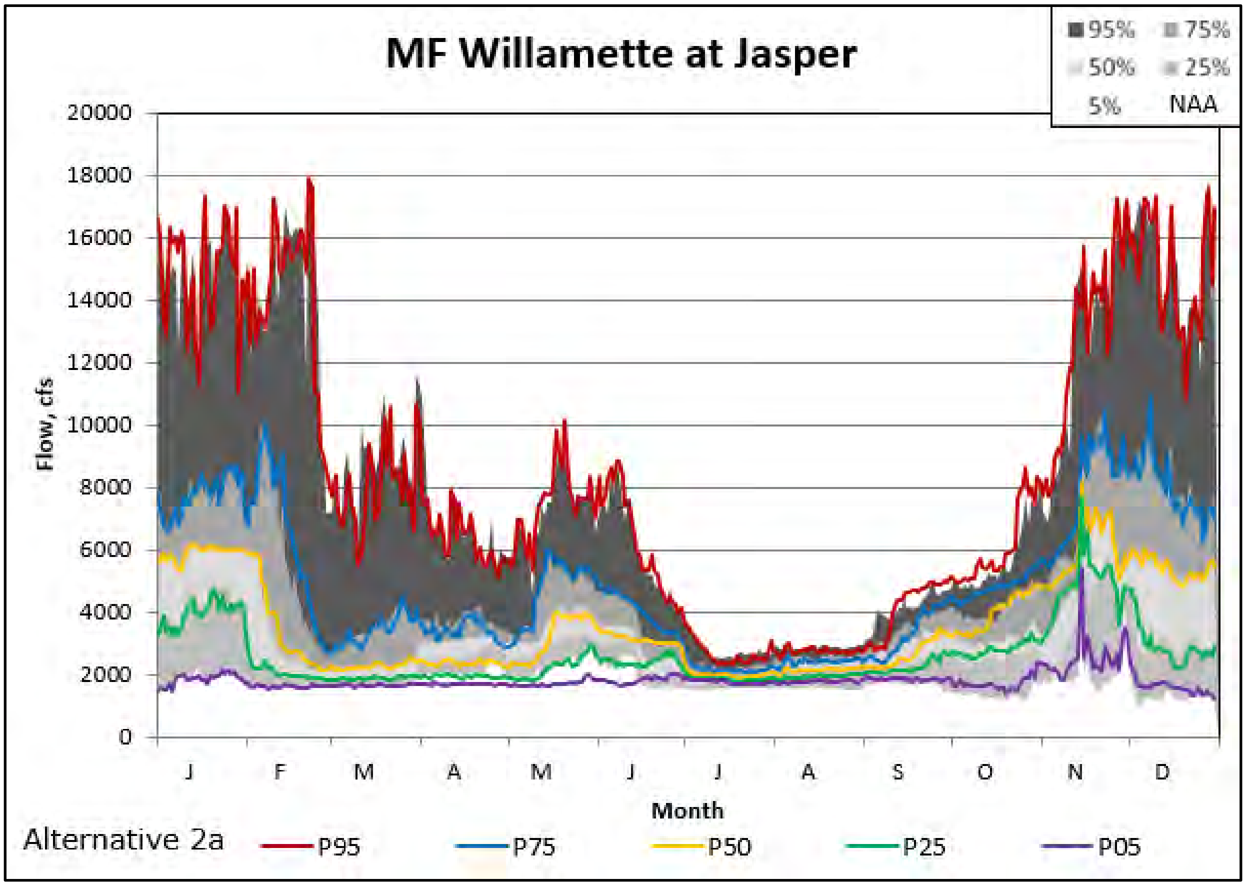

**Figure 3.2-65. Alternative 2A Middle Fork of the Willamette River at Jasper flow non-exceedance compared with NAA**

### *3.2.2.5.5 Coast Fork of the Willamette Subbasin*

For Alternative 2A, the Coast Fork subbasin would also store more water in the spring and release it during the summer and fall during dry years. It is generally similar to the NAA in wet years. Reservoir elevations would be somewhat higher at both Dorena (Figure 3.2-66) and Cottage Grove for Alternative 2A during the late spring and summer, with other times similar to the NAA. Figure 3.2-67 shows the control point at Goshen. Since the pools stay higher throughout the summer, more water would be released during September and October.

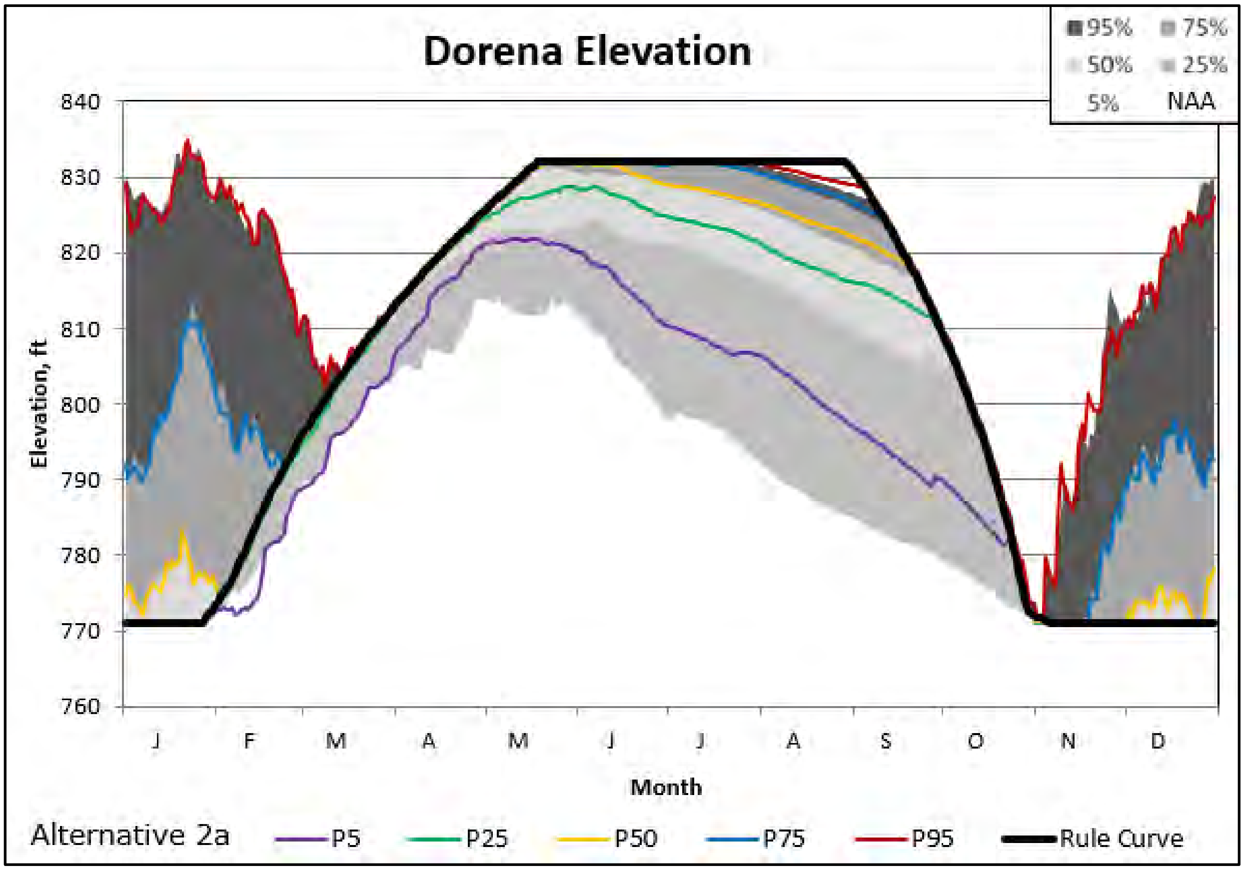

**Figure 3.2-66. Alternative 2A Dorena water surface elevation non-exceedance compared with NAA**

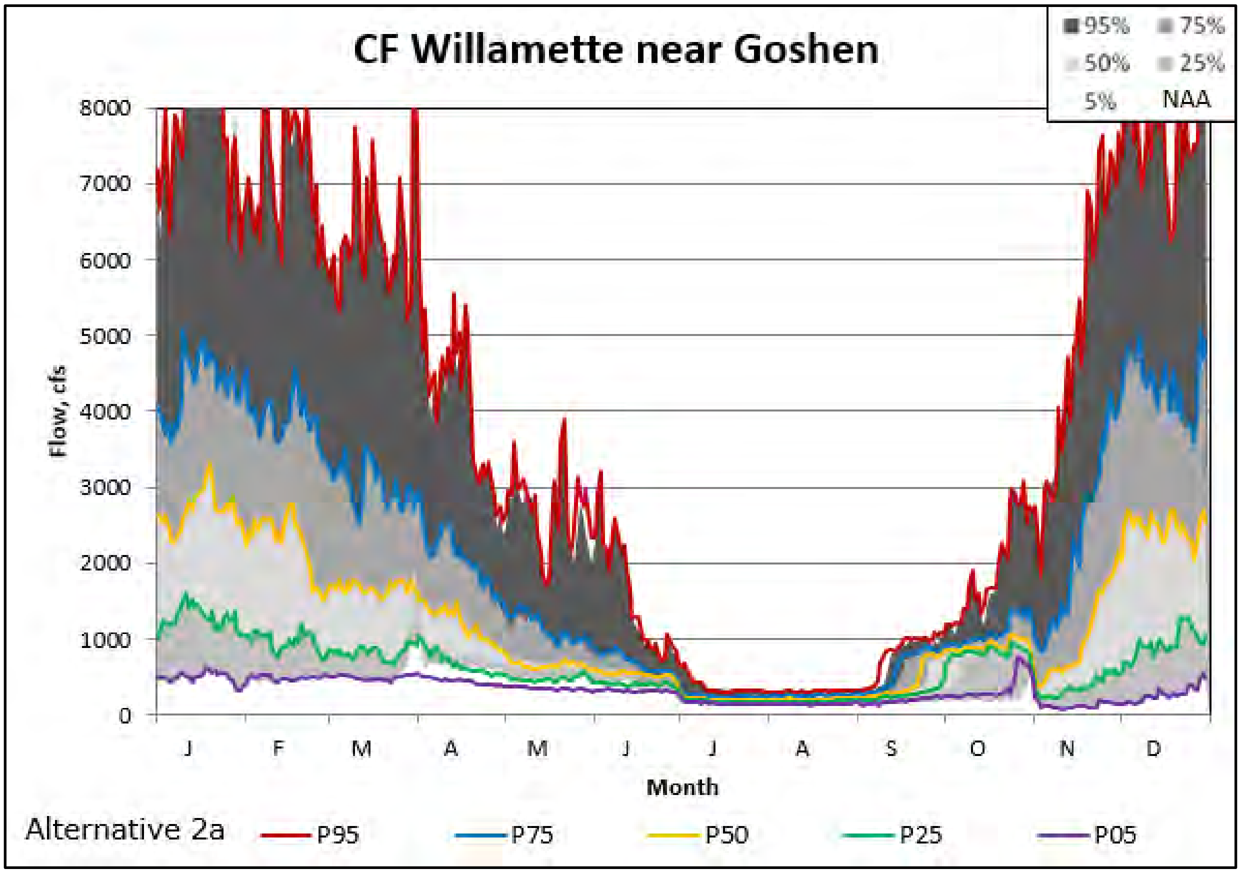

**Figure 3.2-67. Alternative 2A Coast Fork of the Willamette River at Goshen flow non-exceedance compared with NAA**

### *3.2.2.5.6 Mainstem Willamette River*

Alternative 2A would alter the regulated hydrology of the mainstem Willamette River control points, storing water more water in the spring and releasing it during the summer. The Willamette River at Albany (Figure 3.2-68) would show dry years below their NAA equivalents from April to June and a compressed flow regime through the summer, with the higher flow years reduced and the low flow years increased compared to the NAA. The WVS would nearly always meet the lower integrated temperature and habitat flow regime target at Albany, missing only a few days in the fall of the driest years. The increased flow in September and October would be due to the WVS higher reservoir levels at the start of the preparation for flood season.

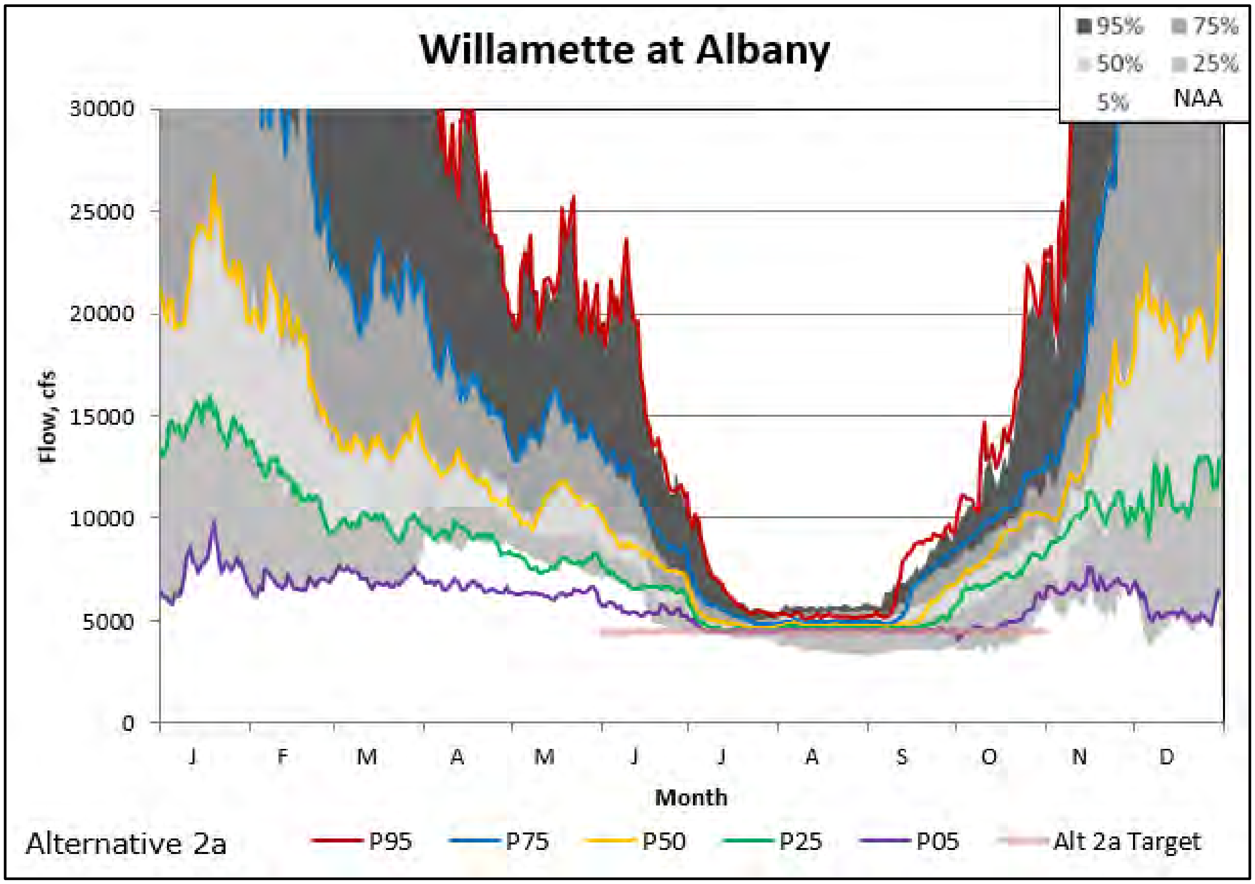

**Figure 3.2-68. Alternative 2A Willamette River at Albany flow non-exceedance compared with NAA**

Like the Albany control point, the Willamette River at Salem (Figure 3.2-69) would show reduced flows from April to June of dry years, while meeting the integrated temperature and habitat flow regime variable air-temperature-guided target compared to the NAA. Summer and fall flows would increase across all years as compared to the NAA. The increase flows from September to November would be due to the deeper fall reservoir drawdown at Green Peter. These increases are within the river channel (up to 90,000 cfs), meaning they would not impact flood risk.

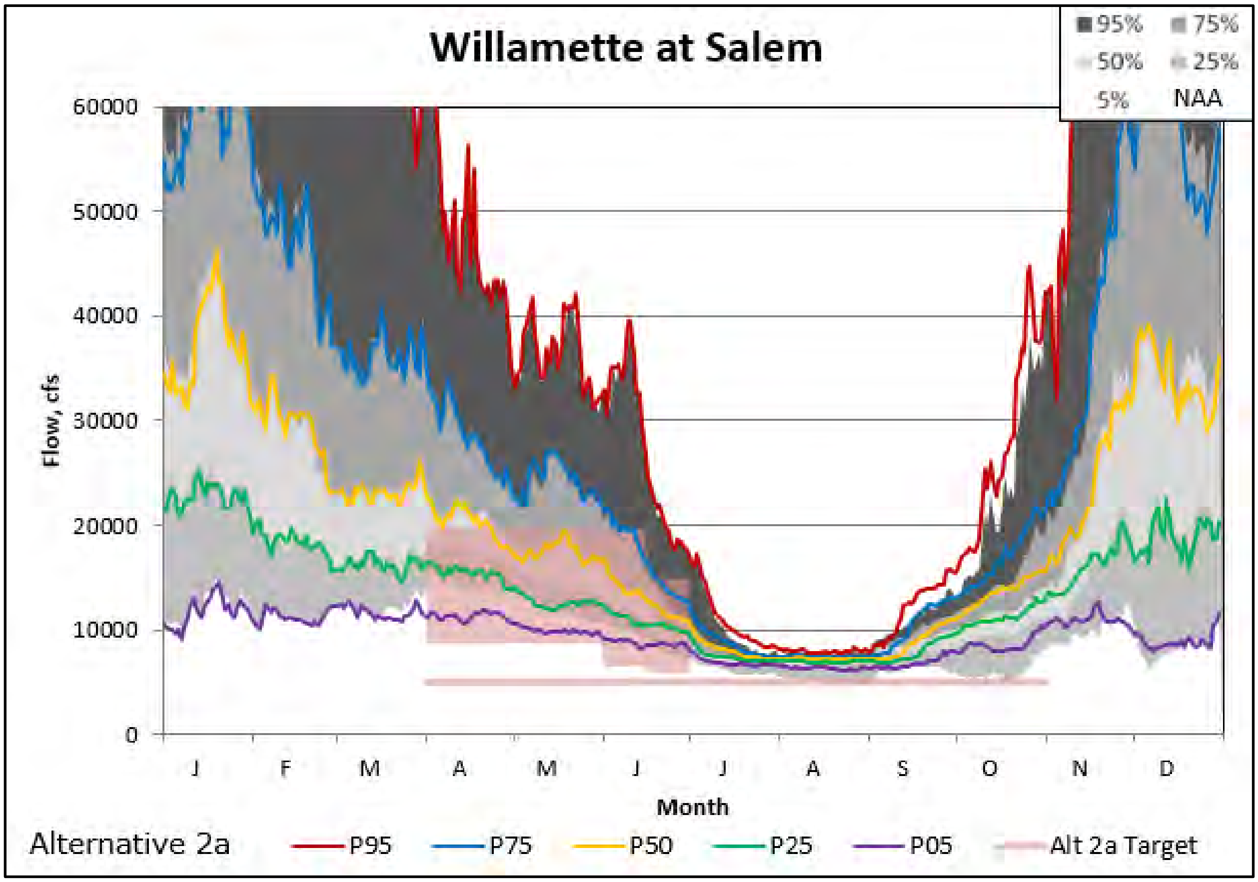

**Figure 3.2-69. Alternative 2A Willamette River at Salem flow non-exceedance compared with NAA**

*3.2.2.5.7 Near-Term Operations*

The descriptions of the Near-Term Operations can be found within Section 2.2.5, Suite of Near-term Operations Measure. The analysis of effects of the near-term operations measure on hydrologic processes is broken down into subbasins. Only the actions that affect the flow from a WVS dam are modeled. Other actions in the Near-Term Operations Measure, such as the reintroduction of salmonids in selected river reaches, do not affect flow and are not included in this section. Although there are some additional operations that affect flow (Appendix B, Hydrologic Processes Technical Information, contains a complete hydrologic operations model explanation) the most notable operations modeled in this section are:

- Change in outlet operations at Detroit based on reservoir water surface elevation
- Deeper fall reservoir drawdown at Green Peter and increase in the use of the spillway during the spring
- Delayed spring refill and earlier reduction in pool elevation at Foster
- Delayed spring refill and deeper fall reservoir drawdown at Cougar, with a downstream flow restriction during some drawdown periods.

- Change in outlet operations at Hills Creek based on reservoir water surface elevation
- Lower spring and summer maximum reservoir elevation at Lookout Point and a deeper fall reservoir drawdown. Increased use of the spillway based on reservoir water surface elevation
- Delayed spring refill from the longer fall reservoir drawdown at Fall Creek, with step increases in reservoir water surface elevation through the winter

The Near-Term Operations Measure is only contained in Alternatives 2A, 2B, 3A, 3B and 4 so the “Integrated Temperature and Habitat Flow Regime” targets were used. Briefly, this would modify flow targets at a WVS reservoir if it is at more or less than 90 percent of rule curve elevation. Flows are reduced within a range down to minimums needed for fish survival when reservoirs are under the 90 percent threshold. Section 2.2.1, Flow Measures, contains a complete explanation of the flow targets.

The Near-Term Operations Measure would reduce WVS storage in the conservation season as compared to the NAA in the Middle Fork and McKenzie subbasins. The shift in flow from spring to summer and fall that is evident in some PEIS alternatives using the integrated temperature and habitat flow regime is notably muted by this reduction in WVS storage. The delayed refill or lower maximum pool elevation require the WVS to release water in the spring that is stored in the NAA and some other alternatives, which means lower reservoir elevations and outflows throughout the summer and early fall.

On the mainstem Willamette River, Albany would show a greater impact from the lower WVS storage than Salem. This is mostly due to Detroit and Green Peter reservoirs releasing water to contribute to the Salem flow target, whereas Albany is upstream of the Willamette’s confluence with the Santiam River.

**Santiam Subbasin**

Detroit Reservoir would fill more often during conservation use season and would achieve a higher elevation when it does not fill, as shown in Figure 3.2-70. The integrated temperature and habitat flow regime target is lower than the 2008 NMFS BiOp flows during drier years. More water would be released from storage during average and wetter years, meaning the reservoir water surface elevation would meet the rule curve later in the year at levels above the P50 non-exceedance line compared to the NAA.

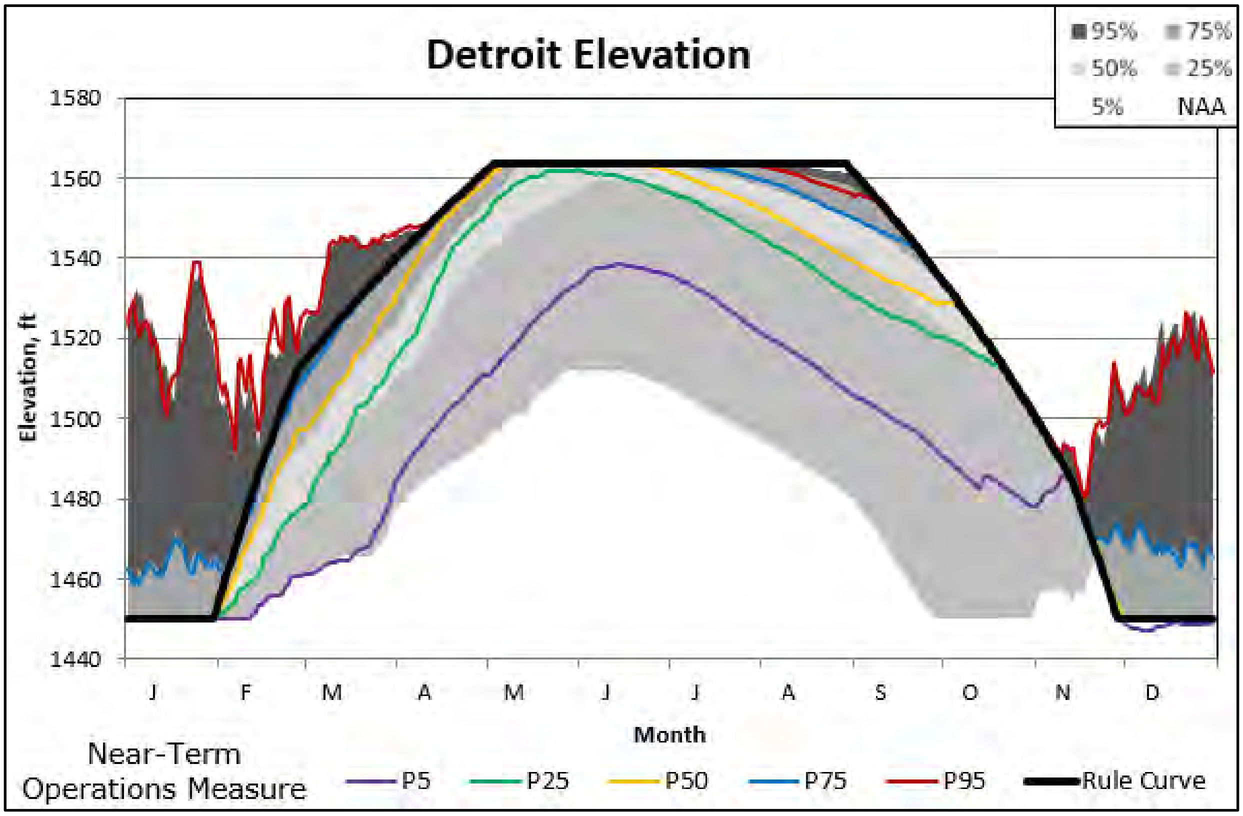

**Figure 3.2-70. Near-Term Operations Measure Detroit water surface elevation non-exceedance compared with NAA**

Green Peter reservoir (Figure 3.2-71) would fill to lower levels in the spring and elevations continue to be lower in the summer and fall as compared to the NAA. Although the lower integrated temperature and habitat flow regime flow targets downstream of Foster would still be in effect for this measure, Green Peter would also be required to use the spillway, which imposes a minimum flow of 800 cfs while in use. Over the course of several months, this would lead to lower reservoir elevations, and higher flow directly downstream, than the NAA.

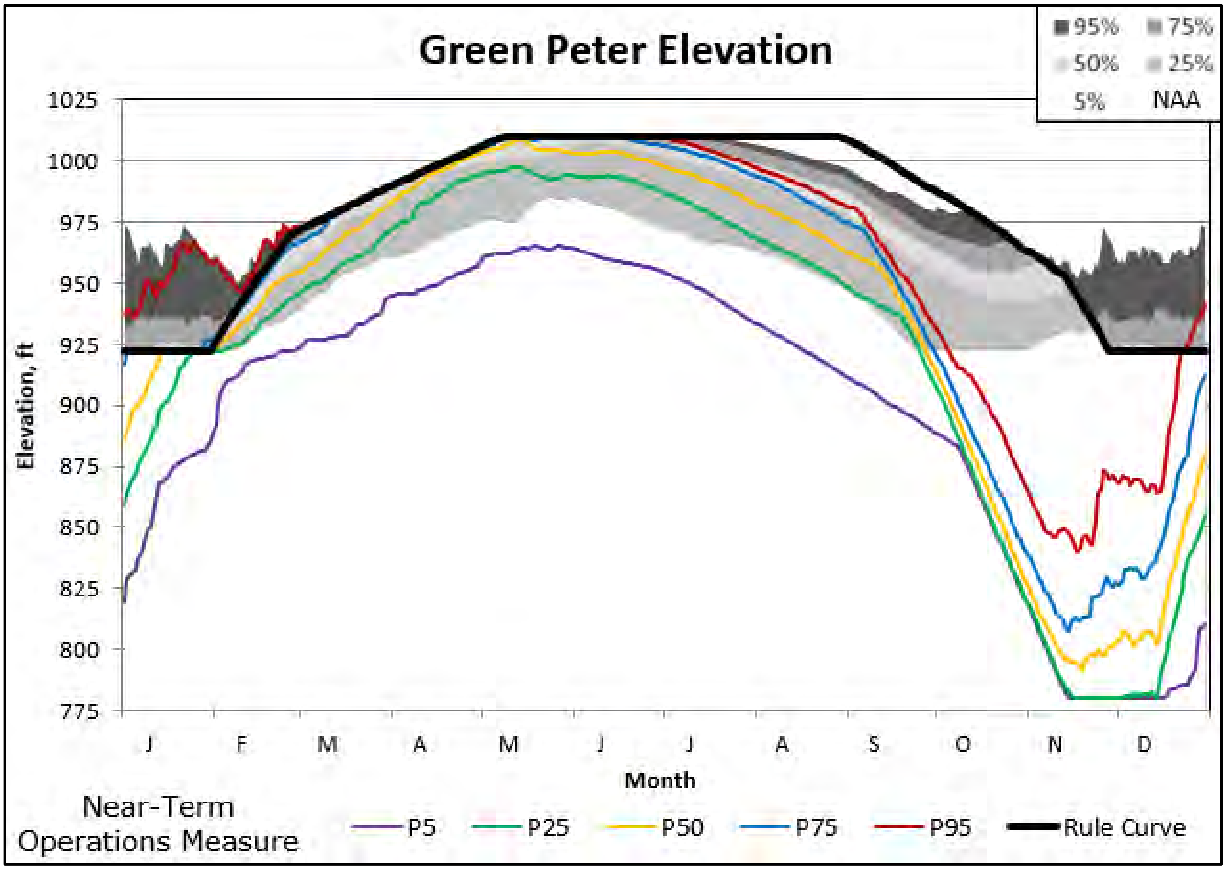

**Figure 3.2-71. Near-Term Operations Measure Green Peter water surface elevation non-exceedance compared with NAA**

The small dip in reservoir elevation at Green Peter in May is the result of Foster's delayed refill until that time, as shown in Figure 3.2-72. Since the usable storage in Foster is less than 10 percent that of Green Peter (28.3 kaf and 312.5 kaf, respectively), Green Peter would be easily able to supplement natural flows to prioritize refill at Foster in May. During drawdowns, Foster must also release the water volume originating from Green Peter. The additional flow from Green Peter during its deeper fall reservoir drawdown, combined with downstream flow restrictions, would typically delay the Foster reduction in pool elevation starting in September compared to the NAA.

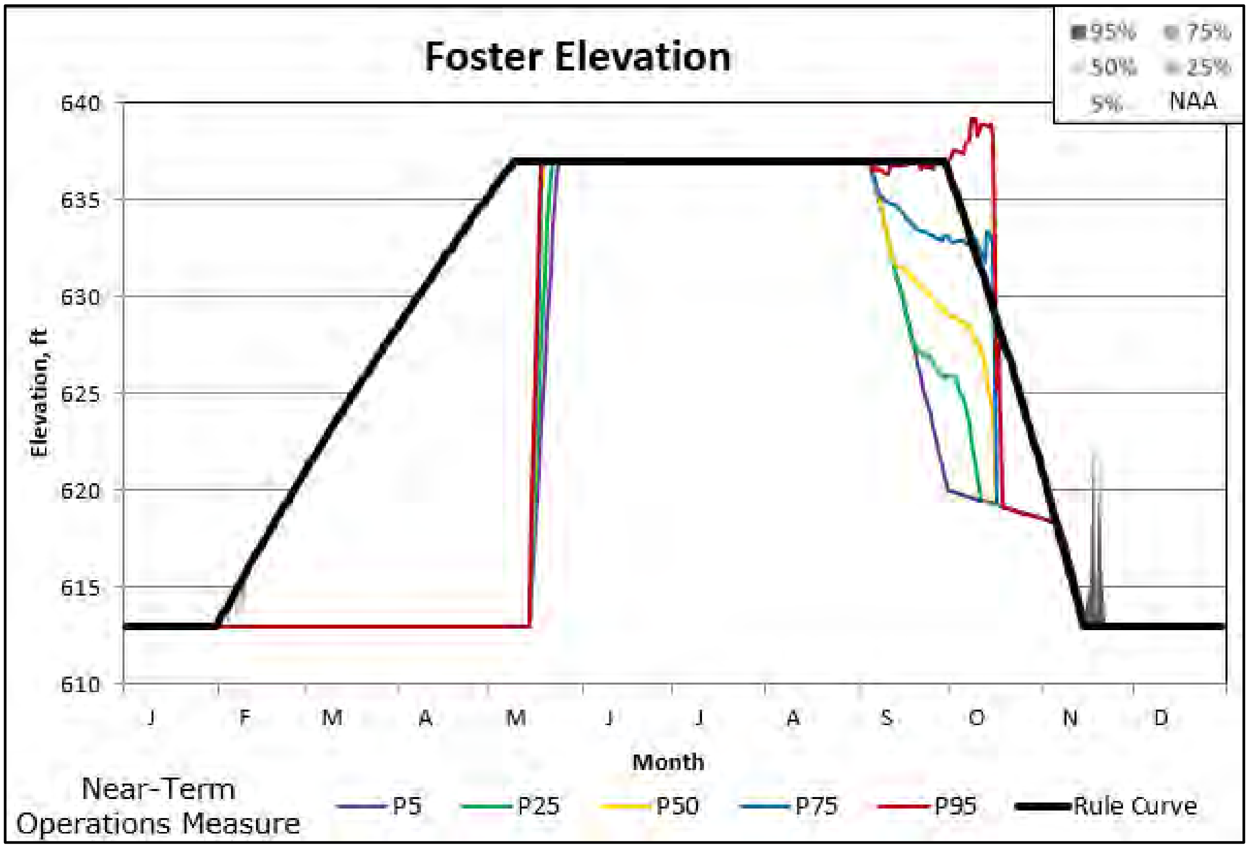

**Figure 3.2-72. Near-Term Operations Measure Foster water surface elevation non-exceedance compared with NAA**

The flow comparison out of Foster (Figure 3.2-73) shows the downstream effects of these operational changes compared to the NAA. Although the integrated temperature and habitat flow regime would remain the target flows throughout the year, it would really only dictate the flow downstream of Foster during July, August and early September. During other periods, different flow targets would be in control, such as the spillway release from Green Peter in the spring or the deeper fall reservoir drawdown in September and October. The refill of Foster is also evident in the flow downstream as it would be cut to minimum for a while in May. The actual operation would probably take place over a longer period than the modeled operation to balance refill with a higher downstream flow.

The lower November flows in the driest years would be a result of Green Peter already being at the minimum drawdown elevation, when it still had some water stored in the NAA.

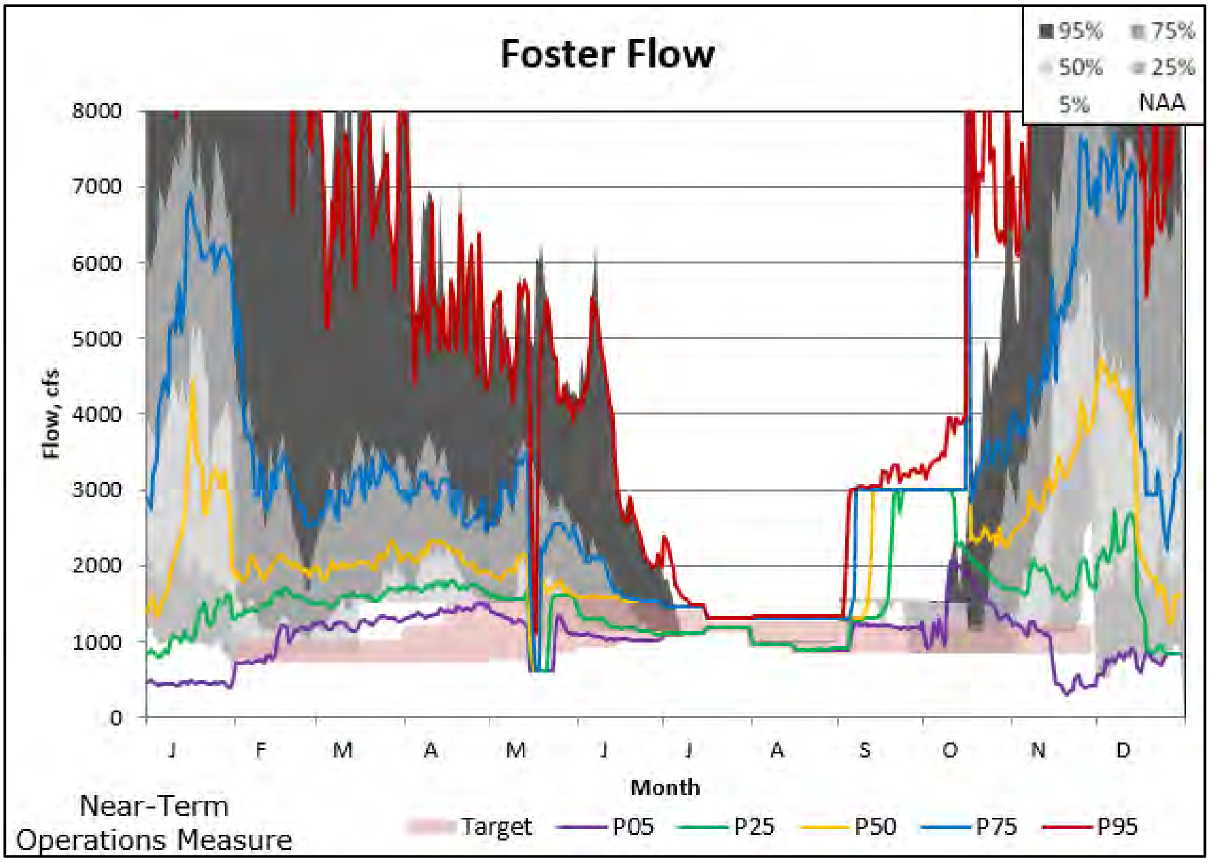

**Figure 3.2-73. Near-Term Operations Measure Foster outflow non-exceedance compared with NAA**

Although there are not specific flow targets further downstream at the combined Santiam control point at Jefferson (Figure 3.2-74), the revised operations and flow targets from upstream would be evident. The water stored during dry years, principally in Detroit, from March to June, would be released during the summer. Upstream summer integrated temperature and habitat flow regime targets would be higher than those in the 2008 NMFS BiOp, so Jefferson would show higher flows in all years compared to the NAA. There would be a small reduction in flow during the refill period at Foster – during May – though not nearly as pronounced as it is directly downstream of the dam. The elevated flows during September would be due to the deeper fall reservoir drawdowns. The lower November dry-year flows in the South Santiam would all but disappear as compared to the NAA due to the contributions from Detroit reservoir.

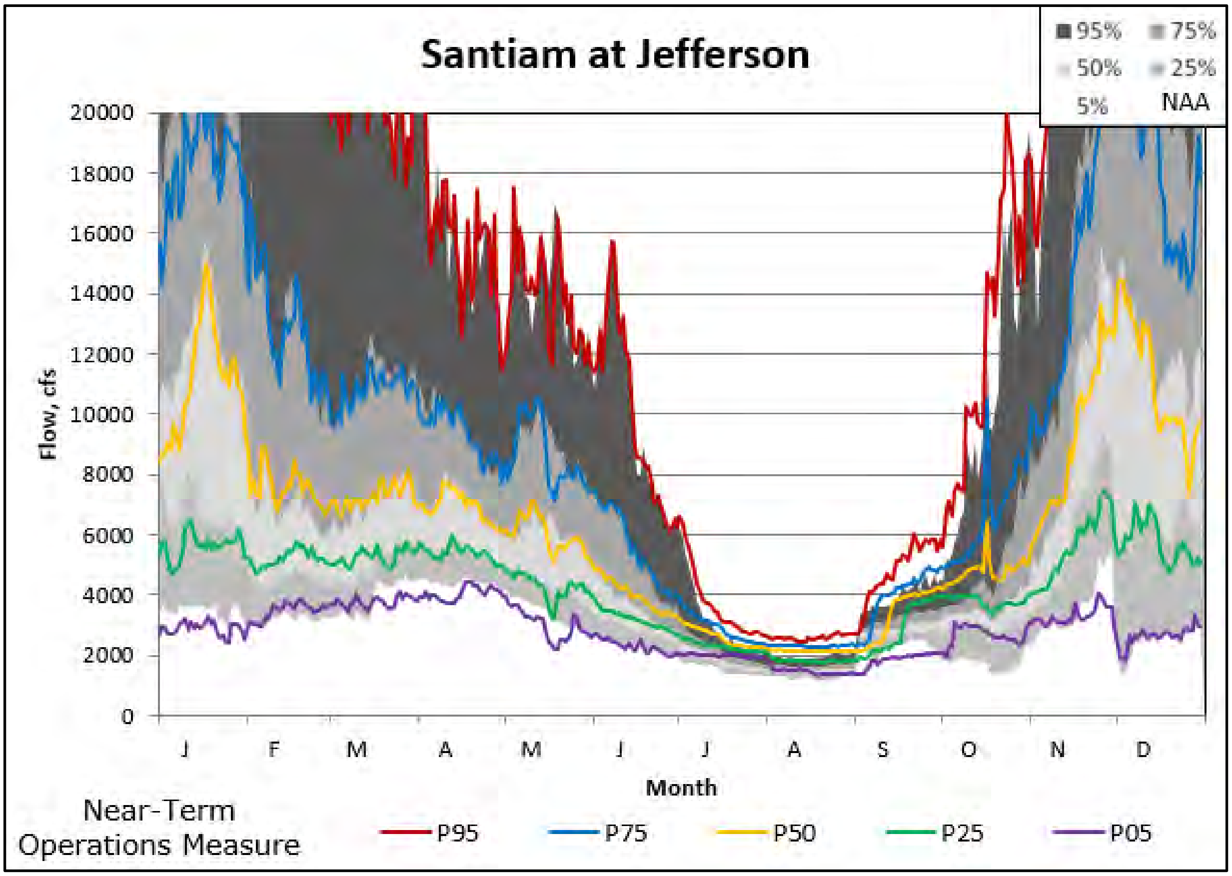

**Figure 3.2-74. Near-Term Operations Measure Santiam River at Jefferson flow non-exceedance compared with NAA**

## Long Tom Subbasin

As explained in the NAA, Fern Ridge reservoir is operated for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. The Near-Term Operations Measure does not appreciably change this goal and the hydrologic patterns are nearly the same as the NAA, as shown in Figure 3.2-75. The Near-Term Operations Measure downstream control point flows at Monroe show a similar lack of change from the NAA.

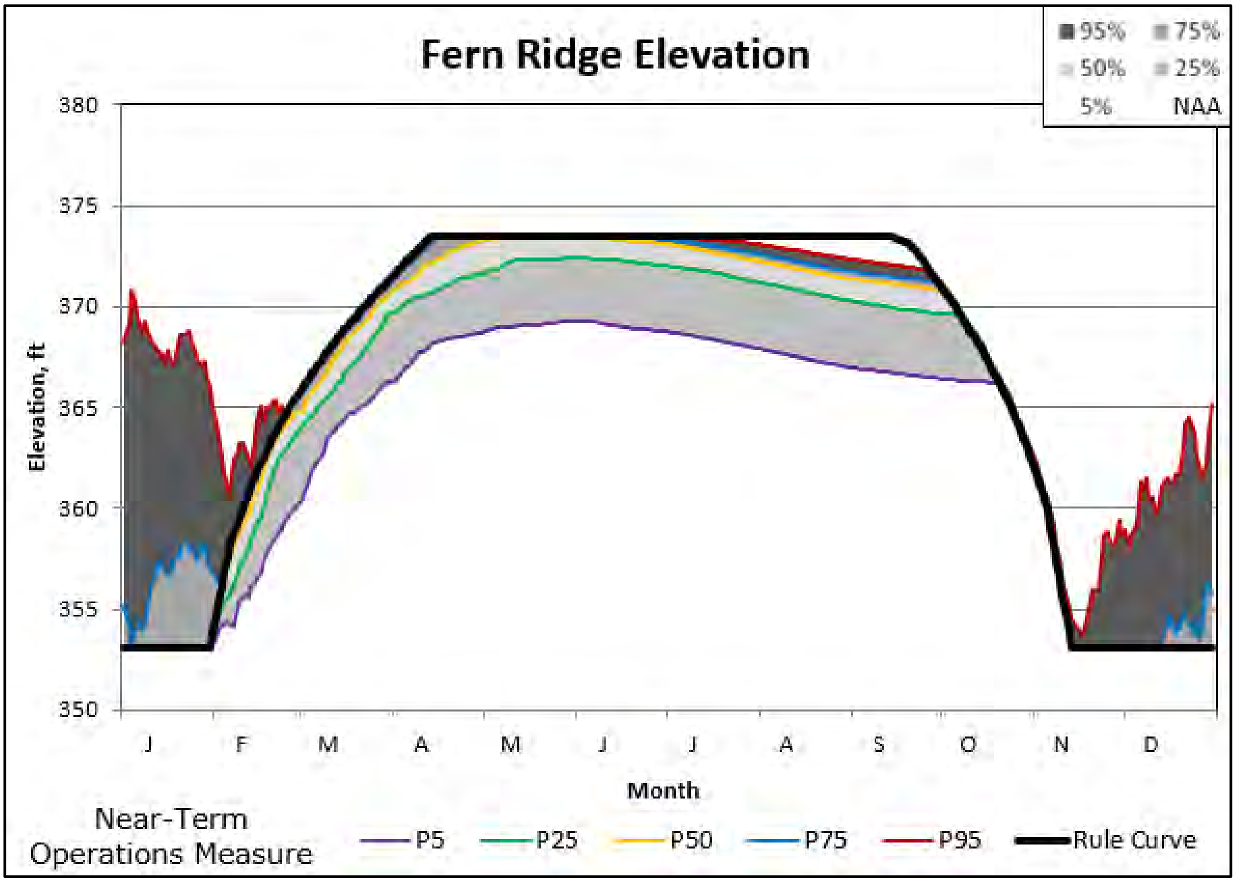

**Figure 3.2-75. Near-Term Operations Measure Fern Ridge water surface elevation non-exceedance compared with NAA**

**McKenzie Subbasin**

Blue River (Figure 3.2-76) reservoir would fill to higher elevations in dry years due to the lower spring flow targets in the McKenzie River and Salem. Since the reservoir would fill in wetter years, there is limited difference in everything above the P25 line for the conservation season. The Near-Term Operations measure would allow Blue River to augment instream flows by using the inactive pool. This would draft the reservoir below minimum conservation elevation and it would do so during very dry Novembers.

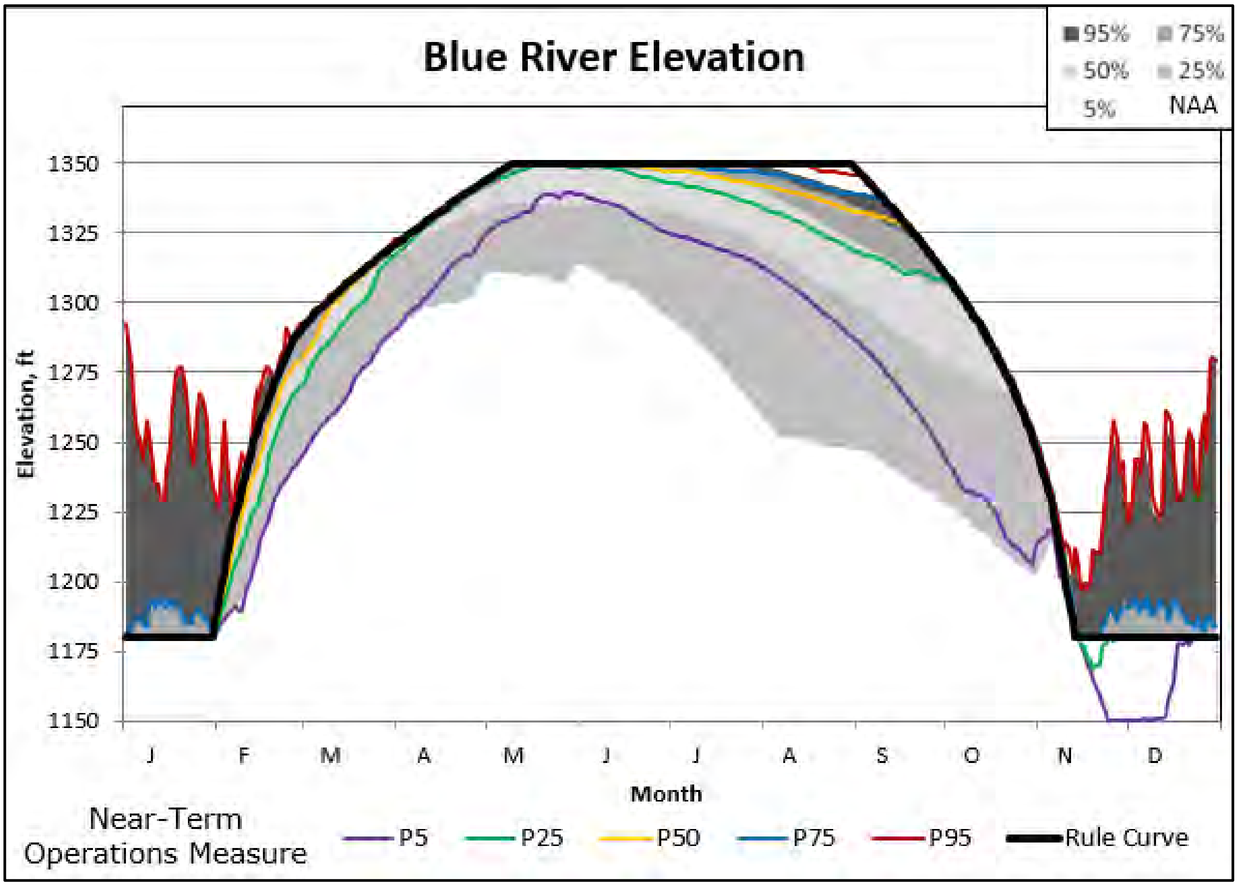

**Figure 3.2-76. Near-Term Operations Measure Blue River water surface elevation non-exceedance compared with NAA**

Cougar reservoir (Figure 3.2-77) would have a drawdown target below minimum conservation elevation (1532 ft) during the spring (1505 ft) and fall (1520 ft). The operation would also limit releases to less than about 900 cfs for water quality concerns, which is less than typical inflow during the spring and late fall compared to the NAA. This would result in the reservoir only meeting the drawdown target elevations in dry years and only for relatively brief periods.

If the operation were to prioritize the maintenance of the drawdowns over the maximum downstream flow, Cougar would not fill nearly as often as presented in Figure 3.2-77. Alternative 3A provides a similar operation of Cougar reservoir, though that spring reservoir drawdown ends in June instead of May. While ending in May would generally mean somewhat higher average inflows to Cougar at the end of the spring reservoir drawdown, it is still be expected that the reservoir would be near minimum conservation elevation for most of the summer months compared to the NAA. While the reservoir would be at minimum elevation, outflow from Cougar reservoir would be equal to inflow, which is typically lower than flow target minimums directly downstream of the dam.

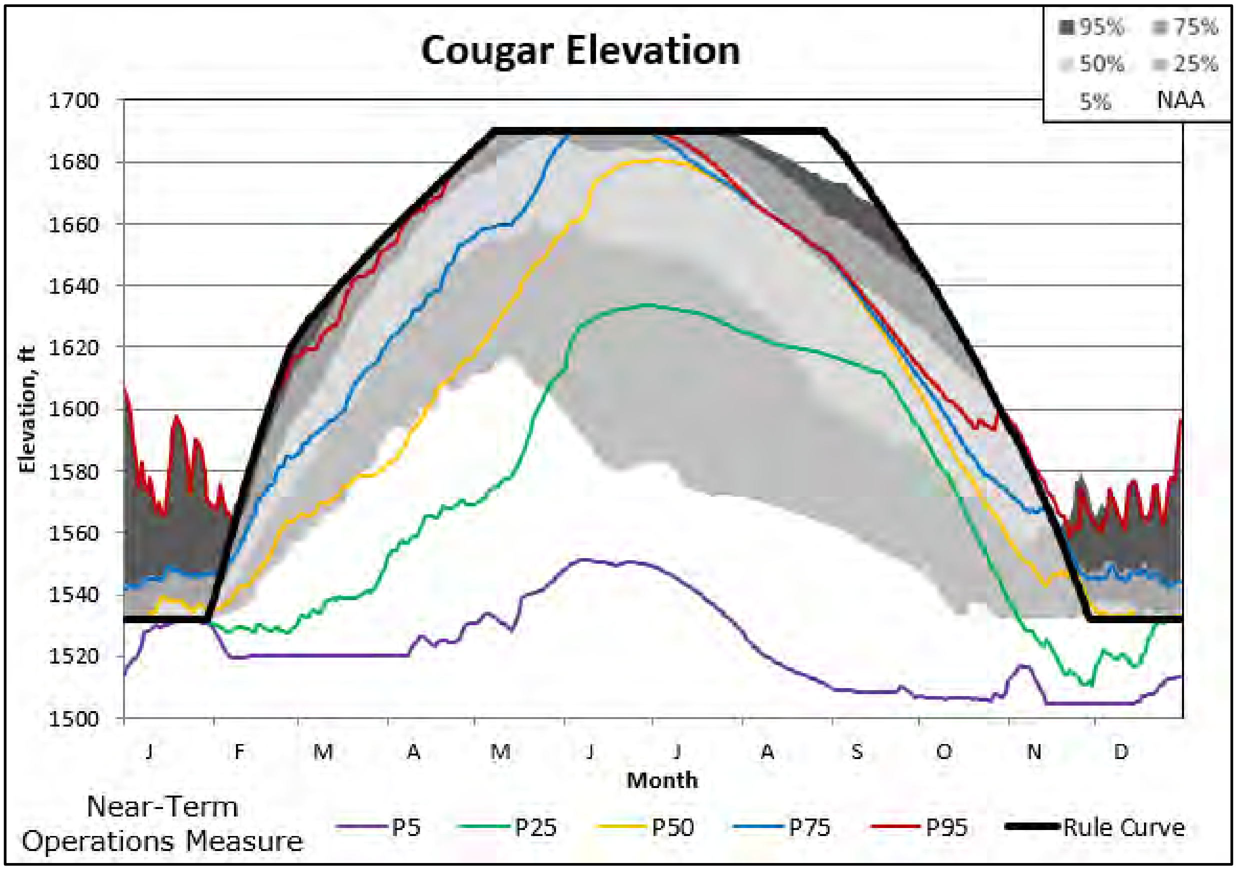

**Figure 3.2-77. Near-Term Operations Measure Cougar water surface elevation non-exceedance compared with NAA**

Cougar outflow would meet or exceeds its integrated temperature and habitat flow regime target except during the driest falls compared to the NAA, when Cougar would be at its minimum elevation and only passing inflow, as shown in Figure 3.2-78. However, those flow targets would seldom determine the actual flow in the complete set of Near-Term Operations. The drawdown flow operation of about 900 cfs determines the flow for much of the spring and fall, and maximum pool elevations dictate releases for average and wetter years throughout most of the summer.

If the maximum flow during the drawdowns were raised and the drawdown elevations maintained more frequently, the flow downstream of Cougar would only be equal to the inflow for most of the summer and fall. After May 15th there would be limited inflow to accumulate storage and the flow targets directly downstream of the reservoir would only be met in the wettest years.

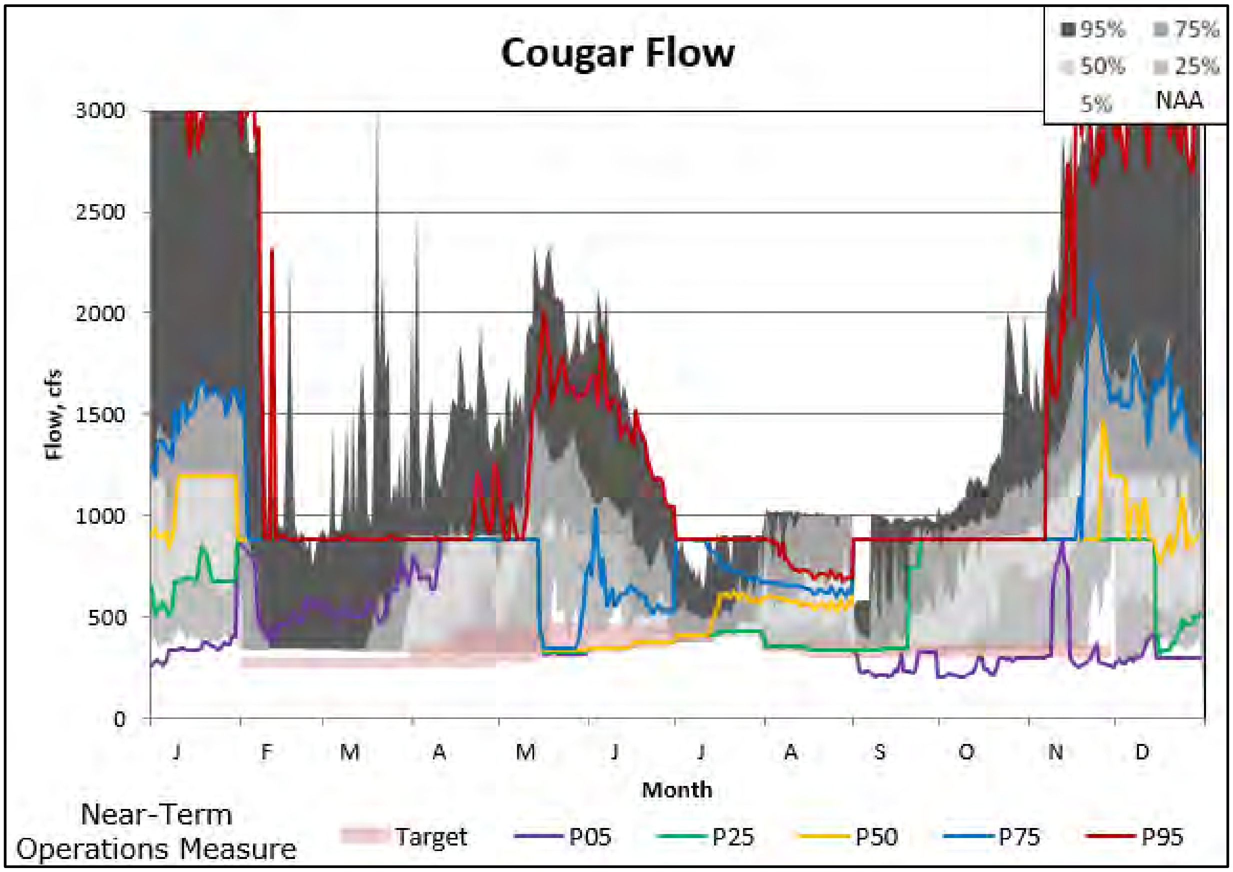

**Figure 3.2-78. Near-Term Operations Measure Cougar outflow non-exceedance compared with NAA**

Figure 3.2-79 (McKenzie River at Vida) shows the effects of lower elevations at Cougar at higher elevations at Blue River. While there are differences in timing and precise flow rates, the overall results are similar at Vida when compared to the NAA. The relatively high summer base flow in the McKenzie River also contributes to the consistency with the NAA.

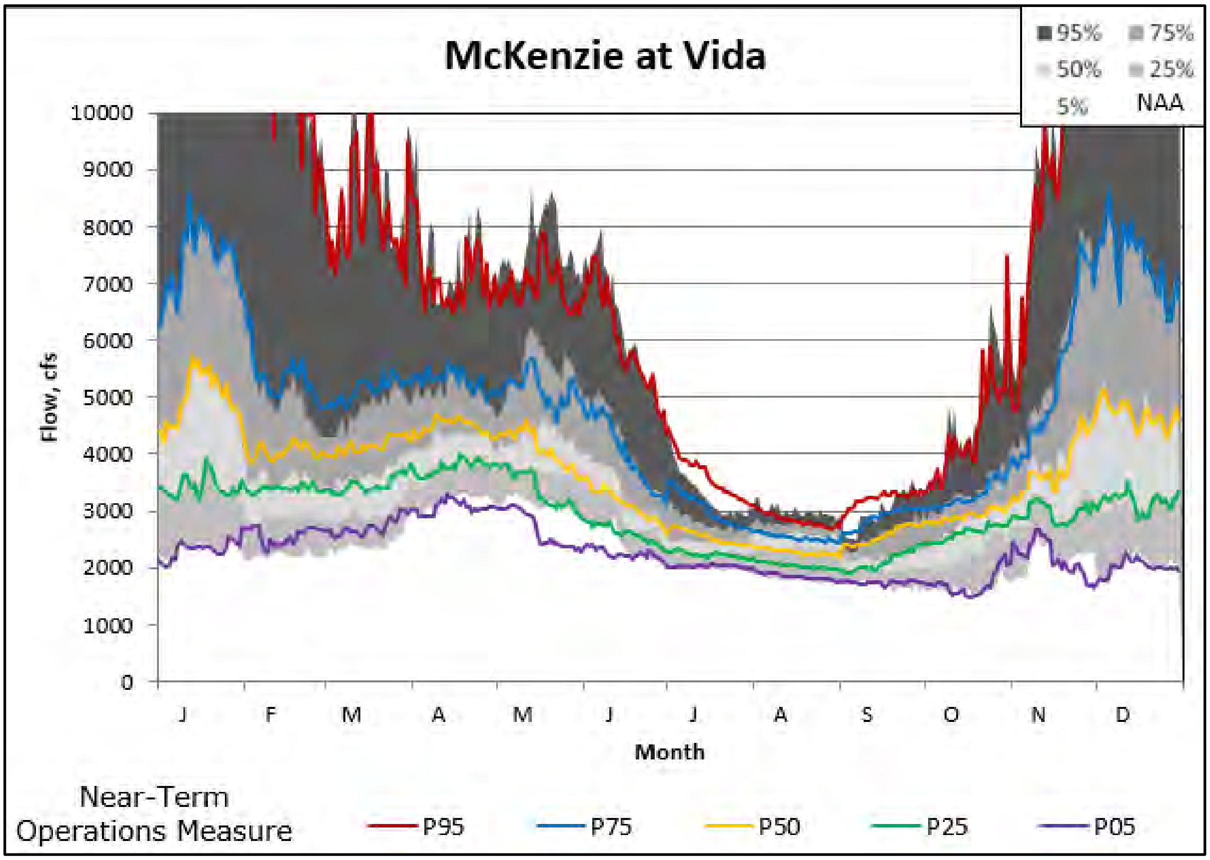

**Figure 3.2-79. Near-Term Operations Measure McKenzie River at Vida flow non-exceedance compared with NAA**

__Middle Fork of the Willamette Subbasin__

Hills Creek (Figure 3.2-80) initially would fill more slowly than the NAA due to the Near-Term Operations Measure's mandate to prioritize refill at Lookout Point (Figure 3.2-81). In other words, early in the year, water that was stored at Hills Creek in the NAA would be released to Lookout Point instead. After Lookout Point reaches its lower maximum elevation (893 feet instead of maximum conservation pool of 926 feet), Hills Creek would fill to higher elevations than the NAA due to the lower integrated temperature and habitat flow regime targets downstream.

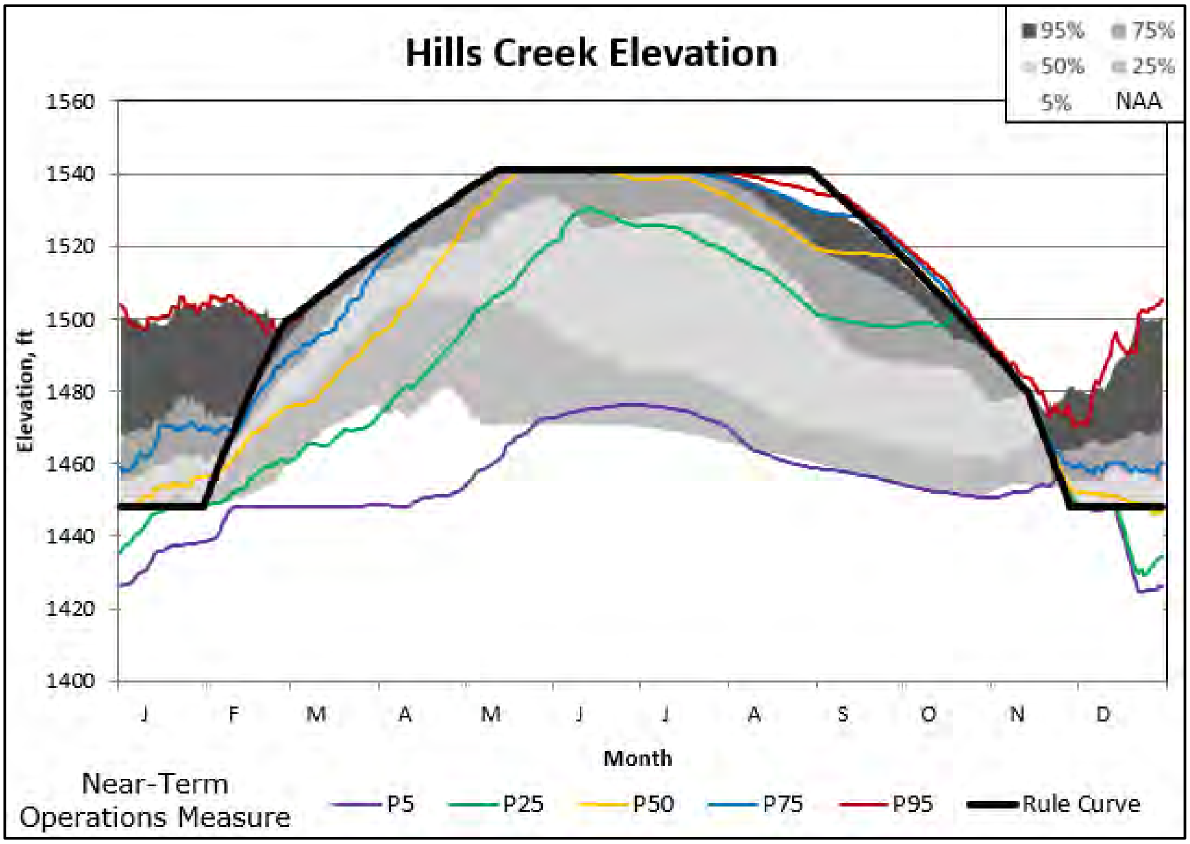

**Figure 3.2-80. Near-Term Operations Measure Hills Creek water surface elevation non-exceedance compared with NAA**

Lookout Point reservoir would fill more often to its lower target elevation than it does to maximum conservation pool in the NAA. The is due to supplementary releases from Hills Creek and because there is more volume for each foot of elevation higher in the reservoir. The deeper fall reservoir drawdown target would be achieved nearly every year, with unusually wet Novembers preventing the reservoir from making the 761-foot target. This is due to high seasonal inflow and the lower outlets would not able to release water fast enough with the pool elevation at low levels.

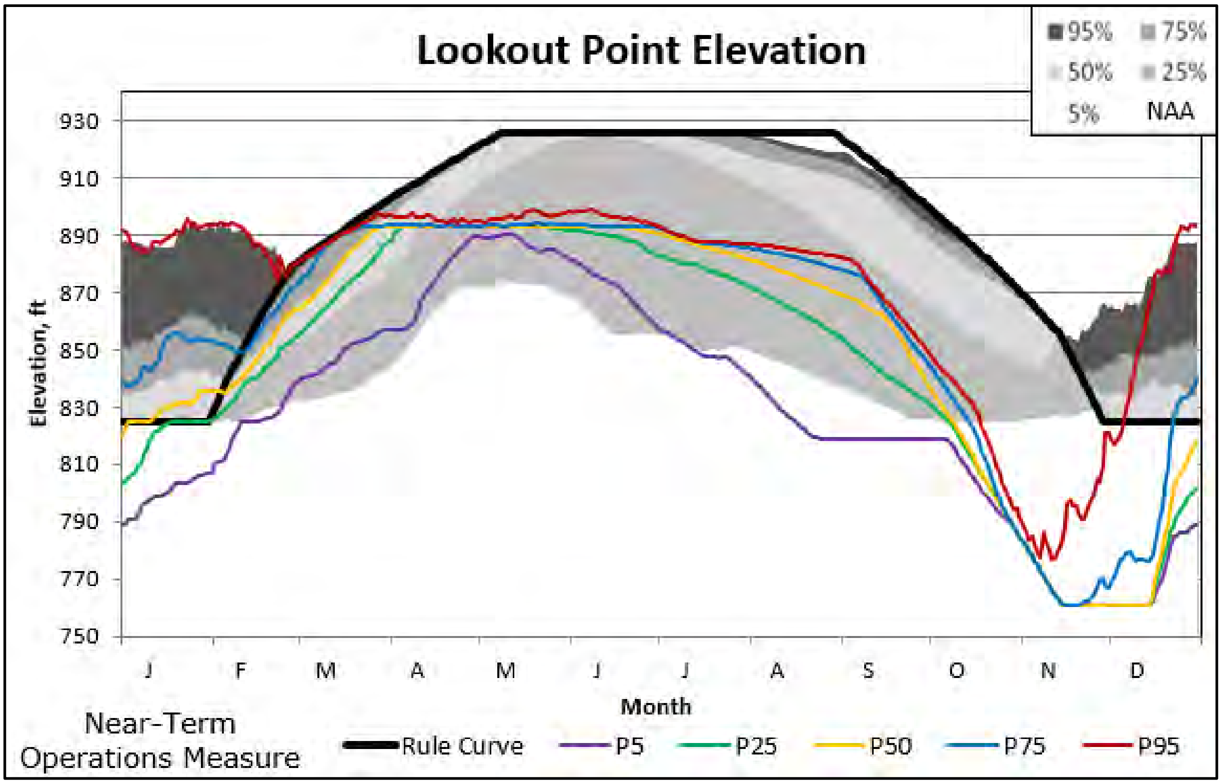

**Figure 3.2-81. Near-Term Operations Measure Lookout Point water surface elevation non-exceedance compared with NAA**

The Near-Term Operations Measure extends the lower target elevation at Fall Creek reservoir through May, increasing in steps from the deeper fall reservoir drawdown elevation already implemented in the NAA, as shown in Figure 3.2-82. The target is 700 feet after the deeper fall reservoir drawdown through March 15th and 728 feet to May 15th, after which the reservoir refills as inflow and other operations allow. Reservoir elevations are lower throughout the conservation season at Fall Creek and the releases would be below the downstream target in the fall of drier years (Figure 3.2-83). The reservoir would only pass inflow when it reaches its minimum water surface elevation, and these inflows are much less than the downstream targets. The elevated wet-year flows in the spring would be due to the reservoir releasing water to hold the target elevation rather than storing water, as it did in the NAA. These higher flows would be within the bankfull maximum.

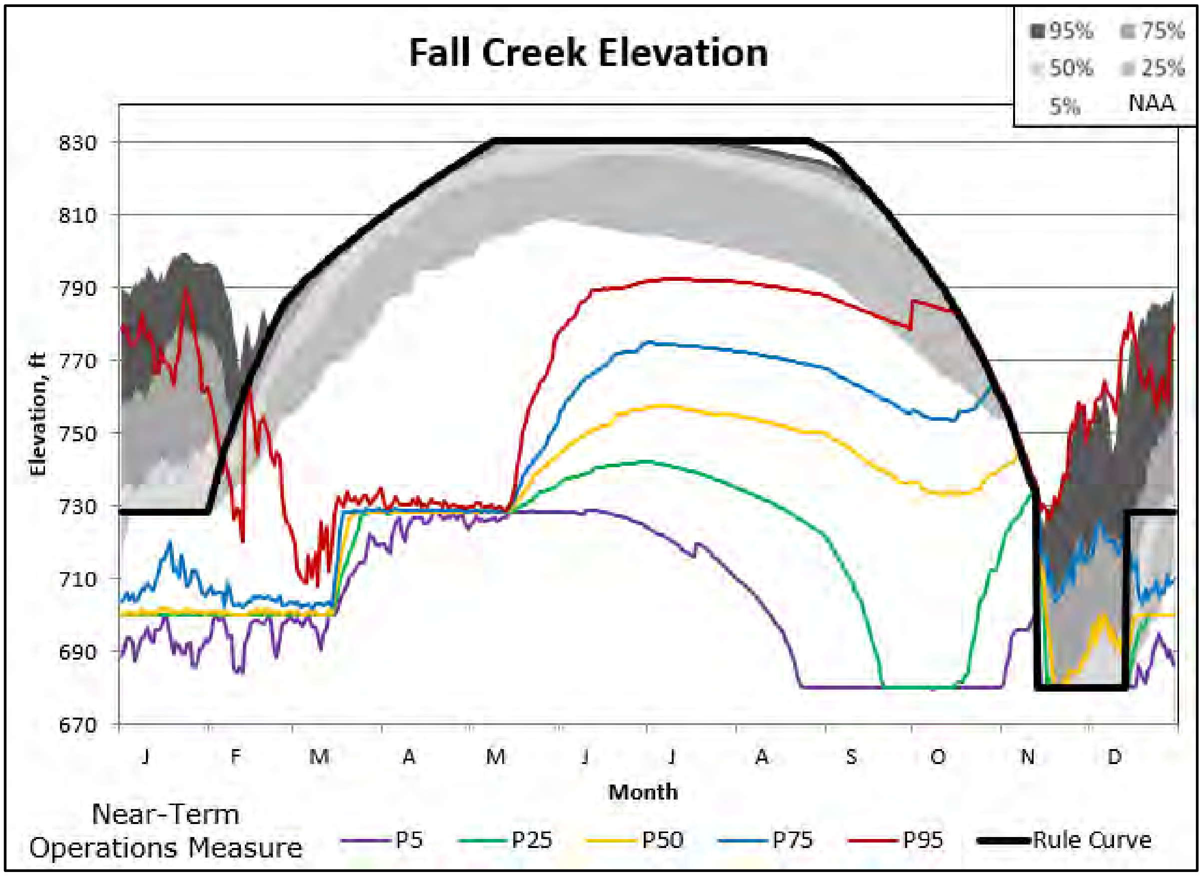

**Figure 3.2-82. Near-Term Operations Measure Fall Creek water surface elevation non-exceedance compared with NAA**

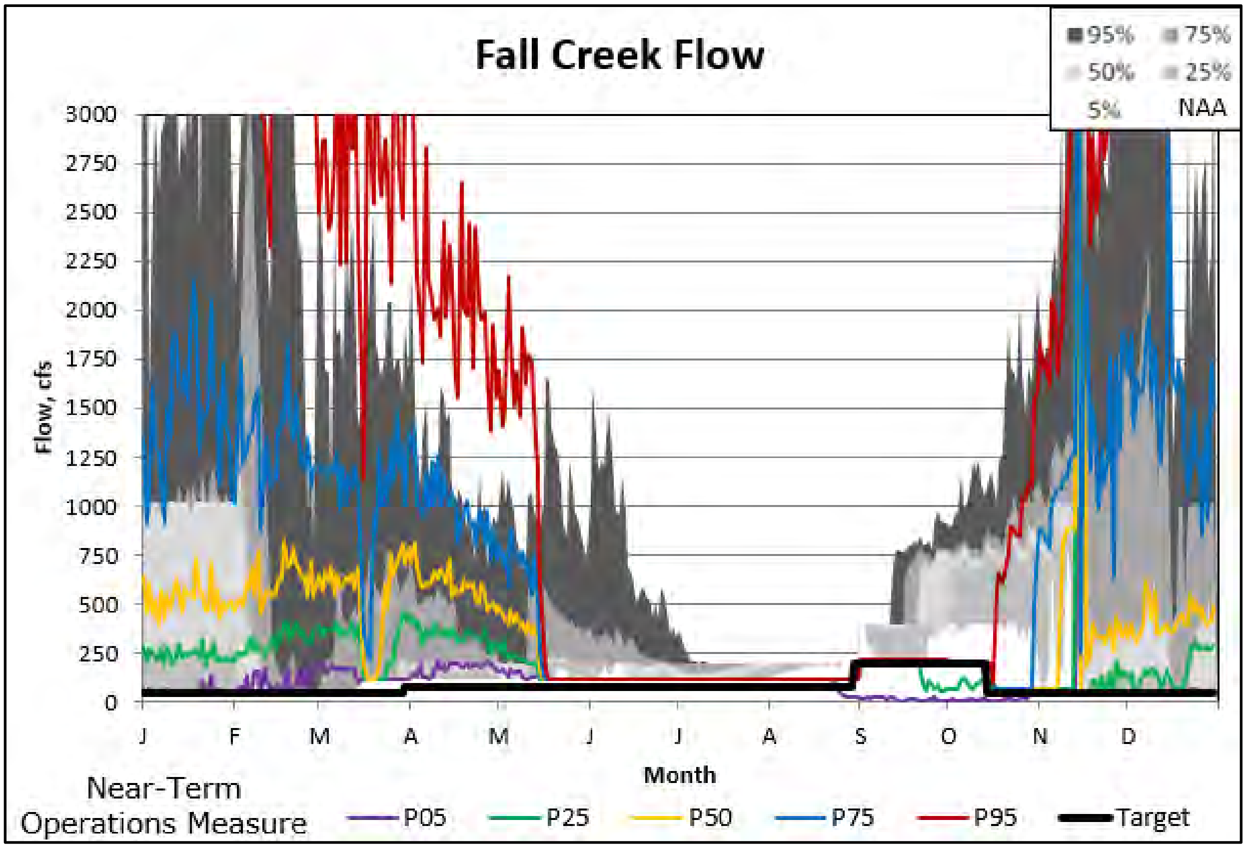

**Figure 3.2-83. Near-Term Operations Measure Fall Creek outflow non-exceedance compared with NAA**

At the Middle Fork of the Willamette River at Jasper (Figure 3.2-84), the control point for Hills Creek, Lookout Point and Fall Creek, elevated spring flows would be evident in all except the driest years. Water that would have been stored in the NAA would be released from Lookout Point and Fall Creek due to their lower target water surface elevations. Into summer and fall, a lower amount of stored water would lead to somewhat lower flows across all years. The driest Septembers would show notably lower flows compared to the NAA as all three upstream storage reservoirs would be at or near their minimum water surface elevation for that period and only able to release inflow.

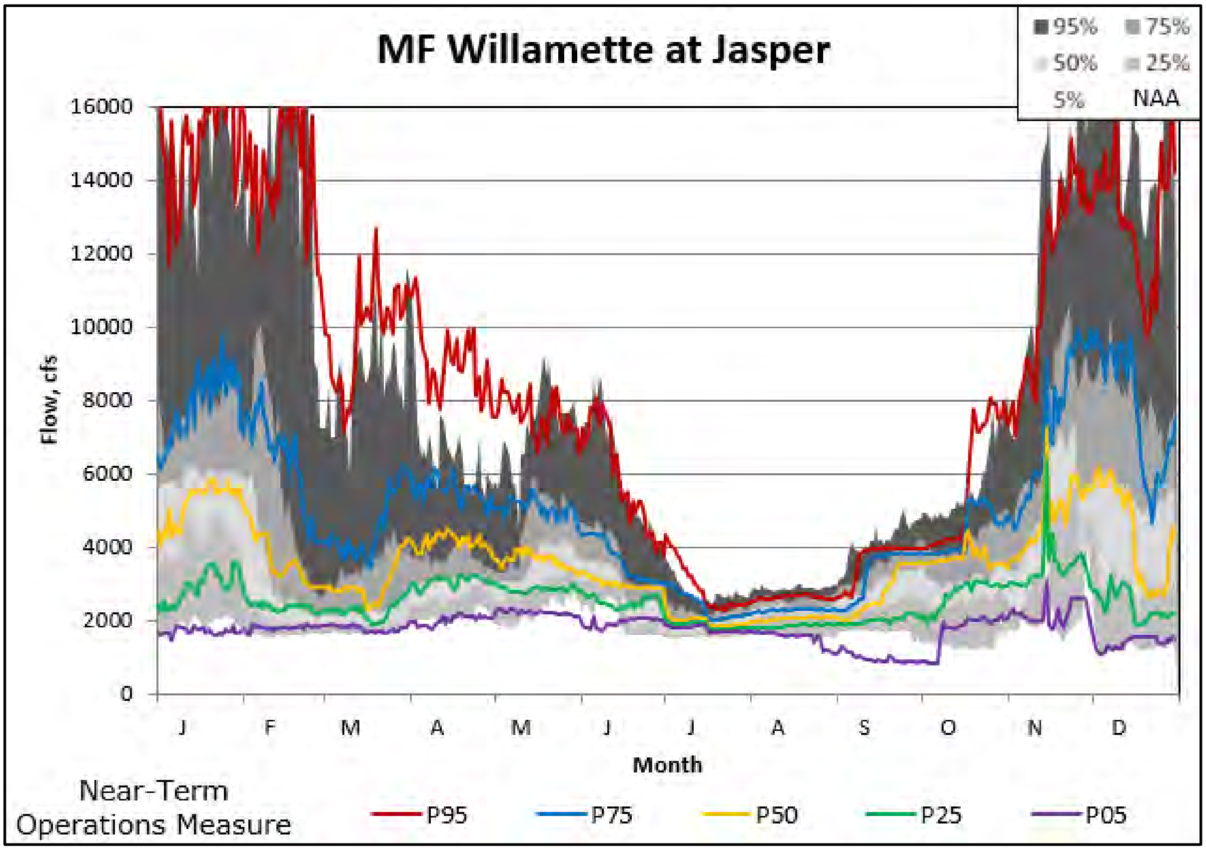

**Figure 3.2-84. Near-Term Operations Measure Middle Fork of Willamette River at Jasper flow non-exceedance compared with NAA**

__Coast Fork of the Willamette Subbasin__

For the Near-Term Operations Measure, the Coast Fork subbasin reservoirs would store more water in the spring and release it during the summer and fall during dry years. They are generally similar to the NAA in wet years. Reservoir elevations would be somewhat higher at both Dorena (Figure 3.2-85) and Cottage Grove for Near-Term Operations Measure during the late spring and summer, with other times similar to the NAA. Figure 3.2-86 shows the control point at Goshen. Since the pools would stay higher throughout the summer, more water would be released during September and October.

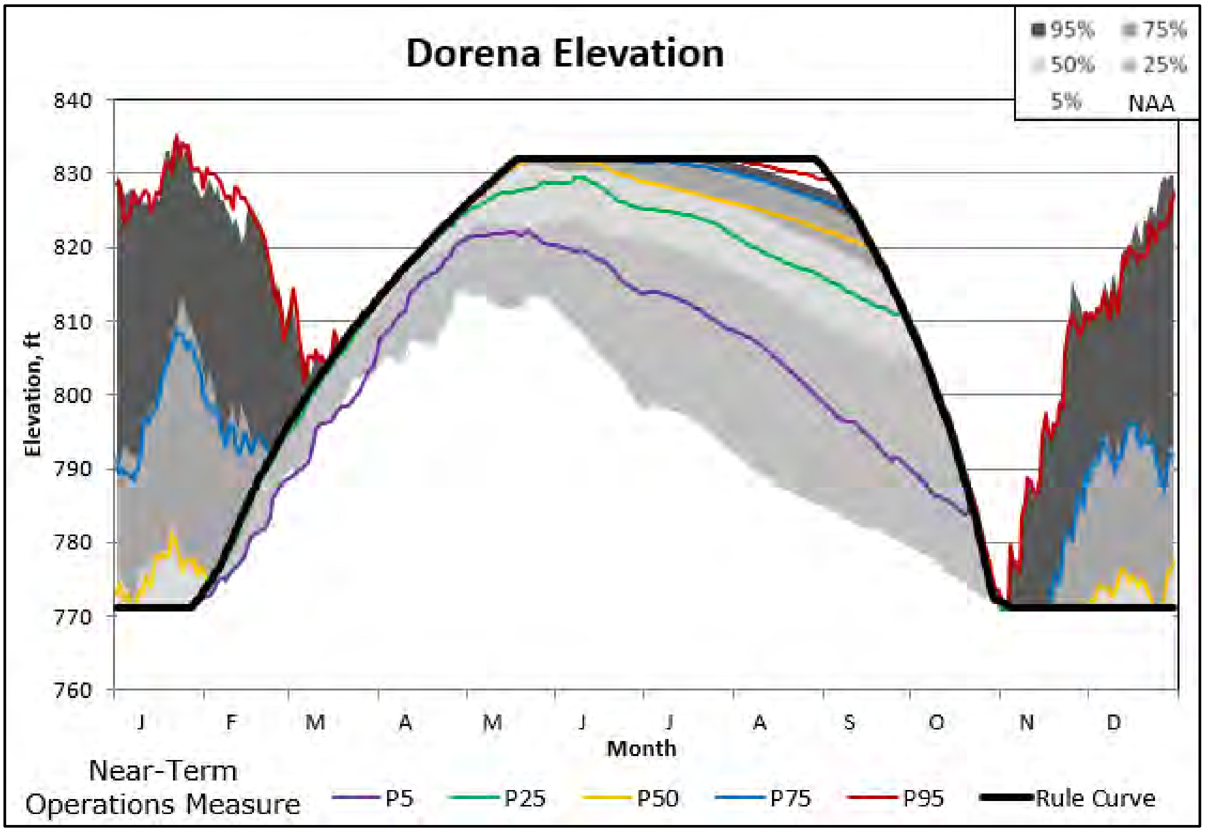

**Figure 3.2-85. Near-Term Operations Measure Dorena water surface elevation non-exceedance compared with NAA**

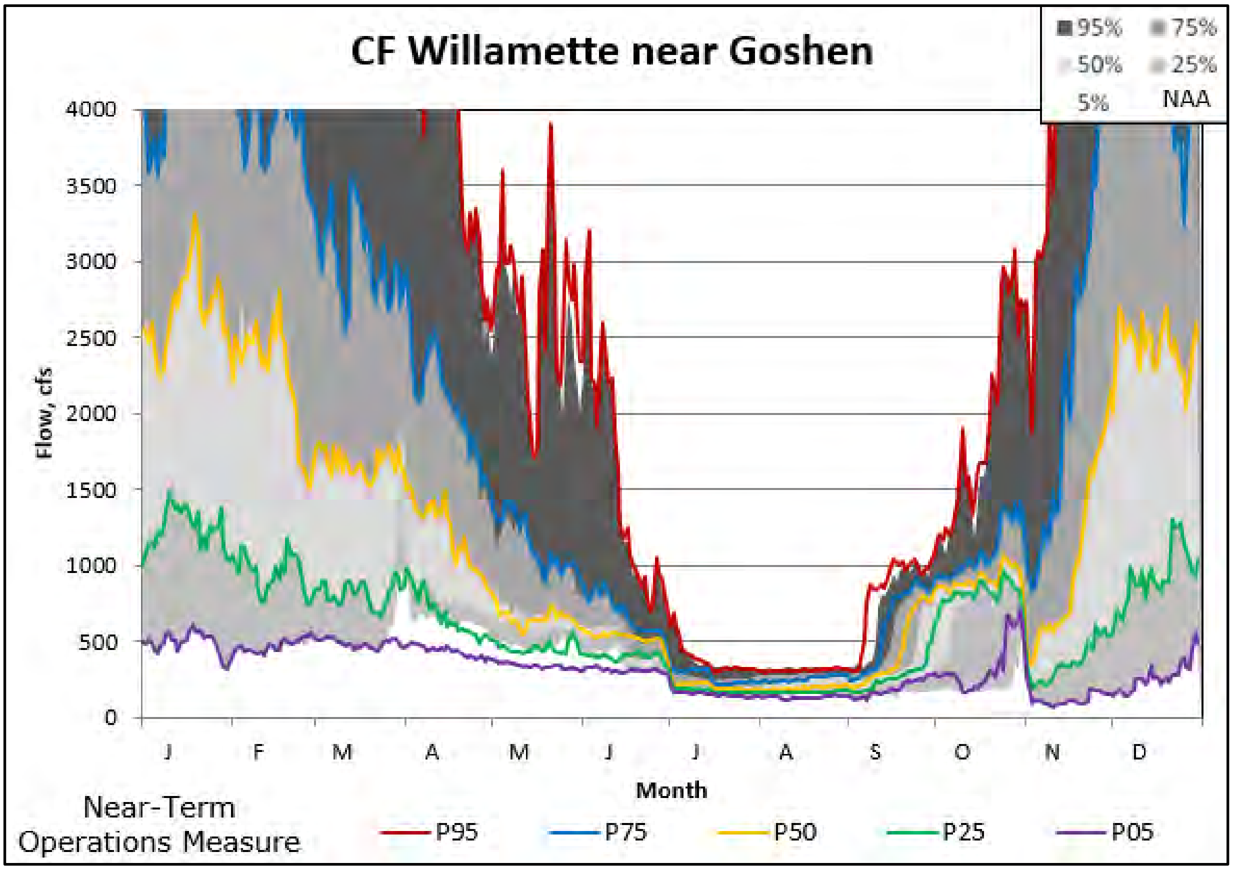

**Figure 3.2-86. Near-Term Operations Measure Coast Fork of Willamette River at Goshen flow non-exceedance compared with NAA**

**Mainstem Willamette River**

The Near-Term Operations Measure flow targets on the mainstem Willamette River at Albany and Salem (Figures 3.2-87 and 3.2-88, respectively) are the integrated temperature and habitat flow regime targets, which are lower than the BiOp targets in the NAA and modify the flow target at Salem during warm weather (the flow target region in the figure). Section 2.2.1, Flow Measures, contains a more detailed explanation of these flow targets.

In wet years, the Near-Term Operations Measure would have consistently higher flow during the springtime at both Albany and Salem as compared to the NAA. The driest years would have lower flow in the spring due to the lower effective flow target at Salem. A decrease in total upstream storage means lower flows across all years at Albany for the Near-Term Operations Measure as compared to the NAA. When the largest upstream reservoirs hit their minimum elevation in September of the driest years (P05 line), flows at Albany would fall below the target and the NAA until Lookout Point releases water for its the deeper fall reservoir drawdown.

If Cougar reservoir were to operate to lower elevations during its delayed refill – instead of being limited to a maximum downstream flow – Albany would miss its flow target more often.

Since most years (P75 line) are already at the flow target for about a month and for longer periods in drier years, removing most of Cougar reservoir's stored water would likely push flows below the target much more often.

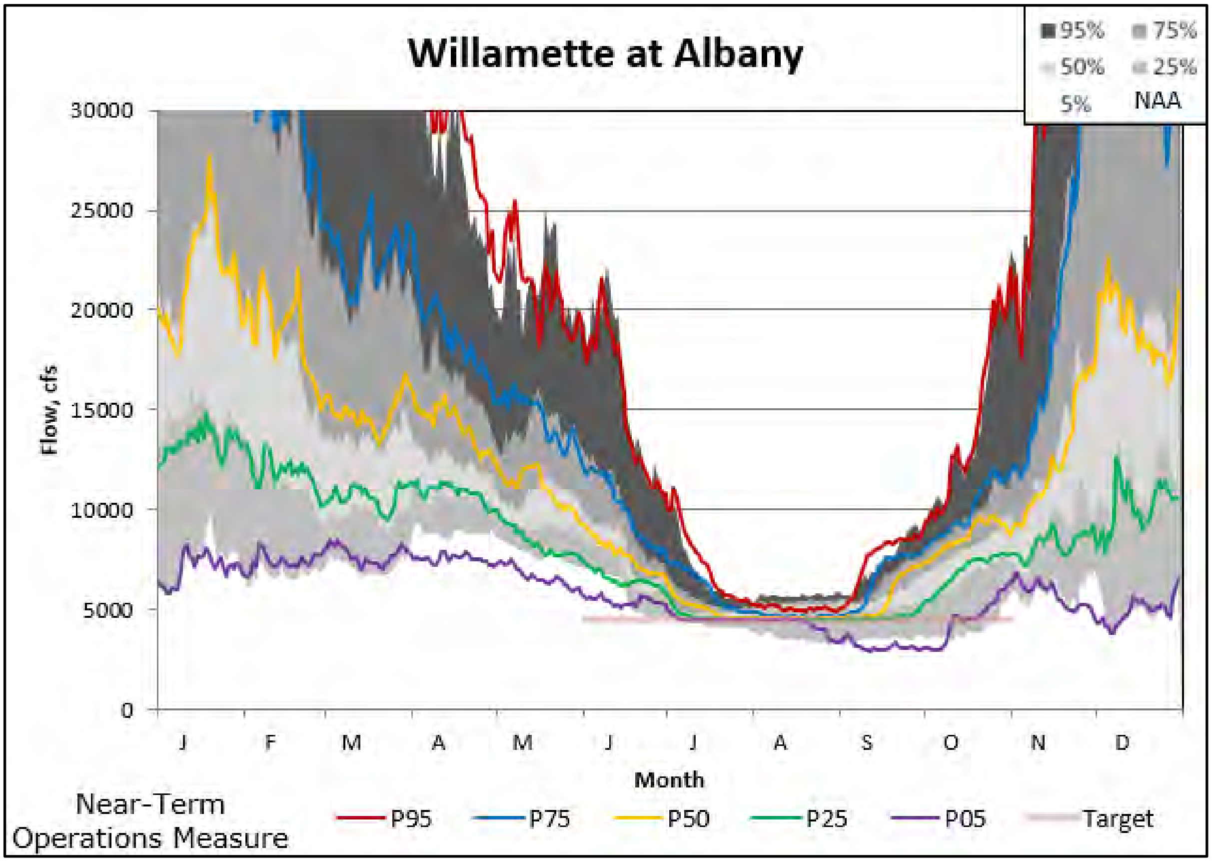

**Figure 3.2-87. Near-Term Operations Measure Willamette River at Albany flow non-exceedance compared with NAA**

Despite the lower targets of the integrated temperature and habitat flow regime, flow at Salem would be fairly similar to the NAA in the spring and summer. Since actual outflows from various dams (e.g., spillway flows at Green Peter) would be higher than would be required to meet minimum flow targets, the flows at Salem would behave similar to the higher BiOp requirements in the NAA for these periods. Detroit Reservoir would have higher storage for the Near-Term Operations Measure than the NAA across all years, so it can supplement the lower storage in the Middle Fork reservoirs. Therefore, Salem would meet its target in the driest years in later summer and early fall while Albany may not. The releases for the deeper fall reservoir drawdowns at Green Peter and Lookout Point would show an increase in flows as compared to the NAA during September and October that would be evident even as far downstream as Salem.

Lower water surface elevations at Cougar Reservoir are not likely to have as much of an effect at Salem as Albany. Detroit Reservoir would remain above its minimum across all years and could likely supplement for some of the Cougar storage reduction downstream of the Santiam's confluence with the mainstem Willamette River.

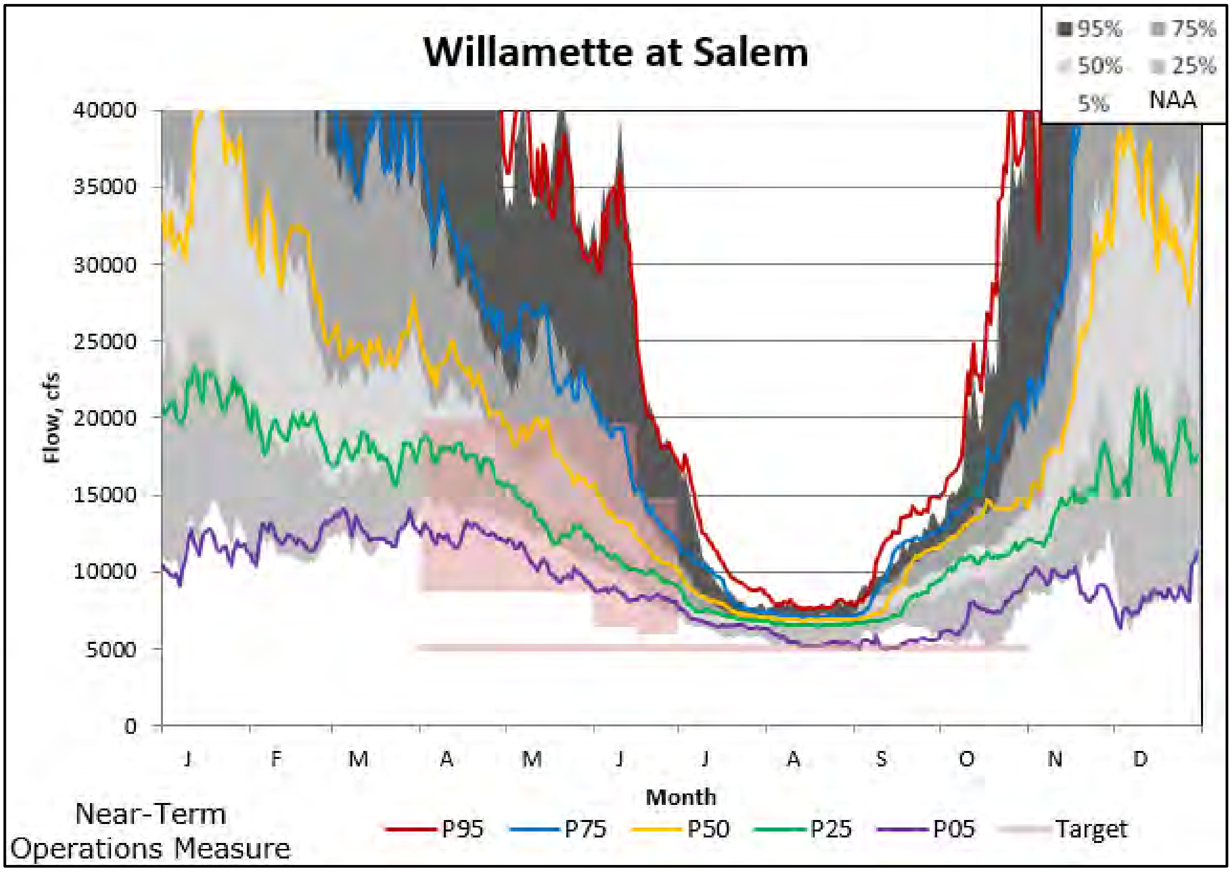

**Figure 3.2-88. Near-Term Operations Measure Willamette River at Salem flow non-exceedance compared with NAA**

### *3.2.2.5.8 Climate Change*

The WVS will likely experience increasing wintertime flow volumes in the future. Some flood magnification (increased severity during flood season) is also likely. Because the WVS system storage will remain about the same, it is likely that FRM operations will face future challenges. An upward shift in winter median future project inflows may increase both the average reservoir water surface elevation as well as outflows downstream of the WVS dams. Reservoirs located within higher elevation subbasins, such as Detroit and Cougar, are likely to see higher rainfall and runoff volumes in the winter. Higher projected temperatures in the future would mean less snowpack than currently experienced. Lower snowpack would also reduce spring volume as the snow melts. Lower elevation subbasin projects such as Fern Ridge and Cottage Grove, with little or no snowpack, are projected to experience higher wintertime flow volumes, but similar peak runoff timing compared to historical baselines.

During conservation season, climate change will affect Alternative 2A similar to the NAA, though Alternative 2A may be able to store and release more water in the spring and summer of dry years as compared to the NAA. Since the Alternative 2A integrated temperature and habitat flow regime minimum targets are lower than the NAA BiOp requirements, the reservoirs can store more water during conservation season as compared to the NAA. However, reservoirs will have to use more of this stored water to meet downstream flow targets with projected increased variability in the spring shoulder months, drier and hotter summers, and lower summer baseflow. Therefore, reservoirs are projected to have lower water surface elevations compared to the baseline.

Reservoirs in Alternative 2A would sometimes reach minimum elevation during the summer, but less often than the NAA, meaning they would be able to augment summer flows for longer than the NAA even with projected decline in late spring and summer flows. The lowest reservoir water surface elevations will occur in the driest years, which would be drier than the WVS currently encounters, as the reservoirs are drafted more to meet downstream flow targets. The WVS would miss the mainstem Willamette flow targets less often under Alternative 2A than the NAA. Climate change effects, and potential implications as discussed above, draw on the climate change projection and trend information provided in the climate change appendices (F1 and F2).

#### *3.2.2.6 Alternative 2B -- Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2B would shift stored water releases from the spring to the summer and fall, most prominently in dry years. The “Integrated Temperature and Habitat Flow Regime” would replace the 2008 NMFS BiOp in the NAA. Briefly, this would modify the BiOp targets at a WVS reservoir if it is at more or less than 90 percent of rule curve elevation. Flows would be reduced within a range down to minimums needed for fish survival when reservoirs are under the 90 percent threshold. While these minimums would be less the BiOp targets, these would be adaptive within a water year and can return to return to levels higher than the BiOp flows downstream of the dams if reservoir levels rise about 90 percent full.

At the mainstem Willamette control points – Albany and Salem – flow targets would be reduced to 4,500 and 5,000 cfs, respectively. The higher BiOp targets, particularly in the spring and early summer, are designed to help migrating fish and keep the river from getting too hot, so much more water would be added in the spring. As a replacement, the integrated temperature and habitat flow regime would require additional flow based on the air temperature, with total flow minimum at Salem ranging from 5,900 cfs to 19,800 cfs. This would allow the WVS to store additional water when it is not needed to keep the river, and fish in it, cool.

Alternative 2B would alter storage in drier than average years, and especially the 25 and 5 percent non-exceedance (P25 and P05 in the figures) years, shifting flow releases from April to June into July through October. Flows would be lower than NAA flows in the year during the April to June period. Later flow targets from July to October would be met more frequently due to the additional accumulated stored water. Compared to NAA, the spring and early flows would be similar or somewhat lower across the WVS, so reservoir elevations would be somewhat higher than the NAA throughout the conservation season.

Cougar and Green Peter reservoirs have drawdowns in Alternative 2B. Cougar releases waters down to the diversion tunnel elevation in both spring and fall and Green Peter has a deeper fall reservoir drawdown. During these drawdowns there is more flow downstream of these two reservoirs as compared to the NAA.

Since the spring reservoir drawdown at Cougar occurs during the NAA refill period, storage at Cougar is reduced. As compared to Alternative 2A, which would not draw down Cougar, the reduced storage means that other WVS reservoirs, notably in the Middle Fork of the Willamette River subbasin, are required to release additional water to meet mainstem Willamette River flow targets. Regardless, the flow target at Albany is missed more often in dry years as the larger WVS reservoirs reach their minimum elevations earlier in the year.

Although there are structural actions in Alternative 2B at the WVS dams to aid fish survival, many of these do not affect the flow out of any WVS dam. These do not appear in the reservoir flow model. An example of this is the WTC tower at Detroit, which allows for greater control of the temperature of the water released from the dam but does not alter the flowrate or outlet used for dam operations. A more detailed analysis of Alternative 2B by subbasin follows.

Lower spring flows in dry years and higher summer flows in nearly all years would have long term effects on the WRB. Effects from the Alternative 2B to hydrologic processes: Major compared to the NAA.

##### *3.2.2.6.1 Santiam Subbasin*

Alternative 2B would fill Detroit Reservoir more often and narrow the range of reservoir elevations prior to drafting the reservoir for flood season (Figure 3.2-89) compared to the NAA. The lower tier of the integrated temperature and habitat flow regime requires lower flows downstream of Detroit, so the reservoir would be able to fill more often and has more volume to supply to downstream targets later in the year, meeting all its immediate downstream flow targets across all years.

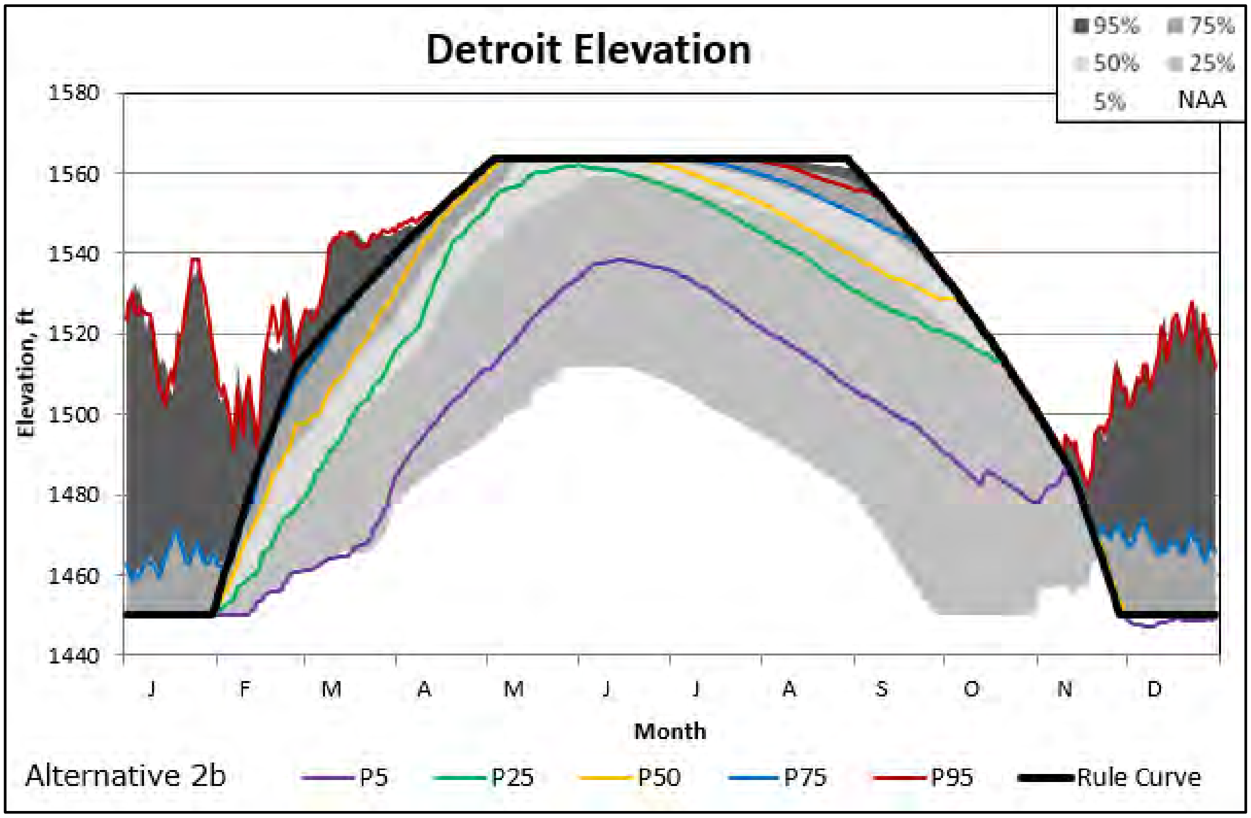

**Figure 3.2-89. Alternative 2B Detroit water surface elevation non-exceedance compared with NAA**

Green Peter reservoir (Figure 3.2-90) would also fill more often during conservation season in Alternative 2B as compared to the NAA, despite implementation of a deeper fall reservoir drawdown. In very dry years, the reservoir elevation would be well below the rule curve through the winter but would recover to higher levels than the NAA by summer due to the lower integrated temperature and habitat flow regime targets. However, the percentage of time that Green Peter reaches top of conservation storage would remain about the same since all inflow above that level would be released from the reservoir. Lower reservoir levels would be expected throughout the winter flood season, even during the wettest years.

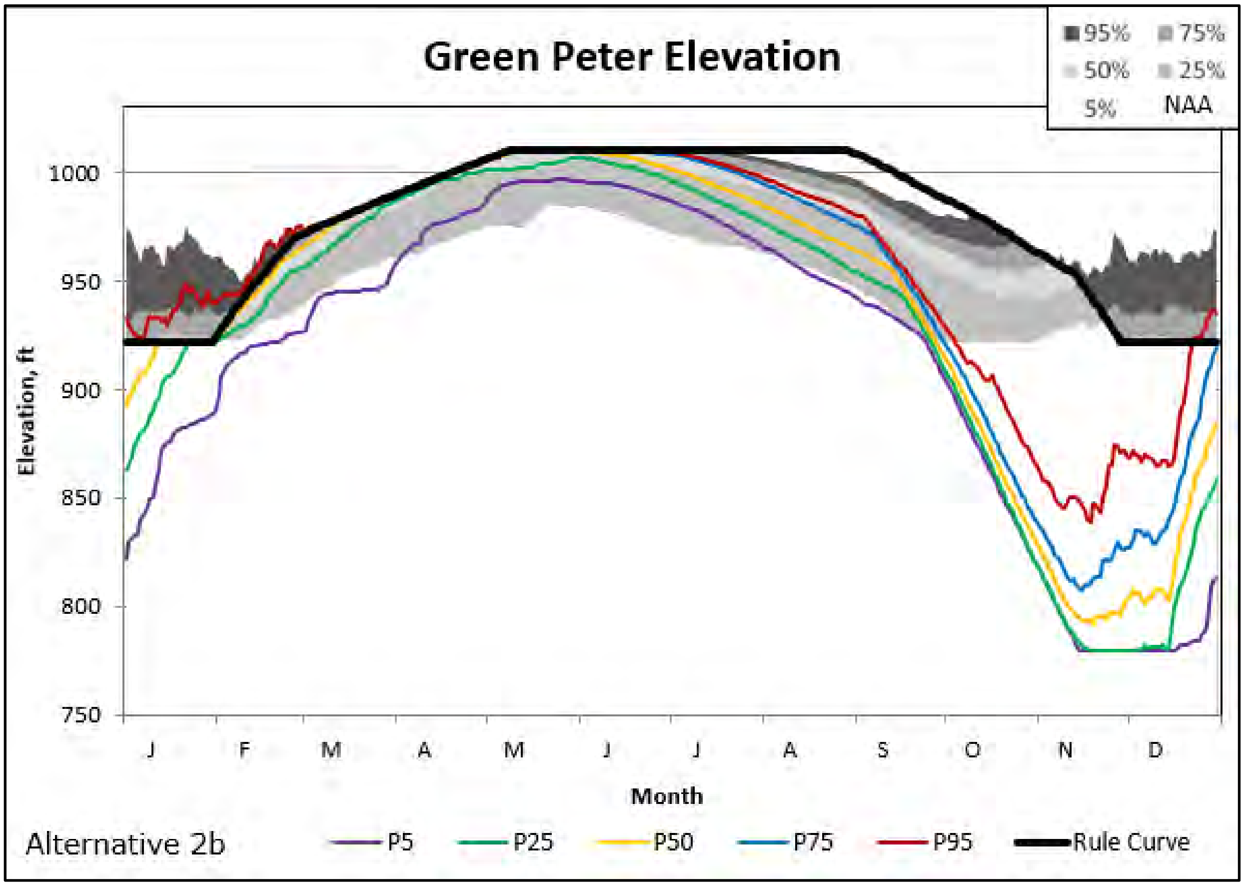

**Figure 3.2-90. Alternative 2B Green Peter water surface elevation non-exceedance compared with NAA**

Outflow from Foster Dam (Figure 3.2-91) would meet the integrated temperature and habitat flow regime targets except in November of very dry years when Green Peter would have already reached the minimum deeper fall reservoir drawdown elevation. The increased flows in September are the result of Green Peter releasing water for the deeper fall reservoir drawdown. Immediately downstream, winter flows across all but very wet years would be lower. This is also due the Green Peter deeper fall reservoir drawdown, as it holds back water to get back up to minimum conservation pool. Foster Reservoir would seldom deviate from the rule curve – and the NAA – for Alternative 2B.

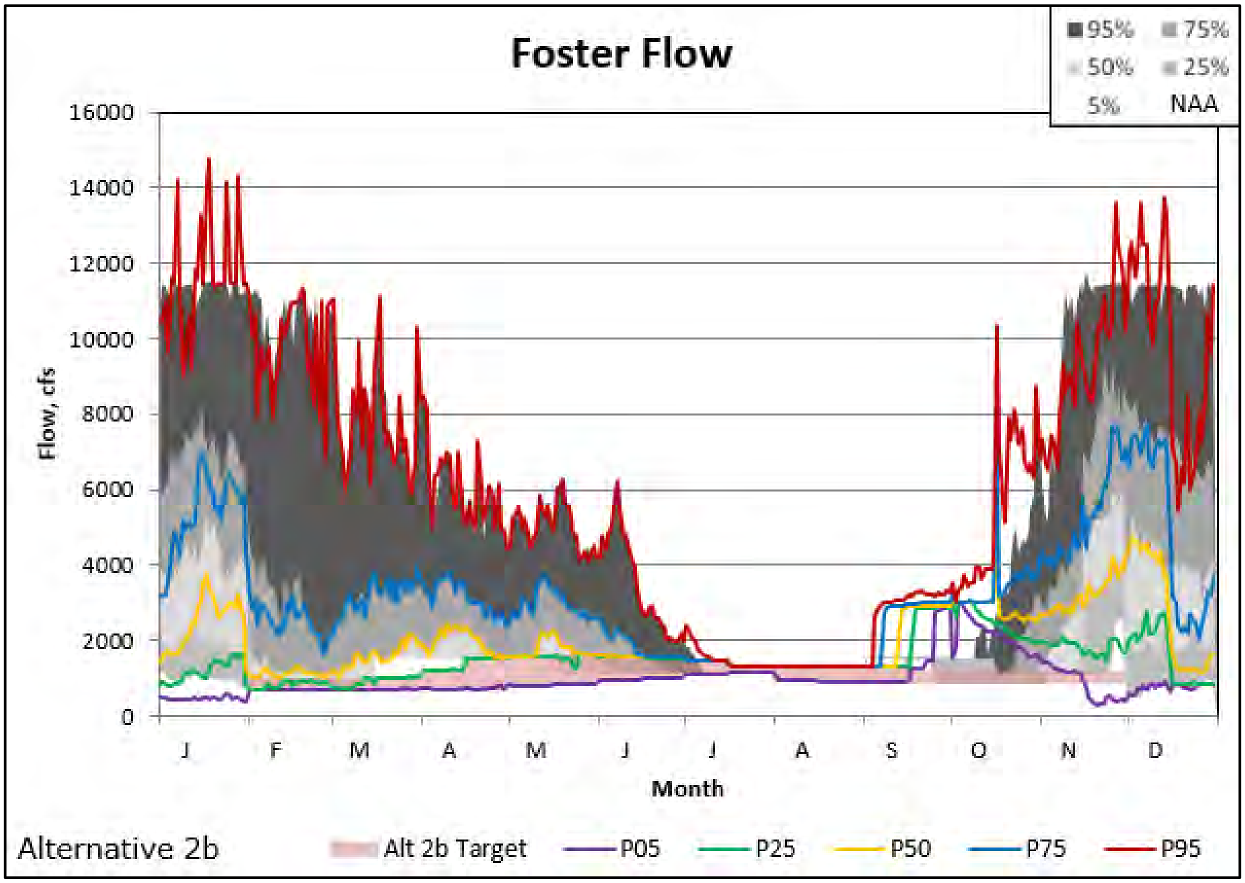

**Figure 3.2-91. Alternative 2B Foster flow non-exceedance compared with NAA**

The Santiam at Jefferson (Figure 3.2-92) would show some of the flow changes at Foster but any potential winter flood management benefits from the deeper fall reservoir drawdown at Green Peter would no longer be present. Wet weather flows would be very similar to the NAA during the winter and lower flows would be only slightly lower, though these flows are already well below flood stage. In the spring, lower flows in the driest years would be due to the lower requirements of the integrated temperature and habitat flow regime, both directly downstream of the dams and mainstem flow targets. Detroit, with its higher storage volumes, can supply water throughout the summer, resulting in higher flows than the NAA. The increased flows in September from the Green Peter deeper fall reservoir drawdown would be evident at Jefferson.

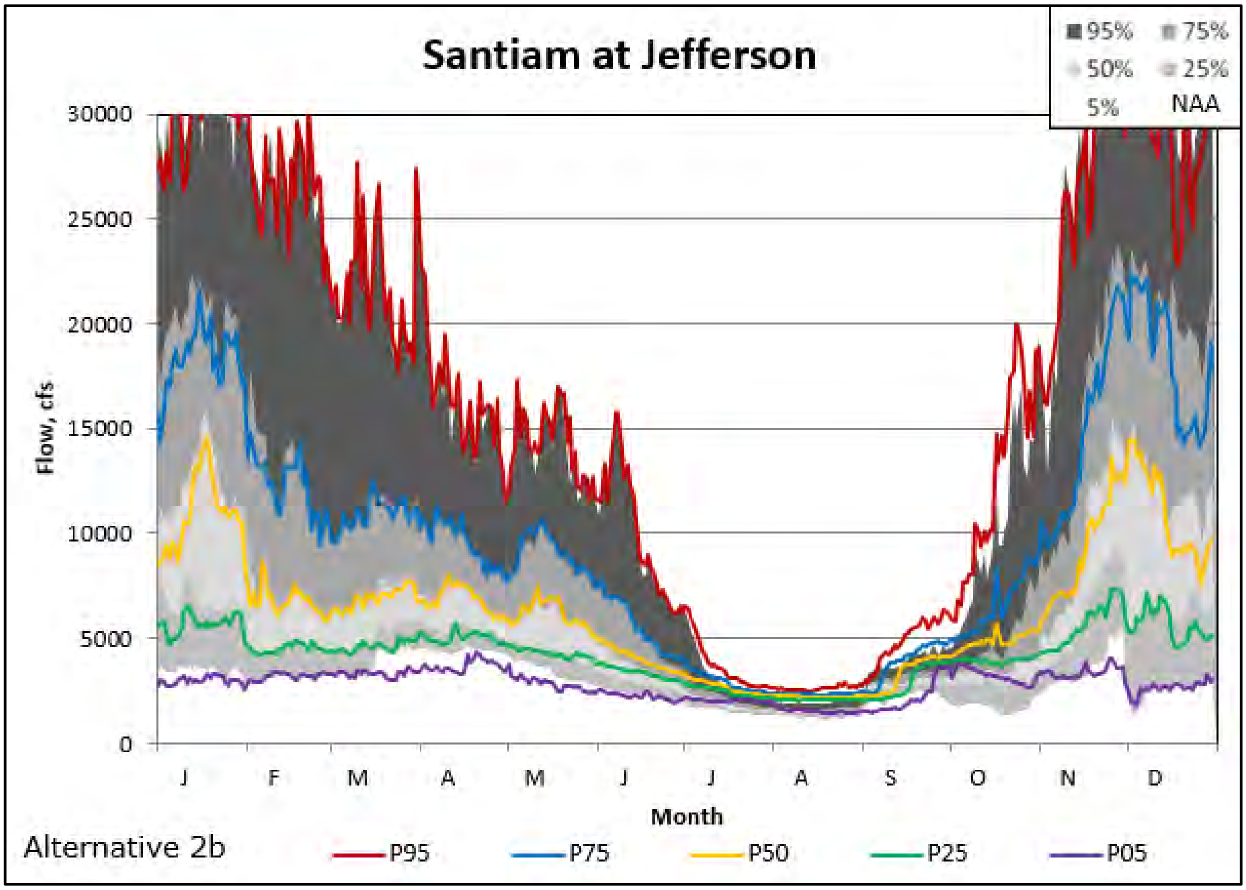

**Figure 3.2-92. Alternative 2B Santiam at Jefferson flow non-exceedance compared with NAA**

#### *3.2.2.6.2 Long Tom Subbasin*

As explained in the NAA, Fern Ridge reservoir (Figure 3.2-93) is operated for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. Since Fern Ridge has a large surface area and small volume compared to the other WVS reservoirs, there is limited scope to change its operation and the water surface elevations within Fern Ridge would remain nearly the same as the NAA. Downstream flows at Monroe would remain similarly unchanged for Alternative 2A.

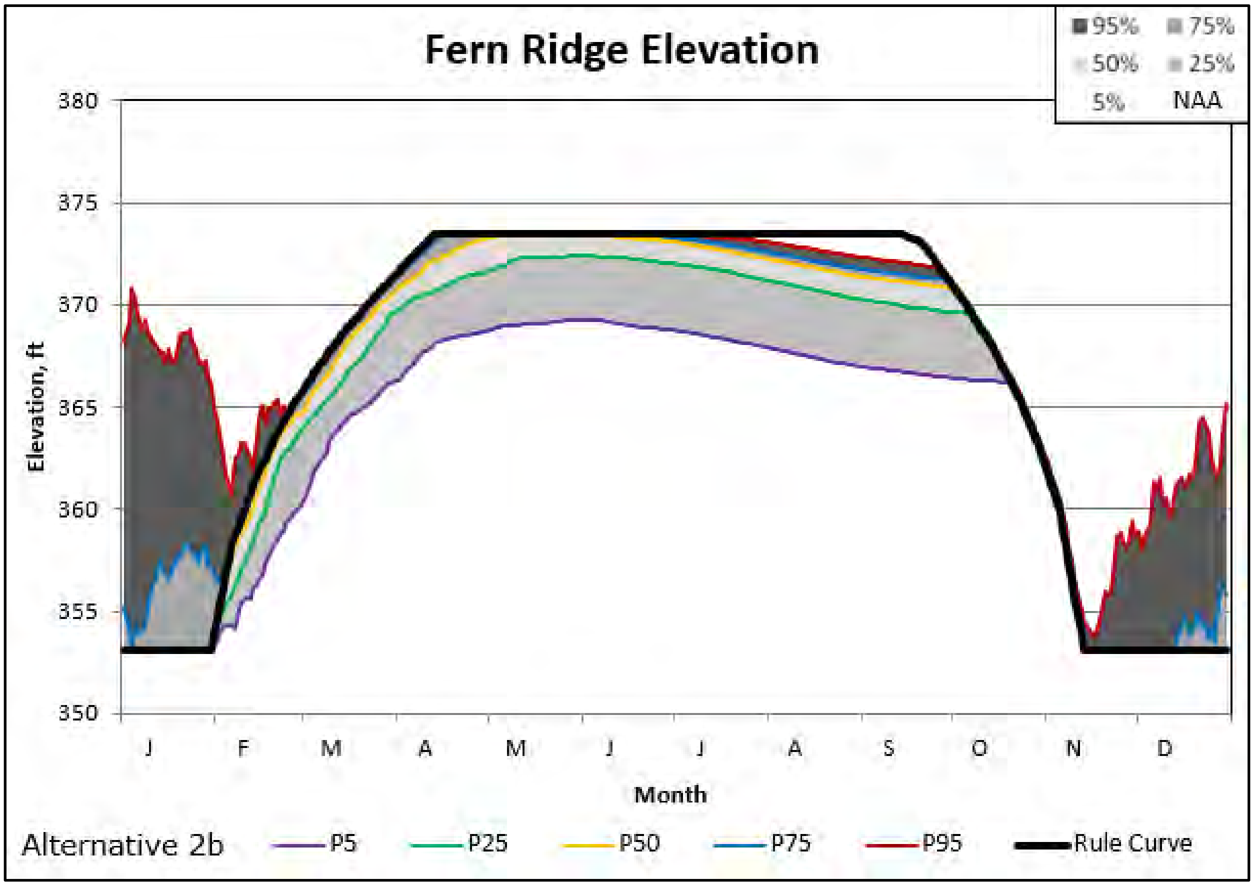

**Figure 3.2-93. Alternative 2B Fern Ridge water surface elevation non-exceedance compared with NAA**

#### *3.2.2.6.3 McKenzie Subbasin*

Cougar reservoir (Figure 3.2-94) would have both a spring and fall reservoir drawdown in Alternative 2B, down to 1330 feet. This is a significant change from the NAA. The reservoir water surface elevation would only be at or above minimum conservation pool at the end of winter and only the wettest summers (P95 line). An average year (P50) would achieve the spring reservoir drawdown target elevation, but would not during the fall. Cougar would also miss its downstream flow target when it is at minimum elevation during the summer and fall, sometimes for many months.

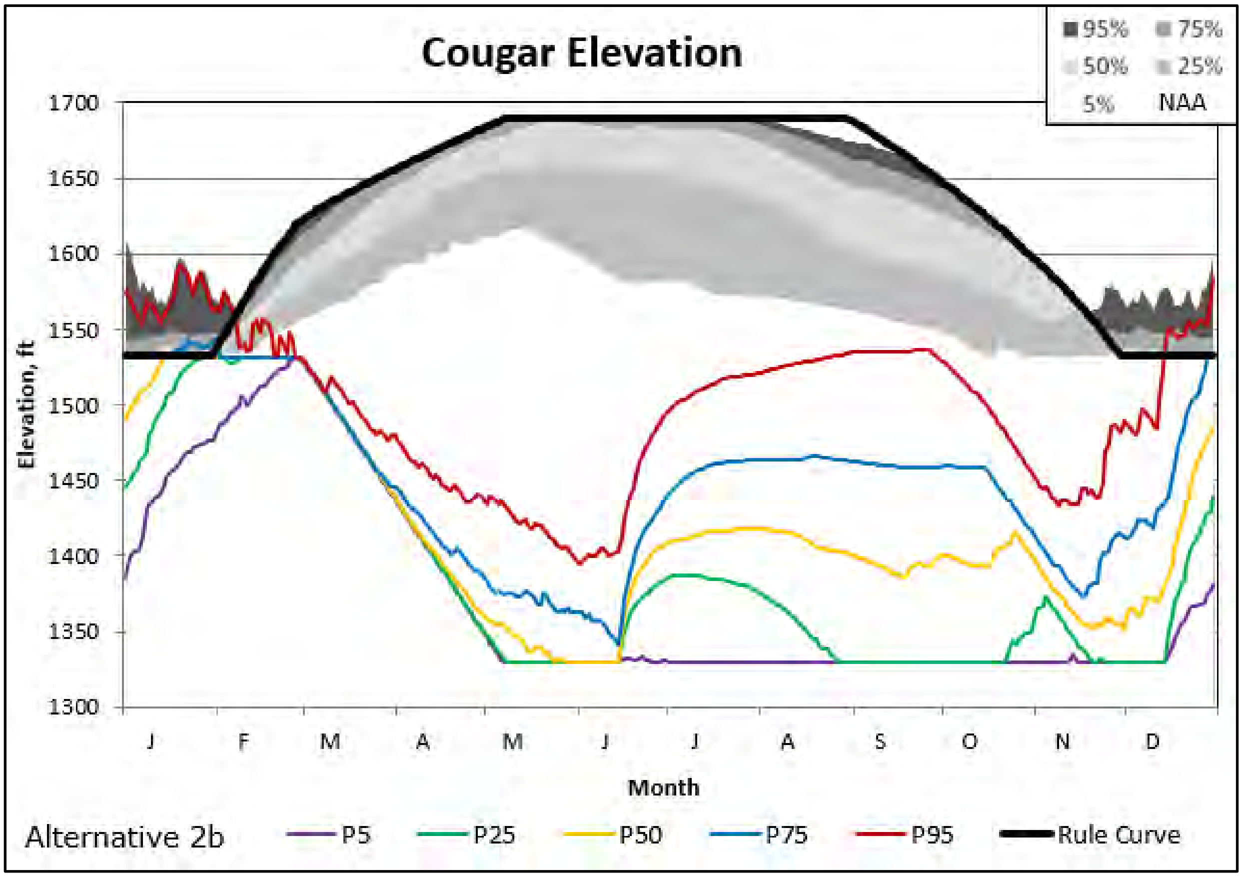

**Figure 3.2-94. Alternative 2B Cougar water surface elevation non-exceedance compared with NAA**

Blue River reservoir (Figure 3.2-95) would fill more often as compared to the NAA and uses the inactive pool to supplement downstream flow targets during October of the driest years. There are two changes due to the Cougar diversion tunnel operation, as compared to Alternative 2A. Blue River would be required to store more water during very wet years for the McKenzie River at Vida to remain at or below bankfull since Cougar is drafting for the spring reservoir drawdown. Additionally, Blue River would augment instream flows by using the power pool more often during the fall of very dry years, since Cougar would not have any accumulated storage during those times.

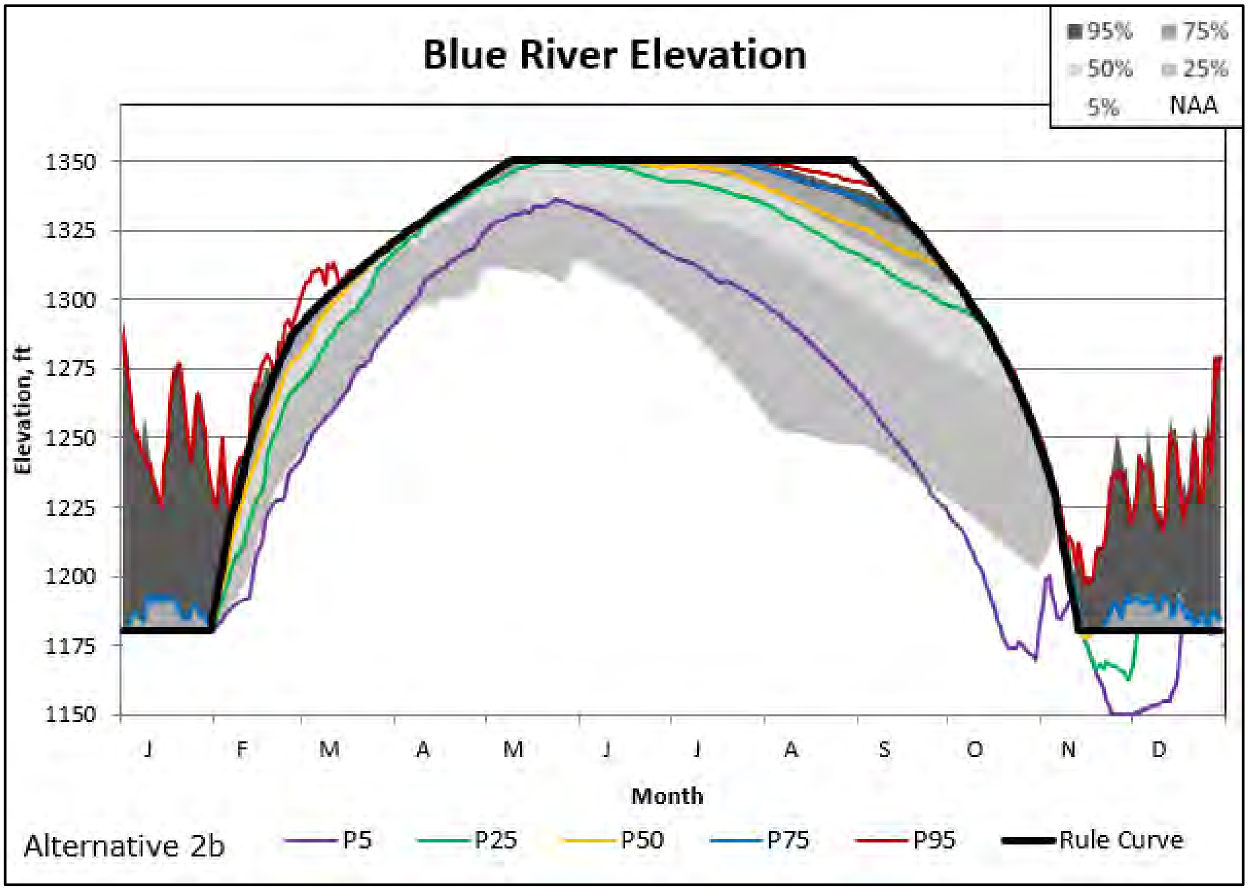

**Figure 3.2-95. Alternative 2B Blue River water surface elevation non-exceedance compared with NAA**

Moving downstream to the control point for both Cougar and Blue River, the McKenzie River at Vida (Figure 3.2-96) would show the effect of the Cougar reservoir drawdowns. The higher flows in the spring would be from Cougar's releases to reach the diversion tunnel elevation. Lower flows starting in June would be the result of Cougar having reduced storage throughout conservation season which would not occur under the NAA. Notably, flow would be only slightly less in the driest years as compared to the NAA due to additional flow from Blue River. However, as compared to Alternative 2A, in which dry-year flows would be above the NAA, flows would be reduced through the summer and fall.

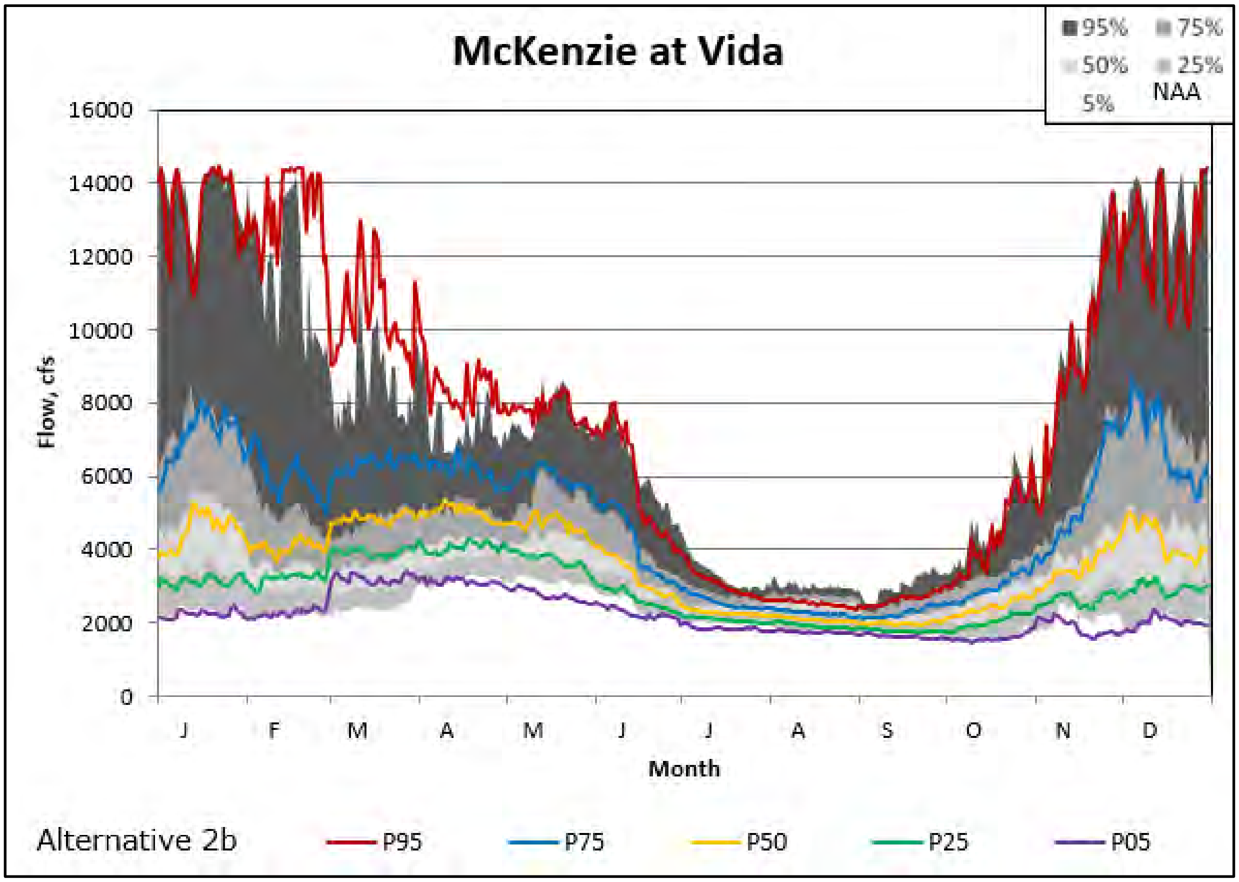

**Figure 3.2-96. Alternative 2B McKenzie River at Vida flow non-exceedance compared with NAA**

### *3.2.2.6.4 Middle Fork of the Willamette Subbasin*

Hills Creek (Figure 3.2-97) initially would fill more quickly due to the lower integrated temperature and habitat flow regime targets and would stay at similar or higher elevations during wet years compared to the NAA. During dry years, the reservoir would augment instream flows by using the power pool, releasing more water to meet the flow target at Albany. Its capacity would be exhausted in the driest years (P05 line), at which point Lookout Point would supply additional water and reach its Alternative 2B minimum in Figure 3.2-98. As compared to Alternative 2A, storage elevations for both Hills Creek and Lookout Point would be slightly lower across all years. Since Cougar has much less storage in Alternative 2B, both reservoirs would release more water to meet mainstem flow targets.

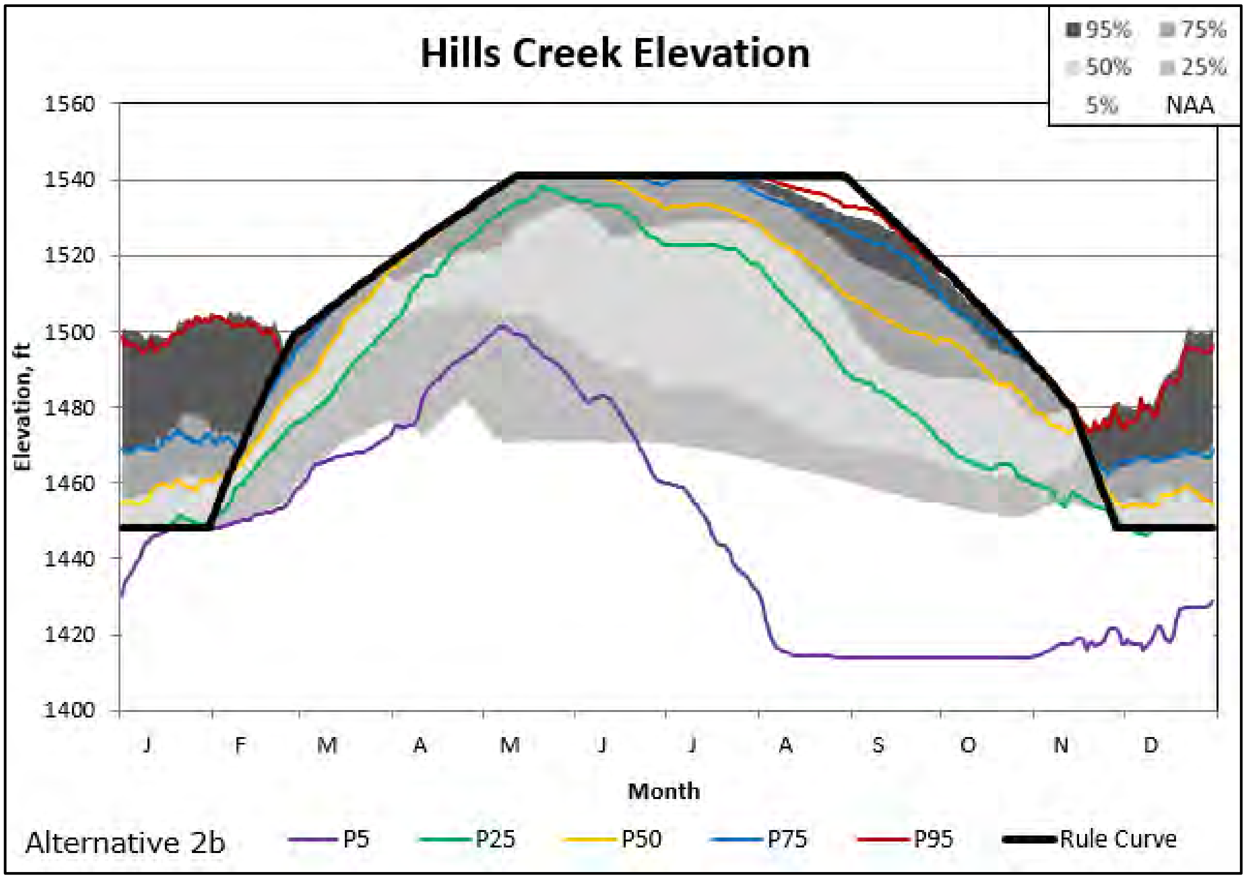

**Figure 3.2-97. Alternative 2B Hills Creek water surface elevation non-exceedance compared with NAA**

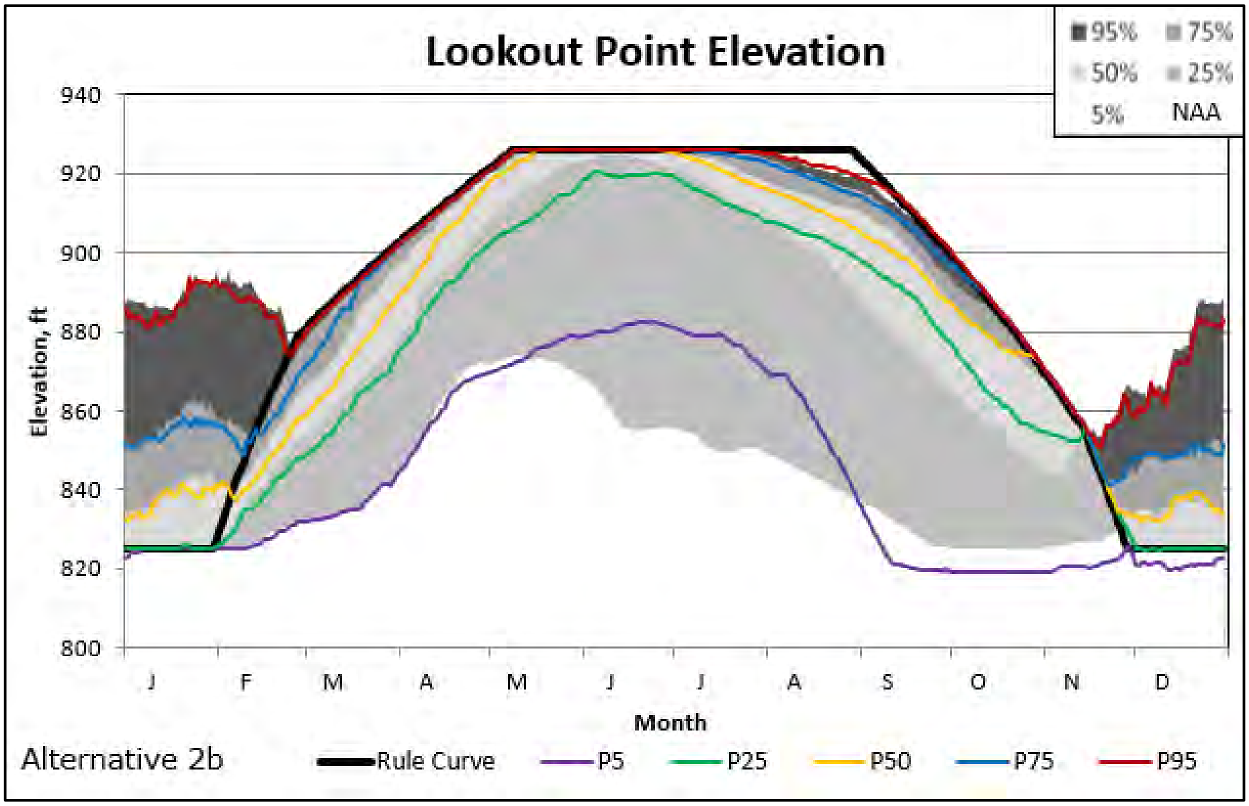

**Figure 3.2-98. Alternative 2B Lookout Point water surface elevation non-exceedance compared with NAA**

Fall Creek reservoir (Figure 3.2-99) would show only marginal differences from the NAA in Alternative 2B, though some elevations would be somewhat below those in Alternative 2A.

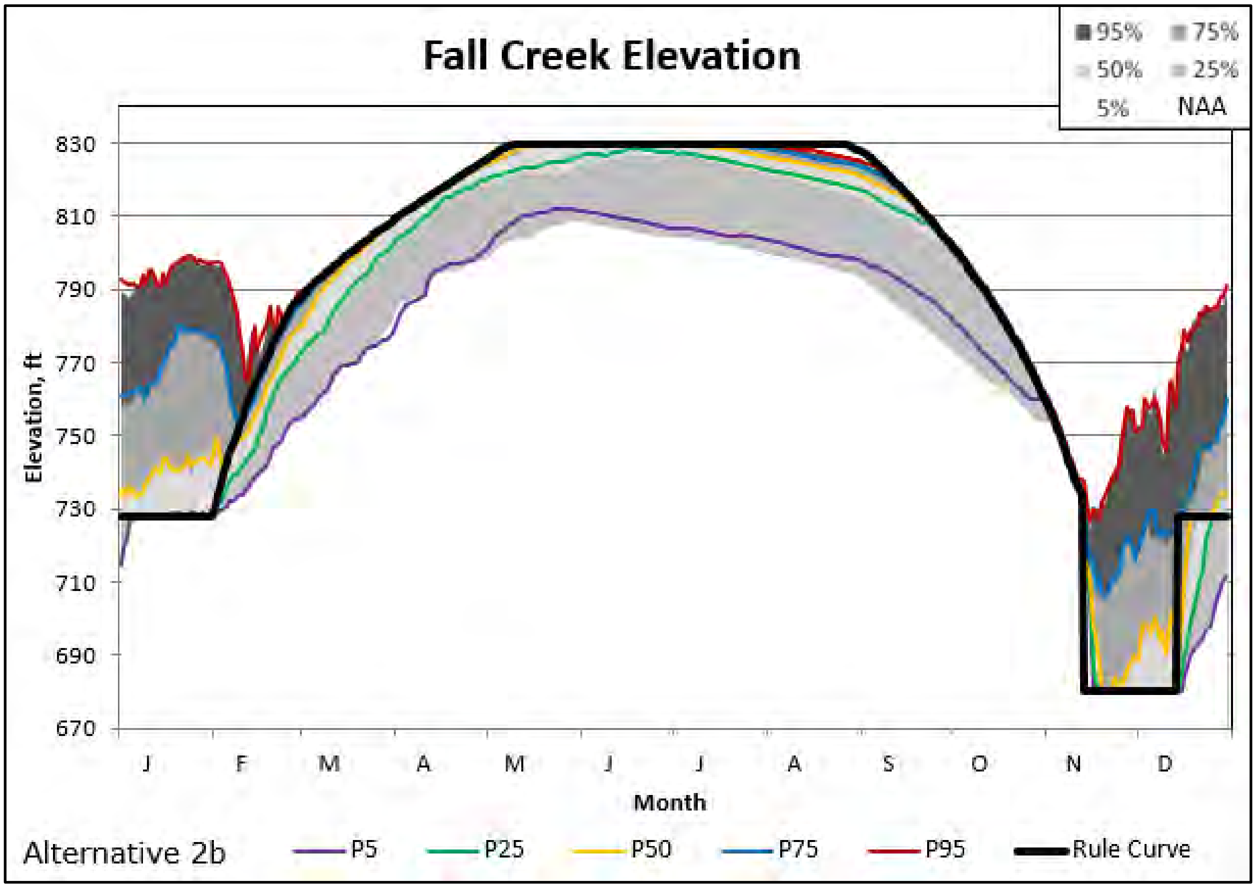

**Figure 3.2-99. Alternative 2B Fall Creek water surface elevation non-exceedance compared with NAA**

At the downstream control point at Jasper (Figure 3.2-100), the shift in flow releases would be evident, especially in dry years, with lower flows in the spring and higher flows in the summer and fall compared to the NAA. The increased fall flows during wet years as compared to the NAA would be due to the reservoirs starting at a higher elevation prior to drafting for flood season. There would be more water to release from the reservoirs so there would be higher flow downstream of them.

In the fall of the driest years (P05 line), flows would be lower than Alternative 2A and sometimes below the NAA. Both Hills Creek and Lookout Point would reach their minimum elevations and only release inflow. Lower storage at Cougar Reservoir would require higher releases from the Middle Fork WVS reservoirs to meet downstream flow targets. Since Lookout Point would already reach its minimum in Alternative 2A, the additional flow requirements would be enough to reach that level in the driest years in Alternative 2B.

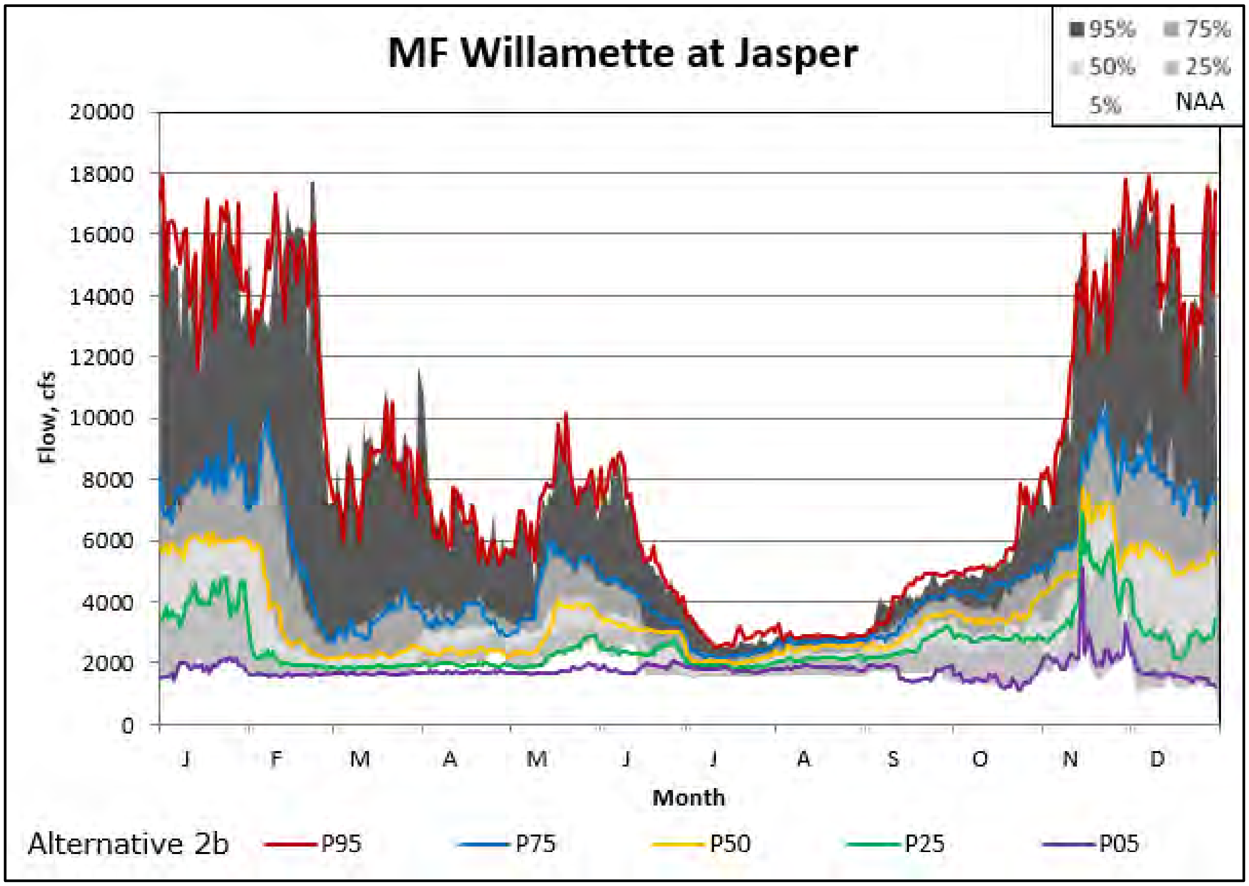

**Figure 3.2-100. Alternative 2B Middle Fork of the Willamette River at Jasper flow non-exceedance compared with NAA**

*3.2.2.6.5 Coast Fork of the Willamette Subbasin*

For Alternative 2B, the Coast Fork subbasin would store more water in the spring and release it during the summer and fall during dry years and it would be generally similar to the NAA in wet years. Reservoir elevations would be somewhat higher at both Dorena (Figure 3.2-101) and Cottage Grove for Alternative 2B during the late spring and summer, with other times similar to the NAA. Figure 3.2-102 shows the control point at Goshen. Since the pools would stay higher throughout the summer, more water would be released during September and October compared to the NAA.

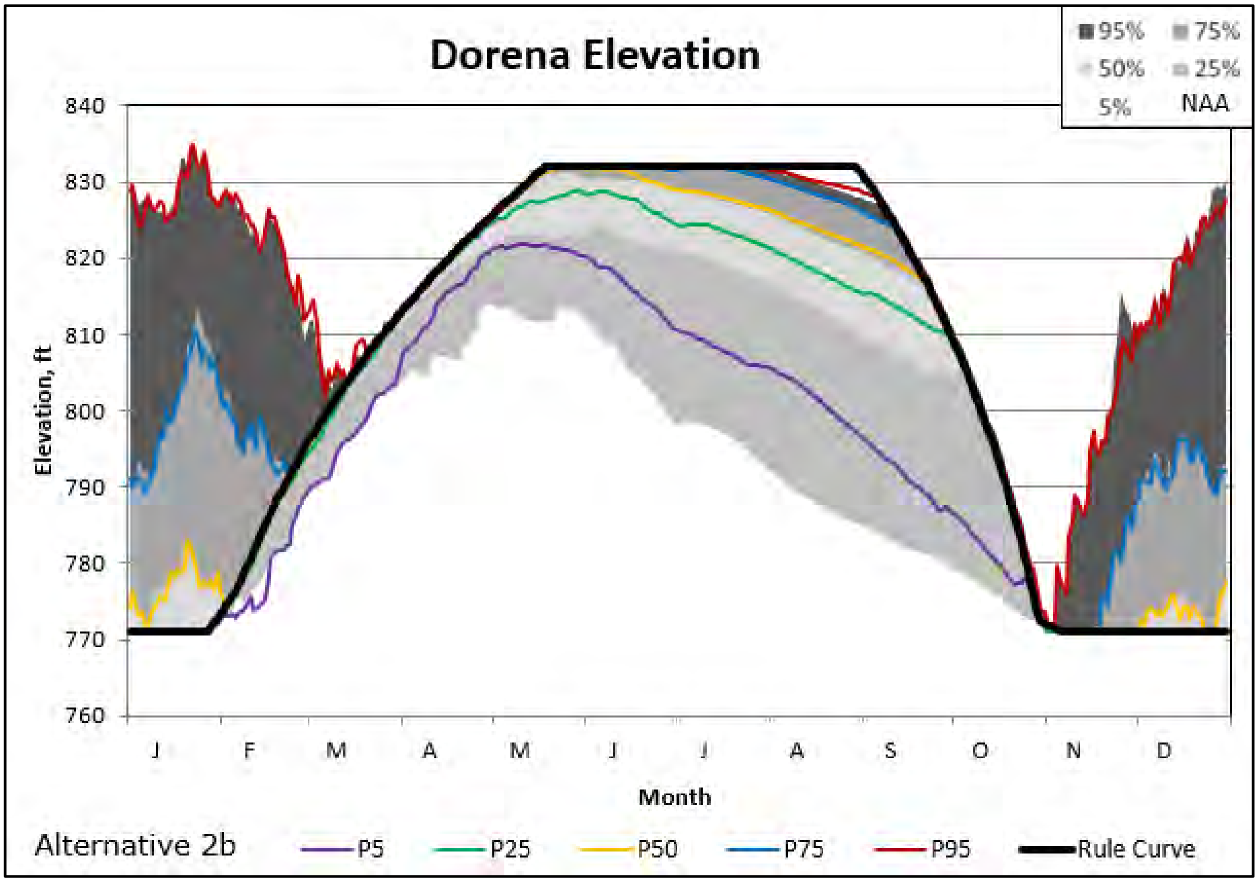

**Figure 3.2-101. Alternative 2B Dorena water surface elevation non-exceedance compared with NAA**

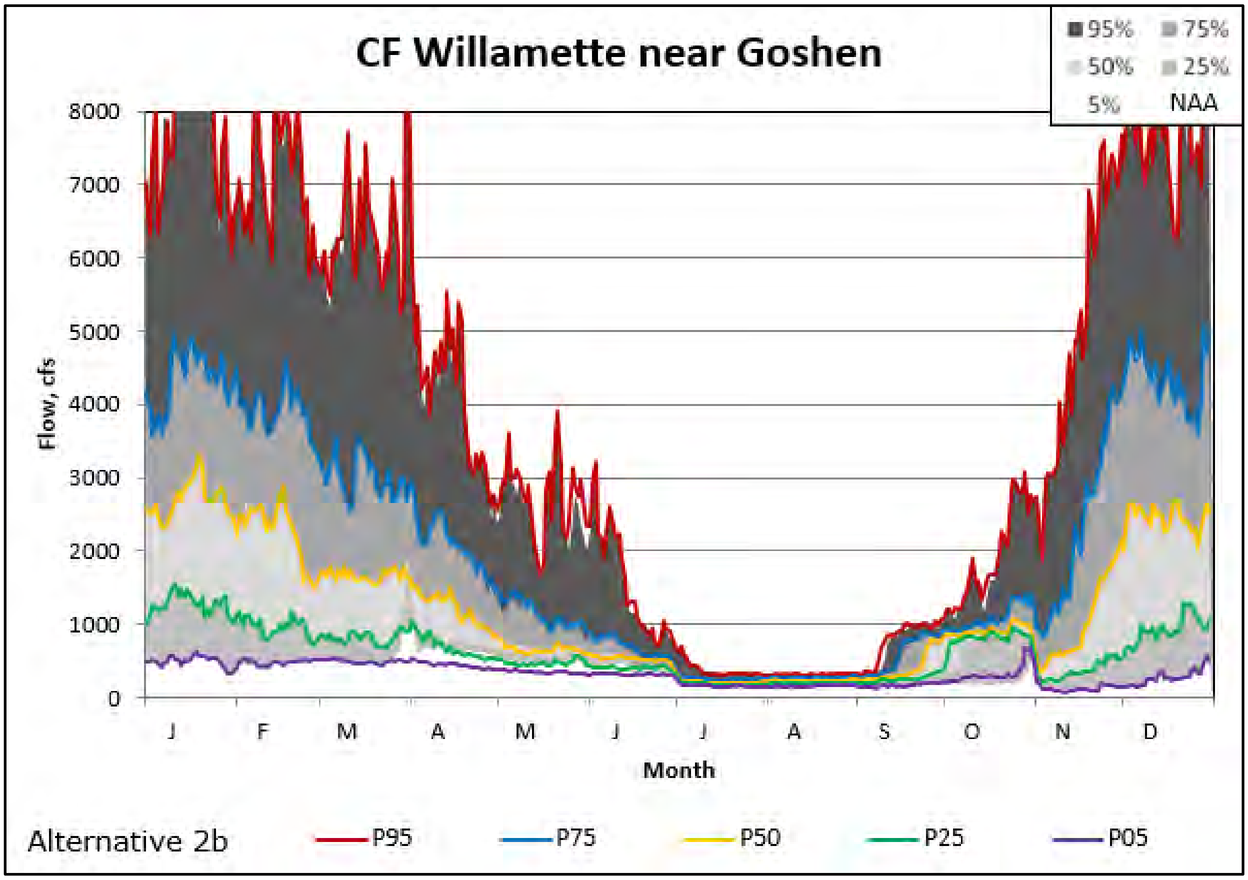

**Figure 3.2-102. Alternative 2B Coast Fork of the Willamette River at Goshen flow non-exceedance compared with NAA**

### *3.2.2.6.6 Mainstem Willamette River*

Alternative 2B would alter the regulated hydrology of the mainstem Willamette River control points, storing water more water in the spring and releasing it during the summer. The Willamette River at Albany (Figure 3.2-103) would show dry years below their NAA equivalents from April to June and a compressed flow regime through the summer, with the higher flow years reduced and the low flow years increased. The WVS would typically meets the lower integrated temperature and habitat flow regime target at Albany, missing during September and October of the driest years. Albany would be below the Alternative 2B target for much more time than the same target during Alterative 2A due to the decreased contributions from Cougar reservoir.

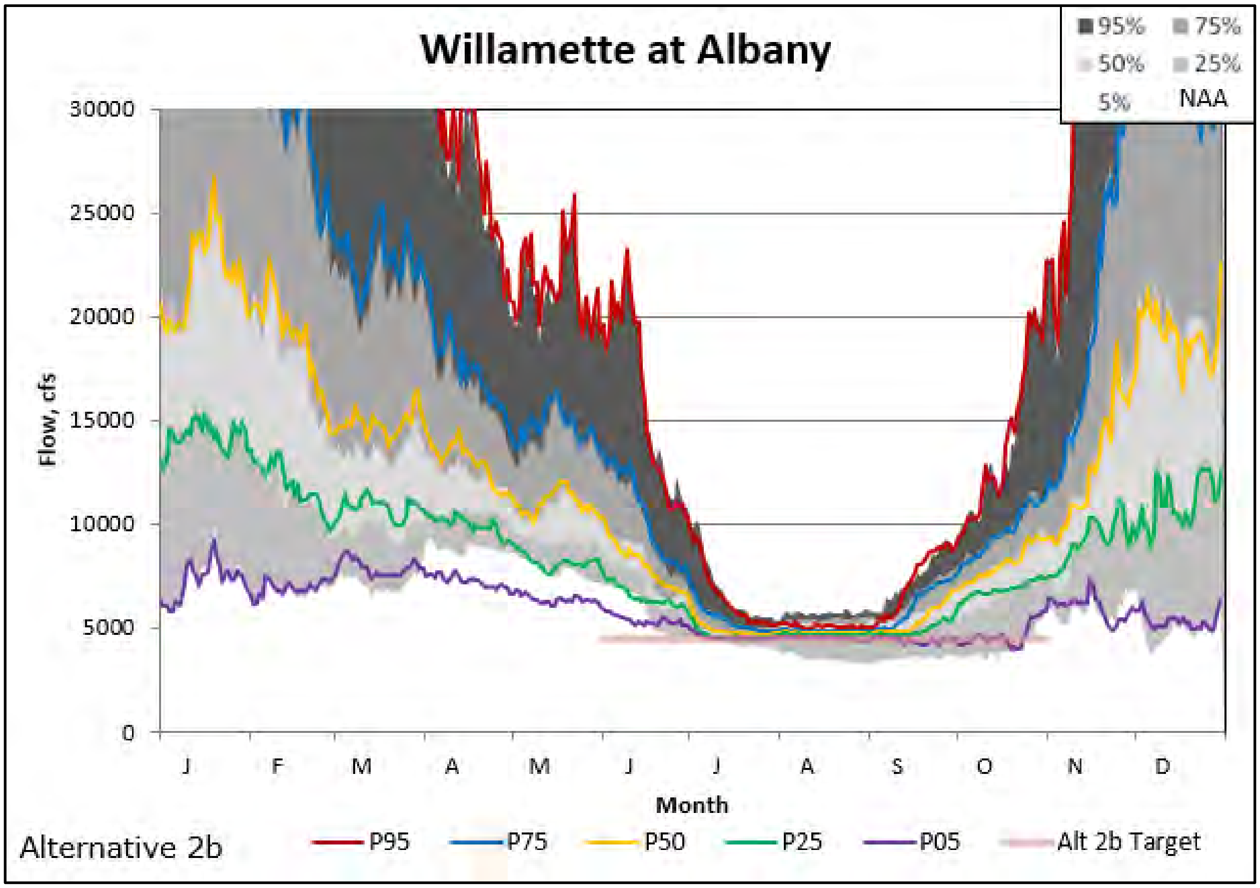

**Figure 3.2-103. Alternative 2B Willamette River at Albany flow non-exceedance compared with NAA**

Like the Albany control point, the Willamette River at Salem (Figure 3.2-104) would show reduced flows from April to June of dry years, while meeting the integrated temperature and habitat flow regime variable air-temperature-guided target. Summer and fall flows would increase across all years as compared to the NAA, though slightly decreased as compared to Alternative 2A. The effect of reduced storage at Cougar would be much less evident at Salem due to the contributions of the Santiam WVS reservoirs and the integrated temperature and habitat flow regime target would nearly always be met.

The increased flows from September to November would be due to the deeper fall reservoir drawdown at Green Peter compared to the NAA. These increases would be within the river channel (up to 90,000 cfs), meaning they would not impact flood risk.

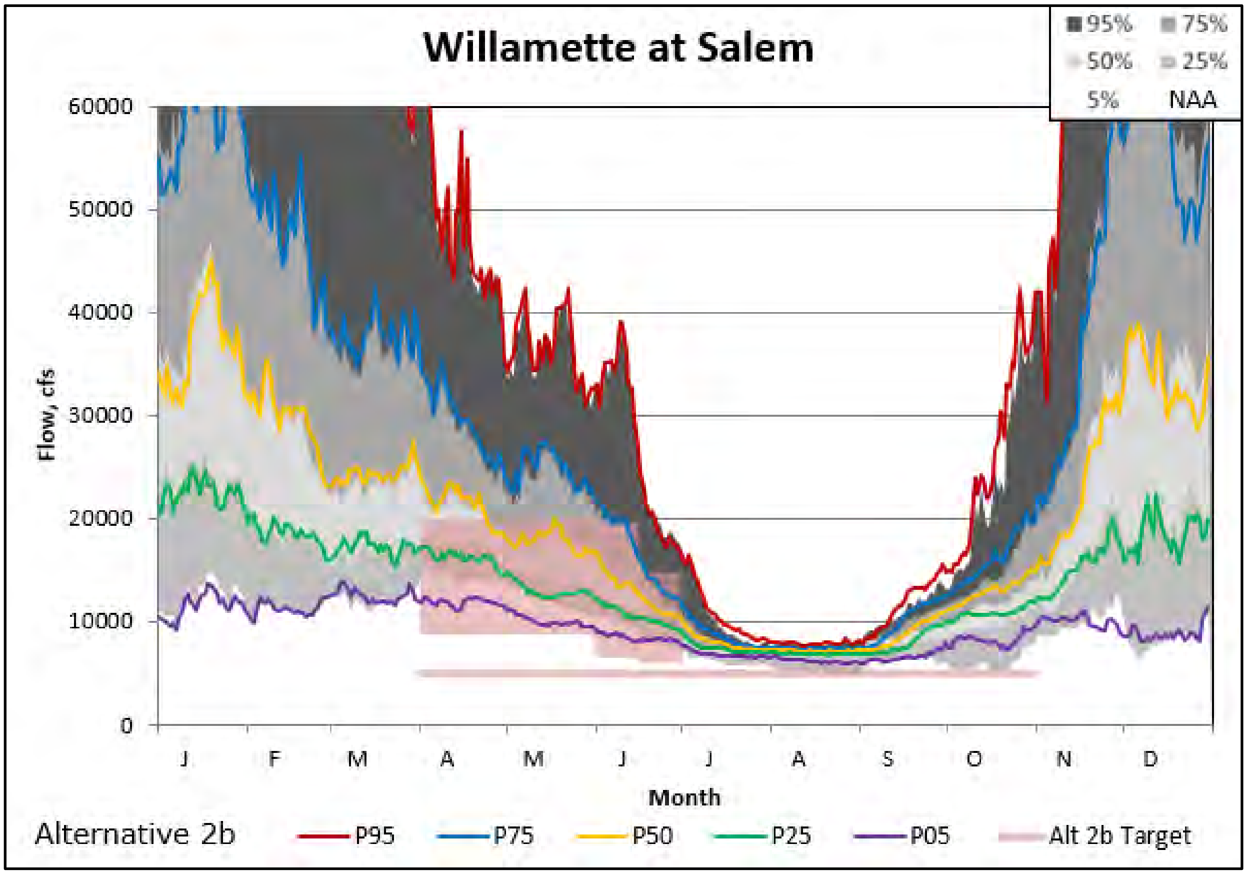

**Figure 3.2-104. Alternative 2B Willamette River at Salem flow non-exceedance compared with NAA**

### *3.2.2.6.7 Near-Term Operations Measure*

See Alternative 2A, Section 3.2.2.4.7, for description of effects due to the Near-Term Operations Measure.

### *3.2.2.6.8 Climate Change*

The WVS will likely experience increasing wintertime flow volumes in the future. Some flood magnification (increased severity during flood season) is also likely. Because the WVS system storage would not increase substantially, it's likely that FRM operations will face future challenges. An upward shift in winter median future project inflows may increase both the average reservoir water surface elevation as well as outflows downstream of the WVS dams. Both Green Peter and Cougar would refill to their conservation pool elevation later in the year after their deeper fall reservoir drawdowns. However, the overall potential benefit may be minimal to future FRM operations. While the lower reservoir elevation at Cougar at the start of flood season is potentially helpful, the storage volume below the minimum conservation elevation is much less than that above it and climate-driven conversion from snowfall to rain may be more impactful than the additional storage. At Green Peter, projections for flow changes are more muted than the higher elevation basins, meaning that it may diminish in importance relative to other WVS reservoirs for FRM operations.

Reservoirs located within higher elevation subbasins, such as Detroit, are likely to see higher rainfall and runoff volumes in the winter. Higher projected temperatures in the future will mean less snowpack than currently experienced. Lower snowpack would also reduce spring volume as the snow melts. Lower elevation subbasin projects such as Fern Ridge and Cottage Grove, with little or no snowpack, are projected to experience higher wintertime flow volumes, but similar peak runoff timing compared to historical baselines.

During conservation season, climate change will affect Alternative 2B similar to Alternative 2A, with the main difference being lower reservoir elevations in the McKenzie and Middle Fork of the Willamette River subbasins and lower flow in the McKenzie River. Since the Alternative 2B integrated temperature and habitat flow regime targets are lower than the NAA BiOp requirements, most WVS reservoirs can store more water during conservation season as compared to the NAA. However, those reservoirs will have to use more of this stored water to meet downstream flow targets with projected increased variability in the spring shoulder months, drier hotter summers, and lower summer baseflow. Outside of flood season, Cougar reservoir would likely never fill to minimum conservation elevation due to decreased inflow after its spring reservoir drawdown to the diversion tunnel which does not occur under the NAA. Hills Creek and Lookout Point would have to release more water to meet the Albany flow target, substituting for the lack of releases available from Cougar.

Across the WVS, reservoirs are projected to have lower water surface elevations as compared to the baseline, though Cougar, Hills Creek, and Lookout Point are most affected. Reservoirs in Alternative 2B would sometimes draft to minimum targeted elevation during the summer, but less often than the NAA, meaning they would be able to augment summer flows for longer than the NAA even with projected decline in late spring and summer flows. The lowest reservoir water surface elevations would occur in the driest years, which would be drier than the WVS currently encounters, as the reservoirs are drafted more to meet downstream flow targets. The WVS would miss the mainstem Willamette flow target at Albany more often under Alternative 2B than Alternative 2A due the reduced system storage, but more often than the NAA. The flow target at Salem under Alternative 2B would remain similar to Alternative 2A since inflow from the Santiam subbasin would reduce the impact storage deficit at Cougar. Climate change effects, and potential implications as discussed above, draw on the climate change projection and trend information provided in the climate change appendices (F1 and F2).

#### *3.2.2.7 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Alternative 3A would primarily use WVS dam operations for fish passage within the WRB and not use structural modifications as in Alternatives 1 and 4. An important part of this is the increased use of different flow outlets from the dams to control temperature, with the spillway supplying warmer water from the upper reservoir and the deeper outlets – ROs and turbines –

supplying cooler water. Although these different outlet flows are calculated in the regulation model, they are not generally going to show up in the standard charts presented here, since they compare total flow with the NAA. The effects of those outlet flow changes – for example, temperature and TDG differences – will show up as inputs to other modeling, such as the temperature and biological models see Section 3.5.

Alternative 3A would also allow reservoirs augment instream flows by using the inactive or power pools, drafting below the NAA rule curves to meet minimum flow requirements. This would most frequently occur during the fall of drier years at reservoirs that do not have a deeper fall reservoir drawdown operation.

The primary set of flow targets are the "Integrated Temperature and Habitat Flow Regime," which replace the 2008 NMFS BiOp targets in the NAA. Briefly, the integrated temperature and habitat flow regime has two sets of bi-weekly targets at a WVS reservoir, each set for whether the reservoir is higher or lower than 90 percent of rule curve elevation. Flows are reduced within a range down to minimums needed for fish survival when reservoirs are under the 90 percent threshold. However, these are adaptive within a water year and can return to levels higher than the NAA 2008 BiOp flows downstream of the dams if reservoir levels increase.

Alternative 3A would implement spring and fall reservoir drawdowns at some WVS reservoirs for volitional downstream fish passage. The spring reservoir drawdown operations are at Detroit, Lookout Point and Cougar (to the regulating outlet) and the deeper fall reservoir drawdown operations are at Blue River, Hills Creek, Green Peter, Detroit, Lookout Point and Cougar. The drawdowns are typically to the lowest level possible given operational constraints (for example, outlet cavitation limits) or the lowest achievable pool. Section 2.2.1, Flow Measures, contains a more detailed explanations of all these actions.

The drawdowns can limit the effectiveness of other actions within Alternative 3A. The spring reservoir drawdown can inhibit refill of the reservoirs into the late winter and spring. Since the reservoirs do not fill more often, there is less available water to augment flows downstream during the summer and fall compared to the NAA. In addition, if the reservoir water surface elevation does not rise to the spillway crest, the dam is unable to discharge water through that outlet, constraining the temperature operations that require the spillway.

As compared to the NAA, Alternative 3A can have the effect of releasing water during the spring and lowering flows in the summer. This is more pronounced during drier years than in wetter years since a larger portion of the summer flow is stored water from the reservoirs. An average flow year would see Detroit and Cougar unable to contribute meaningfully to flow targets downstream.

NAA flow targets and the lower integrated temperature and habitat flow regime flow targets in Alternative 3A would not be met across the WRB during an average flow year. These notably lower flows would have long term consequences across the WRB. Effects from the Alternative 3A to hydrologic processes: Major.

*3.2.2.7.1 Santiam Subbasin*

Alternative 3A would meaningfully alter the use of Detroit Reservoir (Figure 3.2-105) for all years. The reservoir elevation would not reach the top of conservation storage in even the wettest years. Most years, Detroit Reservoir would not appreciably rise above the spring reservoir drawdown elevation (1375 ft) while releasing inflow until the next winter, in January on average. Although it is not shown in the figure (as the lines are non-exceedance percentiles), Detroit would reach minimum conservation elevation (1450 ft) once between April and October during the period-of-record run.

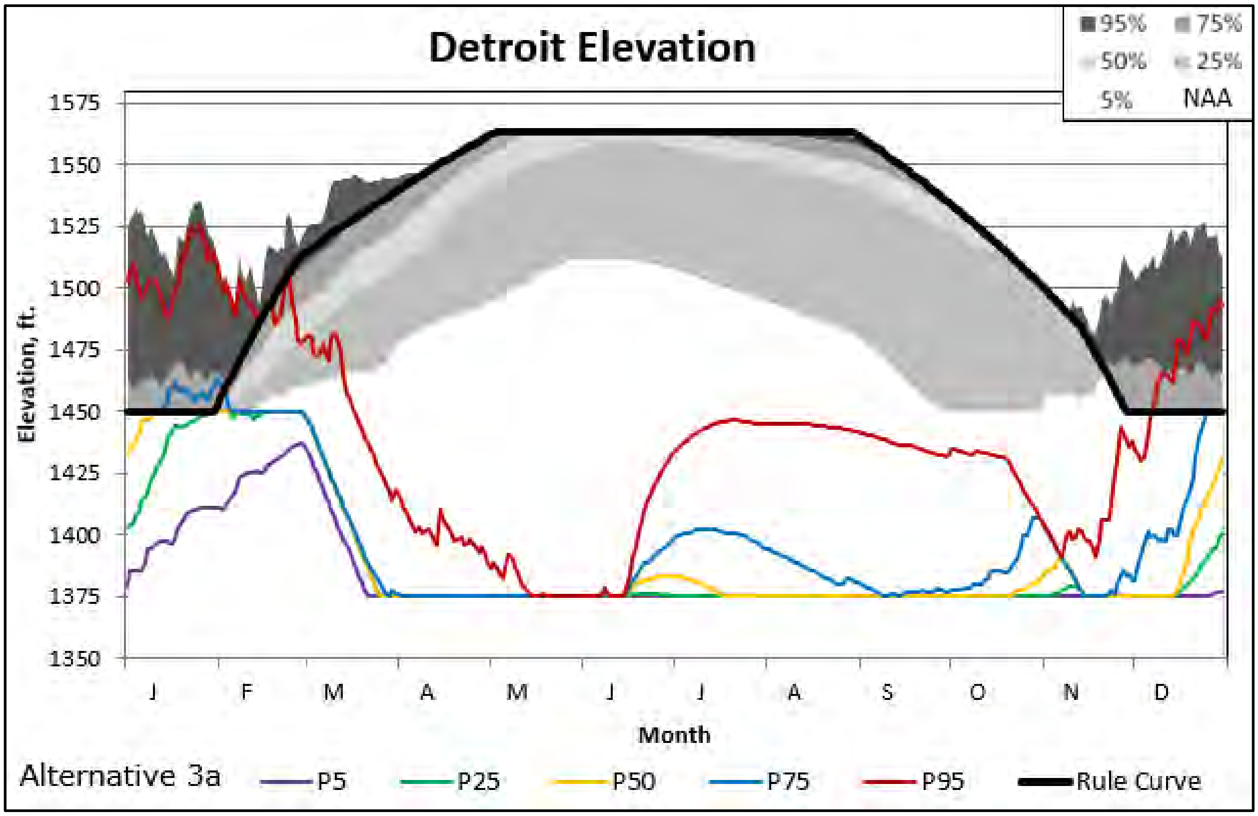

**Figure 3.2-105. Alternative 3A Detroit water surface elevation non-exceedance compared with NAA**

The reservoir would usually be lower across the winter season as well. Particularly wet winters would force the reservoir back to the NAA elevations, but this would happen late in January or early February. The drawdowns and low summer reservoir elevation would have a stark effect on the flow from Detroit Dam as compared to the NAA. The releases from Detroit would be much higher during the spring reservoir drawdown as the reservoir drafts to the minimum elevation of 1375 ft.

During the summer, passing inflow (Figure 3.2-106) would not be enough to maintain the minimum downstream integrated temperature and habitat flow regime target in about 75 percent of years. The average year (P50 line) would be below the target from mid-June to nearly November, with a typical flow of about 600 cfs (the minimum flow target is 1,050 cfs).

The driest years would not reach the minimum flow target from May through December, a much longer time than the NAA, reaching a minimum flow of about 400 cfs.

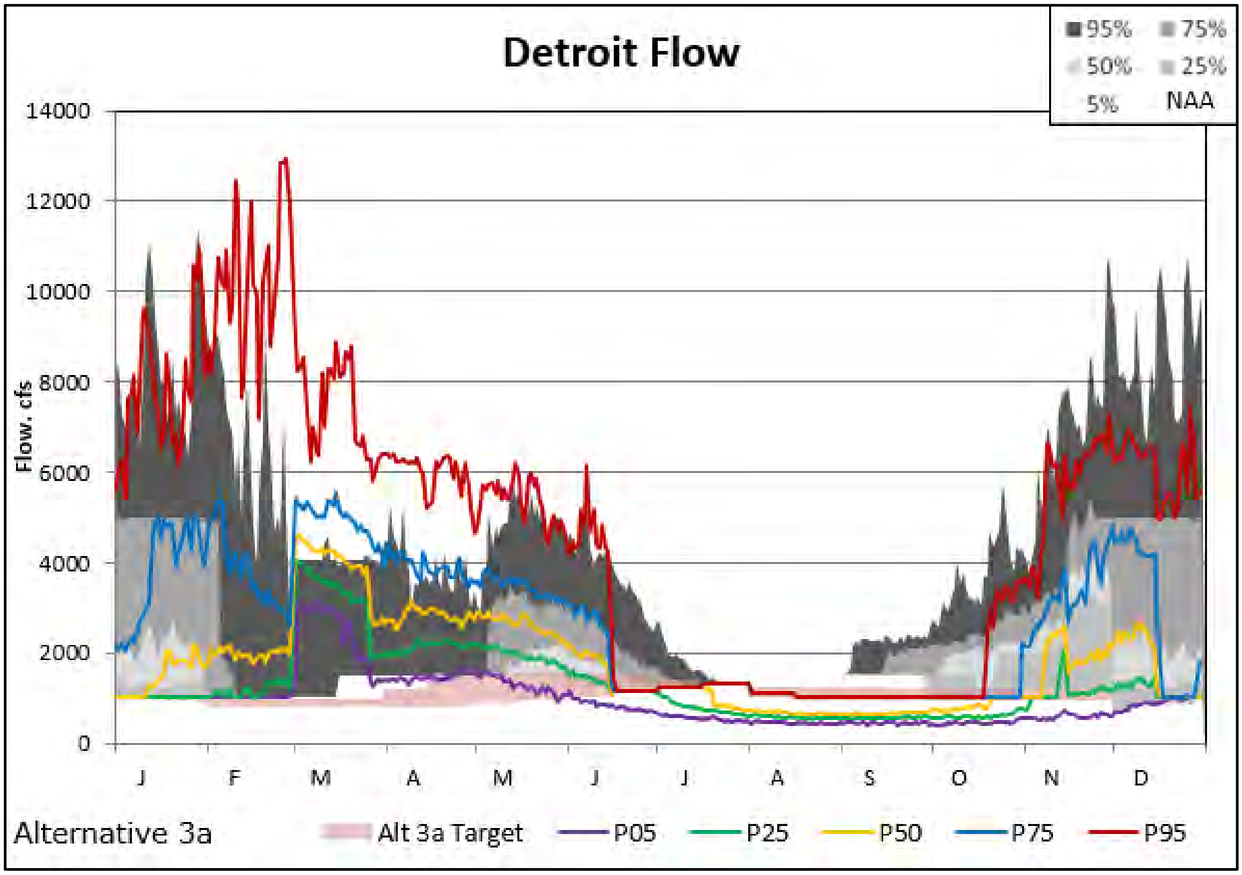

**Figure 3.2-106. Alternative 3A Detroit outflow non-exceedance compared with NAA**

Green Peter (Figure 3.2-107) would have a deeper fall reservoir drawdown but would not have a spring reservoir drawdown in Alternative 3A. The result would be much less impact to reservoir elevation during the rest of the year through the spring and summer. The reservoir would release its additional stored water earlier in the summer to meet the downstream flow targets and to compensate for the lack of water at Detroit, starting about one month earlier than the NAA across water years. The integrated temperature and habitat flow regime targets are lower than the NAA's BiOp targets downstream of Foster (Figure 3.2-108), so the driest years (P05) would peak at a higher elevation in Alternative 3A than in the NAA.

Although the target elevation of the deeper fall reservoir drawdown is 780 feet, Green Peter would be unable to draft that low in slightly more than half of years. This is due to inflow during wetter than typical years. As the reservoir elevation falls, the capacity of the outlets also falls – there is less pressure pushing the water out.

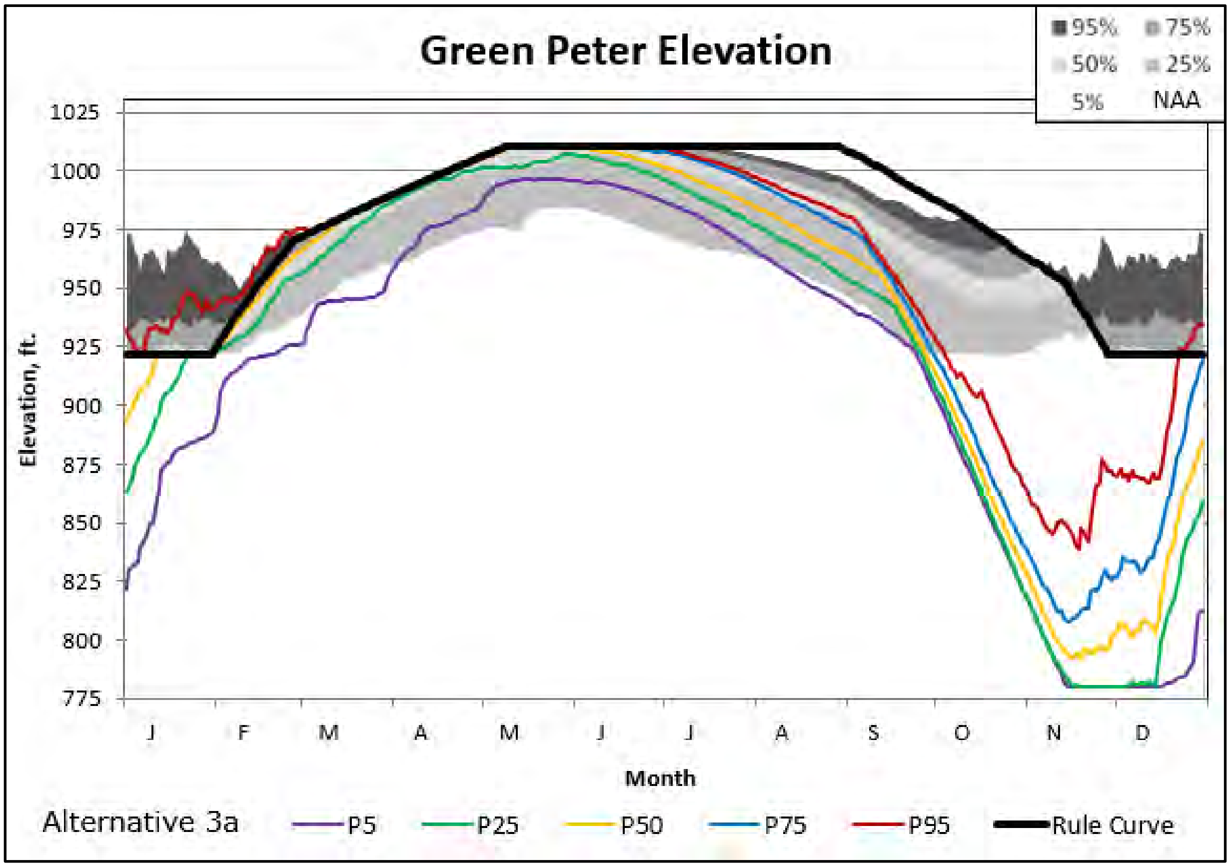

**Figure 3.2-107. Alternative 3A Green Peter water surface elevation non-exceedance compared with NAA**

Downstream of Foster, flow would be similar to the NAA during average to wet years except during the deeper fall reservoir drawdown period at Green Peter. The elevated flows would be a result of the release from Green Peter to reach the low reservoir elevation. The integrated temperature and habitat flow regime targets are met throughout the summer and fall. The dry years trace the bottom of the targets whereas most of the rest are at the top of the range or above it. Only in the driest Novembers, when Green Peter is already at its low elevation, the flow would fall below target for about two weeks.

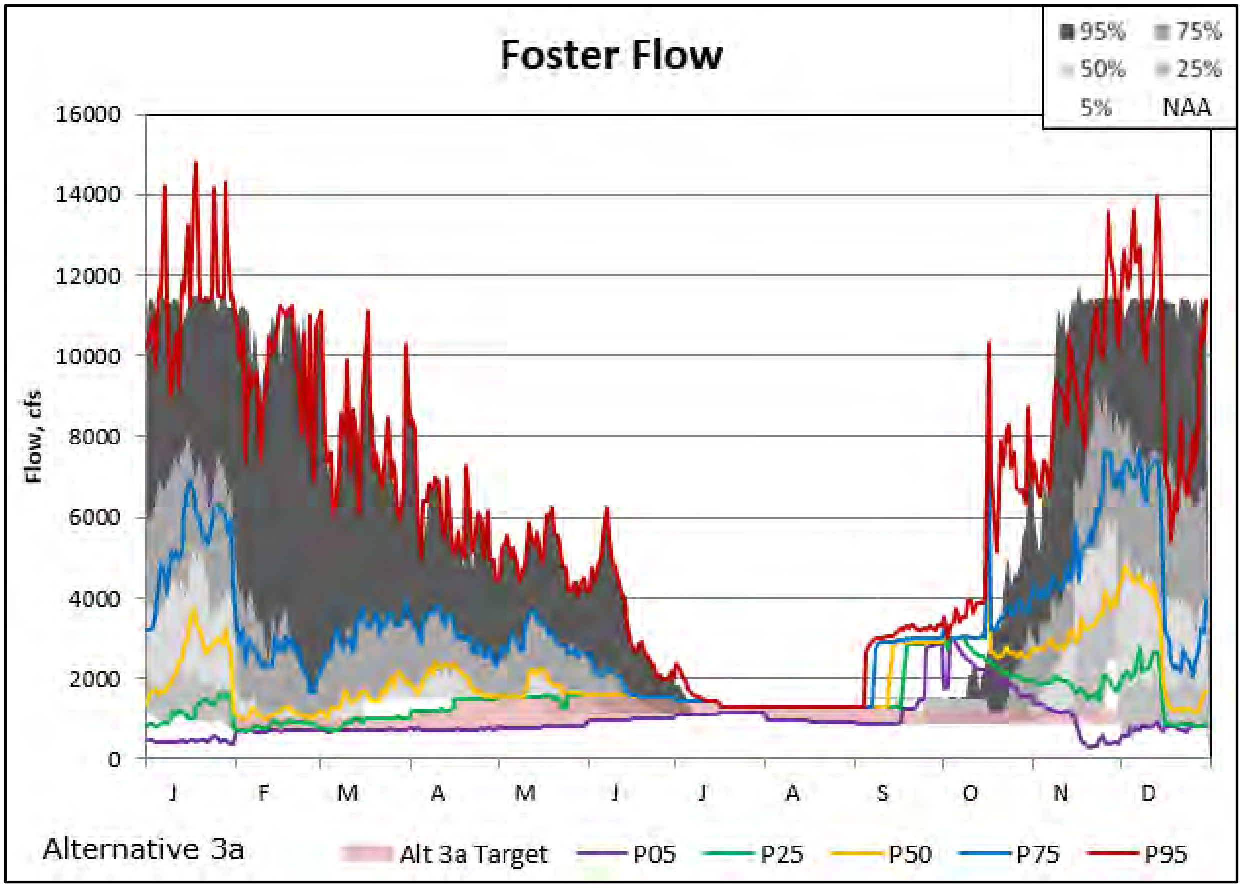

**Figure 3.2-108. Alternative 3A Foster flow non-exceedance compared with NAA**

The Santiam at Jefferson (Figure 3.2-109) would combine the changes at Detroit – in the North Santiam subbasin – and Green Peter – in the South Santiam subbasin. Higher flows would be evident when the reservoirs draft to the drawdowns (principally March and October) compared to the NAA. There would be a larger variation in flow in the summer, with more flow in the wettest years and less flow in the driest years compared to the NAA. There would be much less change in the seasonal flow pattern as compared to Alternatives 1 and 4, as the storage aspects of those alternatives would be constrained by the drawdowns.

Although there are many relatively minor differences, one of the largest differences between Alternatives 3A and 3B is the larger outflow from Detroit in preparation for the deeper fall reservoir drawdown in 3B, which is not required in 3A as the pool does not typically refill during the summer.

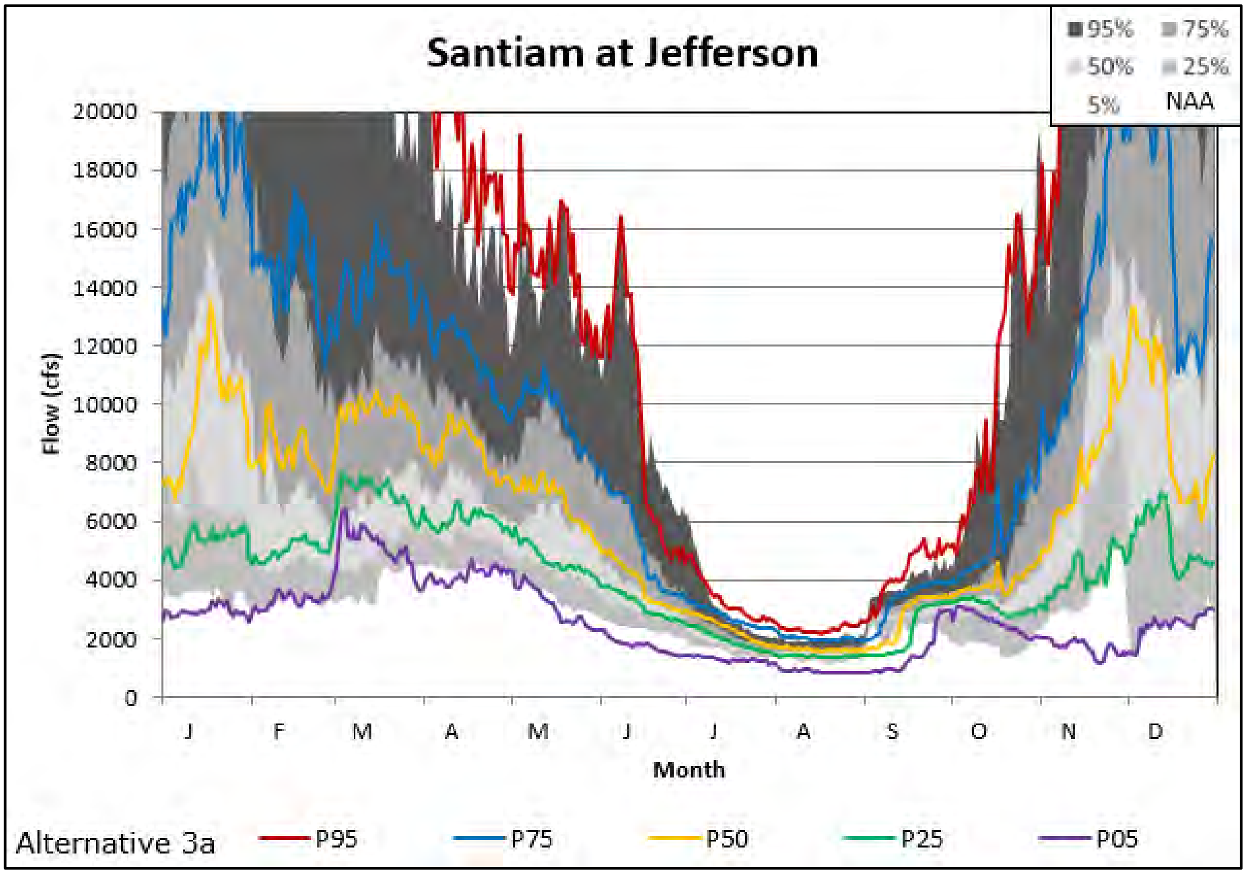

**Figure 3.2-109. Alternative 3A Santiam at Jefferson flow non-exceedance compared with NAA**

#### *3.2.2.7.2 Long Tom Subbasin*

As explained in the NAA, Fern Ridge reservoir (Figure 3.2-110) is operated for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. Since Fern Ridge has a large surface area and small volume compared to the other WVS reservoirs, there is limited scope to change its operation and the water surface elevations within Fern Ridge remain nearly the same as the NAA. Downstream flows at Monroe would remain similarly unchanged for Alternative 3A.

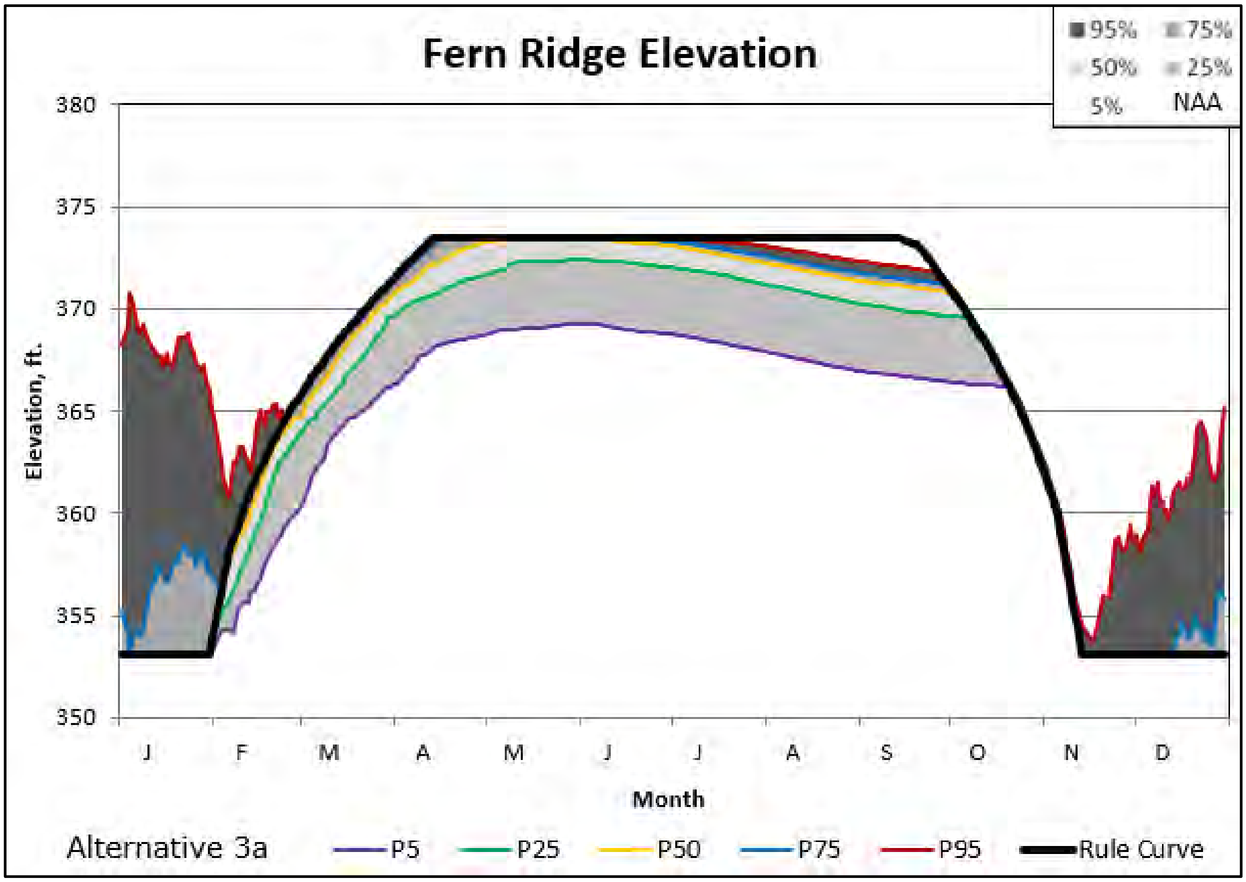

**Figure 3.2-110. Alternative 3A Fern Ridge water surface elevation non-exceedance compared with NAA**

### *3.2.2.7.3 McKenzie Subbasin*

Like Detroit reservoir in the Santiam Subbasin, Cougar reservoir (Figure 3.2-111) would have both a spring and fall reservoir drawdown. Since the spring reservoir drawdown lasts through the typical refill period, Cougar reservoir would only able to rise above the drawdown elevation (1517 feet) during the summer in wetter years, which does not occur under the NAA. The only time Cougar would be full under Alternative 3A would be a FRM operation of a particularly rare and large storm in the winter months. Cougar would only be able to meet its minimum downstream flow target of 300 cfs for the entire summer about 25 percent of the time compared to the NAA. An average year, where the P50 line is at minimum reservoir elevation, would miss this target from August to October.

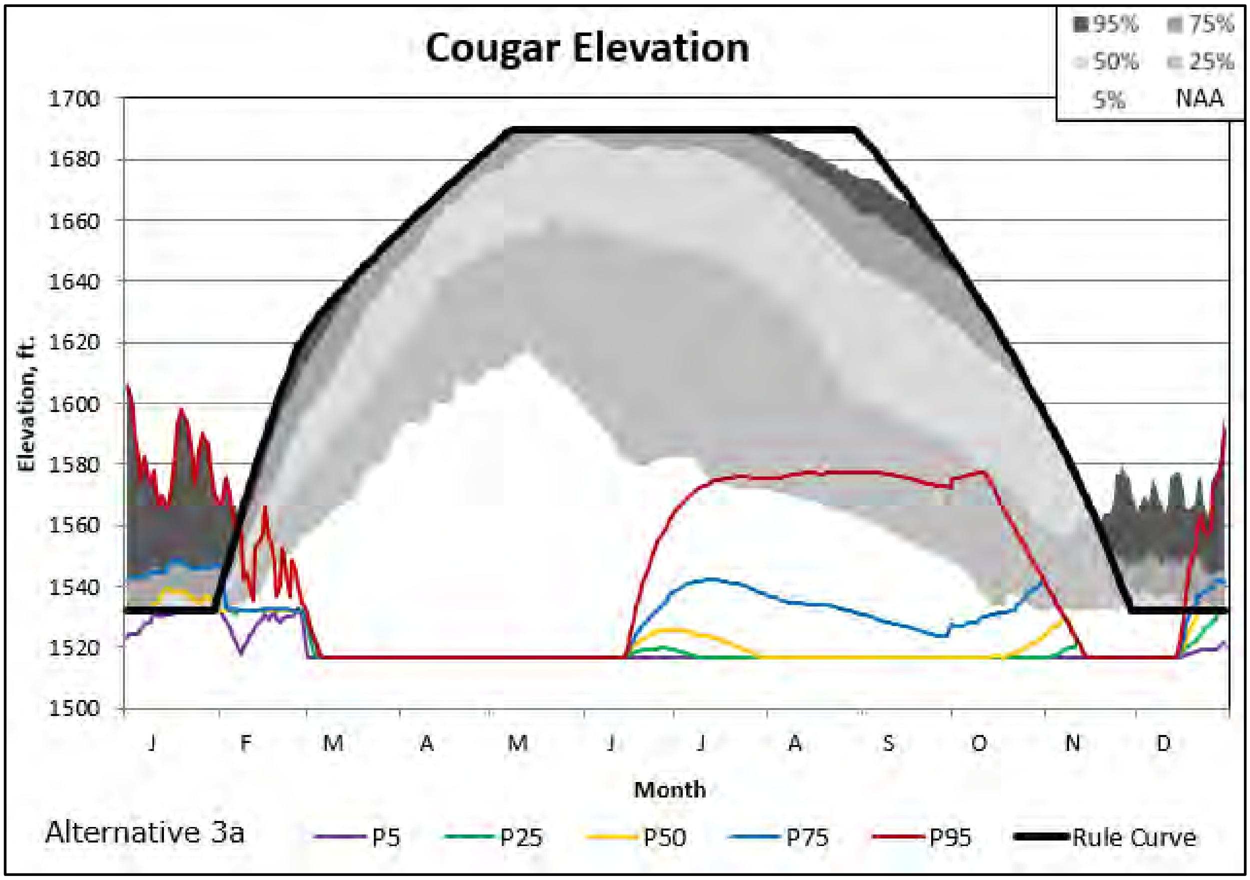

**Figure 3.2-111. Alternative 3A Cougar water surface elevation non-exceedance compared with NAA**

Blue River (Figure 3.2-112) would have a deeper fall reservoir drawdown 15 feet below its minimum conservation pool. The spring refill would reach the maximum conservation elevation more often at Blue River than in the NAA – see the P25 line in the figure – due to the lower integrated temperature and habitat flow regime targets. The reservoir would draft earlier in the summer to augment some of the flow not available at Cougar.

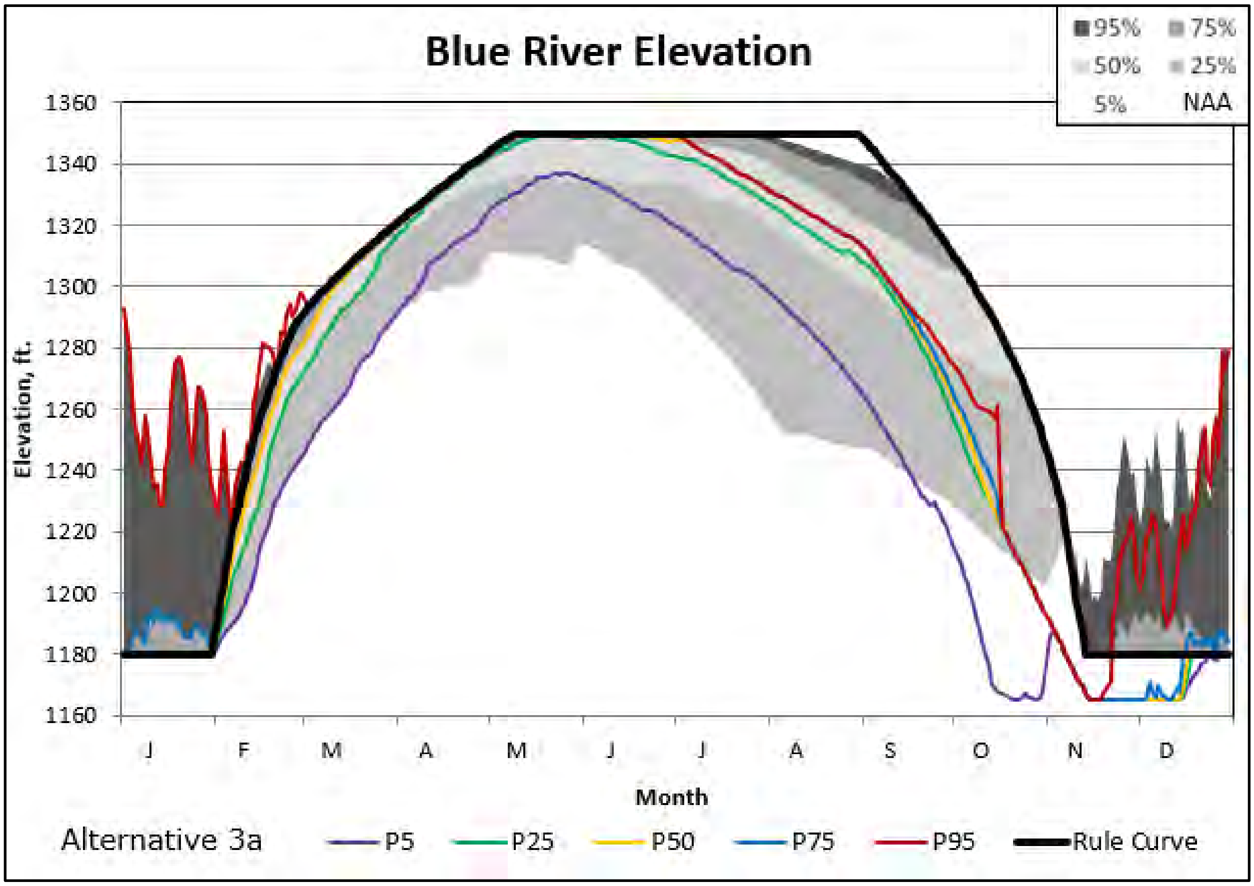

**Figure 3.2-112. Alternative 3A Blue River water surface elevation non-exceedance compared with NAA**

The downstream control point, McKenzie River at Vida (Figure 3.2-113), would show the combined effect of more and less available conservation storage at Blue River and Cougar, respectively. The higher flows during the spring of wet years result from Cougar not filling during conservation season as it does in the NAA. The lower flows during the driest years of April to June are due to Blue River filling more while meeting the lower downstream flow targets. During the summer, Alternative 3A flows would be marginally below the NAA, as the increased storage at Blue River and no storage at Cougar nearly balance out – Blue River is smaller than Cougar, so flows would be a bit lower across the summer.

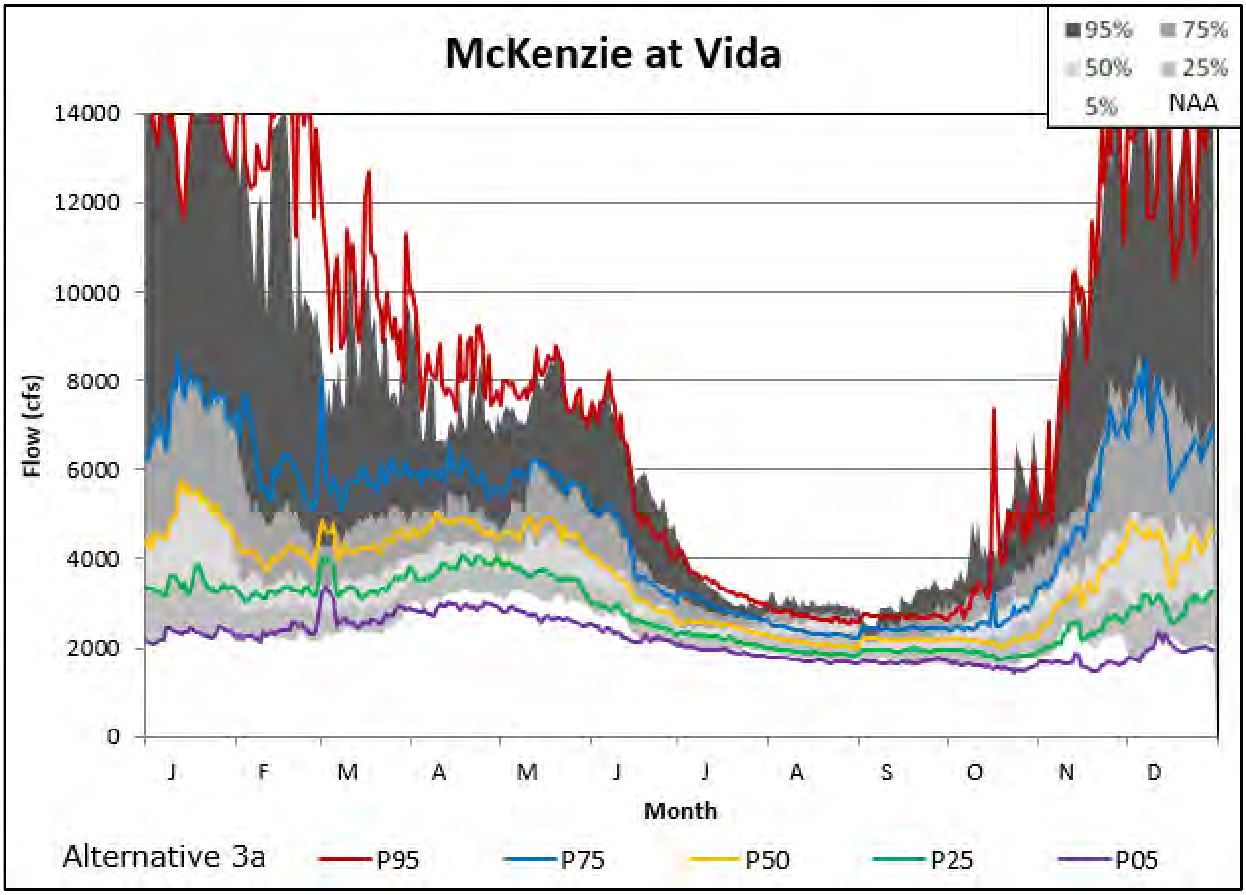

**Figure 3.2-113. Alternative 3A McKenzie River at Vida flow non-exceedance compared with NAA**

### *3.2.2.7.4 Middle Fork of the Willamette Subbasin*

Hills Creek, Lookout Point and Fall Creek would all have deeper fall reservoir drawdowns in Alternative 3A (Fall Creek's is an existing operation in the NAA) and Lookout Point would also have a spring reservoir drawdown. During spring conservation storage season, Hills Creek (Figure 3.2-114) would fill more frequently and achieve a higher elevation during dry years compared to the NAA. The reservoir would then be drafted to meet downstream flow targets, which flows through Lookout Point (Figure 3.2-115). Hills Creek's stored water would be exhausted in mid-September in an average year (P50 line) and most years – between the P25 to P75 lines – would fall within two weeks of average.

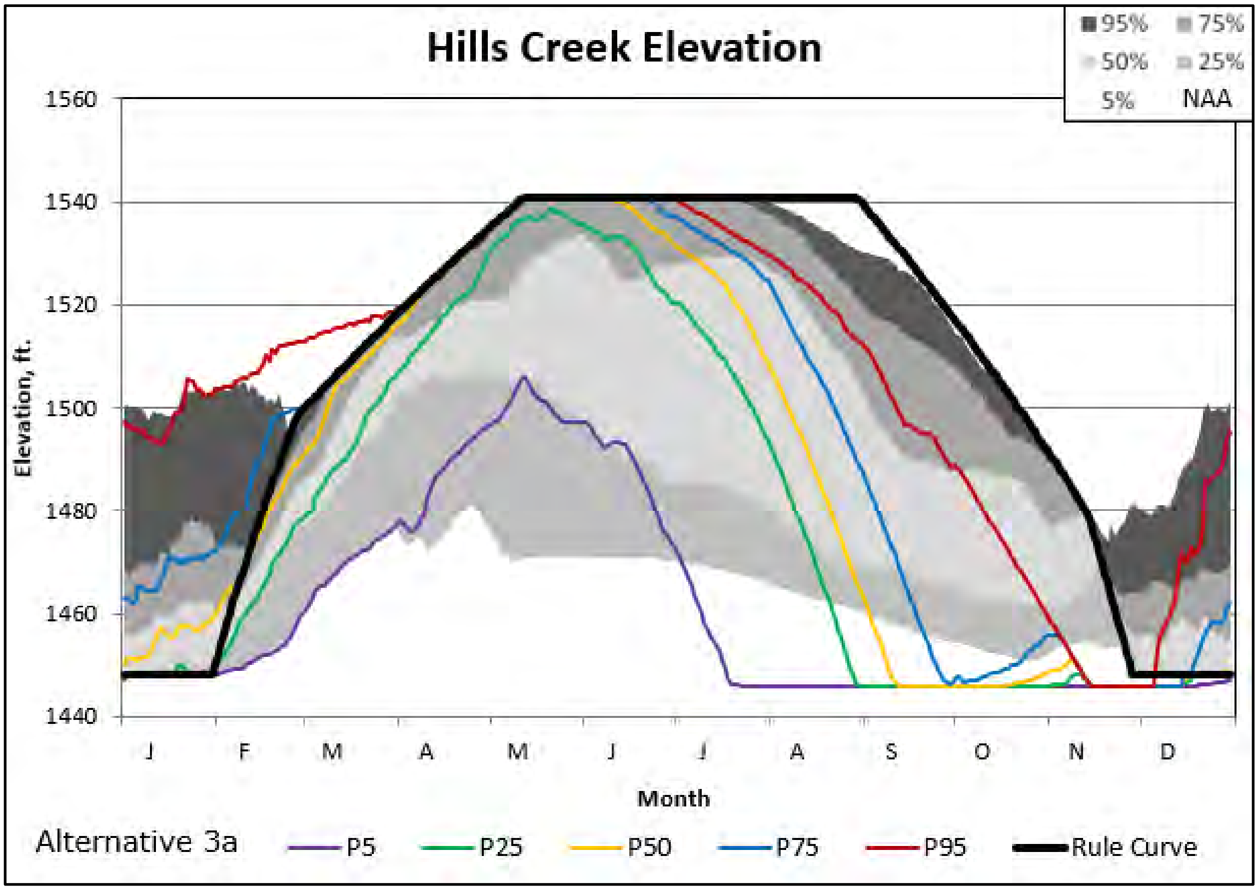

**Figure 3.2-114. Alternative 3A Hills Creek water surface elevation non-exceedance compared with NAA**

Despite having a spring reservoir drawdown like Detroit in the Santiam Subbasin and Cougar in the McKenzie Subbasin, Lookout Point would be able to fill up to minimum conservation elevation in most years (P75 line), meaning there is minor change from the NAA. The reservoir rises from its minimum spring reservoir drawdown elevation in the driest years (P05) but returns to the minimum in about two months. This is due to the stored water from Hills Creek upstream. Neither Detroit nor Cougar has the benefit of being able to refill from water stored in an upstream reservoir.

It should be noted that Lookout Point would not achieve its spring and fall reservoir drawdown target of 761 feet in about 50 and 25 percent of years, respectively. Higher inflows during the drawdowns, inflows from Hills Creek during the spring, and reduced outlet capacity from the lower reservoir elevation – there is less pressure pushing the water out – means that Lookout Point would remain above the target elevation for the duration of the drawdown periods.

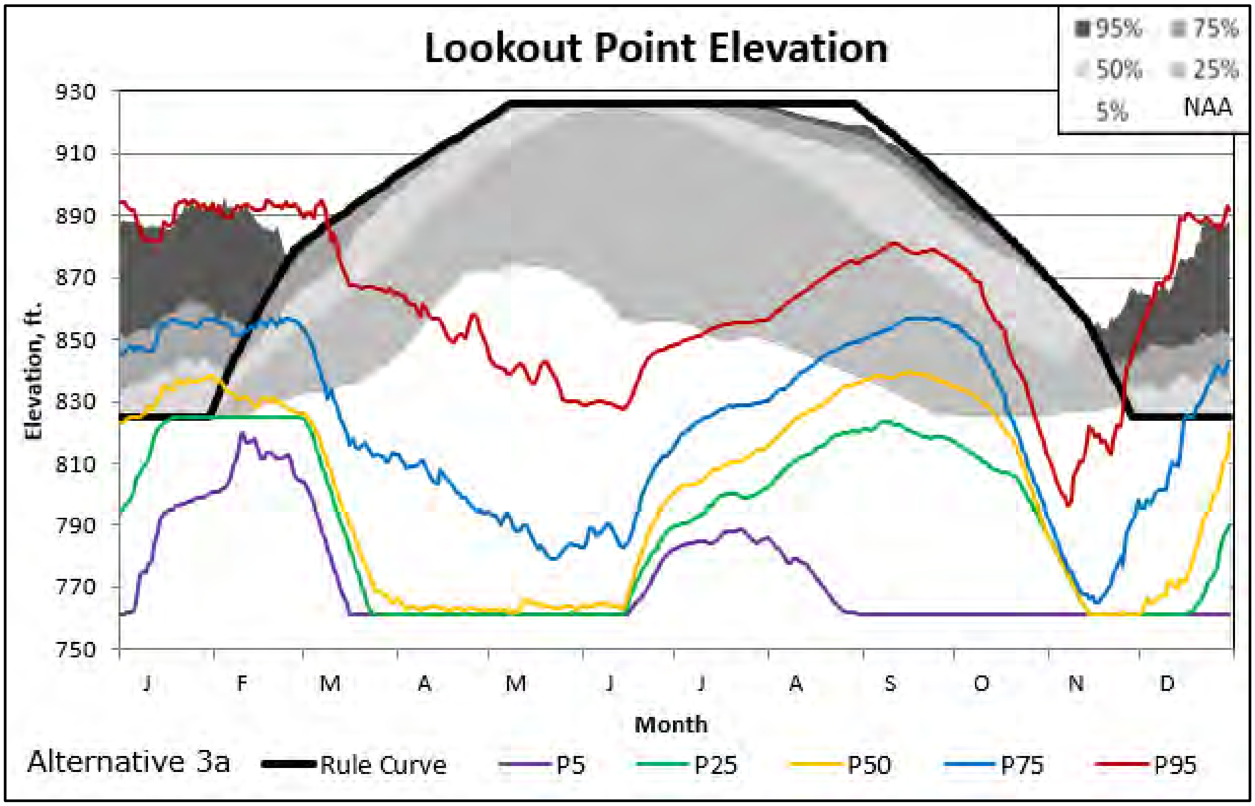

**Figure 3.2-115. Alternative 3A Lookout Point water surface elevation non-exceedance compared with NAA**

Fall Creek (Figure 3.2-116) water surface elevations and outflows would be very similar to the NAA, which already implements a fall drawdown to the same elevation as in Alternative 3A.

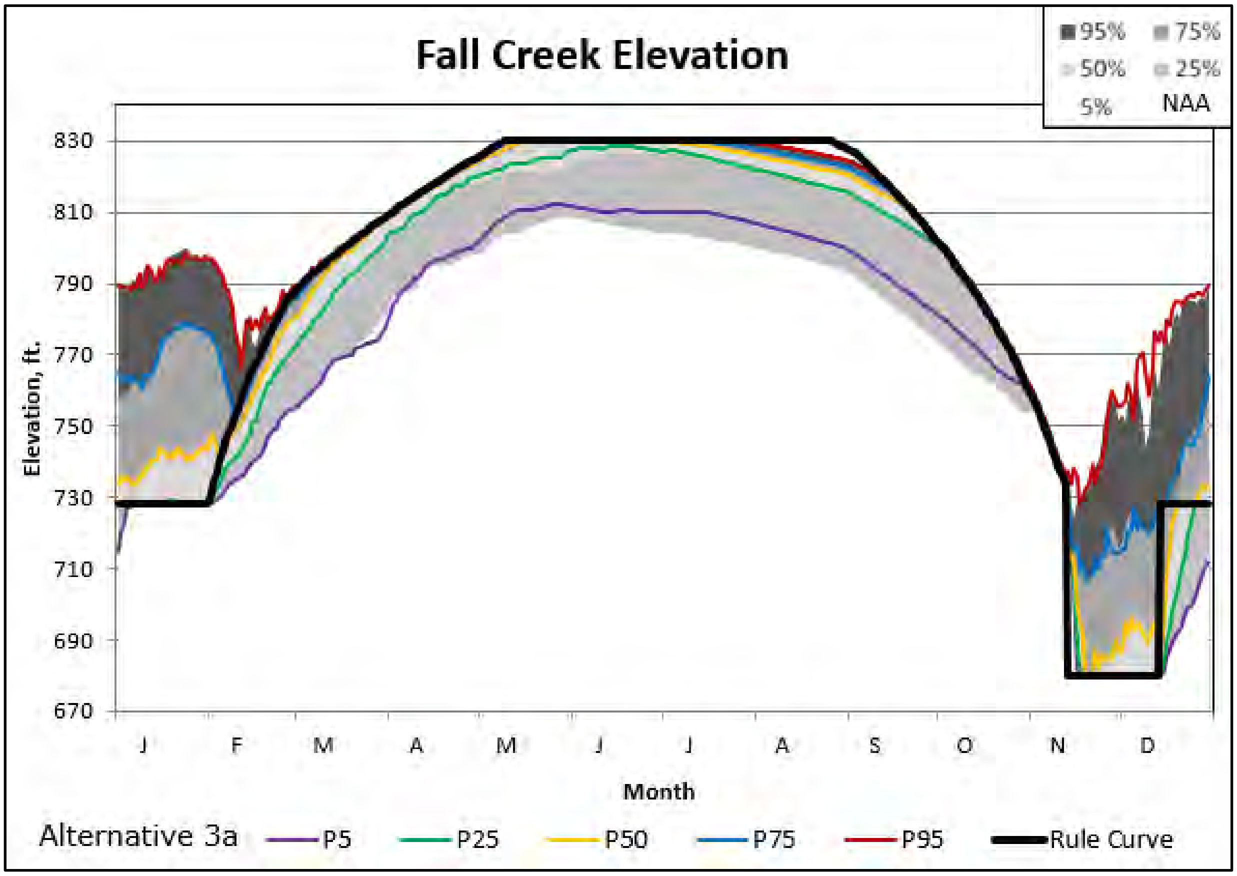

**Figure 3.2-116. Alternative 3A Fall Creek water surface elevation non-exceedance compared with NAA**

The control point for the Middle Fork subbasin WVS dams at Jasper (Figure 3.2-117) would show the changed flow from the drawdowns and limited augmented flow during the summer. Flow at Jasper would be higher across all years from March until May. As summer starts, flow would be drastically reduced as compared to the NAA as the reservoirs attempt to refill with available inflow. From June until September typical wet-year flows would be comparable to driest years in the NAA. The driest years in Alternative 3A would not return to the NAA baseline until late October. Although Lookout Point and Fall Creek are above their minimum elevations during this time, this would represent the WVS attempt to meter out water throughout the summer, preventing even lower flows in the river.

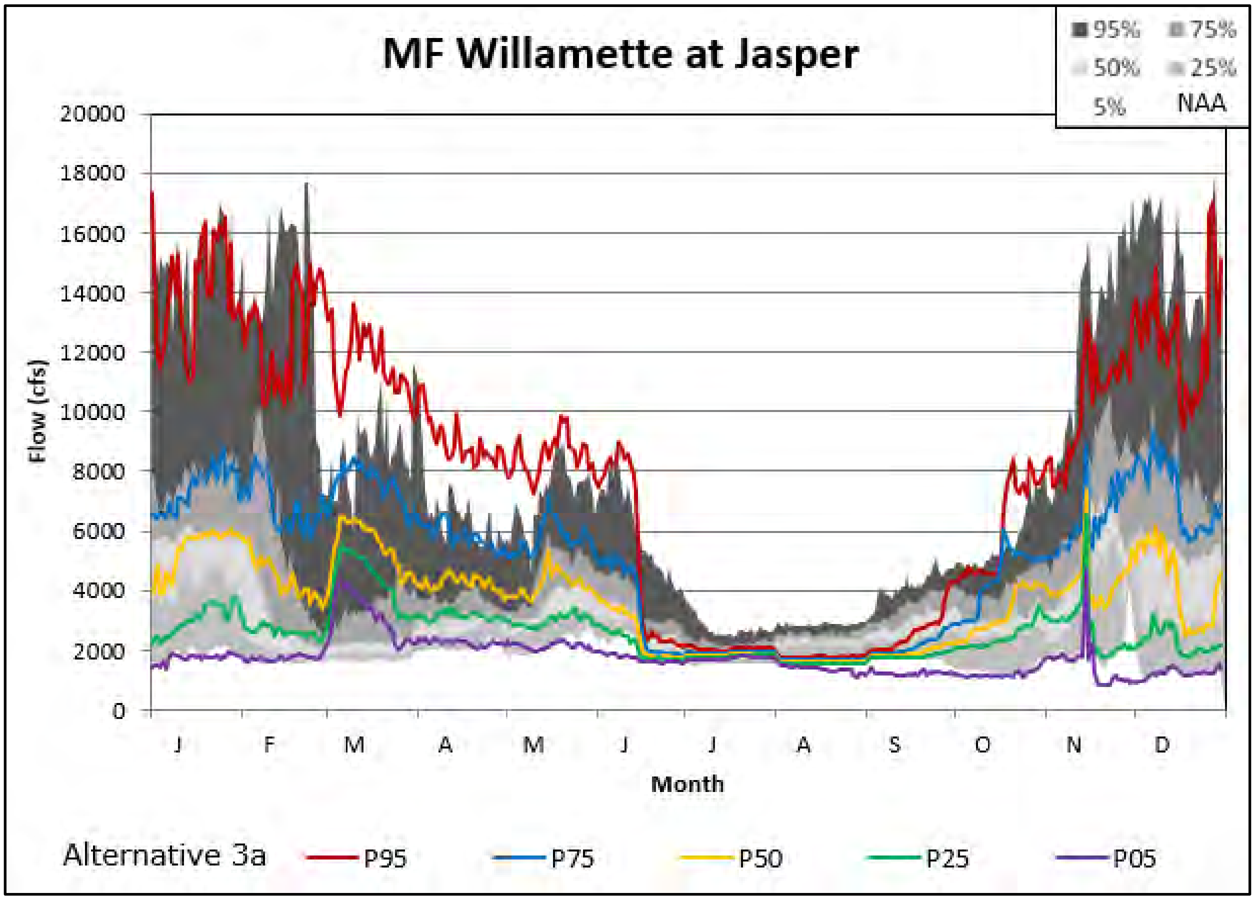

**Figure 3.2-117. Alternative 3A Middle Fork of the Willamette at Jasper flow non-exceedance compared with NAA**

### *3.2.2.7.5 Coast Fork of the Willamette Subbasin*

Dorena and Cottage Grove reservoir elevations behave very similarly in Alternative 3A, as shown in Figures 3.2-118 and 3.2-119, respectively. The refill to slightly higher levels than the NAA due to the lower integrated temperature and habitat flow regime targets downstream. Reservoir storage would be similar for average and wet years throughout the summer and fall. They would draft faster from higher initial water surface elevations in dry years as these reservoirs make up for the lower storage elsewhere in the system. In especially dry falls, the reservoirs would augment instream flows by using the inactive pools, though the lower water surface elevations would be activated a bit less often in Alternative 3A as opposed to Alternative 3B.

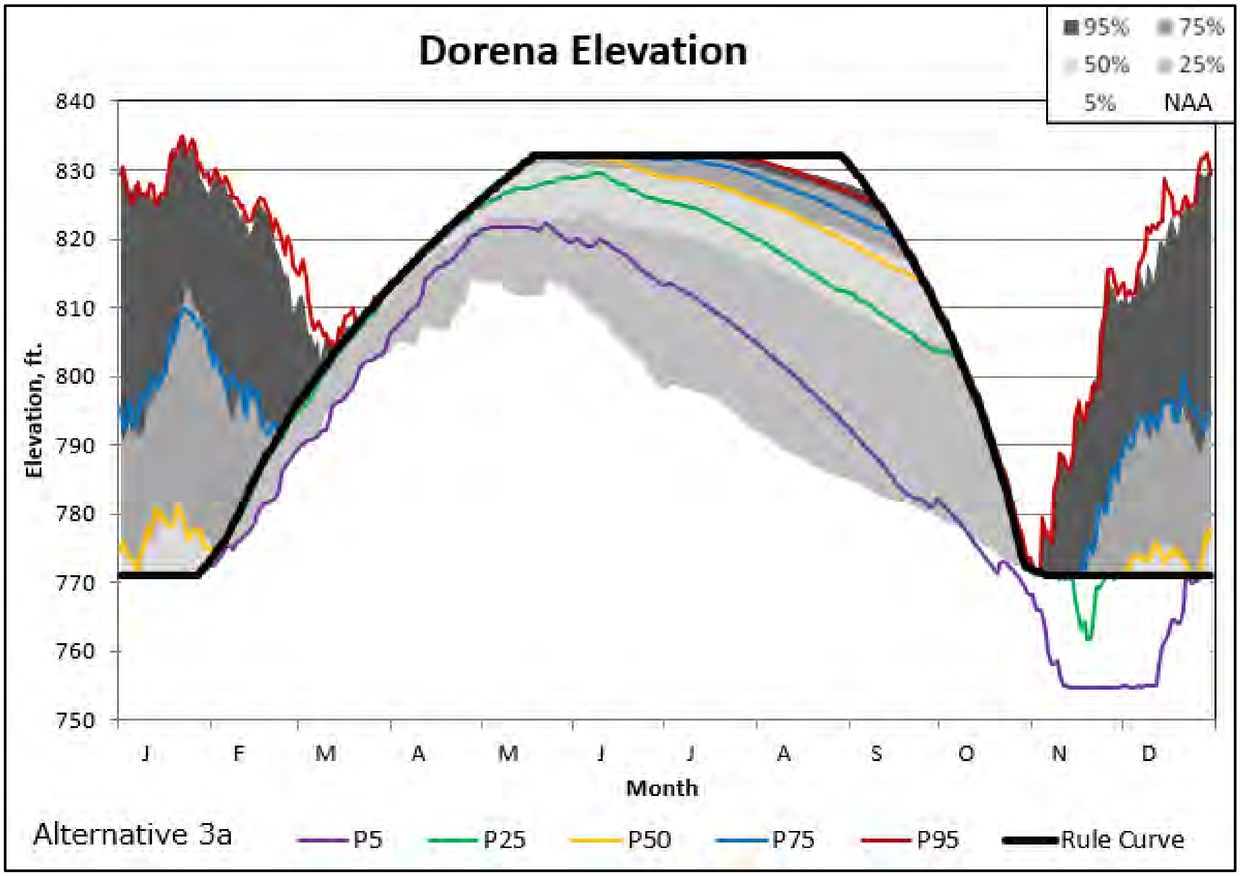

**Figure 3.2-118. Alternative 3A Dorena water surface elevation non-exceedance compared with NAA**

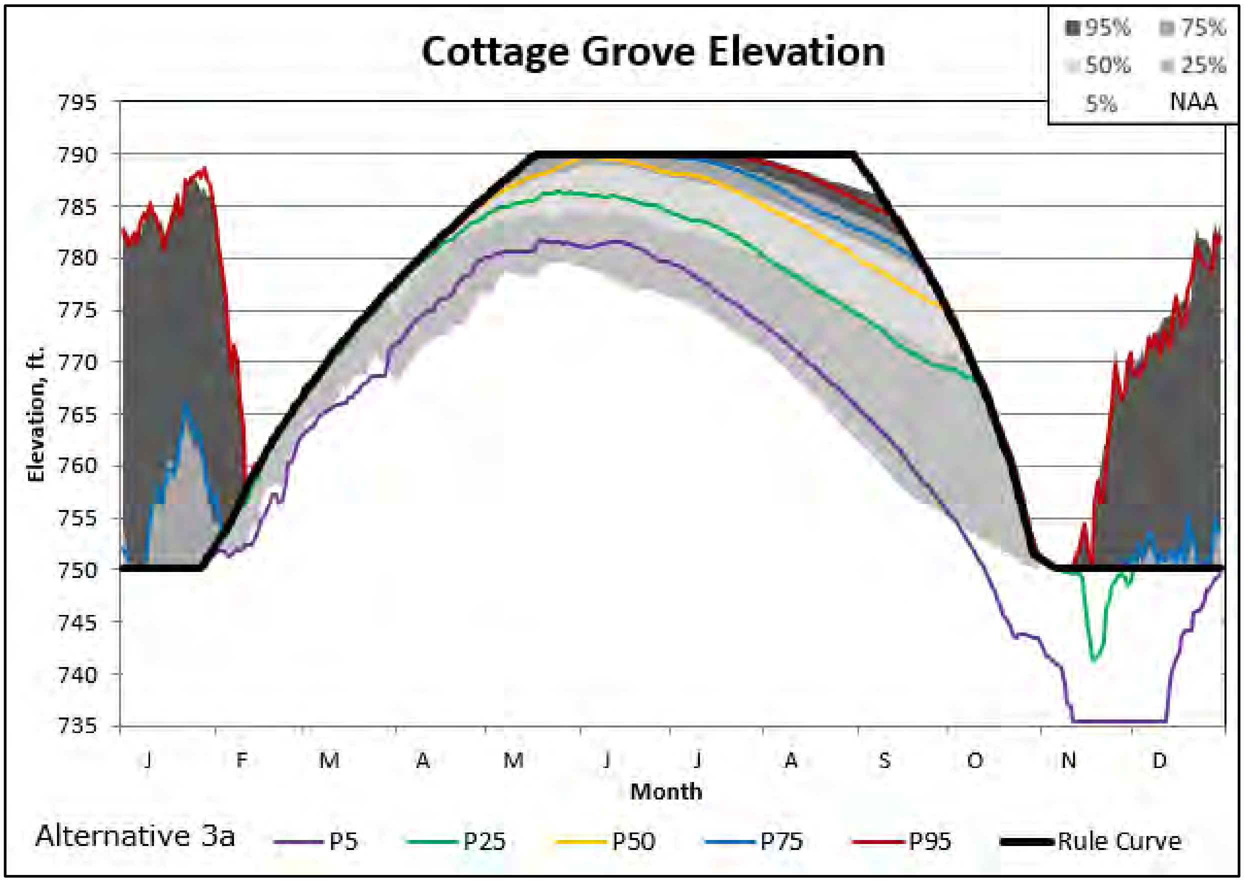

**Figure 3.2-119. Alternative 3A Cottage Grove water surface elevation non-exceedance compared with NAA**

The flow at Coast Fork of the Willamette River at Goshen (Figure 3.2-120) would be most different from the NAA in dry years. The additional stored water accumulated in Dorena and Cottage Grove is evident by the decreased flow from April to June and increased flow July to October as the reservoir released that water. Although there are minor differences, Alternative 3A and 3B are similar at Goshen from a hydrologic perspective.

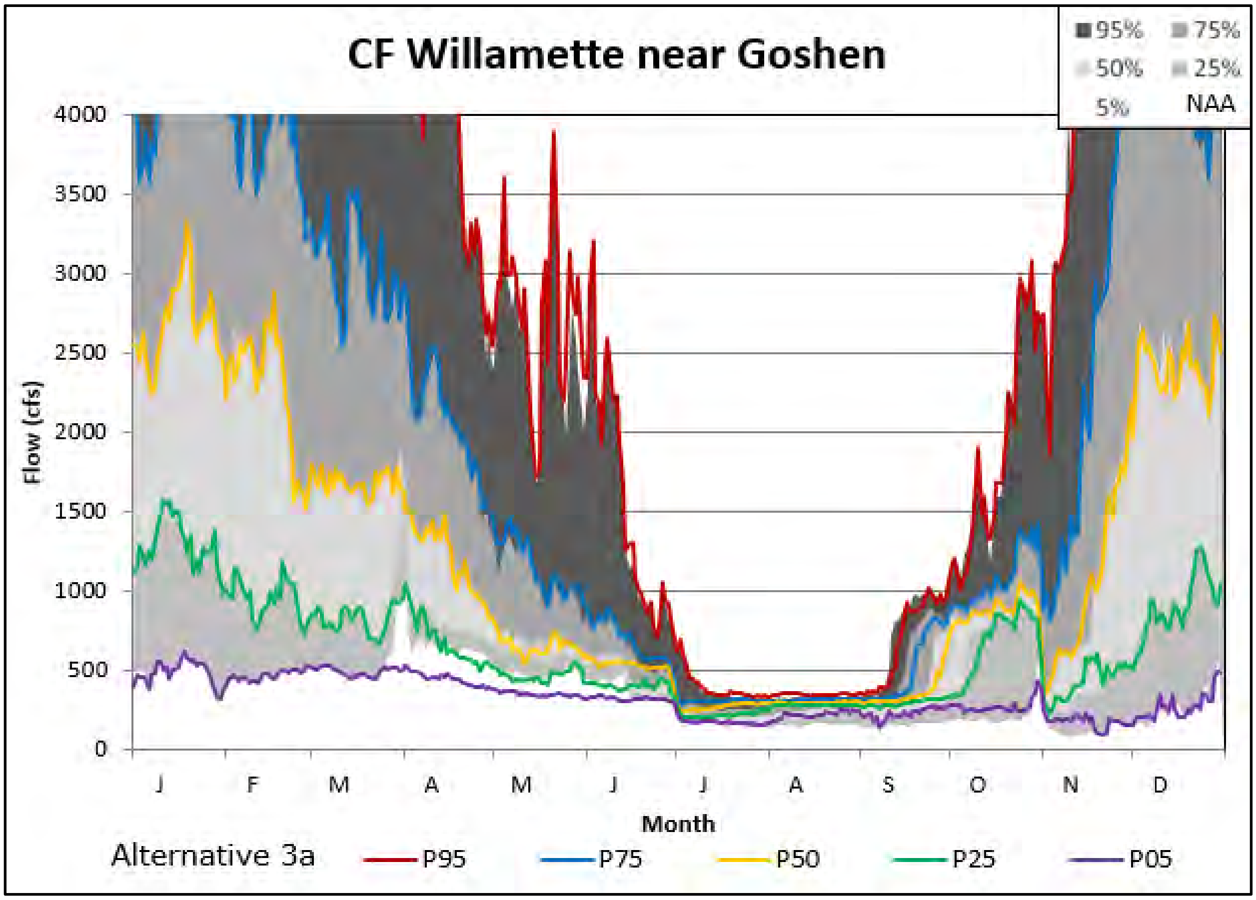

**Figure 3.2-120. Alternative 3A Coast Fork of the Willamette at Goshen flow non-exceedance compared with NAA**

### *3.2.2.7.6 Mainstem Willamette River*

The Alternative 3A flow targets on the mainstem Willamette River at Albany and Salem (Figures 3.2-121 and 3.2-122, respectively) are the integrated temperature and habitat flow regime, which is lower than the BiOp targets in the NAA and add flows to the target at Salem during warm weather (the target box in the figure). Section 2.2.1, Flow Measures, contains a more detailed explanation of these flow targets.

In wet years, Alternative 3A would have consistently higher flow during the springtime at both Albany and Salem as compared to the NAA as storage reservoirs are being held lower for spring reservoir drawdown fish passage operations. The driest years would have lower flow in the spring due to the lower flow target at Salem.

After the end of the WVS spring reservoir drawdowns, flows would drop steeply across all years. The lower amount of total system storage means that the system cannot meet the flow target at Albany for at least one month more than 75 percent of years (P75 line). Flows at Salem would more consistently meet the integrated temperature and habitat flow regime target due the contributions from Green Peter, which does not have a spring reservoir drawdown for Alternative 3A. Even so, summer and fall flows would be comparable or lower across similar years in the mainstem Willamette River for Alternative 3A as compared to the NAA.

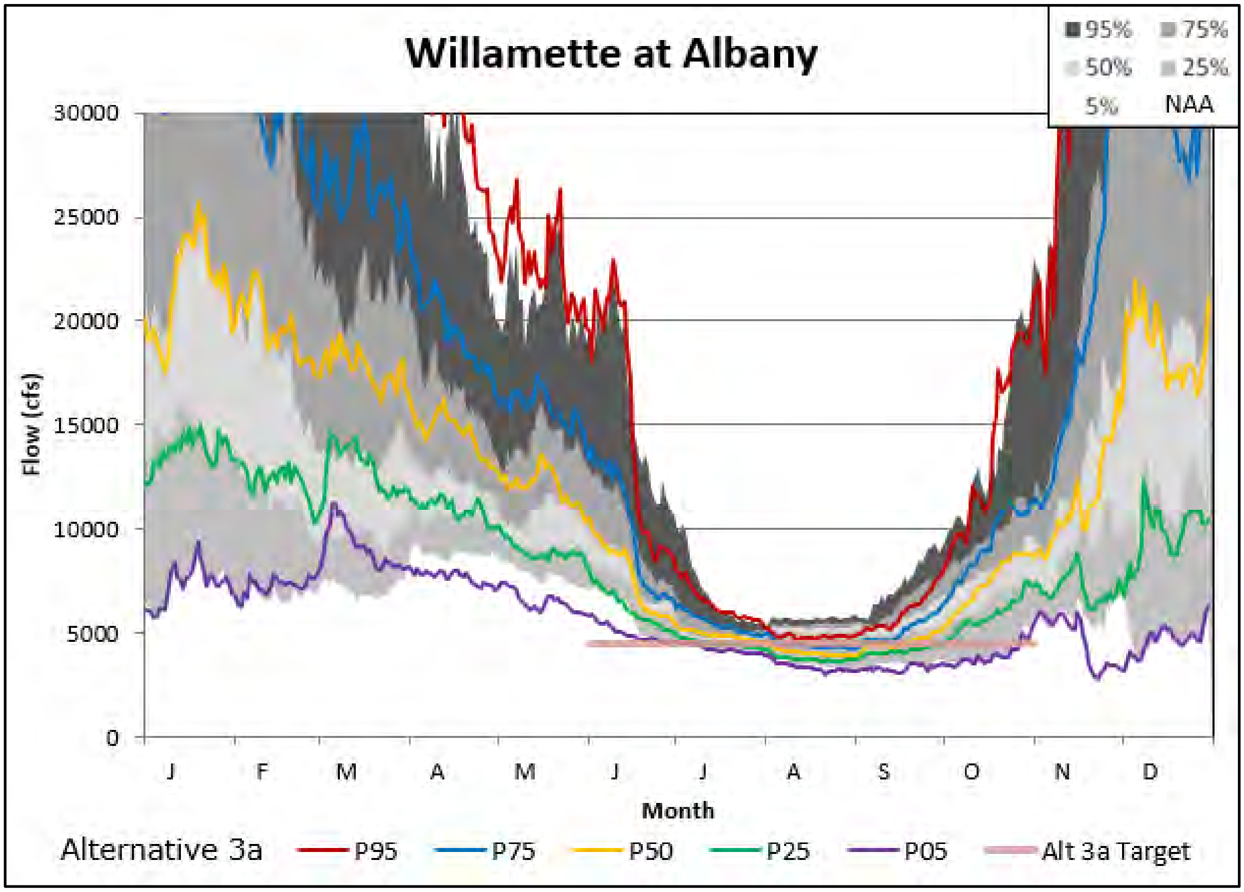

**Figure 3.2-121. Alternative 3A Willamette River at Albany flow non-exceedance compared with NAA**

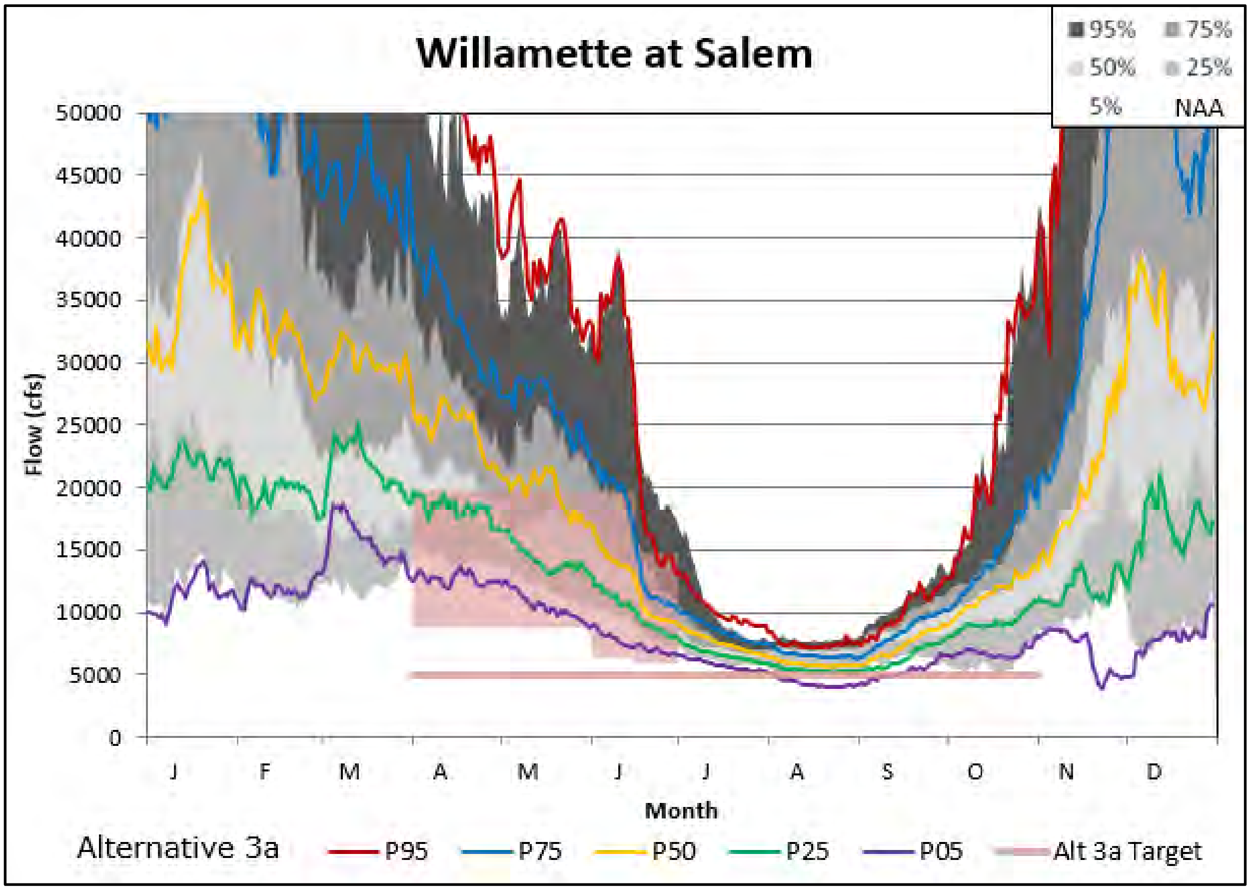

**Figure 3.2-122. Alternative 3A Willamette River at Salem flow non-exceedance compared with NAA**

*3.2.2.7.7 Near-Term Operations Measure*

See Alternative 2A, Section 3.2.2.4.7, for description of effects due to the Near-Term Operations Measure.

*3.2.2.7.8 Climate Change*

Climate change hydrologic factors such as seasonal flow volume shifts may stress the WVS under Alternative 3A operations compared to the NAA. Specifically, future increases in median wintertime flow volumes and average deceases in summertime baseflows will exacerbate effects already present in Alternative 3A. Climate change effects, and potential implications as discussed below, draw on the climate change projection and trend information provided in the climate change appendices.

Lower reservoir pool elevations and flow releases for downstream flow targets are likely in the future. In addition, spring inflow quantity and timing is projected to be more variable in the future as climate change trends take hold. Limited to no snowpack is a consequence of projected warming in the Valley and conversion of snow to wintertime flows. The projection for even drier, warmer, and earlier arriving summers means that the spring reservoir drawdowns leave the reservoirs even lower than the baseline Alternative 3A. Since the spring reservoir drawdowns last past April, when inflows would start to decline precipitously, Detroit and Cougar could struggle to store water for release later in the year. Lookout Point would be able to store some of the water released from Hills Creek, but it is likely to fill much less often compared to the NAA.

Alternative 3A does not currently meet its August downstream flow targets at Albany about 75 percent of the time which does not occur under the NAA. Decreasing summer flow projections indicate that Alternative 3A would rarely, if ever, meet the Albany flow target. Salem would be less notably affected due to flow augmentation from Green Peter, but the flow target would be missed more often, and dry years even drier. After the deeper fall reservoir drawdowns, there is additional storage space between the minimum drawdown elevation and the maximum flood storage elevation. It will typically take until middle of January (though timing varies throughout the WVS) for reservoirs to return to their current rule curve elevation. Downstream winter flows could be kept similar to the baseline with this additional storage capacity, despite projected increased winter peak flow and volume.

#### *3.2.2.8 Alternative 3B – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

As the name implies, Alternative 3B would primarily use WVS dam operations for fish passage within the WRB – with a different mix of operations as compared to Alternative 3A – and not use structural modifications as in Alternative 4. An important part of this is the increased use of different flow outlets from the dams to control temperature, with the spillway supplying warmer water from the upper reservoir and the deeper outlets – ROs and turbines – supplying cooler water which does not occur under the NAA. Although these different outlet flows are calculated in the regulation model, they are not generally going to show up in the standard charts presented here, since the charts compare total flow with the NAA. The effects of those flow changes will show up in the temperature and biological modeling as inputs – both in temperature and TDG see Section 3.5.

Alternative 3B would also allow reservoirs augment instream flows by using the inactive or power pools, drafting below the NAA rule curves to meet minimum flow requirements. This would most frequently occur during the fall of drier years at reservoirs that do not have a deeper fall reservoir drawdown operation.

The primary set of flow targets are the “Integrated Temperature and Habitat Flow Regime,” which replace the 2008 NMFS BiOp in the NAA and Congressionally authorized minimum flows in Alternative 1. The integrated temperature and habitat flow regime targets are generally higher and more variable the Congressionally authorized minimum flows. Briefly, the integrated temperature and habitat flow regime has two sets of bi-weekly targets at a WVS reservoir, each set for whether the reservoir is higher or lower than 90 percent of rule curve elevation. Flows are reduced within a range down to minimums needed for fish survival when reservoirs are under the 90 percent threshold. However, these are adaptive within a water year and can return to return to levels higher than the NAA 2008 BiOp flows downstream of the dams if reservoir levels increase.

Alternative 3B would implement spring and fall reservoir drawdowns at some WVS reservoirs for volitional downstream fish passage. The spring reservoir drawdown operations are at Hills Creek, Green Peter and Cougar (to the diversion tunnel) and the deeper fall reservoir drawdown operations are at Blue River, Hills Creek, Green Peter, Detroit, Lookout Point and Cougar which would not occur under the NAA. The drawdowns are typically to lowest level possible given operational constraints (for example, outlet cavitation limits) or the lowest achievable pool. Both the spring and fall reservoir drawdowns at Cougar make use of the diversion tunnel instead of the RO and turbines. This leads to a much lower drawdown to 1330 feet, instead of 1517 feet as in Alternative 3A. Section 2.2.3, Downstream Fish Passage Measures, contains a more detailed explanations of all these actions.

The drawdowns can limit the effectiveness of other actions within Alternative 3A. The spring reservoir drawdown can inhibit refill of the reservoirs into the late winter and spring. Since the reservoirs do not fill more often, there is less available water to augment flows downstream during the summer and fall. In addition, if the reservoir water surface elevation does not rise to the spillway crest, the dam is unable to discharge water through that outlet, constraining the temperature operations that require the spillway.

Summer flow would be well below the NAA and the adaptability of the WVS would be constrained by a reduced ability to refill during conservation season. All changes to the WRB hydrology would be long term. Effects from the Alternative 3B to hydrologic processes: Major as compared to the NAA.

##### *3.2.2.8.1 Santiam Subbasin*

Detroit Reservoir (Figure 3.2-123) would fill more often during conservation use season and achieve a higher elevation when not full in Alternative 3B as compared to the NAA. Since Detroit does not have a spring reservoir drawdown as in Alternative 3A, Detroit meets its downstream flow targets (Figure 3.2-124) much more consistently throughout the summer. Only the driest years (P05 line) would be at the minimum flow target, with even the P25 line able to hit the upper bound of the target in the summer. The steep draft of the reservoir, though still within ramping rate regulations, to meet the deeper fall reservoir drawdown would require a period of bankfull outflows during October which does not occur under the NAA. WVS operations typically would change more slowly than the maximum allowable, so the flow would probably be spread out over a longer period if possible. Even so, Detroit would not always achieve the deeper fall reservoir drawdown target elevation of 1375 feet. Early fall rain would sometimes fill the reservoir with reduced outlet capacity, hindering its ability to reach the drawdown target elevation.

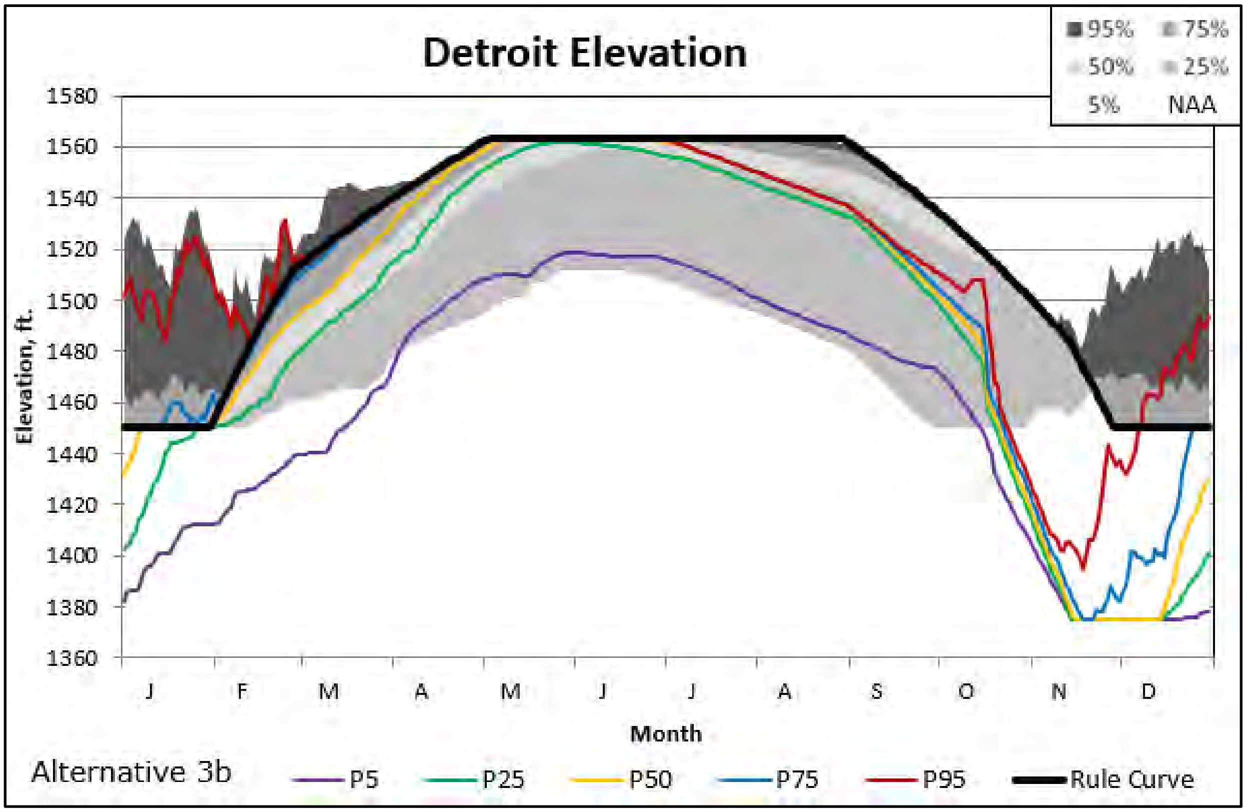

**Figure 3.2-123. Alternative 3B Detroit water surface elevation non-exceedance compared with NAA**

Although there would be generally lower flow during some periods downstream of Detroit as compared to the NAA, the integrated temperature and habitat flow regime targets would be met more often in Alternative 3B than the BiOp targets are in the NAA. The largest miss is in late November of the driest years (P05 line). The reservoir water surface elevation would already be lowered to the deeper fall reservoir drawdown elevation and then passes inflow for the duration of the operation. The inflow would not be enough to meet the target in these years but is enough in 75 percent of the period of record (P25 line).

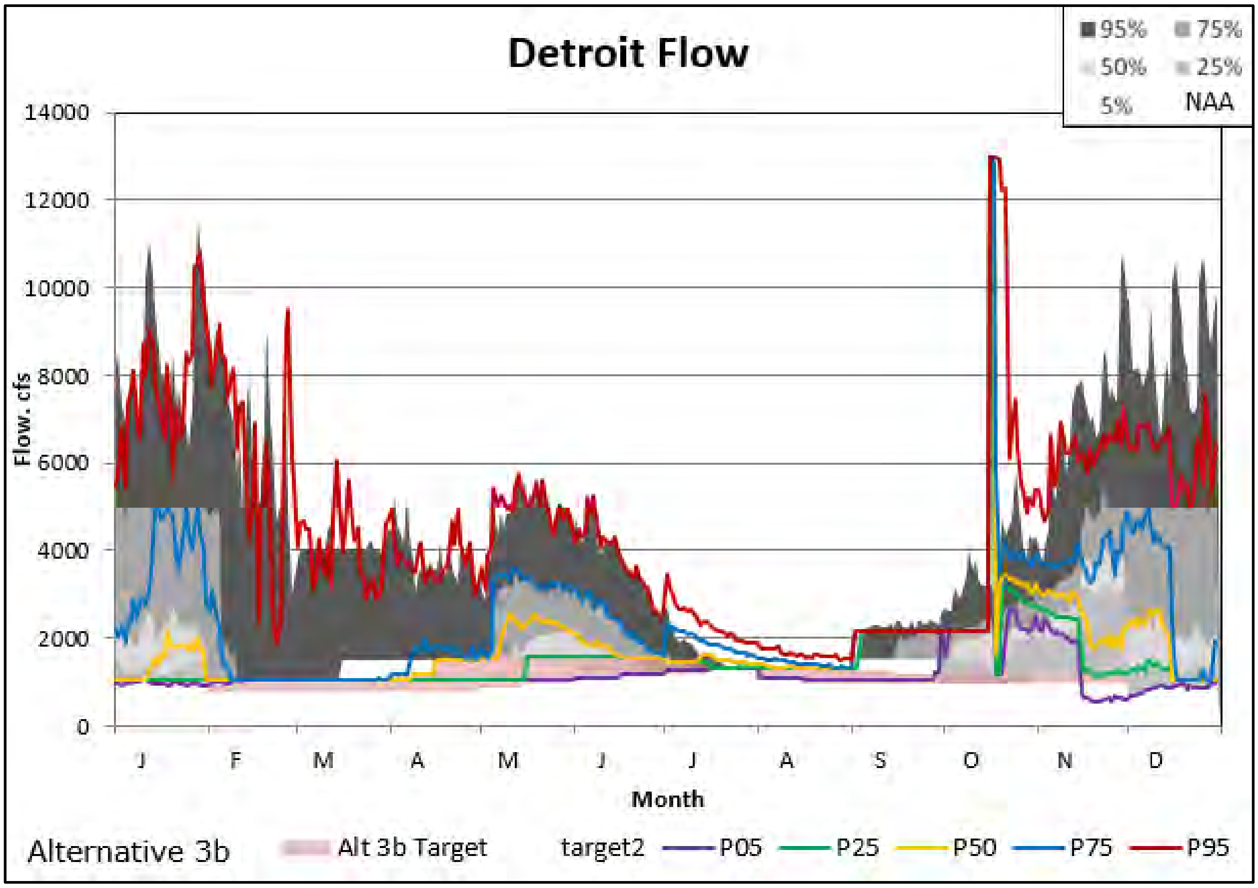

**Figure 3.2-124. Alternative 3B Detroit outflow non-exceedance compared with NAA**

Green Peter Reservoir (Figure 3.2-125) would operate with both spring and fall reservoir drawdowns to elevation 780 feet for Alternative 3B. These elevations would be achieved about half the time due to higher inflows and decreased outlet capacity. An average year (P50 line) would see the reservoir passing inflow from August to October, which is typically below the downstream target streamflow.

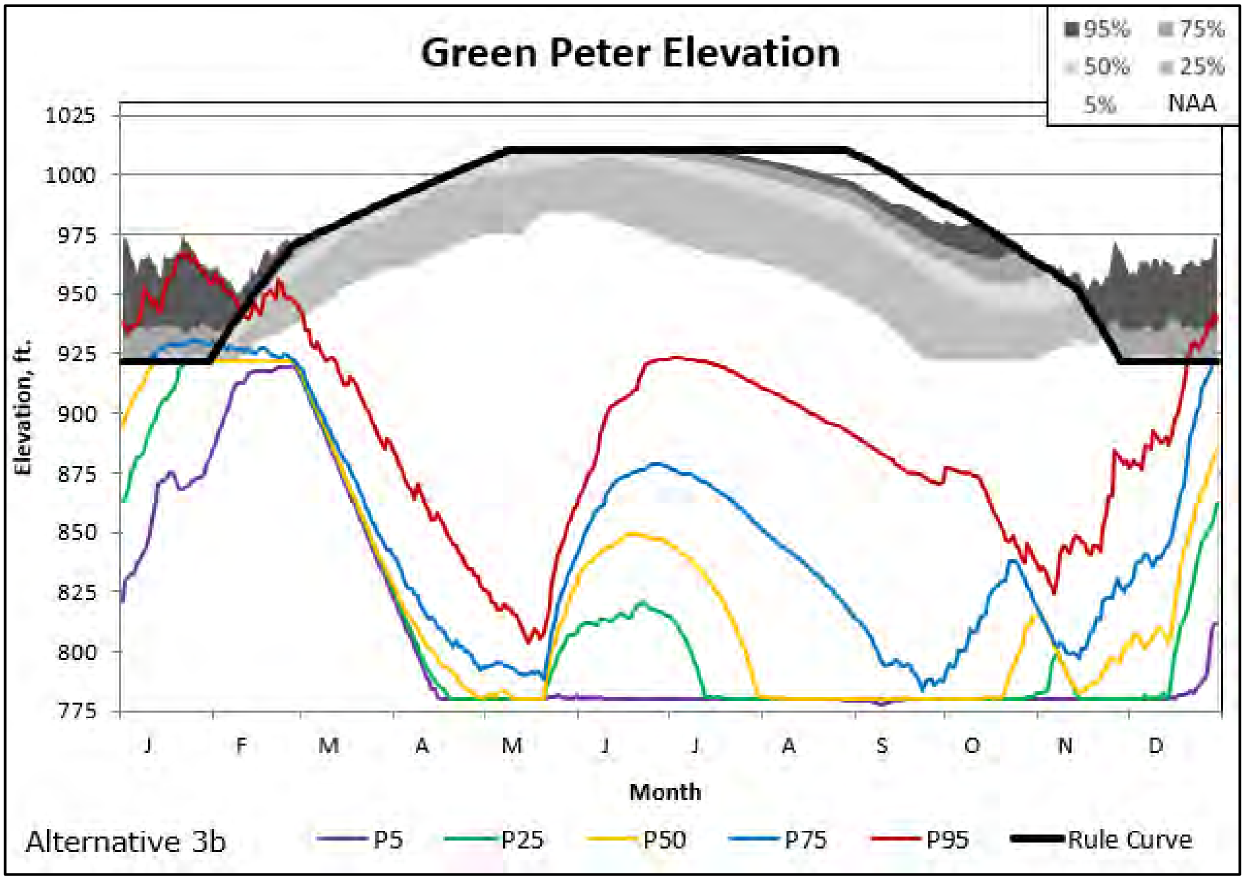

**Figure 3.2-125. Alternative 3B Green Peter water surface elevation non-exceedance compared with NAA**

During an average and drier year, Foster Reservoir (Figure 3.2-126) would also draft down to its minimum pool to supplement downstream flows. Alternative 3B is the only alternative in which this occurs. Foster pool is less than one-tenth the volume of Green Peter pool (28.3 and 312.5 Kaf, respectively), so it would reach its minimum pool elevation within a few weeks of starting to draft. An average year would see the Foster water surface elevation start to fall in early August and the driest years would see it start to fall in the middle of June.

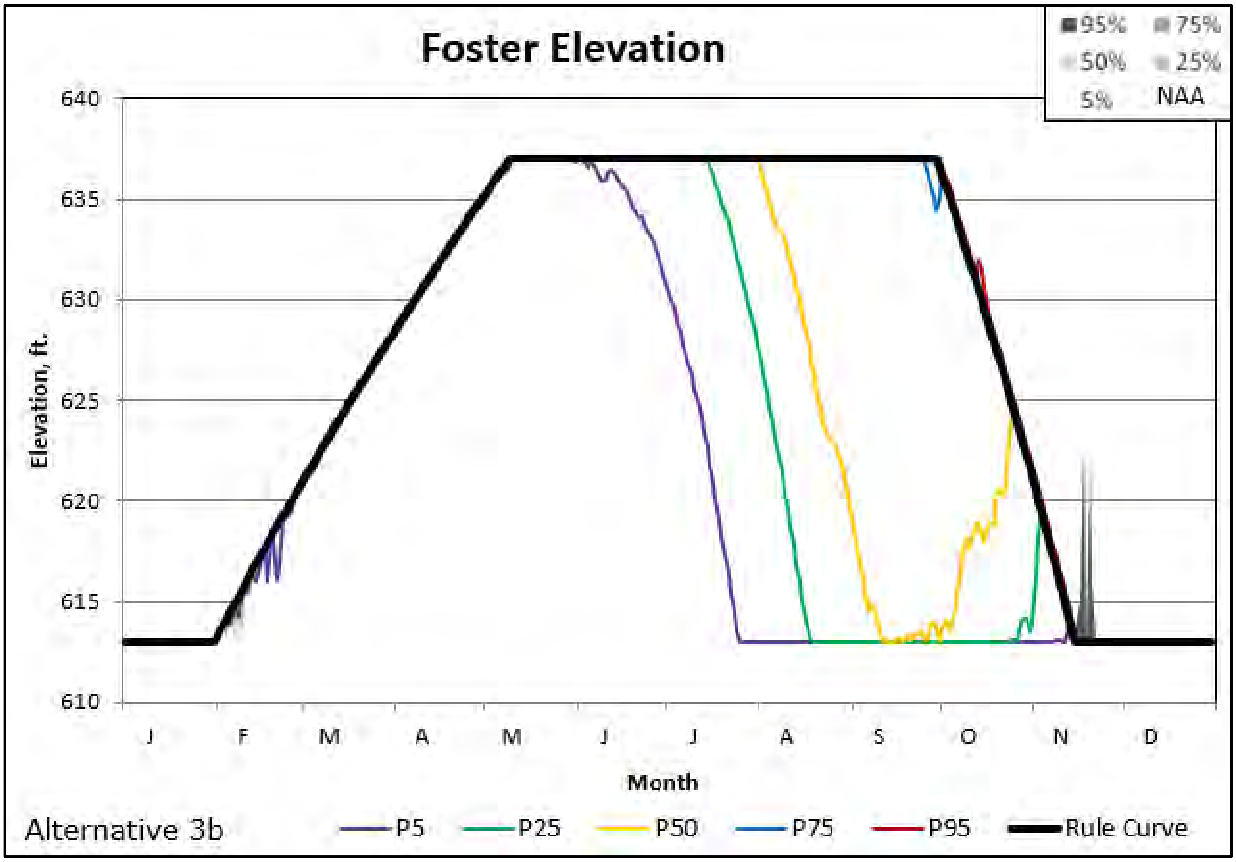

**Figure 3.2-126. Alternative 3B Foster water surface elevation non-exceedance compared with NAA**

The flow downstream of Foster – which combines the output from Foster, Green Peter, and the South Santiam upstream of Foster – would change greatly from the NAA (Figure 3.2-127). Spring flows would be higher across water years as Green Peter releases water for its spring reservoir drawdown. Flows fall suddenly in mid-May as Green Peter starts to refill afterward. The lower bound of the integrated temperature and habitat flow regime target would only be met in wetter-than-average years (P75 line) and the driest years fall short from May until November, even as Alternative 3B uniquely drafts Foster Reservoir's small storage capacity. The typical outflow from Foster in the fall for drier-than-average year would be 100 to 350 cfs, compared to the target flow of 840 cfs.

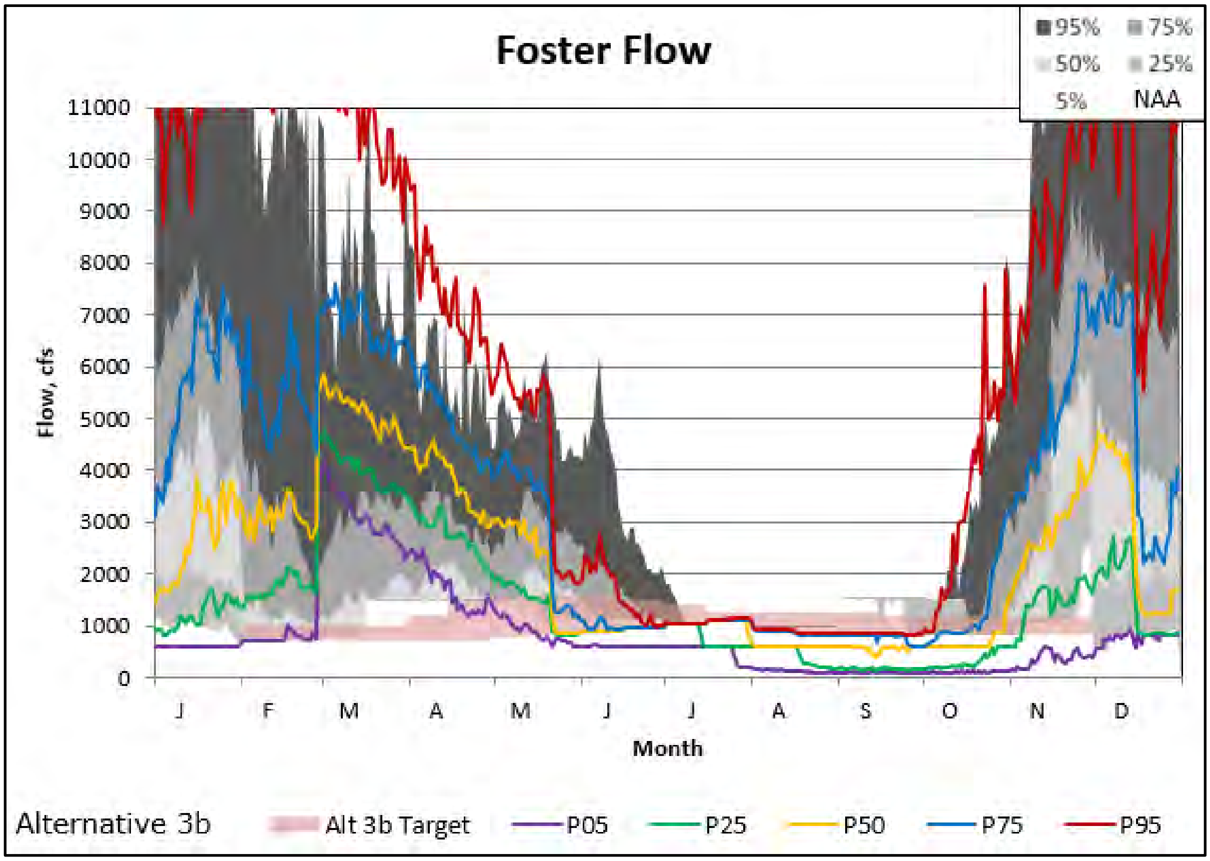

**Figure 3.2-127. Alternative 3B Foster outflow non-exceedance compared with NAA**

The Santiam at Jefferson (Figure 3.2-128) would be affected by the changes at Detroit – in the North Santiam subbasin – and Green Peter – in the South Santiam subbasin. Higher flows would be evident when the reservoirs draft to the drawdowns (principally March for Green Peter and October for both) compared to the NAA. There would also be a larger variation in flow in the summer, with more flow in the wettest years and less flow in the driest years. There would be much less change in the seasonal flow pattern as compared to Alternatives 1 and 4, as the storage aspects of those Alternatives are constrained by the drawdowns.

Although there are many relatively minor differences, the largest difference between Alternatives 3A and 3B is the larger outflow from Detroit in preparation for the deeper fall reservoir drawdown. Although it is a notable spike in flow for October, it is well within bankfull flows and very unlikely to be the highest flow in any given year.

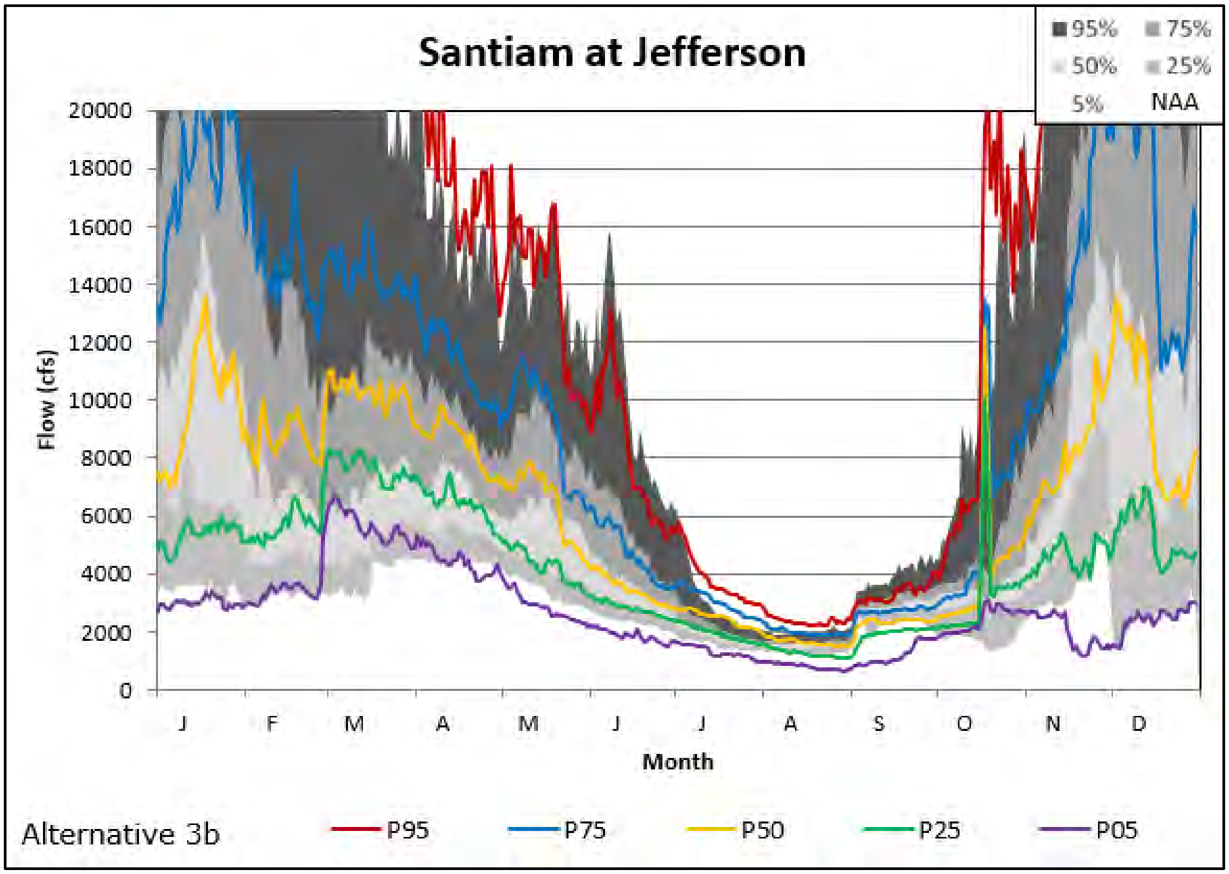

**Figure 3.2-128. Alternative 3B Santiam River at Jefferson flow non-exceedance compared with NAA**

*3.2.2.8.2 Long Tom Subbasin*

As explained in the NAA, Fern Ridge reservoir (Figure 3.2-129) is operated for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. Since Fern Ridge has a large surface area and small volume compared to the other WVS reservoirs, there is limited scope to change its operation and the water surface elevations within Fern Ridge would remain nearly the same as the NAA. Downstream flows at Monroe would remain similarly unchanged for Alternative 3B.

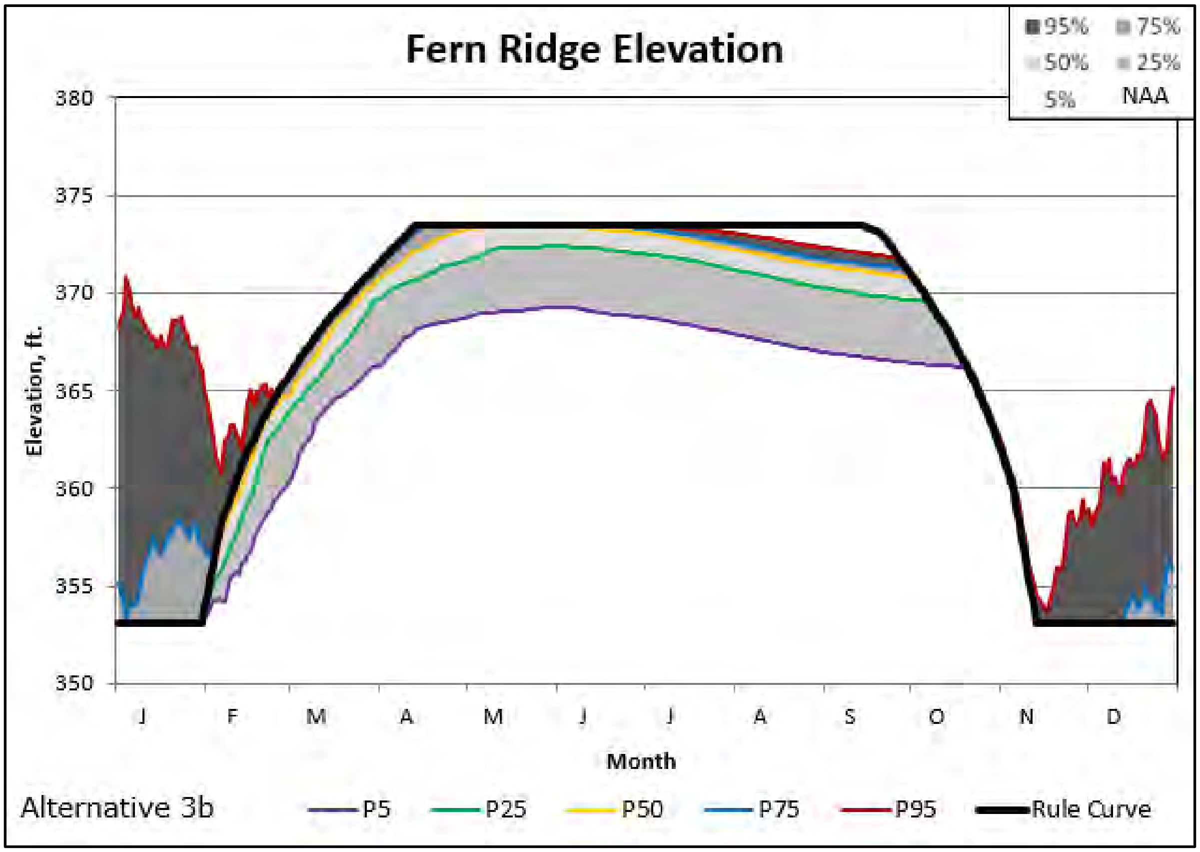

**Figure 3.2-129. Alternative 3B Fern Ridge water surface elevation non-exceedance compared with NAA**

*3.2.2.8.3 McKenzie Subbasin*

Like Green Peter reservoir in the Santiam subbasin, Cougar reservoir (Figure 3.2-130) would have both spring and fall reservoir drawdowns. Although Cougar also would have both drawdowns in Alternative 3A, Alternative 3B drafts Cougar significantly lower using the diversion tunnel to elevation 1330 feet instead of the RO to elevation 1517 feet. The reservoir water surface elevation would only be at or above minimum conservation pool at the end of winter and only the wettest summers (P95 line) a substantial change from the NAA. An average year (P50) would achieve the spring reservoir drawdown target elevation, but not the fall elevation.

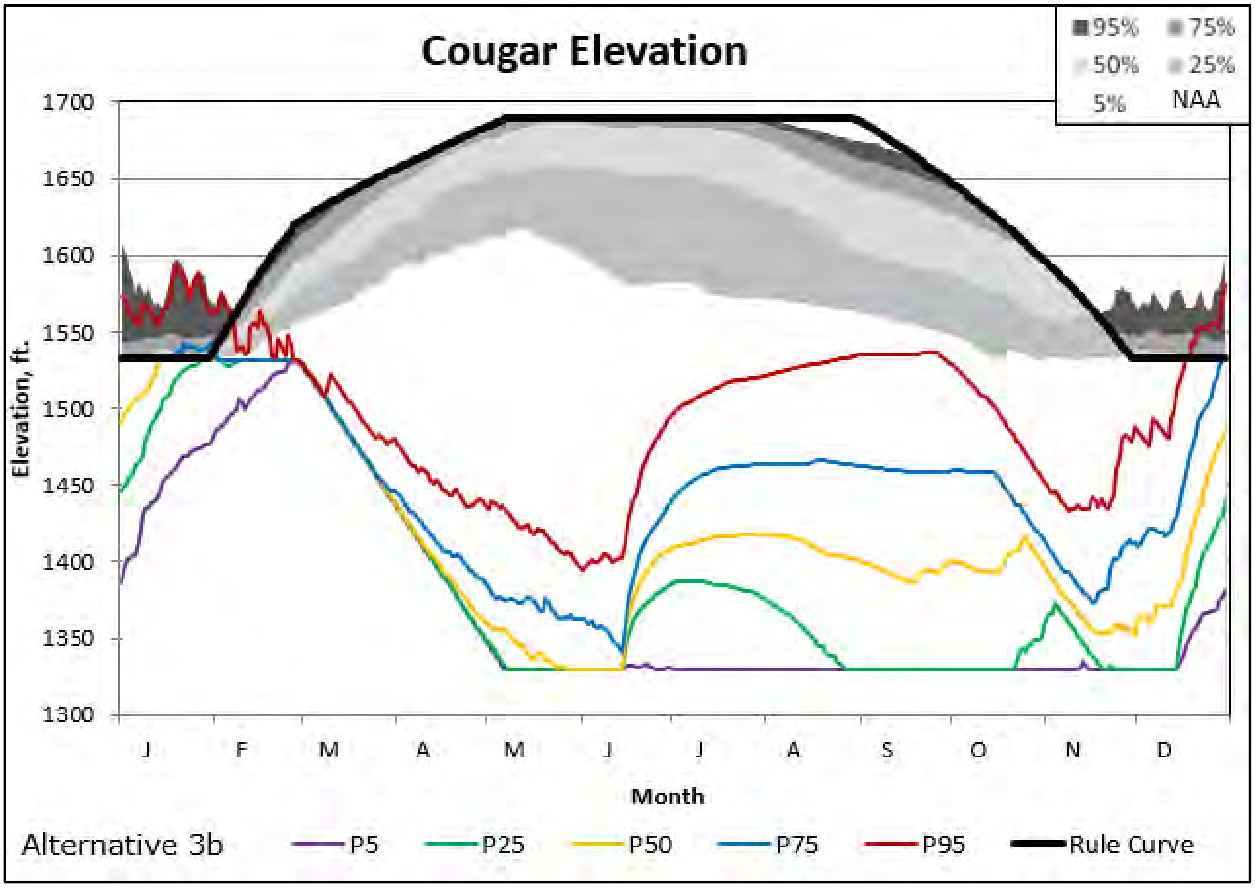

**Figure 3.2-130. Alternative 3B Cougar water surface elevation non-exceedance compared with NAA**

Blue River reservoir (Figure 3.2-131) would fill more frequently in Alternative 3B as compared to the NAA due to the lower downstream integrated temperature and habitat flow regime targets. It would also draft more quickly in the summer to make up for the lower storage volume available from Cougar and has a deeper fall reservoir drawdown to elevation 1165 feet.

Overall, Alternatives 3A and 3B would be very similar at Blue River, except for the driest Octobers. Mainstem flow targets would dictate that Blue River continue to augment instream flows by using the inactive pool in Alternative 3A. In Alternative 3B, other WVS reservoirs – Lookout Point in particular – meet this downstream need in the driest years.

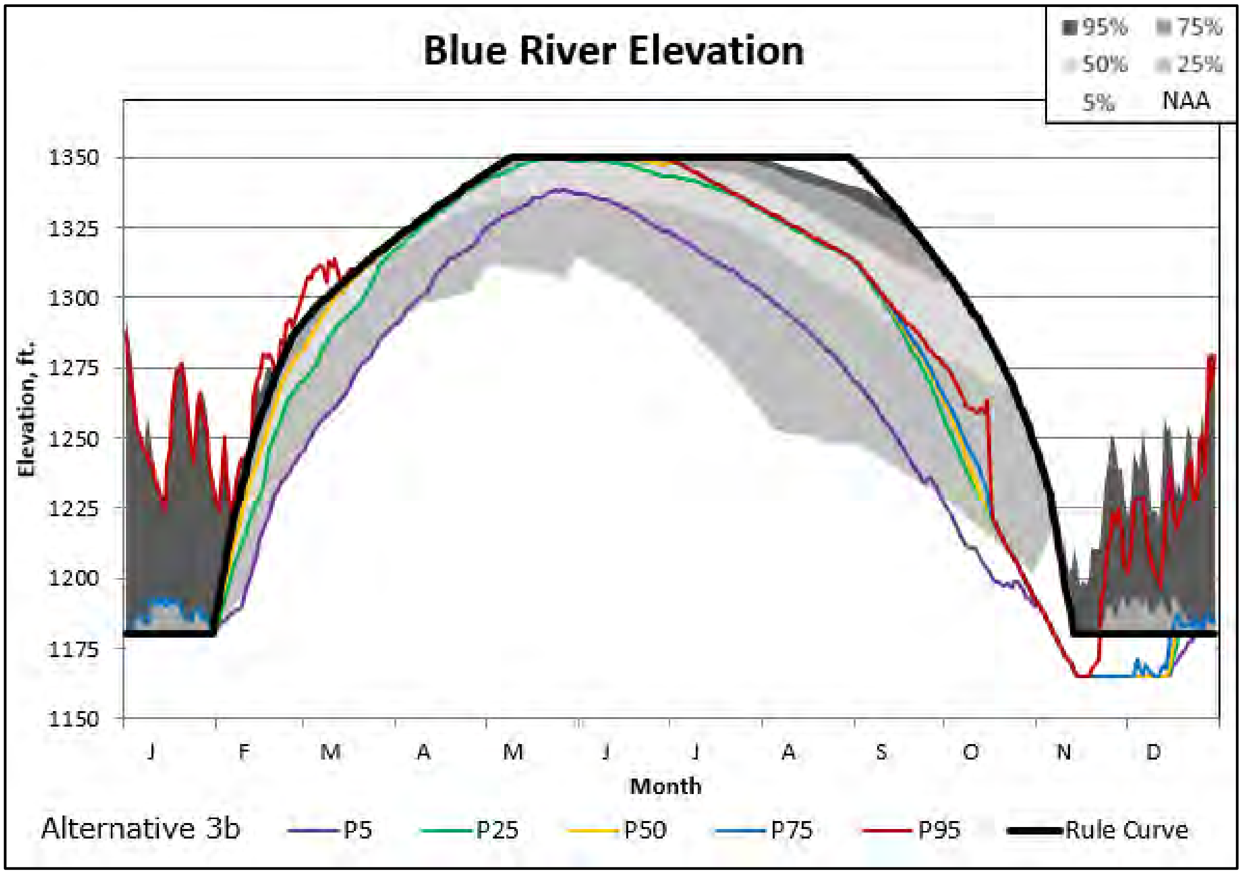

**Figure 3.2-131. Alternative 3B Blue River water surface elevation non-exceedance compared with NAA**

The downstream control point, the McKenzie River at Vida (Figure 3.2-132), shows the combined effect of more and less available conservation storage at Blue River and Cougar, respectively compared to the NAA. The higher flows during March for all years and continuing into April and May of wet years would result from Cougar not filling during conservation season as it does in the NAA. The lower flows during the driest years of April to June are due to Blue River filling more while also meeting the lower minimum downstream integrated temperature and habitat flow regime targets.

During the summer, Alternative 3B flows would be marginally below the NAA as the increased storage at Blue River and no storage at Cougar nearly balance out – Blue River is smaller than Cougar, so flows would be a bit lower across the summer. Despite Cougar's much lower water surface elevations for Alternative 3B as compared to 3A, the amount of volume in the reservoir above the minimum elevation (1330 feet and 1517 feet for 3B and 3A, respectively) is similar across the summer. Therefore, combined with the relatively high baseflow in the McKenzie River, the lower drawdown elevation would only have small effects on the summer and fall flow at Vida.

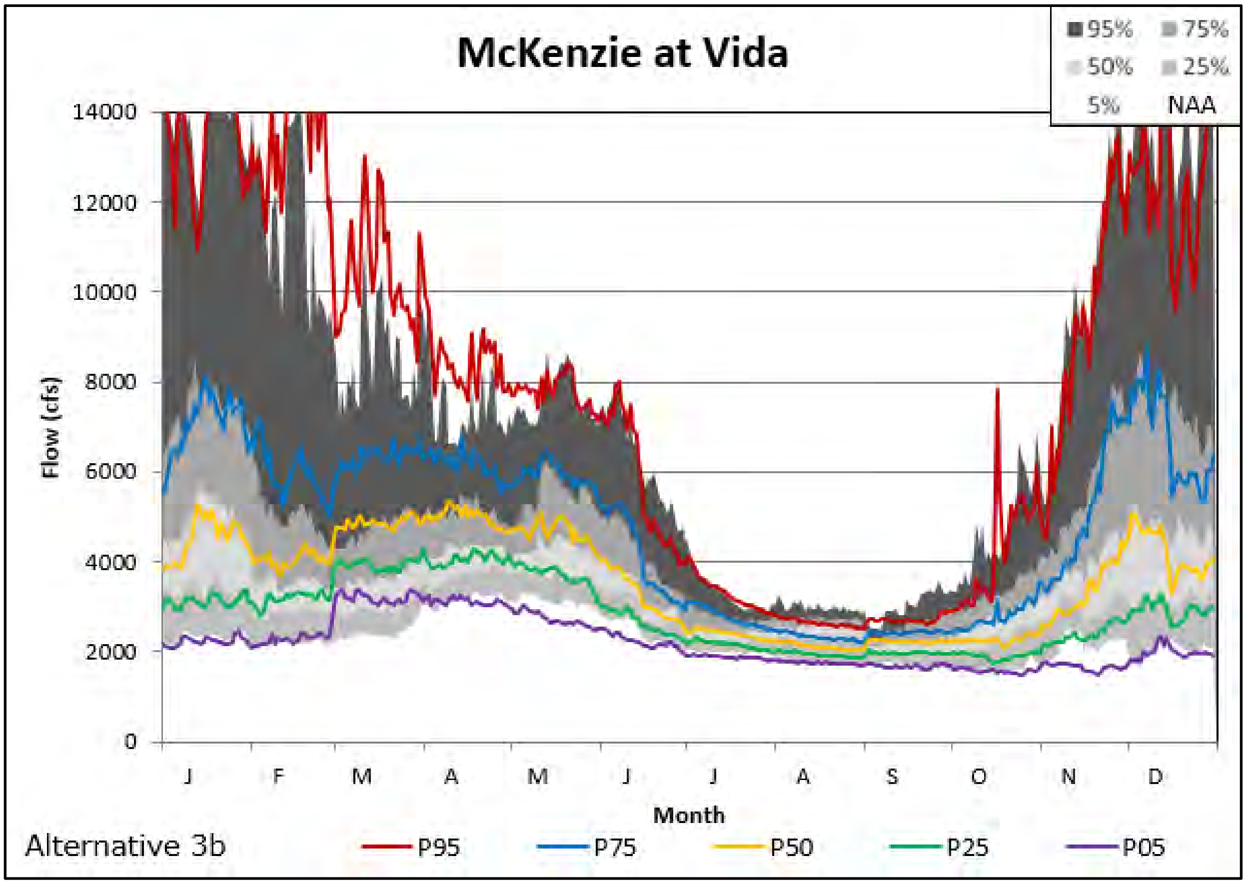

**Figure 3.2-132. Alternative 3B McKenzie River at Vida flow non-exceedance compared with NAA**

### *3.2.2.8.4 Middle Fork of the Willamette Subbasin*

Hills Creek, Lookout Point and Fall Creek would all have deeper fall reservoir drawdowns in Alternative 3B (Fall Creek's is an existing operation in the NAA) and Hills Creek would also have a spring reservoir drawdown. As such, Hills Creek (Figure 3.2-133) does not fill more than about 10 feet above its minimum elevation 75 percent of years during the summer, which is substantially less frequent than the NAA. The drawdown target elevation would be achieved in the wettest years (P95) in contrast to deeper drawdowns at other WVS reservoirs.

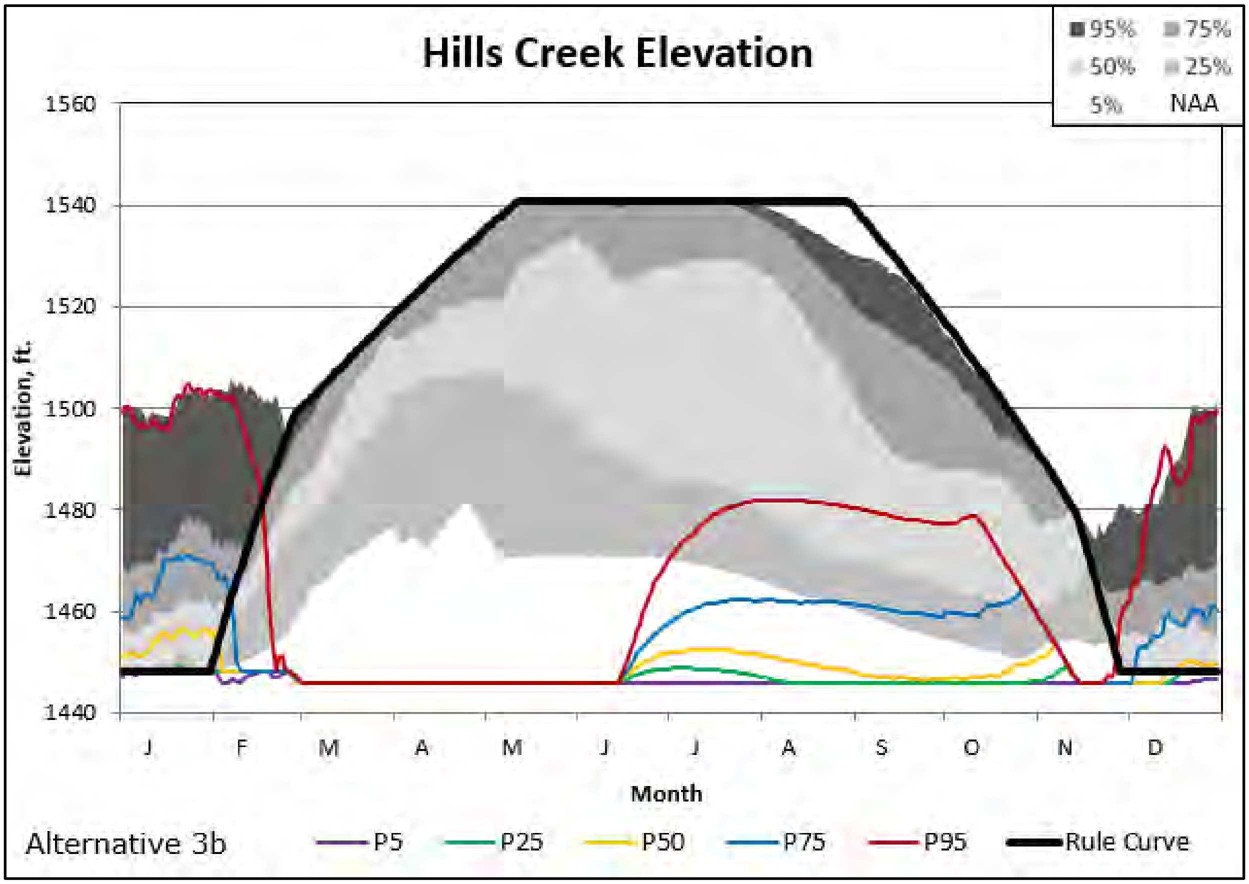

**Figure 3.2-133. Alternative 3B Hills Creek water surface elevation non-exceedance compared with NAA**

During spring conservation storage season, Lookout Point (Figure 3.2-134) would fill more frequently and achieve a higher elevation during dry years as compared to the NAA. This is due to the lower integrated temperature and habitat flow regime targets and some of the water not stored at Hills Creek due to the spring reservoir drawdown there is stored at Lookout Point. Since there would be a lower amount of water stored in the system overall, Lookout Point would draft earlier than in the NAA before releasing water at a higher rate than the NAA for the deeper fall reservoir drawdown. The drawdown target elevation would usually, but not always, be achieved (the P75 line reaches the target, but the P95 line does not).

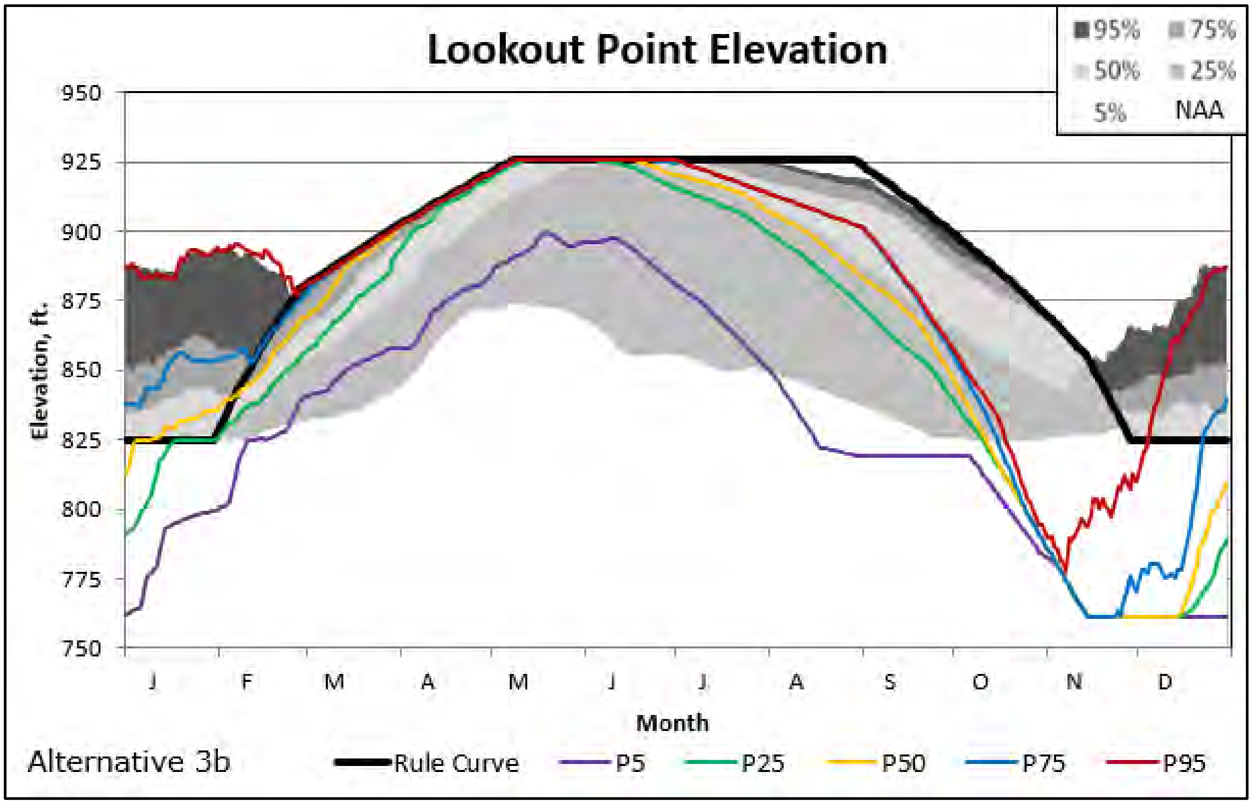

**Figure 3.2-134. Alternative 3B Lookout Point water surface elevation non-exceedance compared with NAA**

Fall Creek (Figure 3.2-135) water surface elevations and outflows would be very similar to the NAA, which already implements a deeper fall reservoir drawdown to the same elevation as in Alternative 3B.

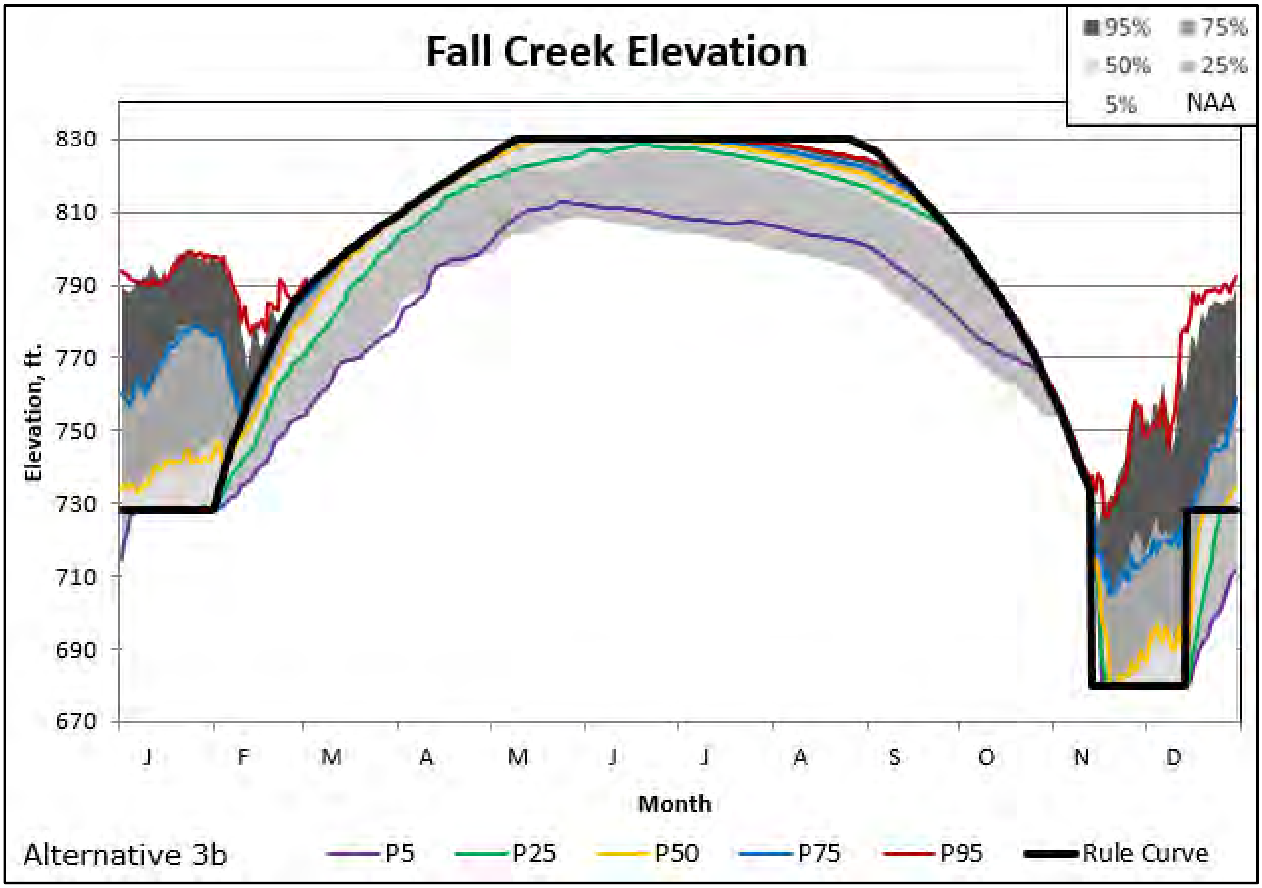

**Figure 3.2-135. Alternative 3B Fall Creek water surface elevation non-exceedance compared with NAA**

The flows at the control point for the Middle Fork subbasin WVS dams at Jasper (Figure 3.2-136) would be more like the NAA for Alternative 3B than it would be for Alternative 3A. There are a couple reasons for this. Since Hills Creek, which is upstream of Lookout Point, has the spring reservoir drawdown in Alternative 3B, Lookout Point can store some of the water that flows from Hills Creek during the spring. Lookout Point is also more than 40 percent larger than Hills Creek (336.4 Kaf and 234 Kaf, respectively), so Alternative 3B conservation season storage volumes are higher compared to 3A.

The driest years during April to June (P05) are due to the lower integrated temperature and habitat flow regime targets downstream, which are met in Alternative 3B. The lower flows during the driest August through October periods coincide with Lookout Point reaching its minimum water surface elevation outside of the drawdown target, at which point it would pass inflow, which would be lower than the augmented flow in the NAA.

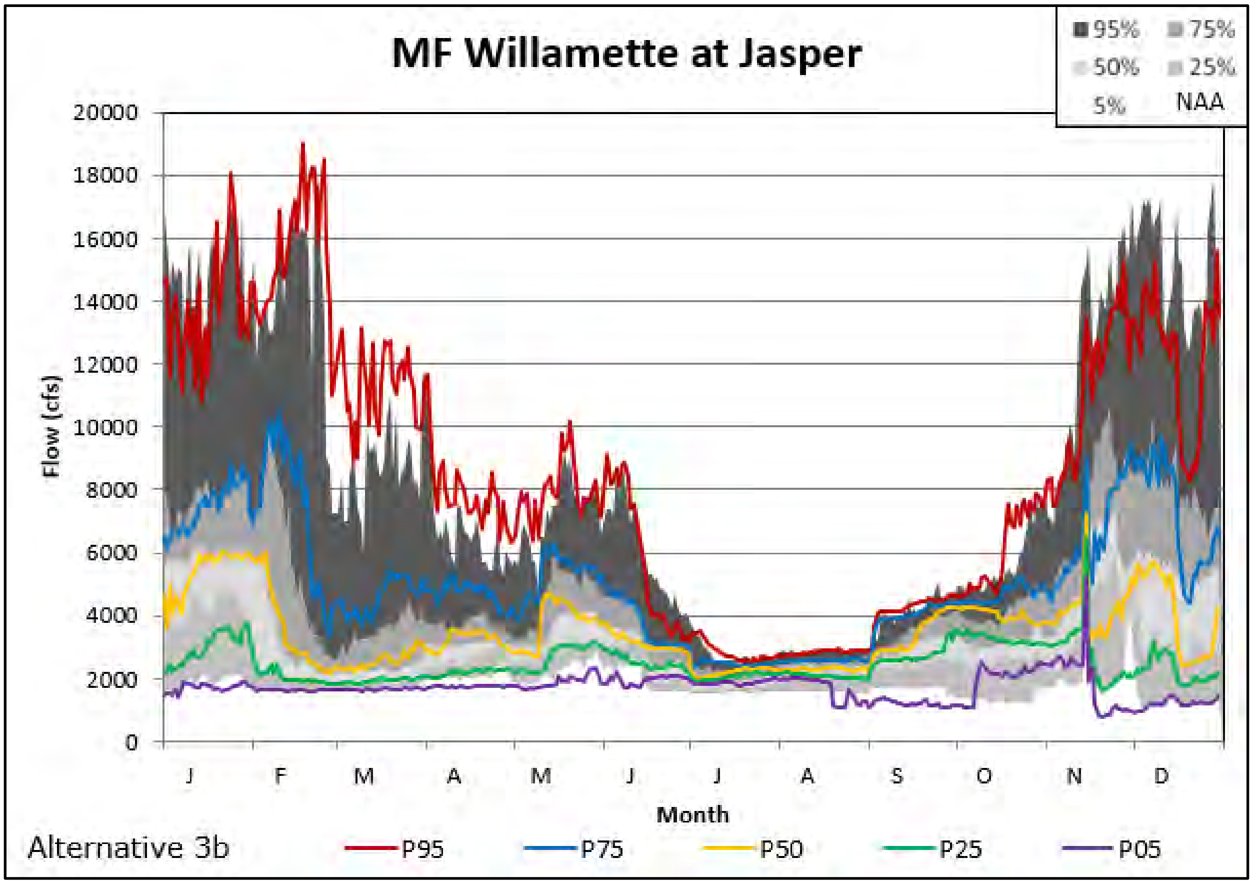

**Figure 3.2-136. Alternative 3B Middle Fork of the Willamette River at Jasper flow non-exceedance compared with NAA**

*3.2.2.8.5 Coast Fork of the Willamette Subbasin*

Dorena and Cottage Grove reservoir elevations would behave very similarly in Alternative 3A, as shown in Figures 3.2-137 and 3.2-138, respectively. The refill to slightly higher levels than the NAA due to the lower integrated temperature and habitat flow regime targets downstream. Reservoir storage would be similar for average and wet years throughout the summer and fall. They would draft faster from higher initial water surface elevations in dry years as these reservoirs make up for the lower storage elsewhere in the system. In especially dry falls, the reservoirs would augment instream flows by using the inactive pool. This operation would be activated a bit more often in Alternative 3B as opposed to Alternative 3A.

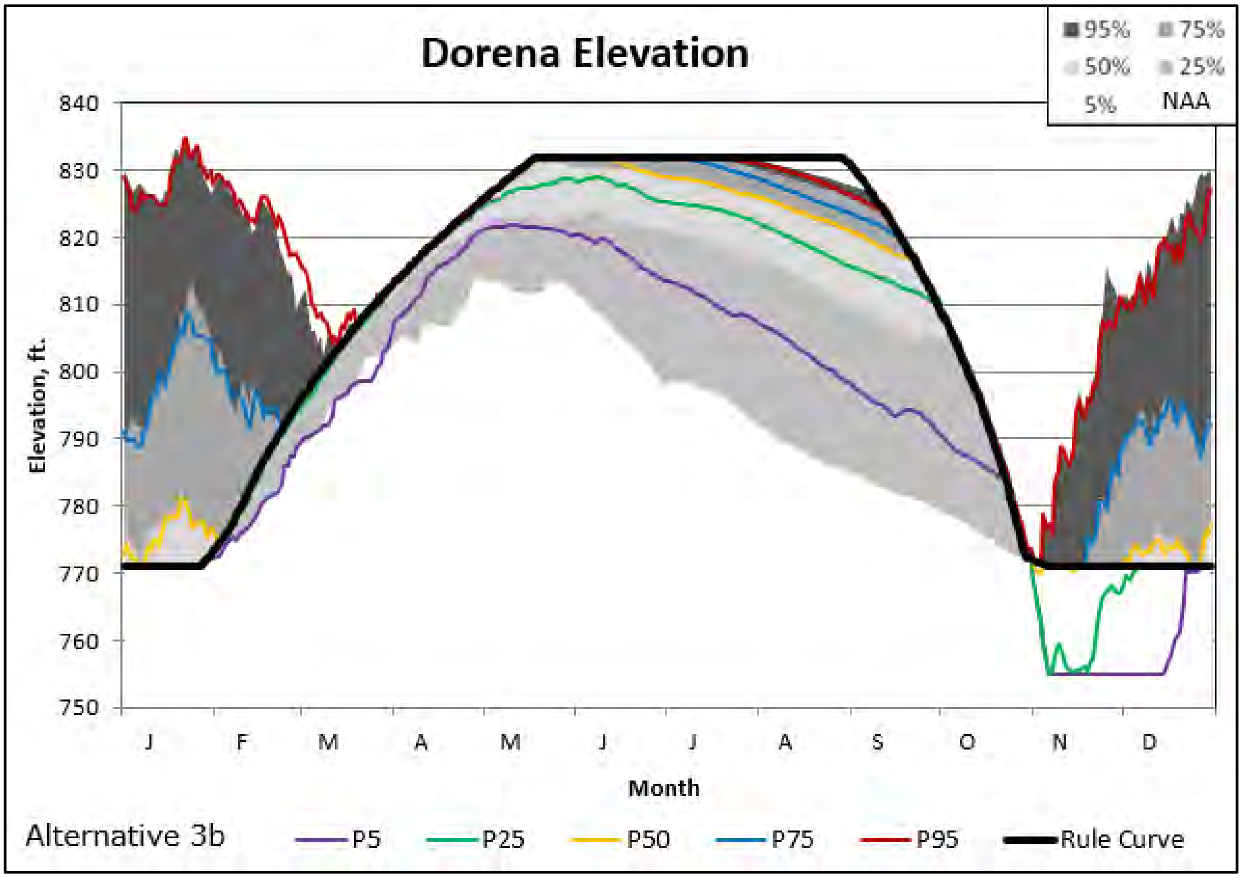

**Figure 3.2-137. Alternative 3B Dorena water surface elevation non-exceedance compared with NAA**

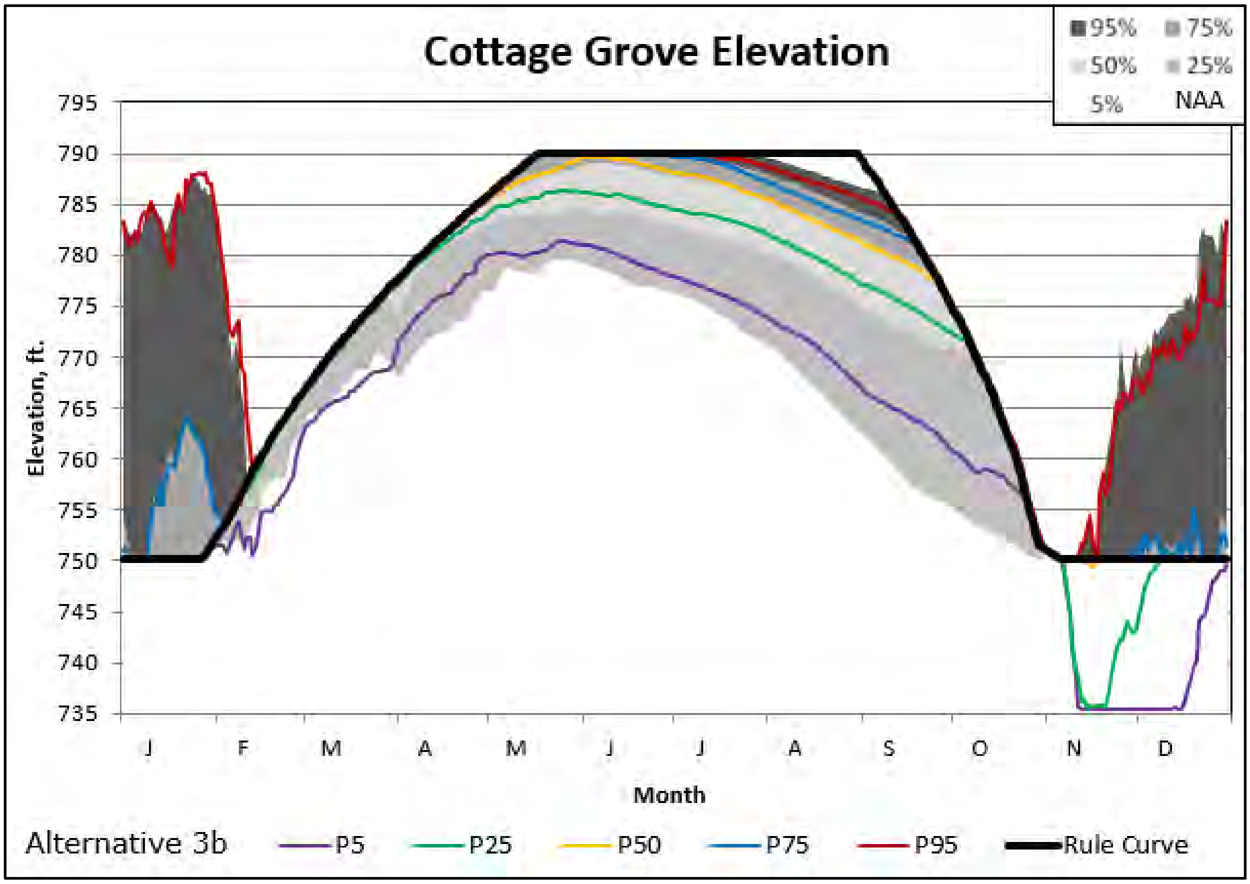

**Figure 3.2-138. Alternative 3B Cottage Grove water surface elevation non-exceedance compared with NAA**

The flow at Coast Fork of the Willamette River at Goshen (Figure 3.2-139) would vary most from the NAA in dry years. The additional stored water accumulated in Dorena and Cottage Grove would be evident by the decreased flow from April to June and increased flow July to October as the reservoirs release that water. Although there are minor differences, Alternative 3A and 3B are similar at Goshen from a hydrologic perspective.

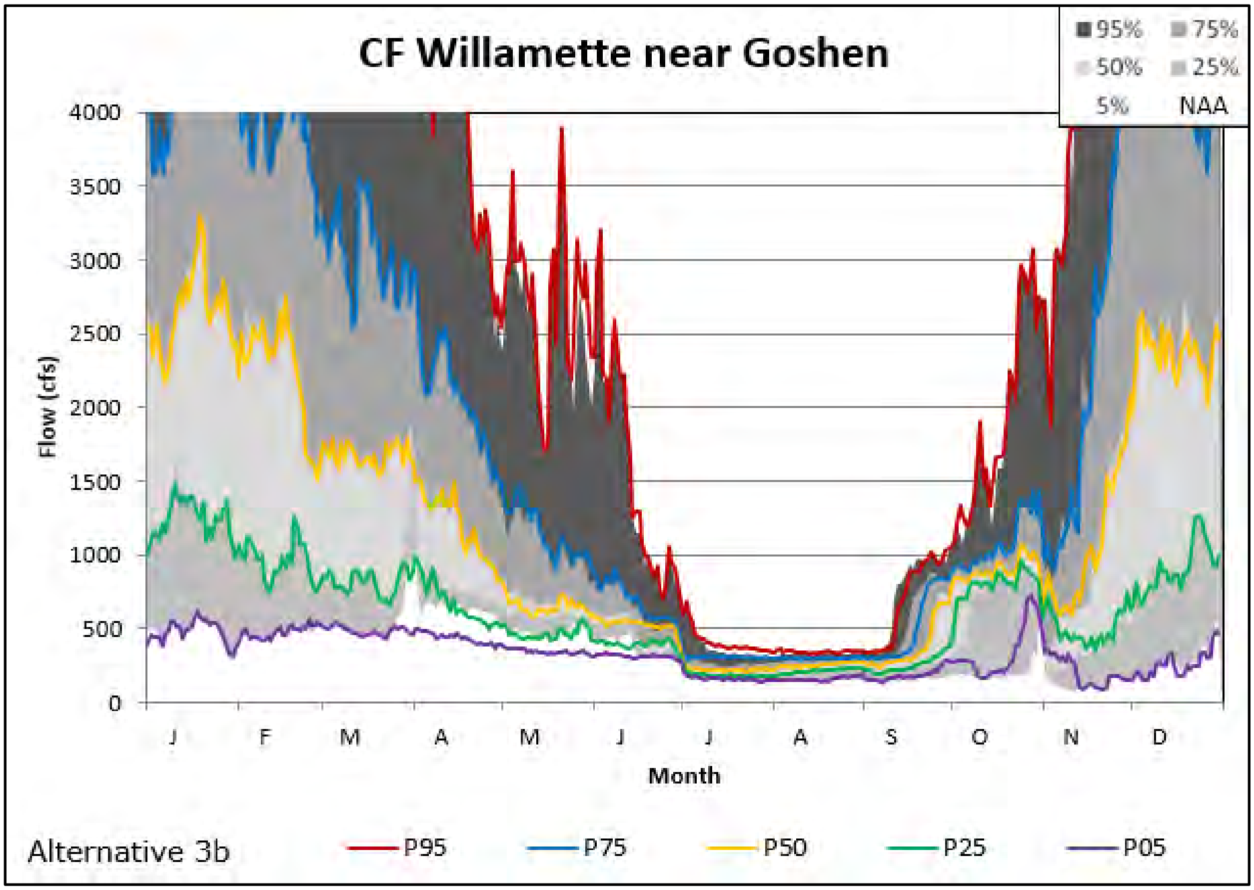

**Figure 3.2-139. Alternative 3B Coast Fork of the Willamette River at Goshen flow non-exceedance compared with NAA**

### *3.2.2.8.6 Mainstem Willamette River*

The Alternative 3B flow targets on the mainstem Willamette River at Albany and Salem (Figures 3.2-140 and 3.2-141, respectively) are the integrated temperature and habitat flow regime targets, which are lower than the BiOp targets in the NAA and modify the target at Salem during warm weather (the target box in the figure). Section 2.2.1, Flow Measures, contains a more detailed explanation of these flow targets.

In wet years Alternative 3B would have consistently higher flow during the springtime at both Albany and Salem as compared to the NAA. The driest years would have lower flow in the spring due to the lower flow target at Salem.

After the end of the WVS spring reservoir drawdowns, flows would decline across all years, but not as steeply as Alternative 3A. The integrated temperature and habitat flow regime target would be met more often during dry years than the NAA meets the 2008 BiOp target. During wetter years, lower overall system storage would mean less flow (P95 and P75 lines) than the NAA. In the driest years (P05 line), flows would be below the target for about 2 months instead of almost 4 months in the NAA. Across all water year types, flows would be higher at Albany for Alternative 3B than Alternative 3A. This is largely due to the Middle Fork spring reservoir drawdown switching from Lookout Point to Hills Creek in Alternative 3B; Lookout Point would be able to store some of the water that Hills Creek releases during its spring reservoir drawdown.

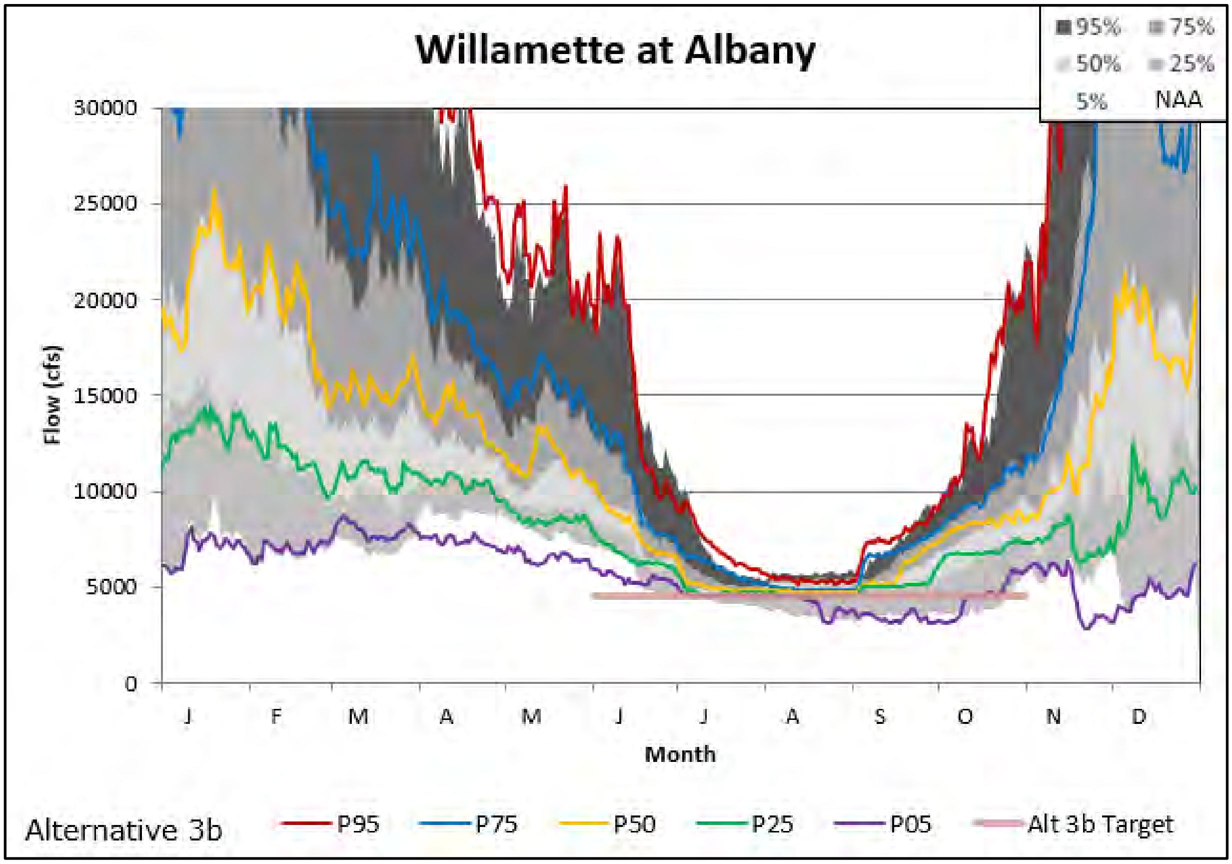

**Figure 3.2-140. Alternative 3B Willamette River at Albany flow non-exceedance compared with NAA**

Flows at Salem would more consistently meet the integrated temperature and habitat flow regime target for Alternative 3B than Alternative 3A, again due to the contributions of Lookout Point. Spring flows would be lower for drier years, as the flow target is lower than the NAA, and higher for wetter years, as the WVS reservoirs with drawdowns are releasing water they would have stored in the NAA.

Summer flow at Salem would be generally somewhat less than the NAA but would only miss the integrated temperature and habitat flow regime target during the driest years (P05 line), when Lookout Point reaches its minimum summer pool. This coincides with low flows at Albany, but augmentation from the Santiam subbasin means there are fewer missed days at Salem.

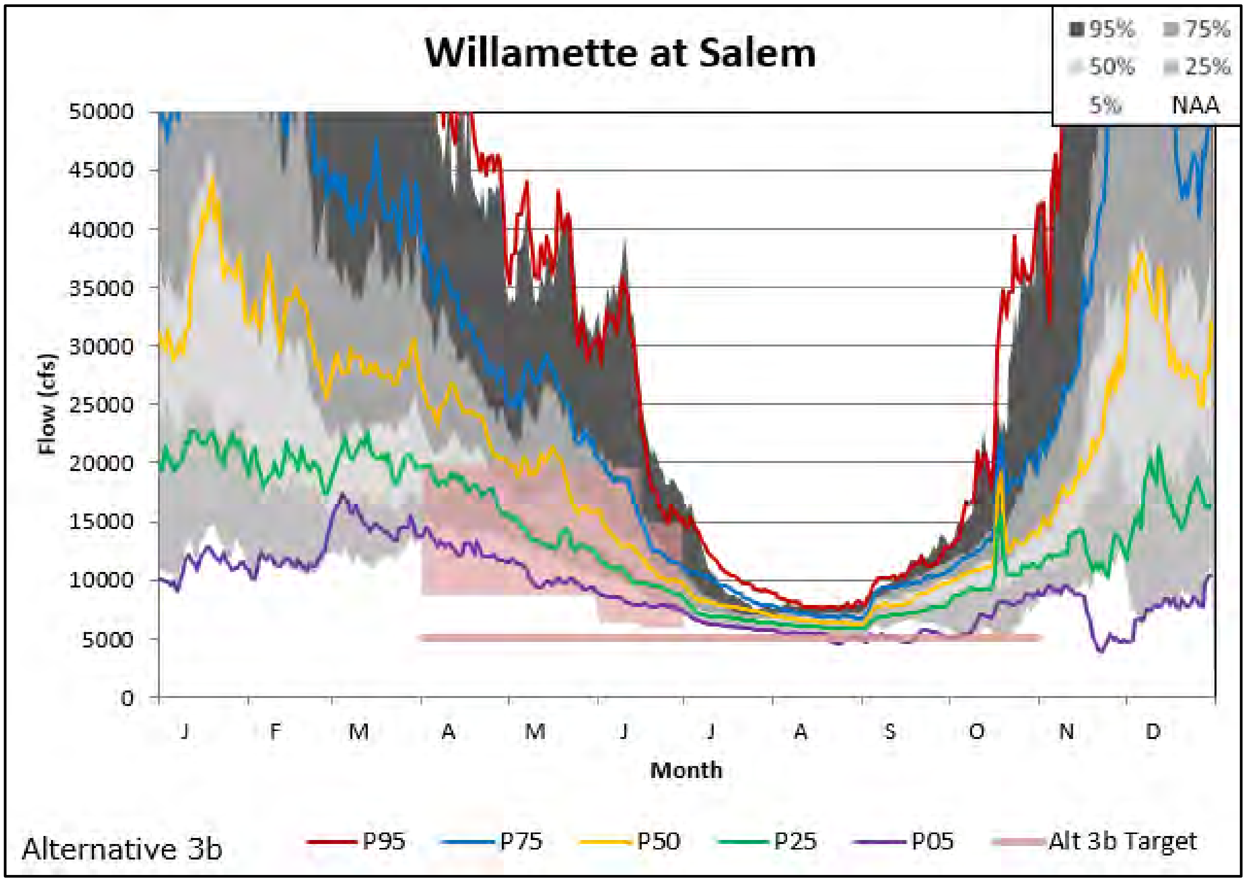

**Figure 3.2-141. Alternative 3B Willamette River at Salem flow non-exceedance compared with NAA**

*3.2.2.8.7 Near-Term Operations Measure*

See Alternative 2A, Section 3.2.2.4.7, for description of effects due to the Near-Term Operations Measure.

*3.2.2.8.8 Climate Change*

Climate change hydrologic factors such as seasonal flow volume shifts may stress the WVS under Alternative 3B operations. Specifically, future increases in median wintertime flow volumes and average deceases in summertime baseflows will exacerbate effects already present in Alternative 3B. Climate change effects, and potential implications as discussed below, draw on the climate change projection and trend information provided in the climate change appendices.

Across the WVS, lower reservoir pool elevations and flow releases for downstream flow targets are likely in the future. Spring inflow quantity and timing is projected to be more variable in the future as climate change trends take hold. Limited to no snowpack is a consequence of projected warming in the Valley and conversion of snowpack to wintertime flows. The projection for even drier, warmer, and earlier arriving summers means that the spring reservoir drawdowns will typically prevent refill. The spring reservoir drawdowns at Hills Creek and Cougar end in the middle of June and at Green Peter in middle of May, well after the projected decline in inflow.

Both the Albany and Salem flow targets will be met less frequently compared to the NAA with projected lower late spring and summer flow, though the differences will be less drastic than in Alternative 3A. There are a couple reasons for this. The South Santiam subbasin has a lower average elevation, so is projected to be relatively less affected by decreasing inflows. Therefore, Green Peter would be able to fill more often after its Alternative 3B spring reservoir drawdown than Detroit (which has a spring reservoir drawdown in Alternative 3A). Also, Lookout Point can store some of the water released from Hills Creek during the spring reservoir drawdown, increasing its chance of complete refill.

After the deeper fall reservoir drawdowns, there is additional storage space between the minimum drawdown elevation and the maximum flood storage elevation. It will typically take until middle of January (though timing varies throughout the WVS) for reservoirs to return to their current rule curve elevation under the NAA. Downstream winter flows could be kept similar to the NAA with this additional storage capacity, despite projected increased winter peak flow and volume.

#### *3.2.2.9 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

From a hydrologic perspective, Alternative 4 is similar to Alternative 1, with a different set of flow targets in the subbasins below the dams and in the mainstem Willamette River. The "Integrated Temperature and Habitat Flow Regime" replace the 2008 NMFS BiOp in the NAA and the Congressionally authorized minimum flows in Alternative 1. Like Alternative 1, Alternative 4 shifts the release of stored water from the spring into the summer and fall, but integrated temperature and habitat flow regime targets are generally higher and more variable than those in the Congressionally authorized minimum flows.

Briefly, the integrated temperature and habitat flow regime would modify the minimum targets at a WVS reservoir if it is at more or less than 90 percent of rule curve elevation. Flows would be reduced within a range down to minimums needed for fish survival when reservoirs are under the 90 percent threshold. However, these are adaptive within a water year and can return to return to levels higher than the NAA 2008 BiOp flows downstream of the dams if reservoir levels increase.

At the mainstem Willamette control points – Albany and Salem – flow targets would be reduced to 4,500 and 5,000 cfs, respectively. The higher NAA 2008 BiOp targets are designed to keep the river from getting too hot, as well as meet other goals so much more water would be added in the spring. As a replacement, the integrated temperature and habitat flow regime would require additional flow based on the air temperature, with total flow minimum at Salem ranging from 5,900 cfs to 19,800 cfs. This allows the WVS to store additional water when it is not needed to keep the river, and fish in it, cooler than the NAA.

In general, Alternative 4 has limited effects during an average or wet year in the WRB. The reservoirs fill during these years while meeting downstream flow targets. Summer flows are sometimes a bit higher due to the reservoir reaching maximum pool somewhat earlier than normal and therefore passing inflow sooner, but flow differences are minimal.

Alternative 4 would alter storage in drier than average years, and especially the 25 and 5 percent non-exceedance (P25 and P05 in the figures) years, shifting flow releases from April to June into July through October. This would result in less flow compared to the NAA earlier in the year during the April to June period. Later flow targets from July to October would be met more frequently due to the additional accumulated stored water. Compared to Alternative 1, the flows are similar or higher across the WVS, so reservoir elevations would be somewhat lower than Alternative 1.

Although there would be many structural actions in Alternative 4 at the WVS dams to aid fish survival, many of these would not affect the flow out of any WVS dam. Only those structures that affect some aspect of flow, such as outlet choice, are included in this analysis. An example of an excluded structure is a WTC tower, which allows for greater control of the temperature of the water released from the dam but ultimately uses the same regulating outlet as without the WTC tower in place. A more detailed analysis of Alternative 4 by subbasin follows.

The shift in releases of stored water to a different season would be very noticeable throughout the basin and would bring long term changes to the WRB. Effects from the Alternative 4 to hydrologic processes: Major as compared to the NAA.

#### *3.2.2.9.1 Santiam Subbasin*

Detroit reservoir would fill more often during conservation use season and would achieve a higher elevation when it does not fill, as shown in Figure 3.2-142, as compared to the NAA. The integrated temperature and habitat flow regime flow target would be lower than the NAA flows during drier years. More water would be released from storage during average and wetter years, meaning the reservoir water surface elevation would meet the rule curve later in the year at levels above the P50 non-exceedance line.

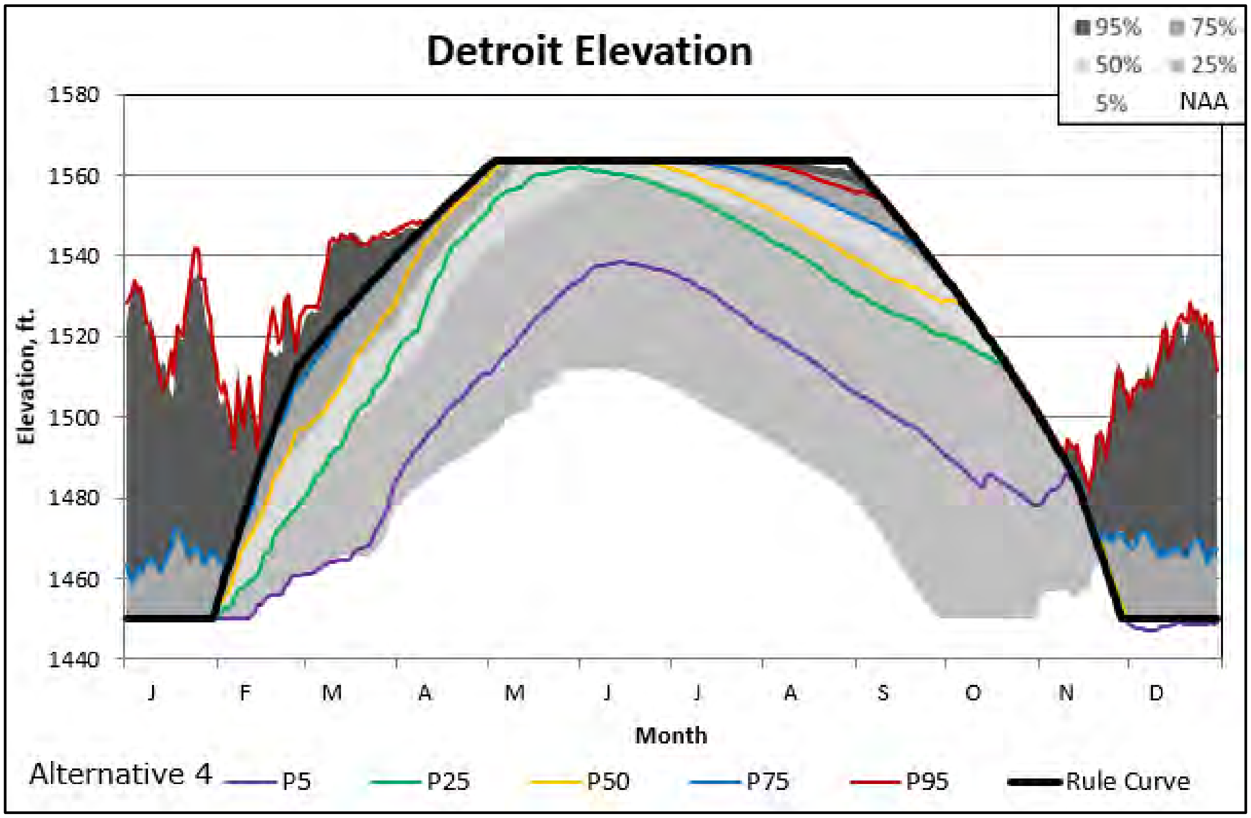

**Figure 3.2-142. Alternative 4 Detroit water surface elevation non-exceedance compared with NAA**

Green Peter reservoir (Figure 3.2-143) would fill to about the same levels or higher in the spring and then elevations would be lower in the summer and fall as compared to the NAA. These differences are driven by the integrated temperature and habitat flow regime flow targets downstream of Foster and how they differ from the BiOp flow targets.

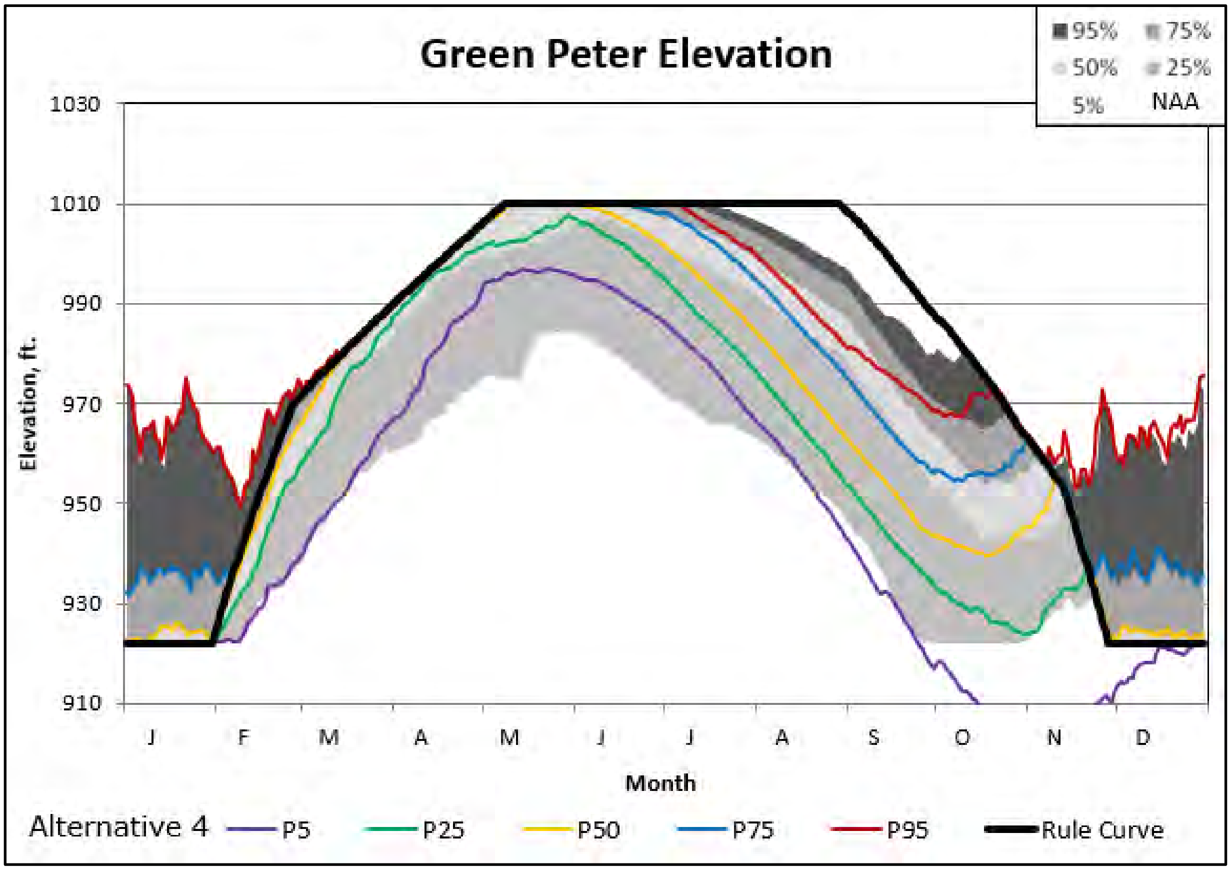

**Figure 3.2-143. Alternative 4 Green Peter water surface elevation non-exceedance compared with NAA**

The flow comparison out of Foster (Figure 3.2-144) shows the shift of water releases from spring to summer and fall in the South Santiam when compared to the NAA. The flow from the dam would meet the integrated temperature and habitat flow regime target range across the year, though this target is below the NAA 2008 BiOp target during the spring. Moving into summer, the system would meet the target range throughout the summer, whereas the NAA was unable to meet the target in October in the driest years. The lower November flows in the driest years are a result of Green Peter already being empty and drawn below minimum conservation pool in Alterative 4, when it still had water stored in the NAA.

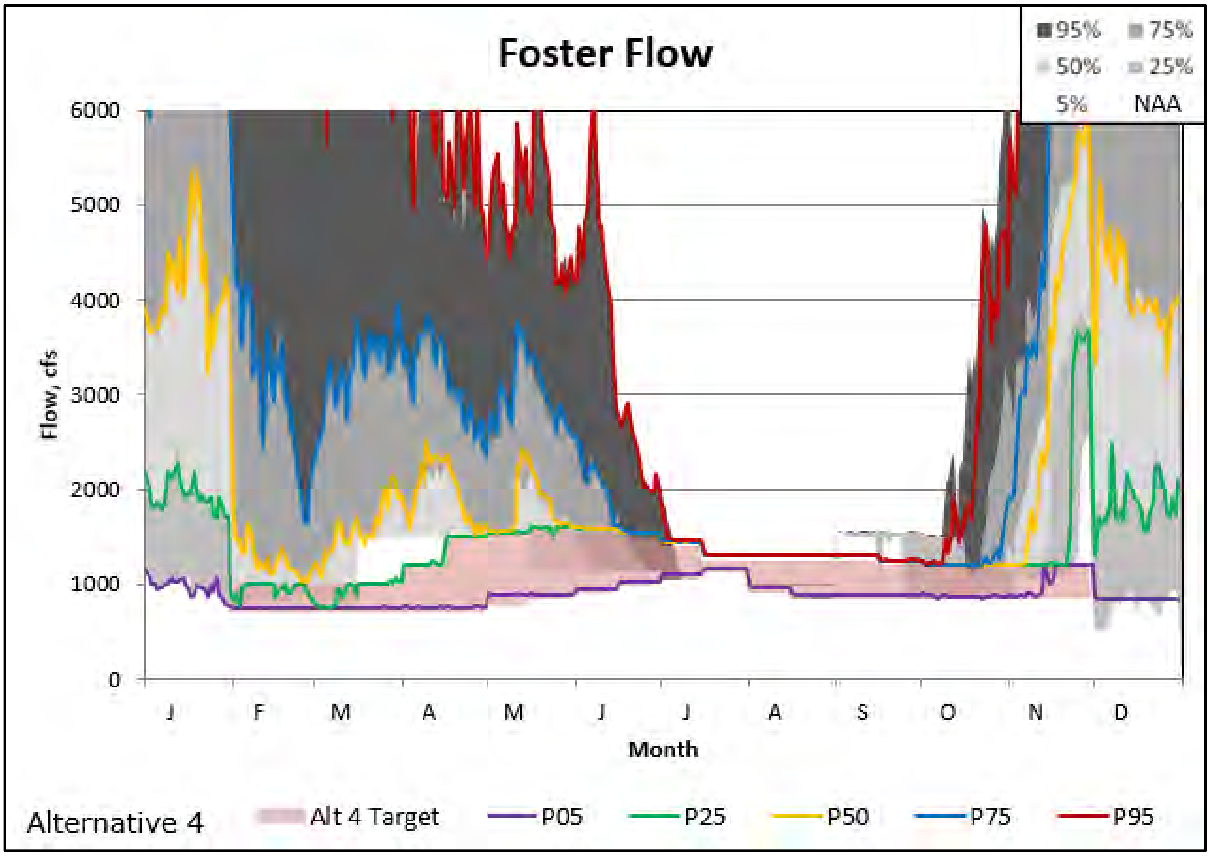

**Figure 3.2-144. Alternative 4 Foster outflow non-exceedance compared with NAA**

Although there would not be specific flow targets further downstream to the combined Santiam control point at Jefferson, the revised flow targets from upstream would be evident. The water stored during dry years from March to June would be released during the summer. Upstream summer integrated temperature and habitat flow regime targets would be higher than the NAA, so Jefferson would show higher flows in all years (Figure 3.2-145). However, the higher September NAA flows are not included in the integrated temperature and habitat flow regime, so Alternative 4 would continue the summer trends instead of bumping up as in the NAA.

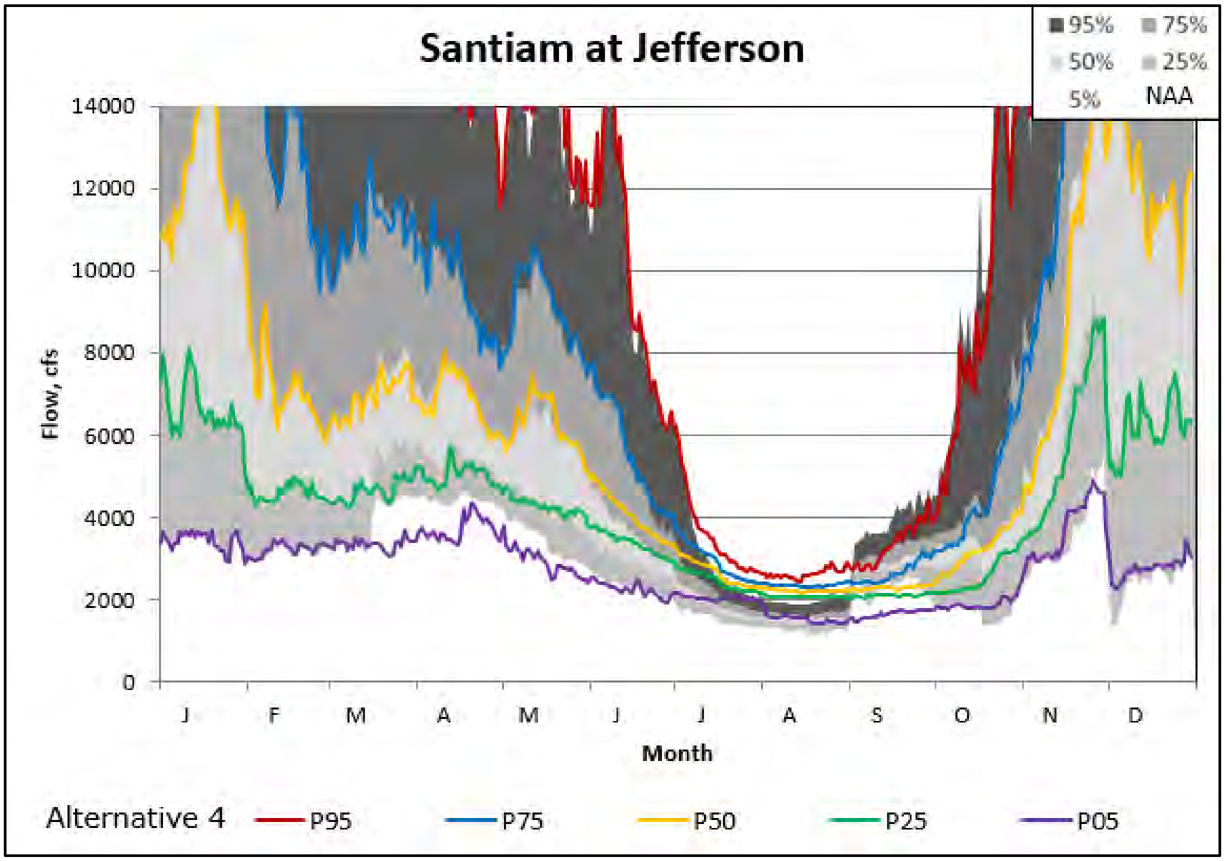

**Figure 3.2-145. Alternative 4 Santiam River at Jefferson flow non-exceedance compared with NAA**

### *3.2.2.9.2 Long Tom Subbasin*

As explained in the NAA, Fern Ridge reservoir is operated for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. Alternative 4 would not appreciably change this goal and the hydrologic patterns would be nearly the same as the NAA, as shown in Figure 3.2-146. The Alternative 4 downstream control point flows at Monroe would show a similar lack of change from the NAA.

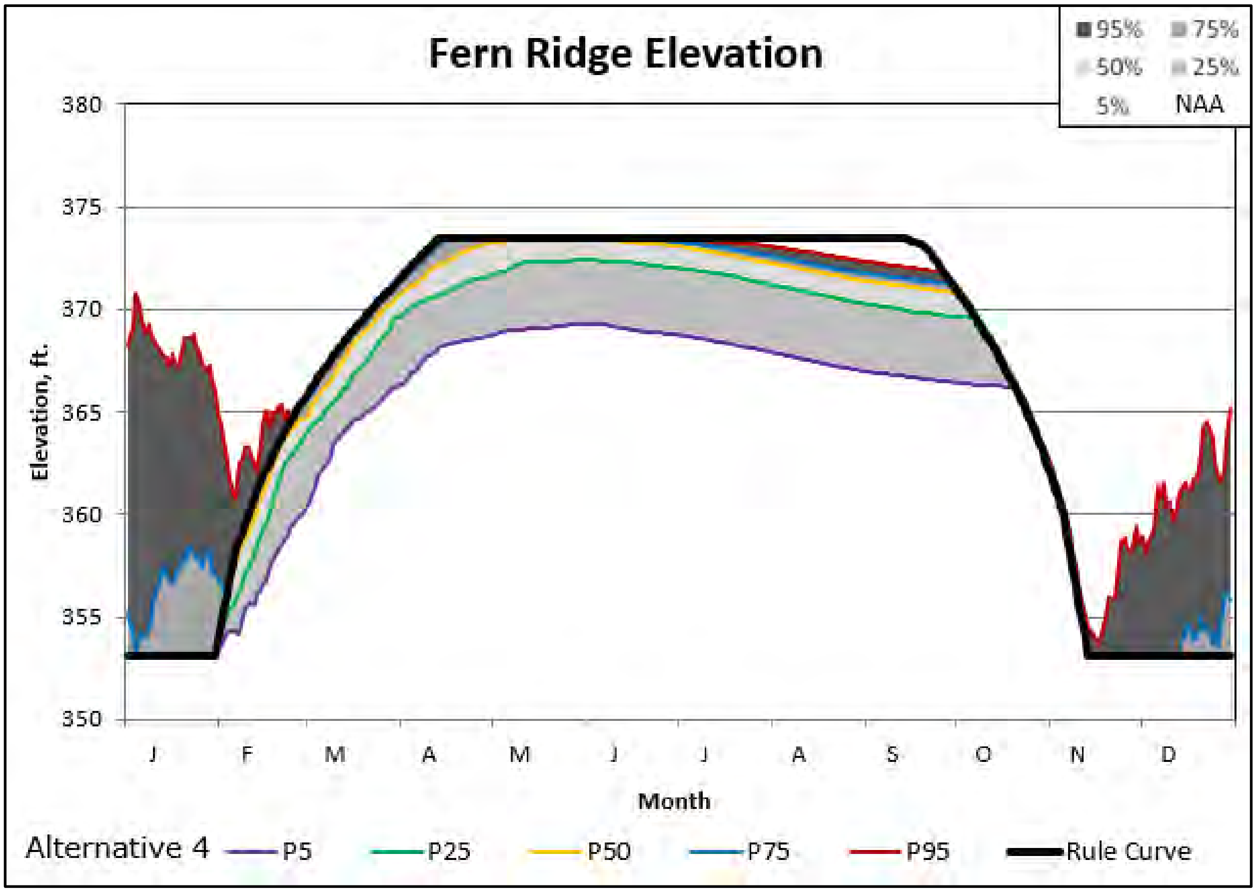

**Figure 3.2-146. Alternative 4 Fern Ridge water surface elevation non-exceedance compared with NAA**

### *3.2.2.9.3 McKenzie Subbasin*

Blue River (Figure 3.2-147) and Cougar reservoirs would fill to higher elevations in dry years due to the lower spring flow targets in the McKenzie River and Salem as compared to the NAA. Both reservoirs fill in wetter years, so there would be limited difference in everything above the P25 for the conservation season. Like Alternative 1, Alternative 4 would allow Blue River to augment instream flows by using the inactive pool below minimum conservation elevation and it would do so during drier than average Novembers.

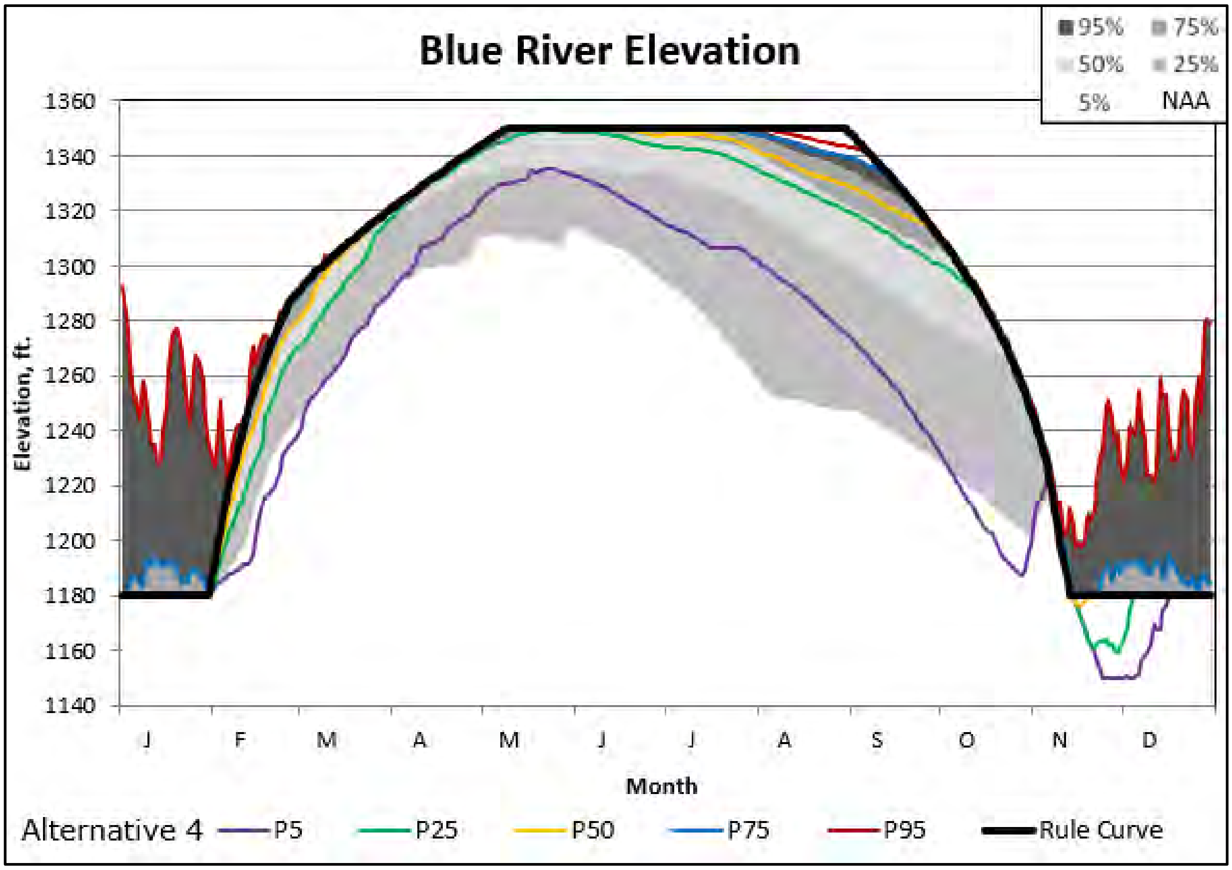

**Figure 3.2-147. Alternative 4 Blue River water surface elevation non-exceedance compared with NAA**

Cougar outflow would meet or exceed its integrated temperature and habitat flow regime target more often throughout the year than under the NAA regime, as shown in Figure 3.2-148. Like Alternative 4 targets at other locations, they would have a lower total volume, but are more variable over the year. The flow changes as compared to the NAA would be limited in wet years and have the effect of shifting flow from spring into summer and fall during dry years.

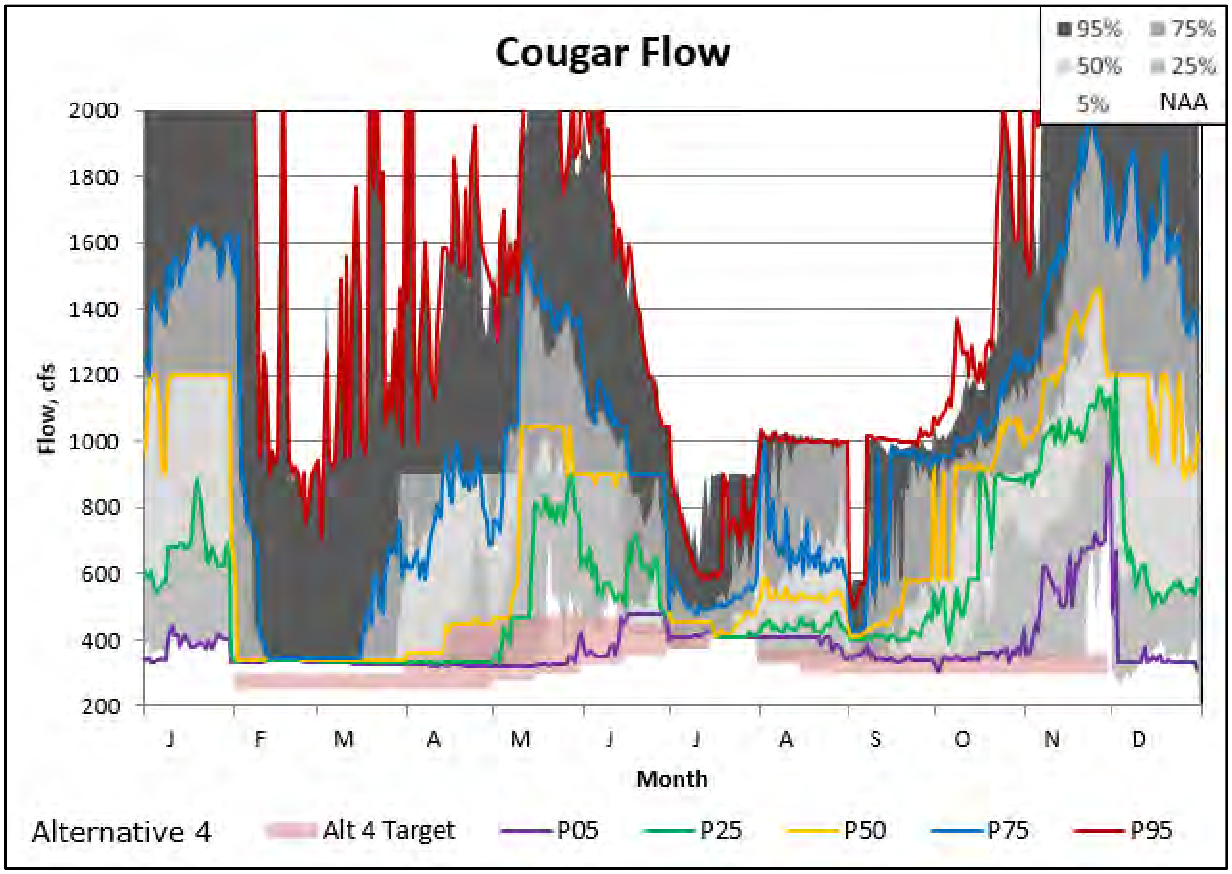

**Figure 3.2-148. Alternative 4 Cougar outflow non-exceedance compared with NAA**

The outflow chart at Cougar in Figure 3.2-148 would show high variability due to its proximity to a single dam, but Figure 3.2-149 (McKenzie at Vida) clearly shows this shift in the drier years – the P05 and P25 lines.

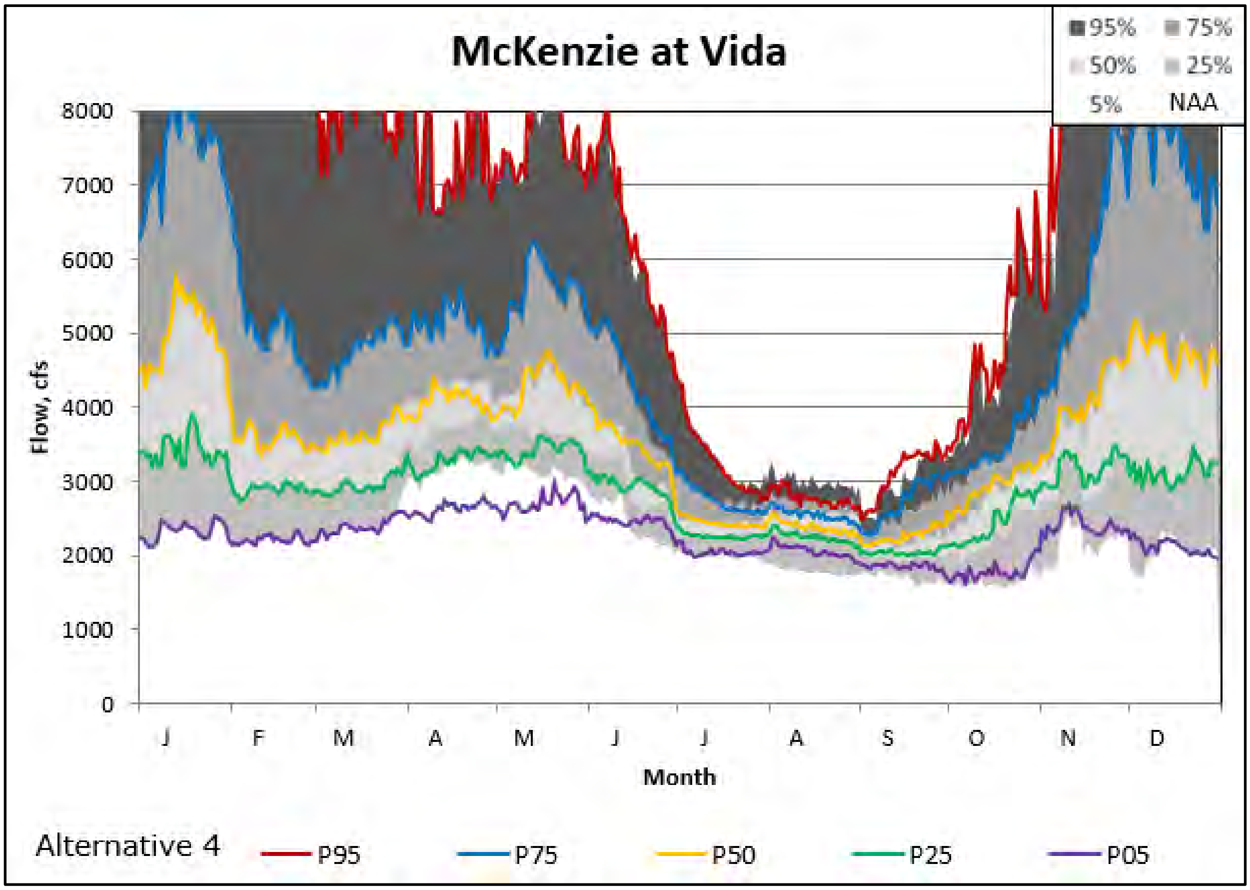

**Figure 3.2-149. Alternative 4 McKenzie River at Vida flow non-exceedance compared with NAA**

### *3.2.2.9.4 Middle Fork of the Willamette Subbasin*

As in Alternative 1, Hills Creek (Figure 3.2-150) initially would fill more quickly due to the lower downstream flow targets and would stay at similar elevations during wet years when compared to the NAA. However, the integrated temperature and habitat flow regime targets are higher than the Congressionally authorized minimum flows. Therefore, during dry years, the Hills Creek reservoir would augment instream flows by using the power pool earlier in the year to meet the flow target at Albany than compared to Alternative 1. Its capacity would be exhausted in the driest years (P05 line), at which point Lookout Point would supply additional water until it too reaches its minimum in Figure 3.2-151.

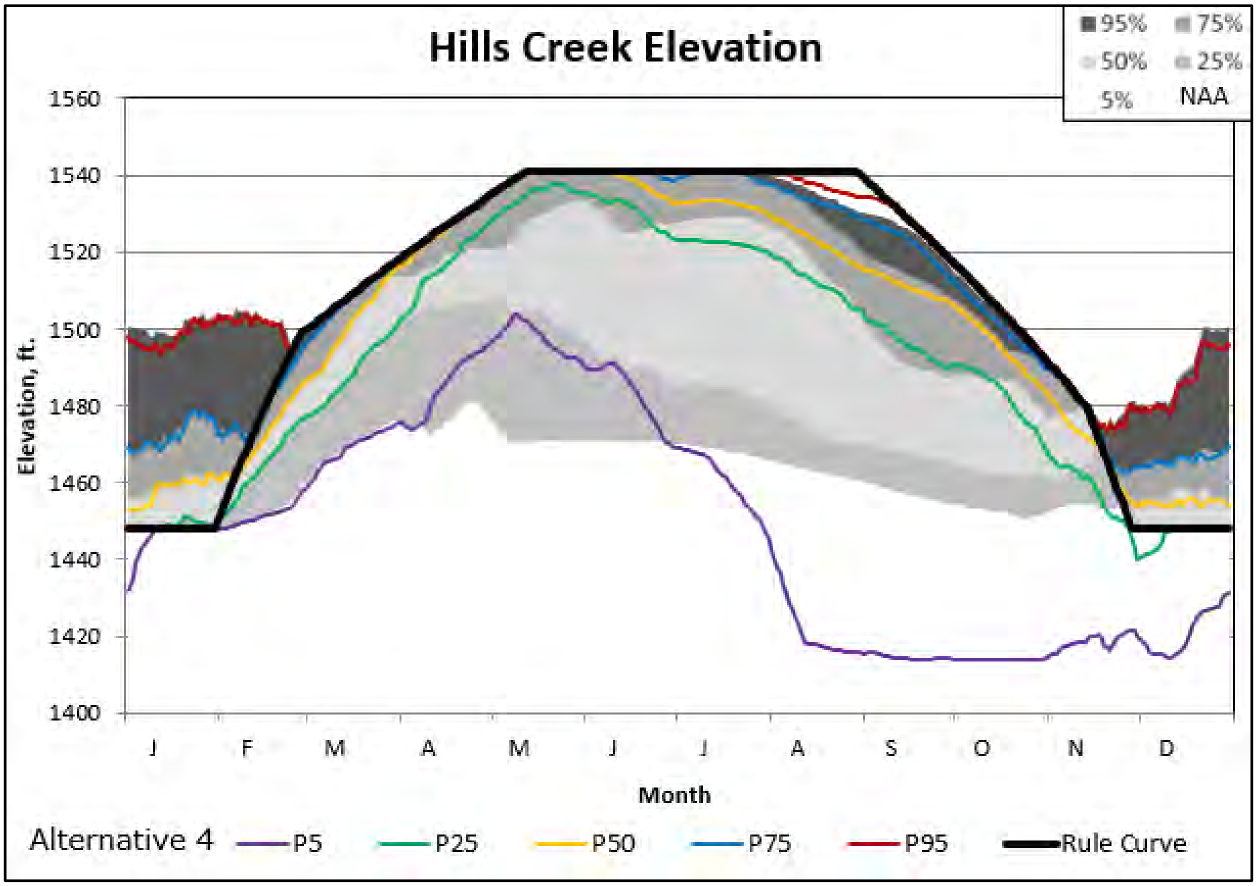

**Figure 3.2-150. Alternative 4 Hills Creek water surface elevation non-exceedance compared with NAA**

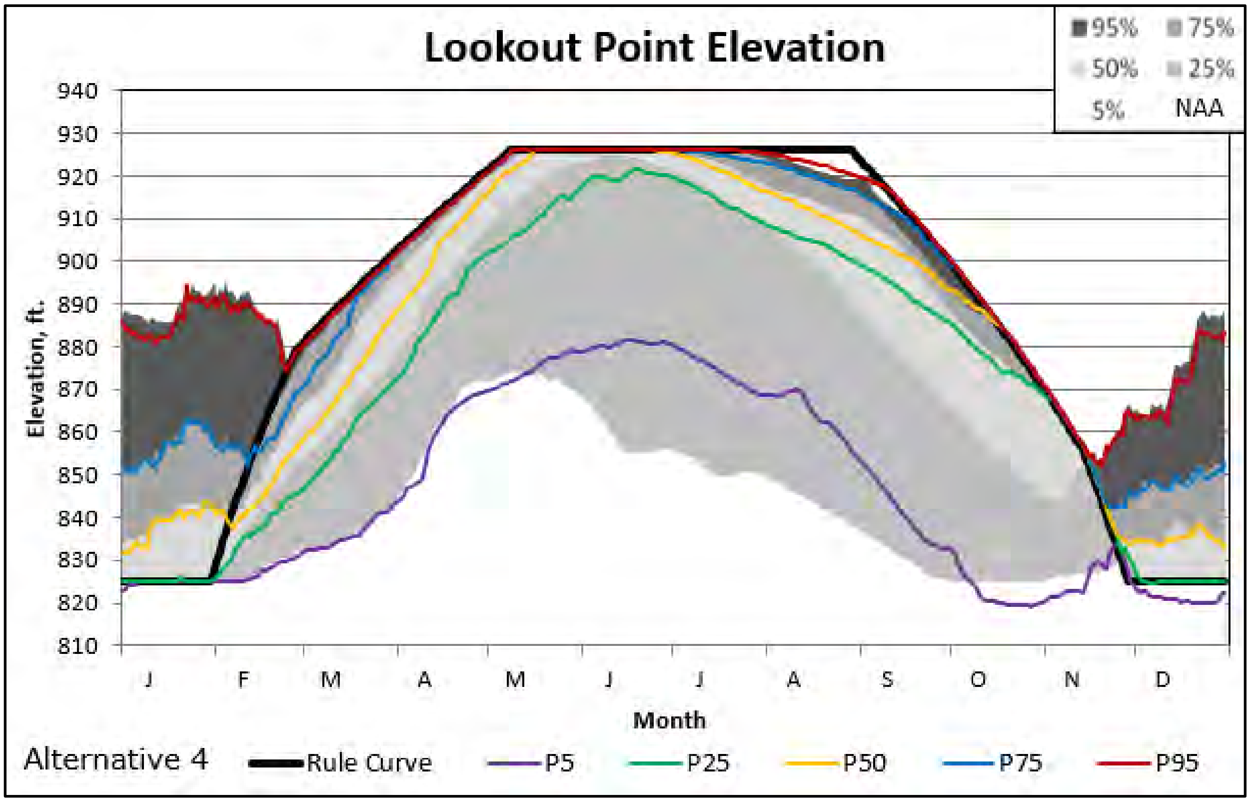

**Figure 3.2-151. Alternative 4 Lookout Point water surface elevation non-exceedance compared with NAA**

Fall Creek reservoir (Figure 3.2-152) would be able to provide some additional flow until its mid-November drawdown since water surfaces would be generally above the NAA baseline.

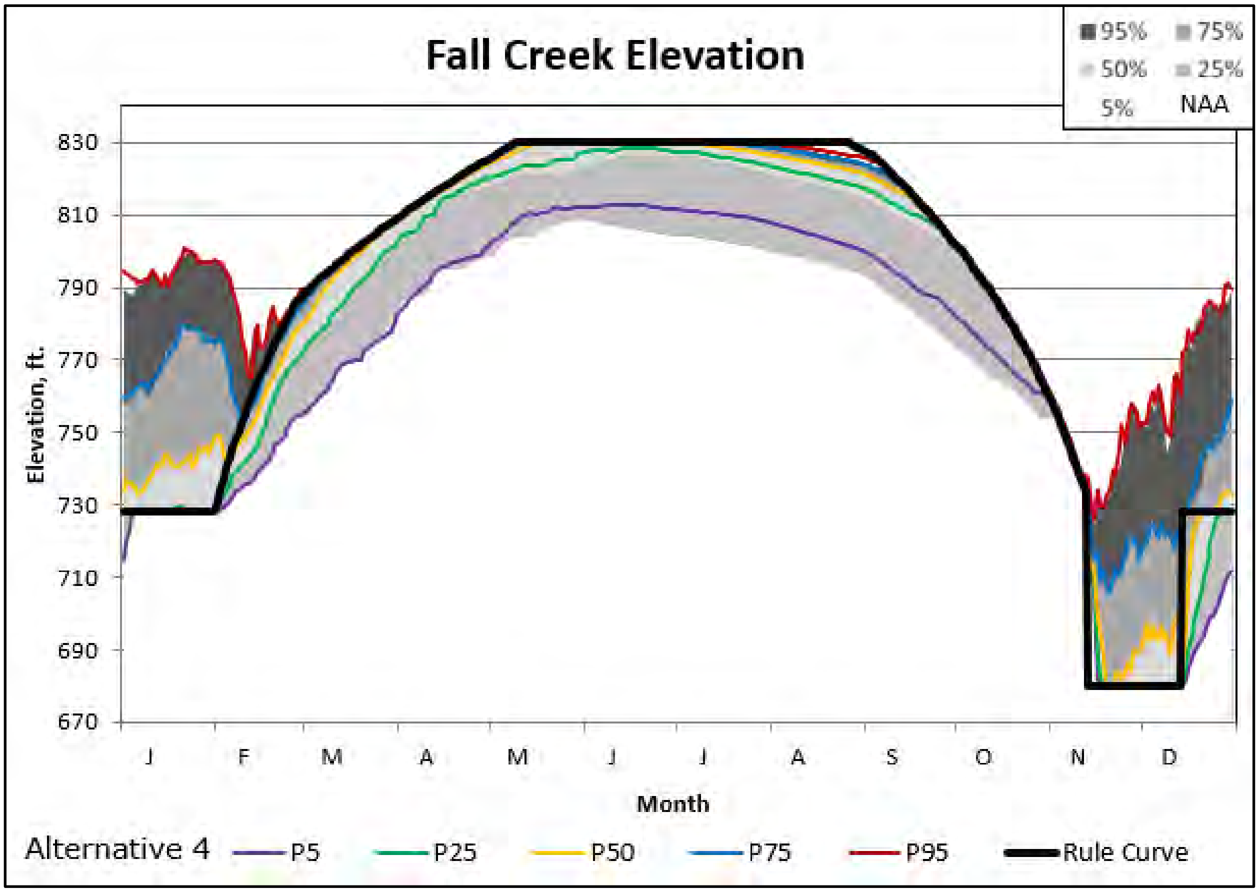

**Figure 3.2-152. Alternative 4 Fall Creek water surface elevation non-exceedance compared with NAA**

At the downstream control point at Jasper (Figure 3.2-153), the dry year water release shift would be evident, with lower flows in the spring and higher flows into the summer and fall compared to the NAA. Since reservoirs pools would usually be at higher elevations leading into flood season, additional releases in October would occur across most water years.

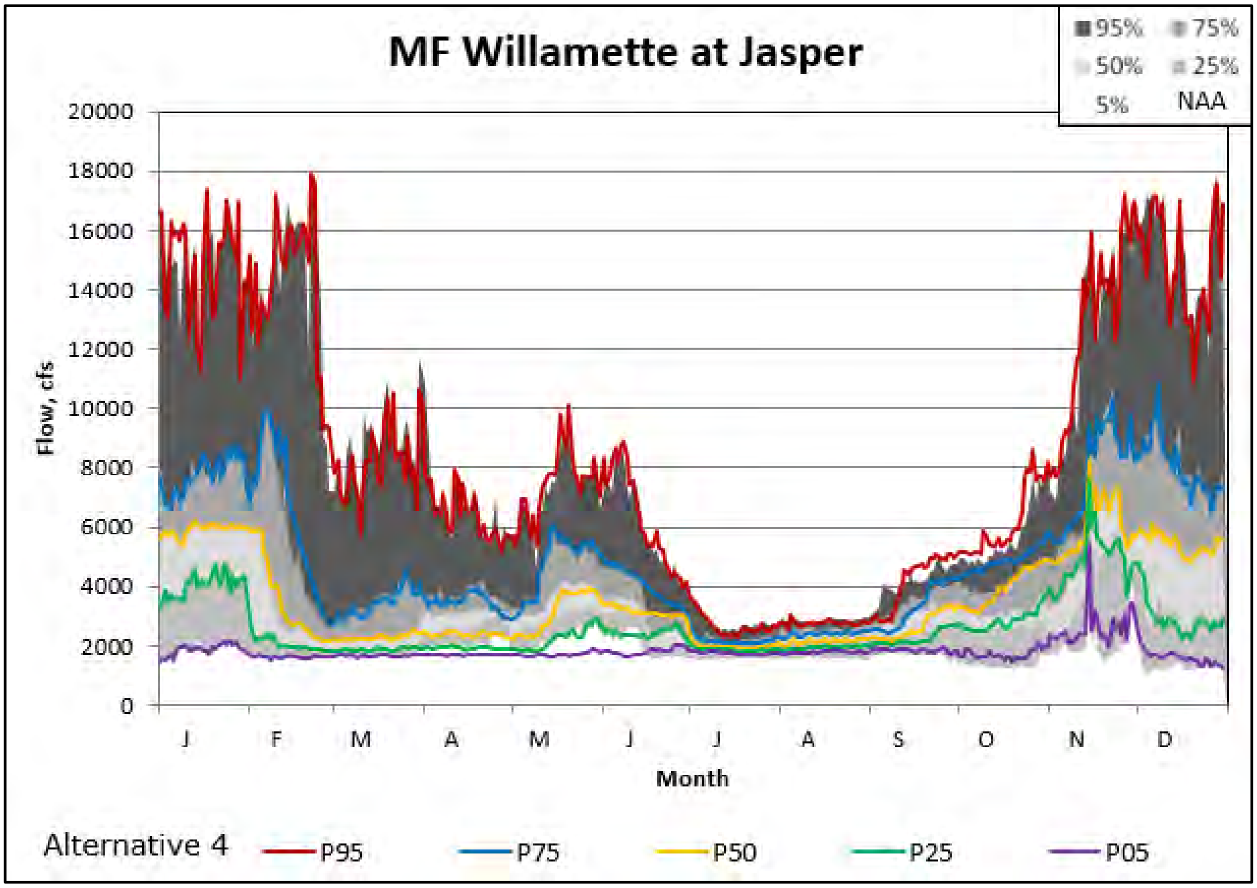

**Figure 3.2-153. Alternative 4 Middle Fork of Willamette River at Jasper flow non-exceedance compared with NAA**

### *3.2.2.9.5 Coast Fork of the Willamette Subbasin*

Dorena (Figure 3.2-154) and Cottage Grove reservoirs would fill more quickly in spring and have generally higher water surface levels throughout the conservation season as compared to the NAA, but lower as compared to Alternative 1. The integrated temperature and habitat flow regime is generally between the BiOp targets of the NAA and the Congressionally authorized minimum flows of Alternative 1. Dorena and Cottage Grove would augment instream flows by using the inactive pool in late fall more frequently than Alternative 1 as they supply water to various points downstream.

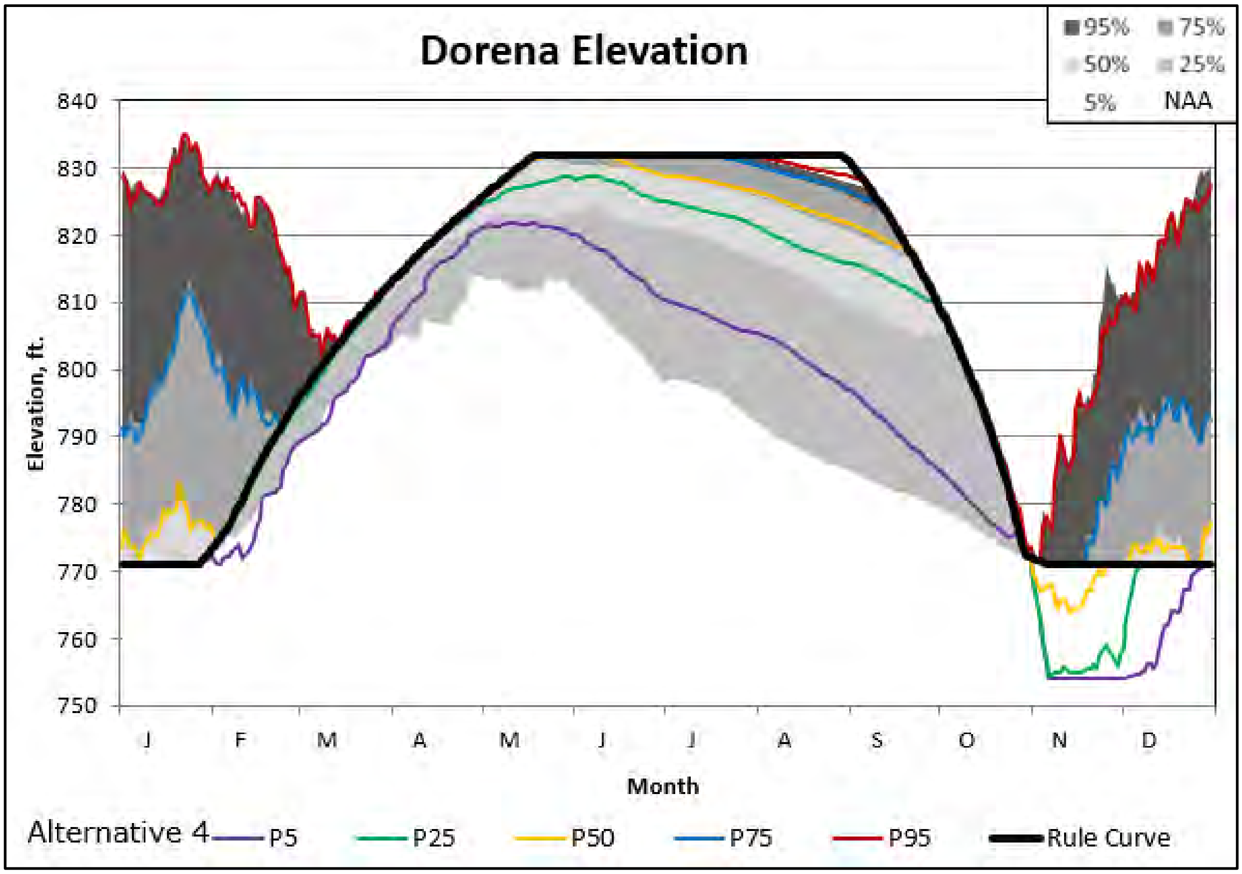

**Figure 3.2-154. Alternative 4 Dorena water surface elevation non-exceedance compared with NAA**

The control point for Dorena and Cottage Grove at Goshen (Figure 3.2-155) shows the characteristic dry-year shift of flow from spring to fall in Alternative 4. Wetter years and summer flows would remain about the same. The P05 and P25 lines at Goshen show the increased November flow using water from below minimum conservation elevation before returning to roughly the same as the NAA in December.

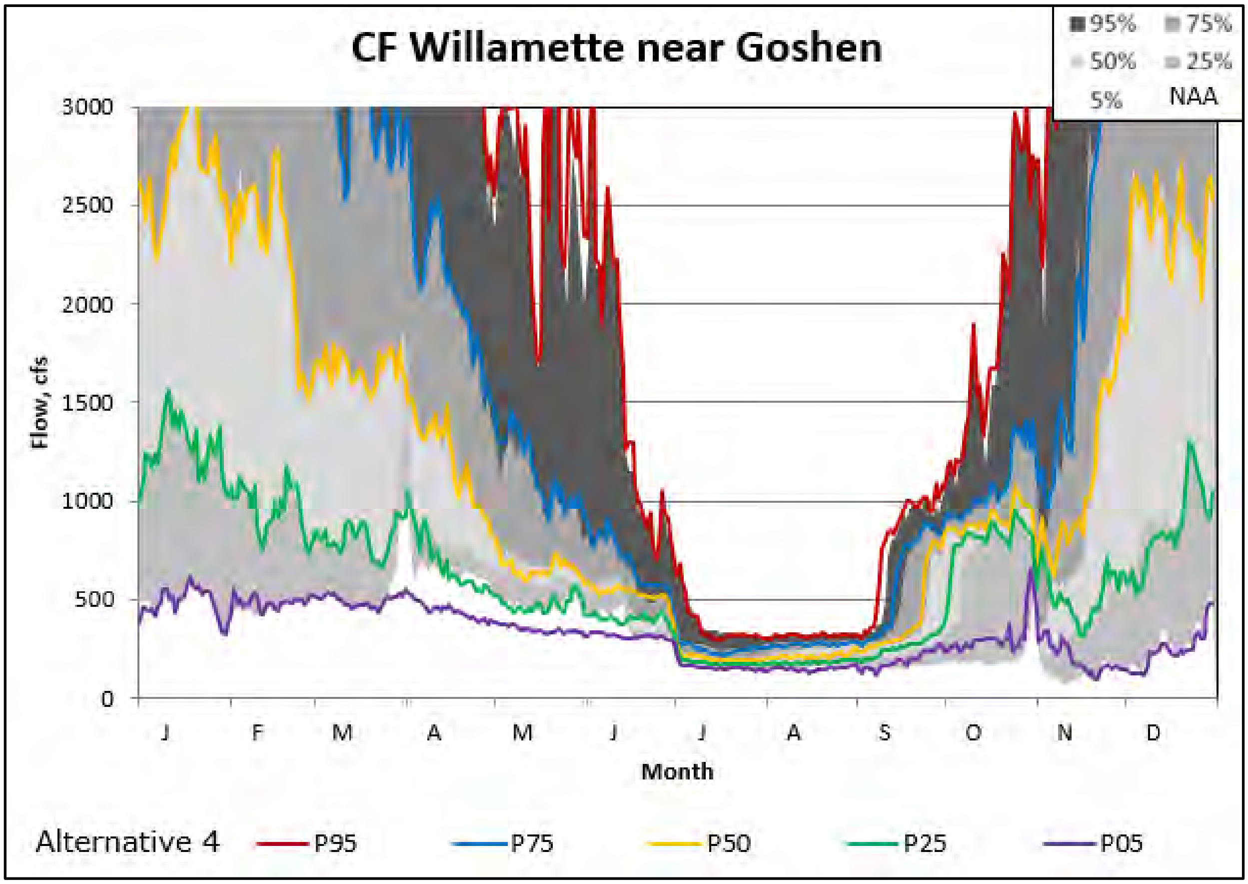

**Figure 3.2-155. Alternative 4 Coast Fork of Willamette River at Goshen flow non-exceedance compared with NAA**

### *3.2.2.9.6 Mainstem Willamette River*

Alternative 4 would alter the regulated hydrology of the mainstem Willamette River control points during the drier years most, with the largest impact to the average and wet years coming in the fall with slightly higher flows as compared to the NAA. The P05 and P25 lines are well below their NAA counterparts from April to June at Albany (Figure 3.2-156). Although the Albany August-to-October flow target is reduced as compared to the NAA (to 4,500 cfs from 5,000 cfs), flows would remain above the target much more frequently with the water stored in the spring released to augment flows in the late summer and fall.

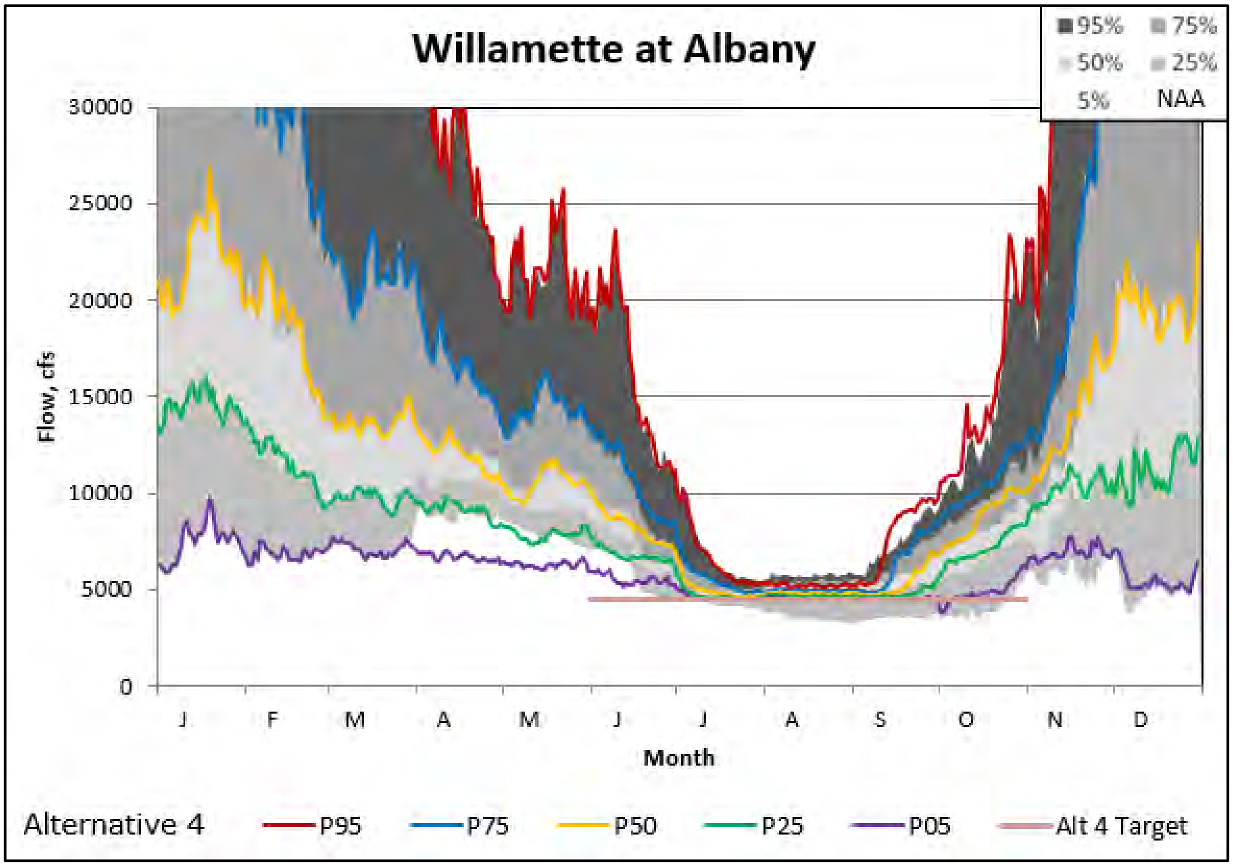

**Figure 3.2-156. Alternative 4 Willamette River at Albany flow non-exceedance compared with NAA**

The integrated temperature and habitat flow regime would alter the flow targets at Salem more than any other location as compared to the NAA. The variable target from April to June (stepped box in Figure 3.2-157) is only active during hot weather. These higher flows would be designed to maintain cooler rivers for fish survival. The hotter the weather, the higher the flow target within the bounds in the figure. If the weather is cool, the target would revert to the lower Alternative 4 baseline target of 5,000 cfs. Section 2.2.1, Flow Measures, contains a more detailed explanation of this flow target.

Since the temperatures required to activate the higher flow targets generally do not last for the entire three months, flows at Salem would be lower during dry years for Alternative 4, routinely missing the NAA 2008 BiOp target but well within the integrated temperature and habitat flow regime targets. As at other upstream locations, Alternative 4 would have higher flows in summer and fall, and would hit its flow target more frequently than the NAA.

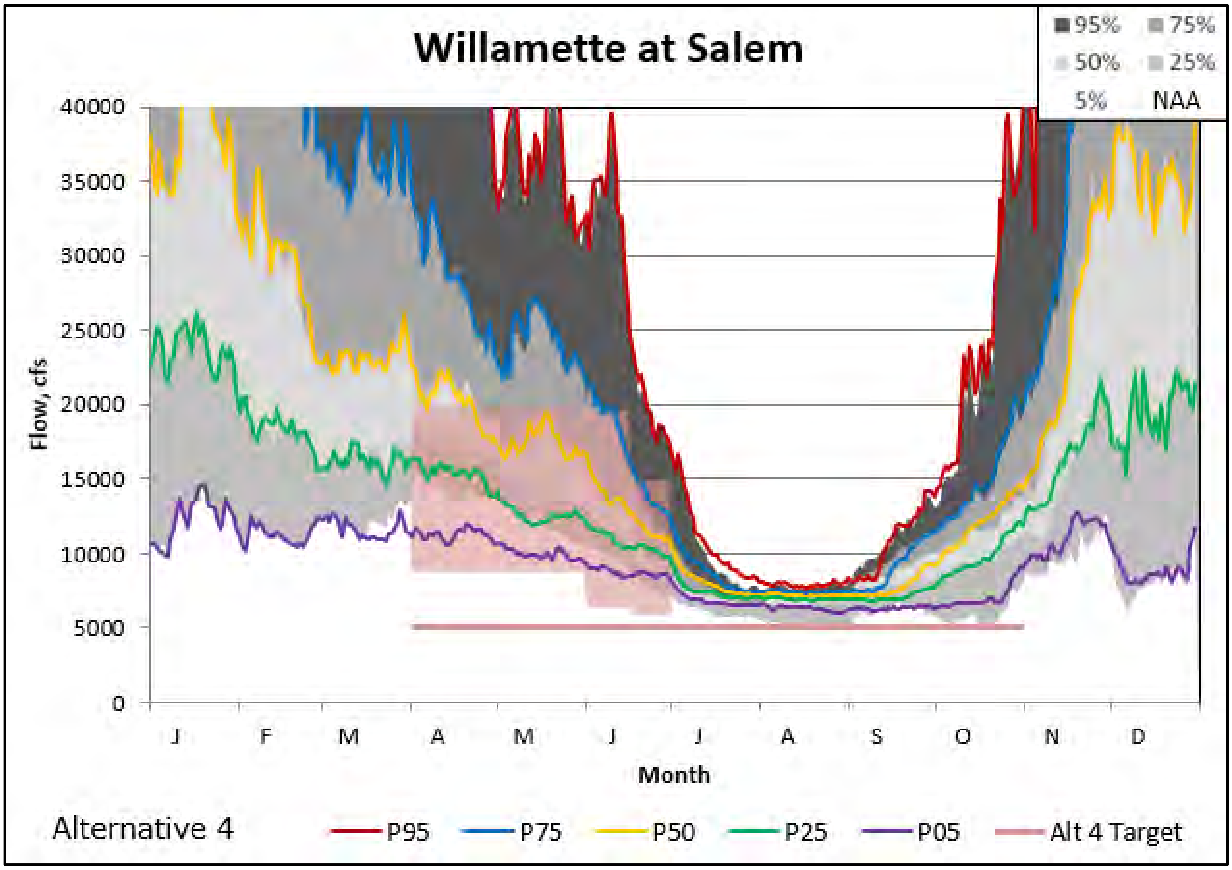

**Figure 3.2-157. Alternative 4 Willamette River at Salem flow non-exceedance compared with NAA**

Summer and fall flows across water year types would be more closely spaced than in the NAA, but this is mostly due to increased flow in the drier years. Increased flows during the wetter falls, the P50 line and above, would be due to the reservoirs preserving more storage during these years and having to release more water in preparation for winter flood season.

### *3.2.2.9.7 Near-Term Operations Measure*

See Alternative 2A, Section 3.2.2.4.7, for description of effects due to the Near-Term Operations Measure.

### *3.2.2.9.8 Climate Change*

The WVS will likely experience increasing wintertime flow volumes in the future. Some flood magnification (increased severity during flood season) is also likely. Because the WVS system storage will remain about the same, it's likely that FRM operations will face future challenges. An upward shift in median future project inflows may increase both the average reservoir water surface elevation as well as outflows downstream of the WVS dams. Reservoirs located within higher elevation subbasins, such as Detroit and Cougar, are likely to see higher rainfall and runoff volumes in the winter. Higher projected temperatures in the future will mean less snowpack than currently experienced. Lower snowpack would also reduce spring volume as the snow melts. Lower elevation subbasin projects such as Fern Ridge and Cottage Grove, with little or no snowpack, are projected to experience higher wintertime flow volumes, but similar peak runoff timing compared to historical baselines.

During conservation season, climate change will affect Alternative 4 most like Alternative 1, with the main difference being somewhat lower reservoir water surface elevations and flow in the summer of dry years. Since the Alternative 4 integrated temperature and habitat flow regime targets are lower than the NAA 2008 BiOp requirements, the reservoirs can store more water during conservation season as compared to the NAA. However, reservoirs will have to use more of this stored water to meet downstream flow targets with projected increased variability in the spring shoulder months, drier hotter summers, and lower summer baseflow. Therefore, reservoirs are projected to have lower water surface elevations compared to the NAA. Reservoirs in Alternative 4 sometimes reach minimum elevation during the summer, but less often than the NAA, meaning they would be able to augment summer flows for longer than the NAA even with projected declines in late spring and summer flows. The lowest reservoir water surface elevations will occur in the driest years, which would be drier than the WVS currently encounters, as the reservoirs are drafted more to meet downstream flow targets. The WVS would miss the mainstem Willamette flow targets more often than in Alternative 1, but much less often than the NAA. Climate change effects, and potential implications as discussed above, draw on the climate change projection and trend information provided in the climate change appendices (F1 and F2).

##### *3.2.2.10 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 would shift stored water releases from the spring to the summer and fall in the driest years by reducing spring mainstem and key tributary targets which would increase the likelihood that stored water would be available to meet minimum flow targets later in the conservation use season as compared to the NAA.

Foster, Detroit, and Lookout Point would have tributary targets higher than the NAA 2008 BiOp targets when reservoirs are more than 90 percent full and lower than the NAA when reservoirs are less than 90 percent full, increasing spring storage in dry years relative to the NAA and providing more storage to call on in dry summers.

Spring flow targets at Salem would be lower than BiOp dry year targets in years when water supply forecasted flows at Salem are projected to be less than 80 percent of normal under the refined integrated temperature and habitat flow regime targets. This would provide additional spring storage in dry years allowing for targets that closely resemble NAA flow targets to be met in dry summers. Additional minimum flow targets based on the air temperature at Salem release additional water when needed to keep the river, and fish in it, cool.

Alternative 5 would shift releases from April through June to July through October. Flow targets July through October would be met more frequently due to the additional accumulated stored water. Lower releases in dry springs would result in higher reservoir elevations in most reservoirs throughout the conservation season which does not occur under the NAA.

Cougar and Green Peter reservoirs have drawdowns in Alternative 5. Flow releases required to meet drawdown targets result in higher tributary and mainstem flows, particularly in the fall compared to the NAA.

Since the spring reservoir drawdown at Cougar occurs during the NAA refill period, storage at Cougar would be reduced. Refill is not initiated until June 15th after most of the reliable spring rain has fallen. As a result of the reduced storage, Cougar would not be able to release more than inflow for portions of the conservation season. The reduced storage means that other WVS reservoirs, notably in the Middle Fork of the Willamette River subbasin, would be required to release additional water to meet mainstem Willamette River flow targets.

Although there are structural actions in Alternative 5 at the WVS dams to aid fish survival, many of these do not affect the flow out of any WVS dam. These do not appear in the reservoir flow model. An example of this is the WTC tower at Detroit, which allows for greater control of the temperature of the water released from the dam but does not alter the flowrate or outlet used for dam operations. A more detailed analysis of Alternative 5 by subbasin follows.

Lower spring flows in dry years and higher summer flows in nearly all years would have long term effects on the WRB. Effects from Alternative 5 to hydrologic processes: Major as compared to the NAA.

#### *3.2.2.10.1 Santiam Subbasin*

Alternative 5 would fill Detroit reservoir more often and narrow the range of reservoir elevations prior to drafting the reservoir for flood season (Figure 3.2-158). The lower tier of the refined integrated temperature and habitat flow regime target requires lower flows downstream of Detroit in years when the reservoir would not fill in the NAA. As a result, more flow would be released later in the conservation season in the driest years and the probability of only being able to pass inflow in extremely dry, low baseflow years is lower than in the NAA.

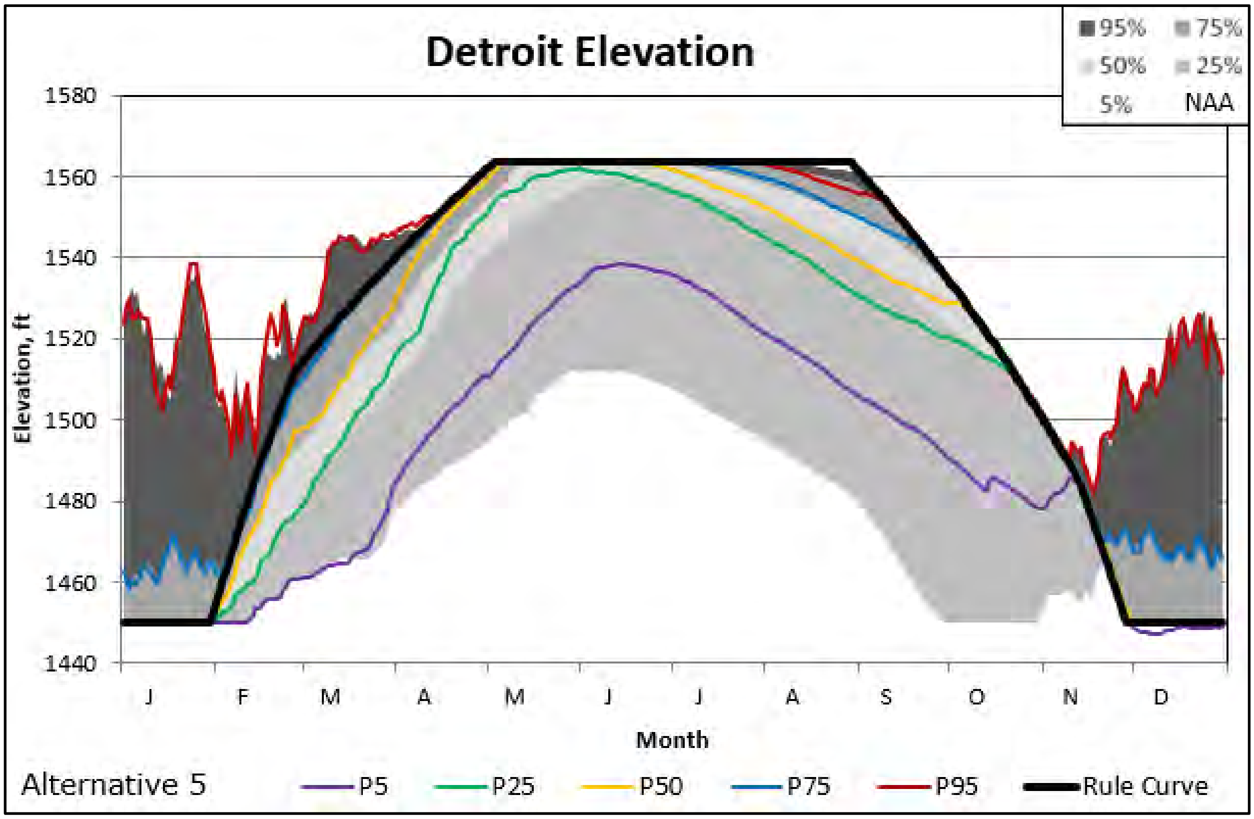

**Figure 3.2-158. Alternative 5 Detroit water surface elevation non-exceedance compared with NAA**

Green Peter reservoir (Figure 3.2-159) targets 35 feet over the regulating outlet in the fall to promote volitional fish passage. Occasionally, this would result in Green Peter beginning the conservation refill season at a lower elevation than in the NAA. Drawing down to the regulating outlet would be most likely in years with dry summers when the reservoir does not fill, and deeper fall reservoir drawdowns of longer duration would be most likely in years with dry late fall and early winter seasons.

Outflow from Foster Dam and the refined integrated temperature and habitat flow regime targets are shown in Figure 3.2-160. Variable flow targets in the spring target would lower minimum flows when Green Peter is less than 90 percent full, resulting in higher conservation season storage in dry years. A summer and fall flow target of 1200 cfs is the same in all years. Higher releases from Foster in the fall are a result of the Green Peter deeper fall reservoir drawdown.

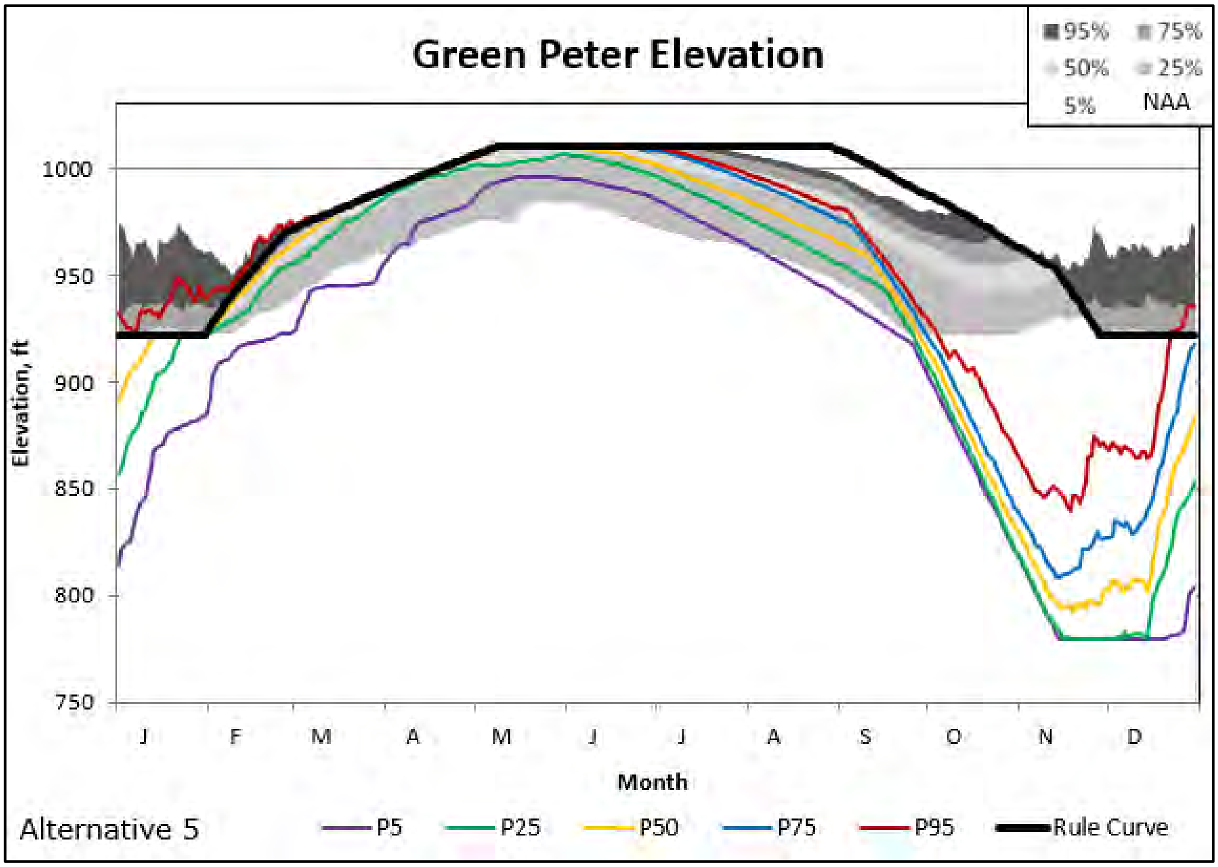

**Figure 3.2-159. Alternative 5 Green Peter water surface elevation non-exceedance compared with NAA**

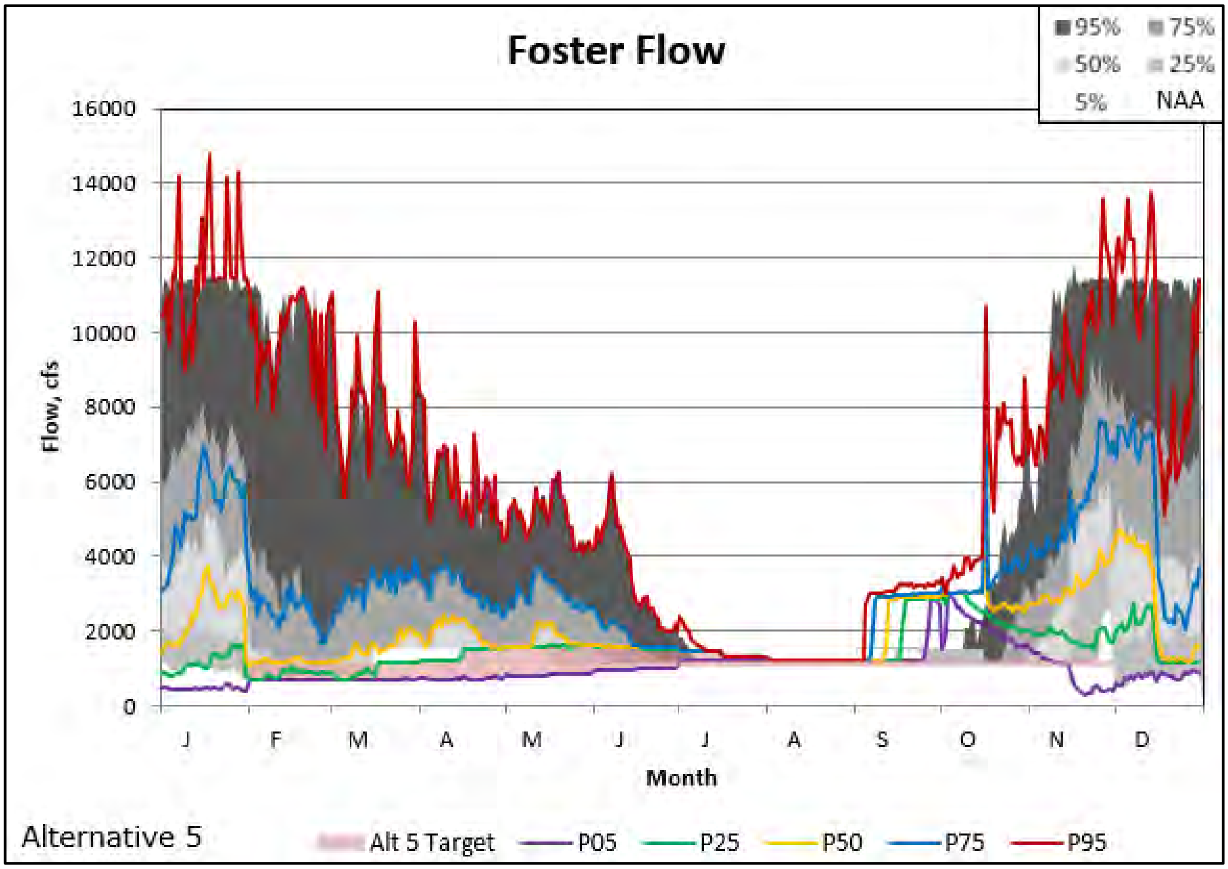

**Figure 3.2-160. Alternative 5 Foster flow non-exceedance compared with NAA**

The Santiam at Jefferson (Figure 3.2-161) shows some of the flow changes resulting from releases at Foster. Lower minimum flow targets would control the outflow from Green Peter from March through June in dry years. Higher outflows would be observed in September when Green Peter draws down for the volitional fish passage operation, while remaining below bankfull. Late fall outflows would typically be lower when Green Peter is refilling after the deeper fall reservoir drawdown as compared to the NAA

Lower flows resulting from lower flow targets in dry years in the spring would be observed at Jefferson (Figure 3.2-161). Additional reservoir storage would enable higher flows than the NAA at Jefferson beginning in July even though combined minimum flow targets below Detroit and Green Peter are slightly lower than in the NAA.

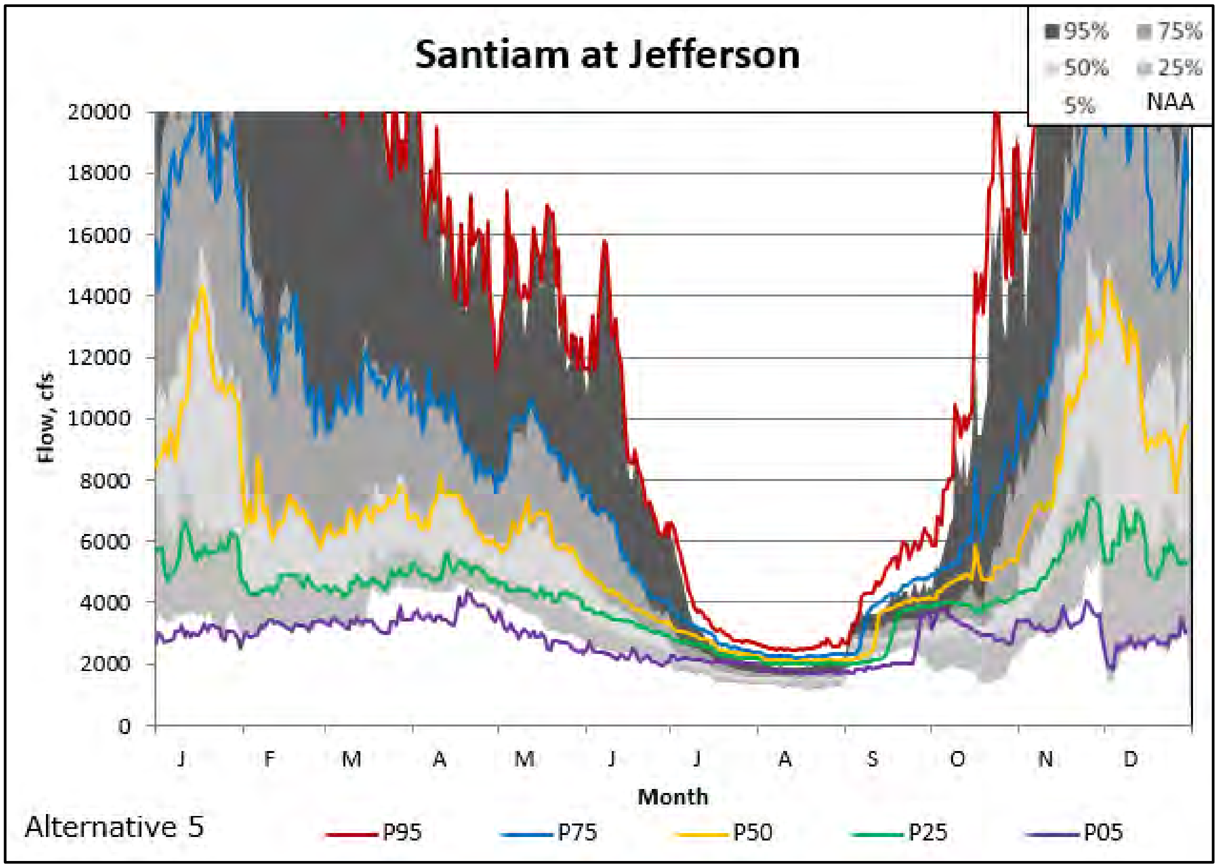

**Figure 3.2-161. Alternative 5 Santiam at Jefferson flow non-exceedance compared with NAA**

### *3.2.2.10.2 Long Tom Subbasin*

As explained in the NAA, Fern Ridge reservoir (Figure 3.2-162) is operated for recreation and fish and wildlife habitat in the conservation season and typically seeks to maximize the reservoir pool during the summer. Since Fern Ridge has a large surface area and small volume compared to the other WVS reservoirs, there is limited scope to change its operation and the water surface elevations within Fern Ridge would remain nearly the same as the NAA. Downstream flows at Monroe would remain similarly unchanged for Alternative 5.

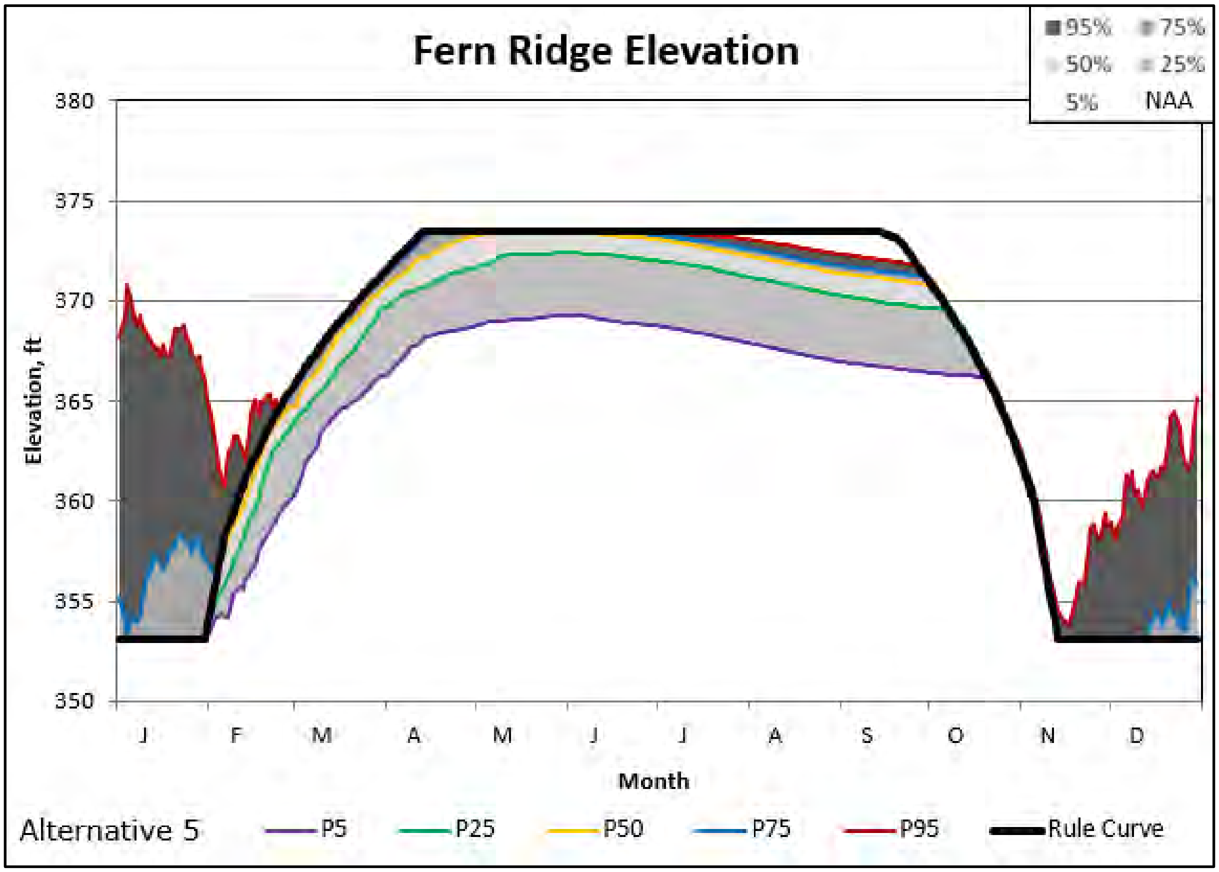

**Figure 3.2-162. Alternative 5 Fern Ridge water surface elevation non-exceedance compared with NAA**

### *3.2.2.10.3 McKenzie Subbasin*

Cougar reservoir (Figure 3.2-163) would have both spring and fall reservoir drawdowns in Alternative 5, down to 1330 feet. Conservation season refill is delayed until June 15th after all of the season's reliable rain has fallen. The reservoir water surface elevation would only rise above minimum conservation pool at the end of winter and only the wettest summers.

Spring reservoir drawdowns would reach target elevations in drier than average conditions and deeper fall reservoir drawdowns are most likely to occur in years with lower-than-average conservation season refill. Cougar would release well below the NAA tributary target of 300 cfs for long durations as a result of the drawdowns.

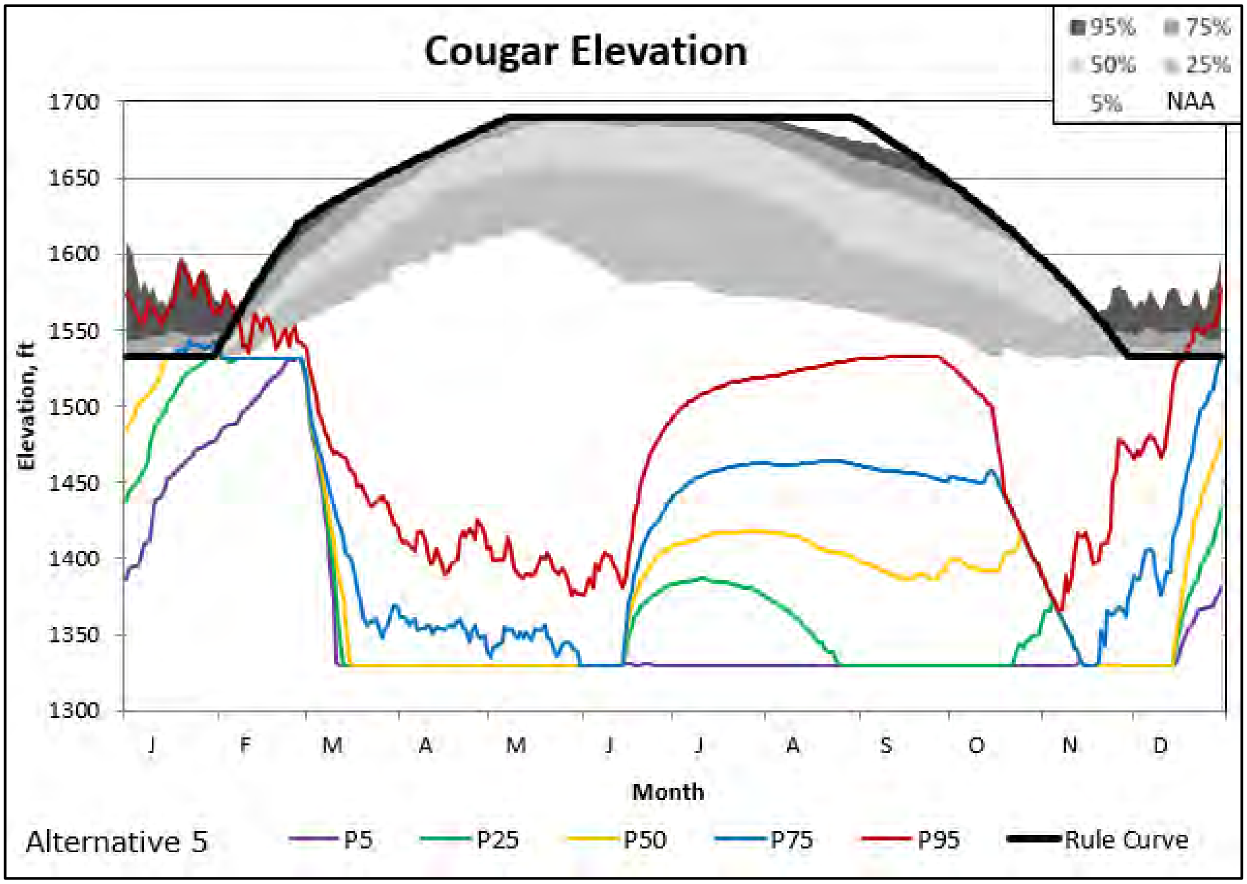

**Figure 3.2-163. Alternative 5 Cougar water surface elevation non-exceedance compared with NAA**

Blue River reservoir (Figure 3.2-164) would fill more often as compared to the NAA and uses the inactive pool to supplement downstream flow targets during October in the driest years. Blue River would be required to store more water during very wet years for the McKenzie River at Vida to remain at or below bankfull since Cougar is drafting for the spring reservoir drawdown. Additionally, Blue River would augment instream flows by using the inactive pool during the fall of very dry years to make up for the low releases from Cougar.

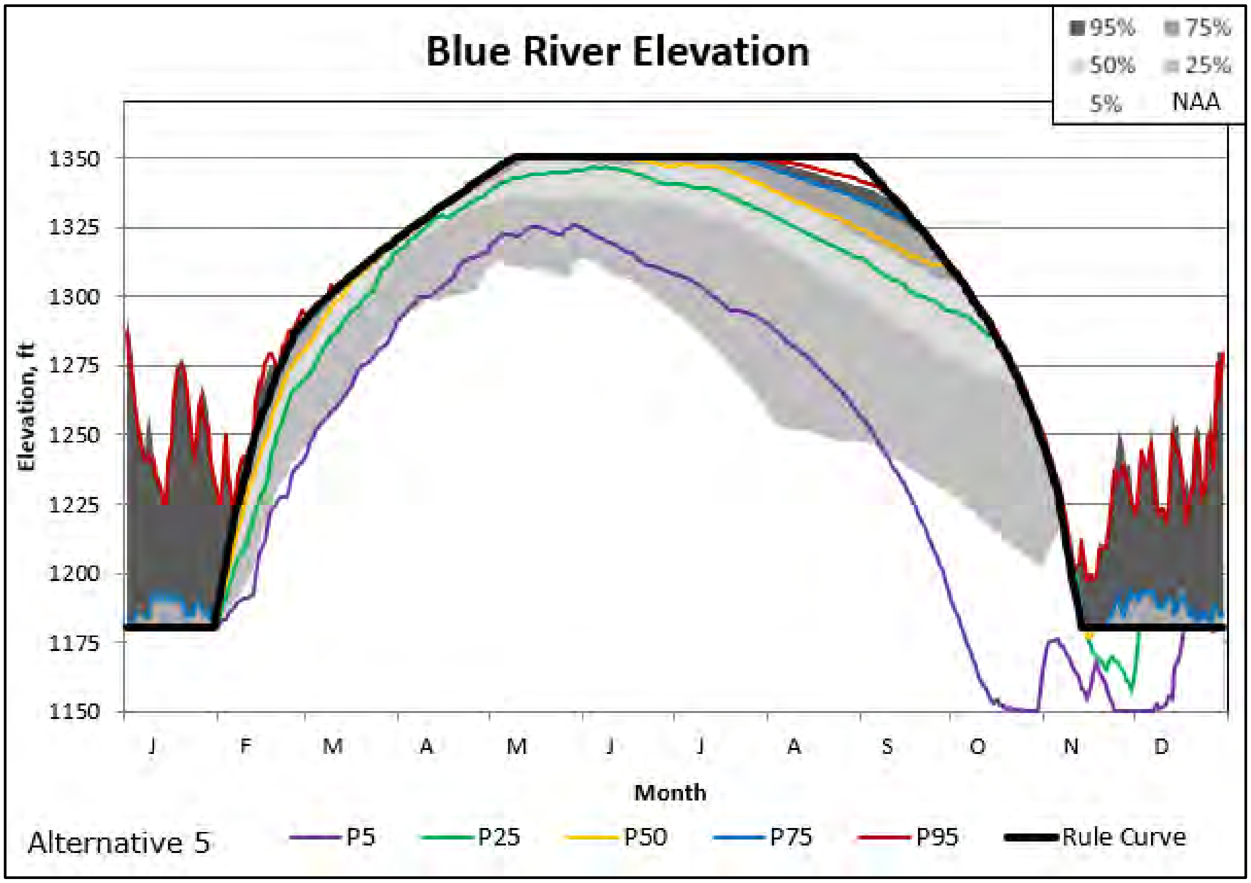

**Figure 3.2-164. Alternative 5 Blue River water surface elevation non-exceedance compared with NAA**

Moving downstream to the control point for both Cougar and Blue River, the McKenzie River at Vida (Figure 3.2-165) would show the effect of the Cougar drawdowns as compared to NAA. The higher flows in the spring would result from Cougar's releases to reach spring reservoir drawdown elevation. Lower flows starting in June would be the result of Cougar having reduced storage throughout the conservation season. Blue River would be capable of making up some of the shortfall in releases from Cougar.

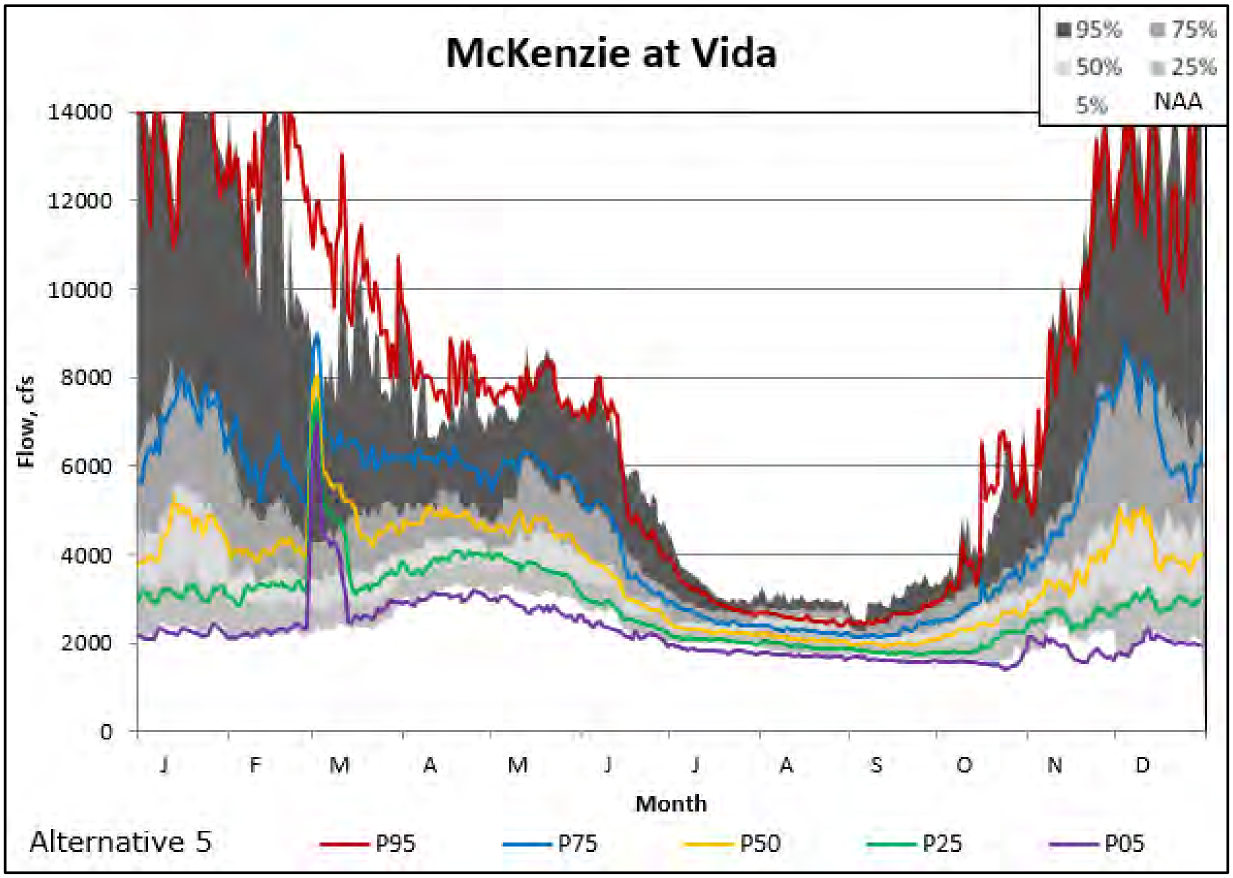

**Figure 3.2-165. Alternative 5 McKenzie River at Vida flow non-exceedance compared with NAA**

### *3.2.2.10.4 Middle Fork of the Willamette Subbasin*

Hills Creek (Figure 3.2-166) initially would fill more quickly due to the lower refined integrated temperature and habitat flow regime targets and would stay at similar or higher elevations during wet years. During dry years, the reservoir would augment instream flows by using the power pool, releasing more water to meet the flow target at Albany. Its capacity would be exhausted in the driest years at which point Lookout Point would supply additional water and reach its Alternative 5 minimum in Figure 3.2-167. As compared to Alternative 2B, storage elevations for both Hills Creek and Lookout Point would be slightly lower across all years because of the higher refined integrated temperature and habitat flow regime mainstem targets, it would also be lower than the NAA. Spring mainstem releases in Alternative 5 would be higher than in Alternative 2B, and as a result, the reservoirs would be more likely to run out of storage and pass inflow in the driest years.

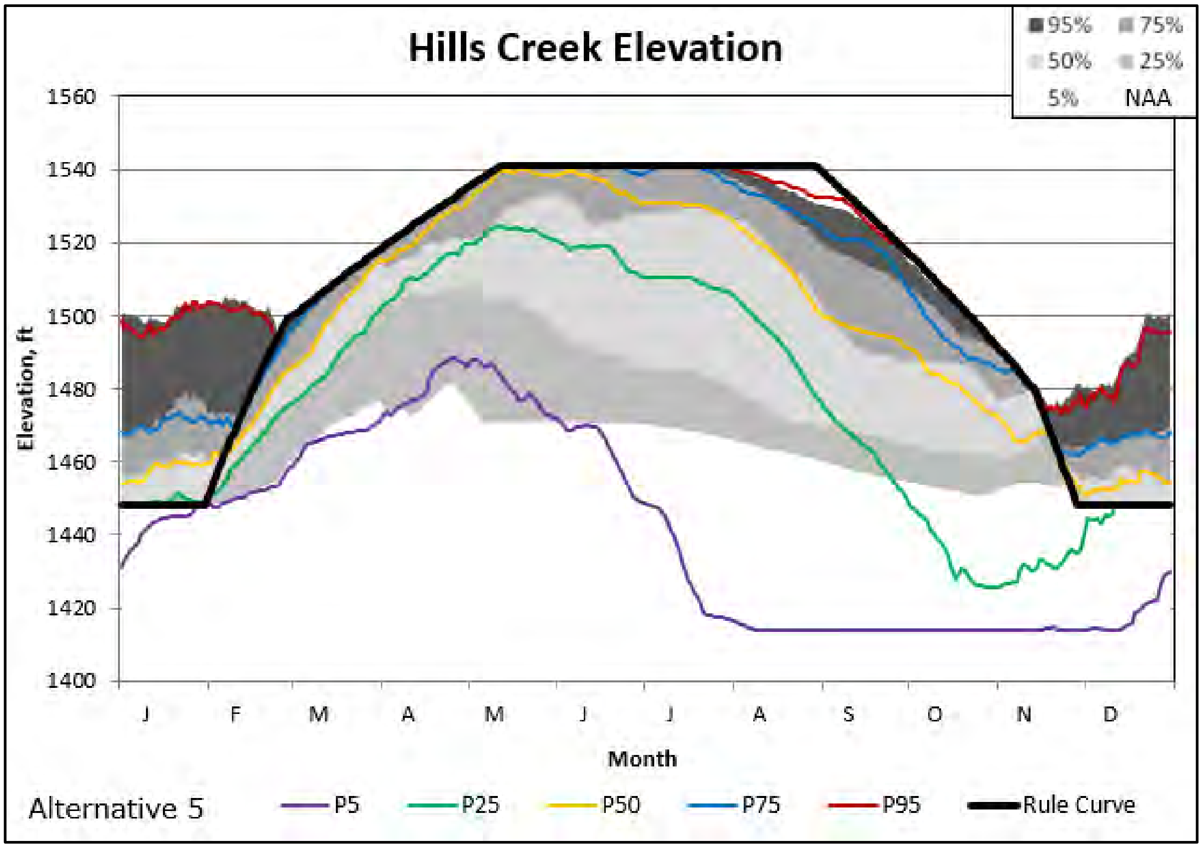

**Figure 3.2-166. Alternative 5 Hills Creek water surface elevation non-exceedance compared with NAA**

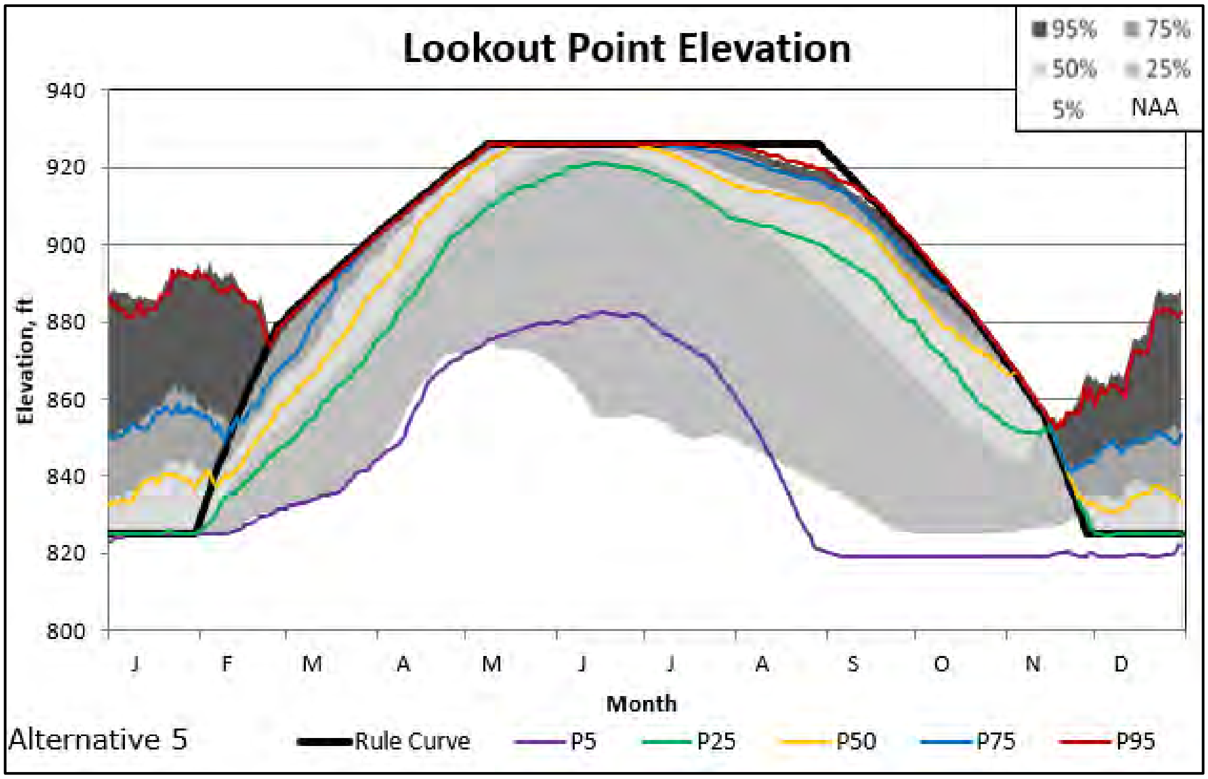

**Figure 3.2-167. Alternative 5 Lookout Point water surface elevation non-exceedance compared with NAA**

Fall Creek reservoir (Figure 3.2-168) would have the same deep fall reservoir drawdown to the bottom of the reservoir in Alternative 5 as the NAA. Therefore, reservoir releases and elevations would vary only slightly from the NAA in Alternative 5.

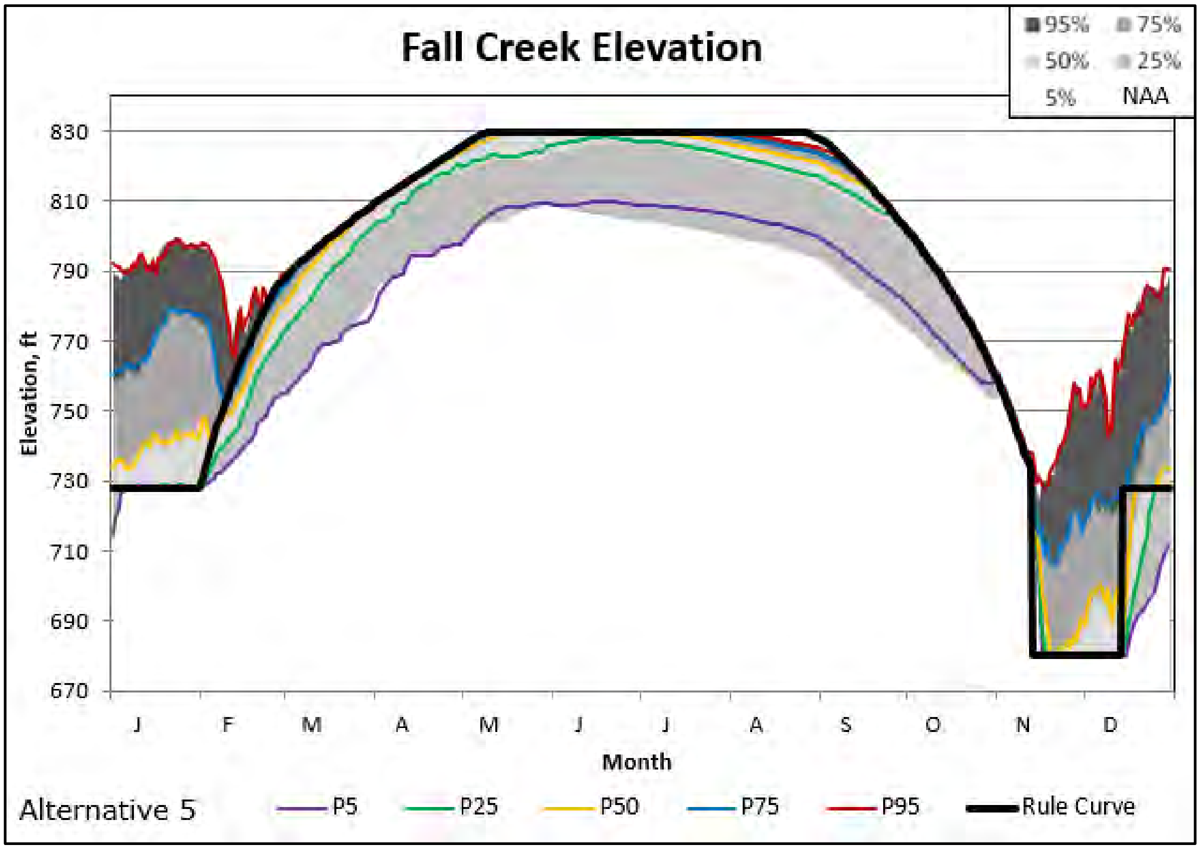

**Figure 3.2-168. Alternative 5 Fall Creek water surface elevation non-exceedance compared with NAA**

At the downstream control point at Jasper (Figure 3.2-169), the shift in flow releases would be evident, especially in dry years, with lower flows in the spring and higher flows in the summer and fall. The increased fall flows during wet years as compared to the NAA would be due to the reservoirs starting at a higher elevation prior to drafting for flood season. There would be more water to release from the reservoirs so there would be higher flow downstream of them.

In the spring of the driest years, refined integrated temperature and habitat flow regime targets at Salem would be lower than the NAA. This would result in lower releases from Hills Creek and Lookout Point and lower flows at Jasper. Fall flows would also be lower in the driest years when Lookout Point and Hills Creek would run out of water, making up for the lack of releases from Cougar. This would happen slightly more often in Alternative 5 than in Alternative 2B because of the higher mainstem flow target at Salem. Since the reservoir would empty earlier, fall flows at Jasper in the driest years would be lower in Alternative 5 than in Alterative 2B.

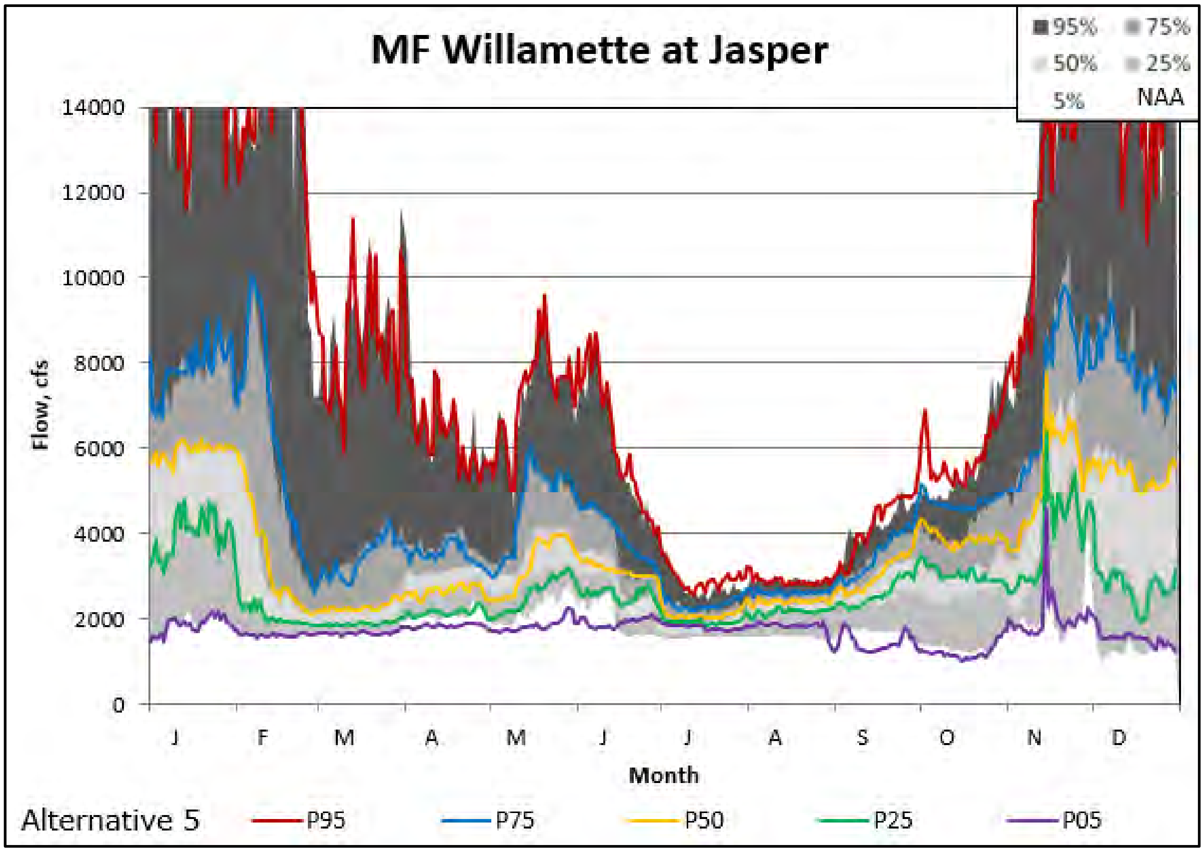

**Figure 3.2-169. Alternative 5 Middle Fork of the Willamette River at Jasper flow non-exceedance compared with NAA**

### *3.2.2.10.5 Coast Fork of the Willamette Subbasin*

For Alternative 5, the Coast Fork subbasin would store more water in the spring and release it during the summer and fall during dry years and it would be generally similar to the NAA in wet years. Reservoir elevations would be somewhat higher at both Dorena (Figure 3.2-170) and Cottage Grove in Alternative 5 during the late spring and summer, with other times similar to the NAA. Dorena and Cottage Grove release slightly more water in the spring than in Alterative 2B to meet the higher mainstem target and draft to lower elevations as a result, but do not run out of water. Figure 3.2-171 shows the control point at Goshen. Since the pools would stay higher throughout the summer, more water is released during September and October.

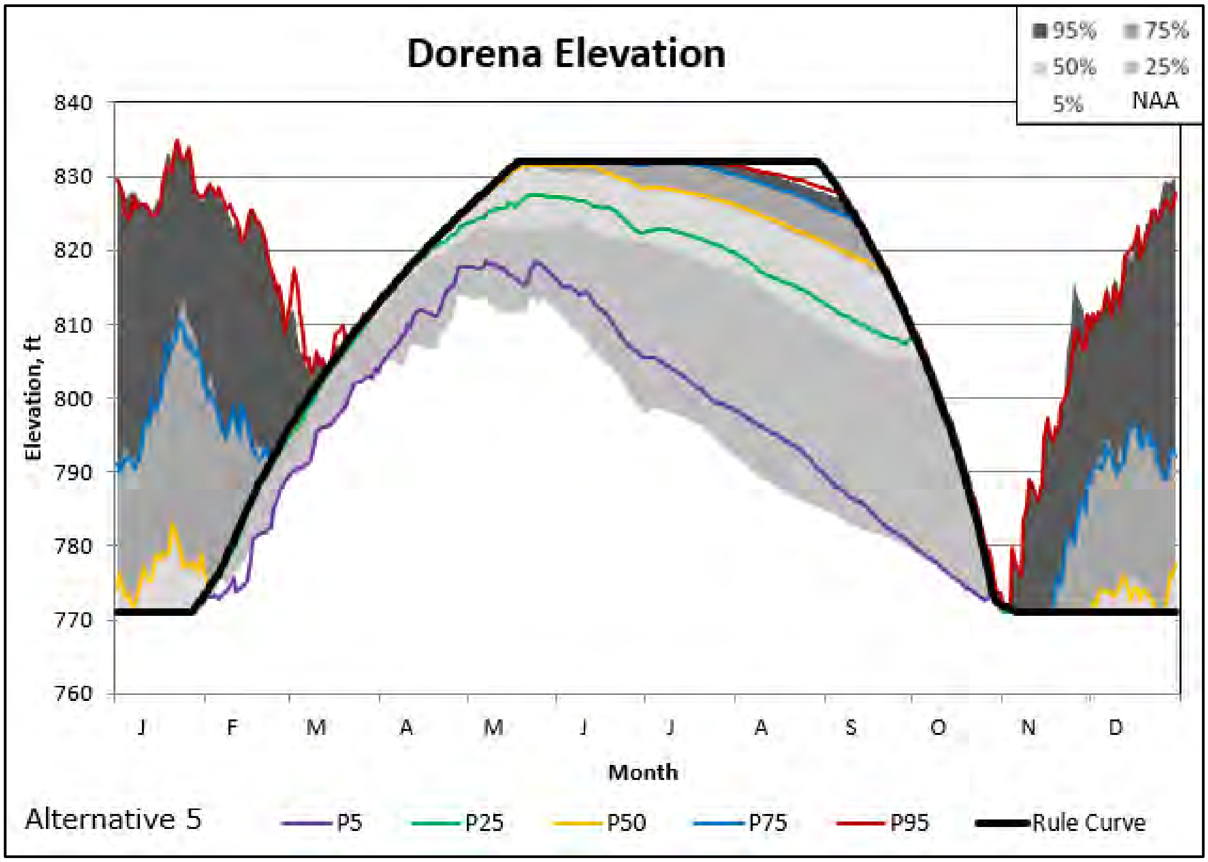

**Figure 3.2-170. Alternative 5 Dorena water surface elevation non-exceedance compared with NAA**

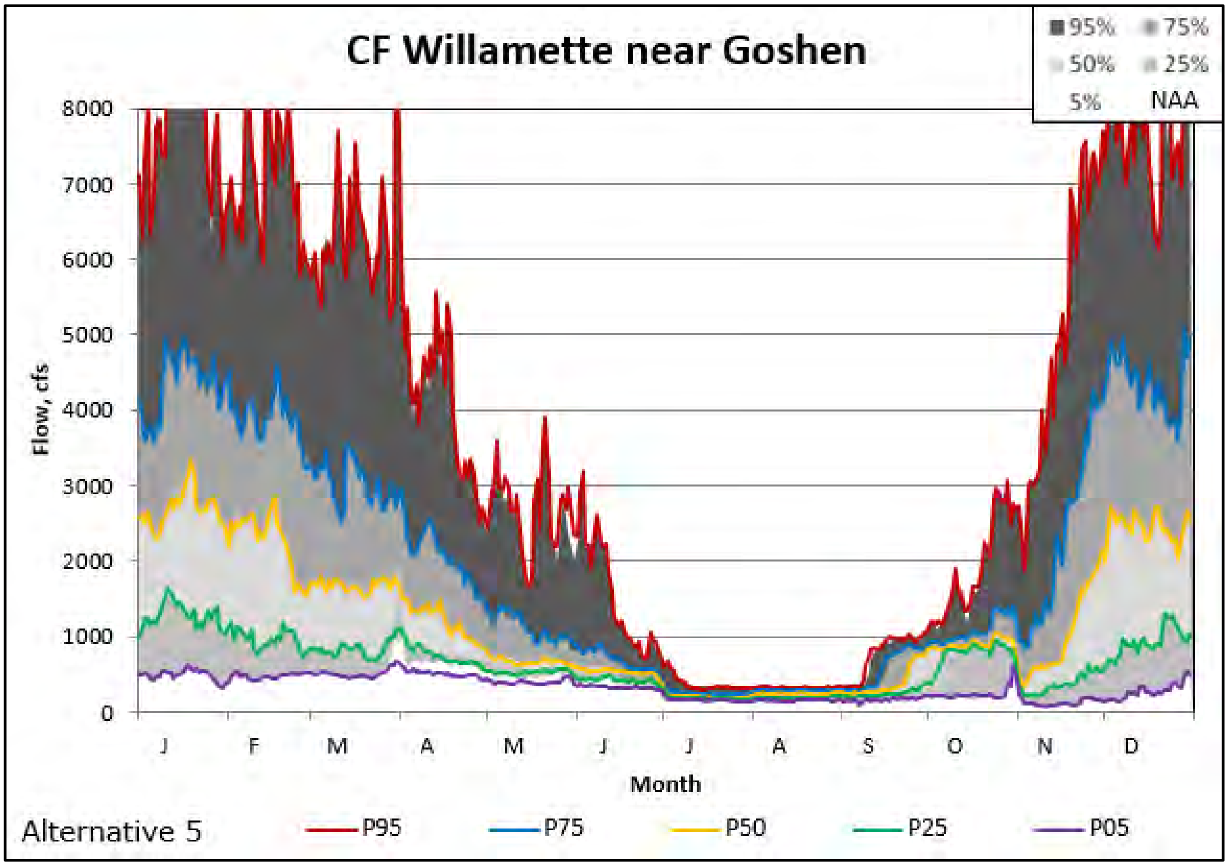

**Figure 3.2-171. Alternative 5 Coast Fork of the Willamette River at Goshen flow non-exceedance compared with NAA**

### *3.2.2.10.6 Mainstem Willamette River*

Alternative 5 would alter the regulated hydrology of the mainstem Willamette River control points under the refined integrated temperature and habitat flow regime, storing more water in the spring and releasing it during the summer. The Willamette River at Albany (Figure 3.2-172) would show dry years below their NAA equivalents from April to June and a compressed flow regime through the summer, with the higher flow years reduced and the low flow years increased. The WVS would typically meet the flow target at Albany, missing during September and October of the driest years. As compared to Alternative 2B, flows at Albany would be slightly higher in the spring and more frequently below the target in the fall of the driest years, a result of higher spring targets at Salem occasionally causing Lookout Point and Hills Creek to run out of water.

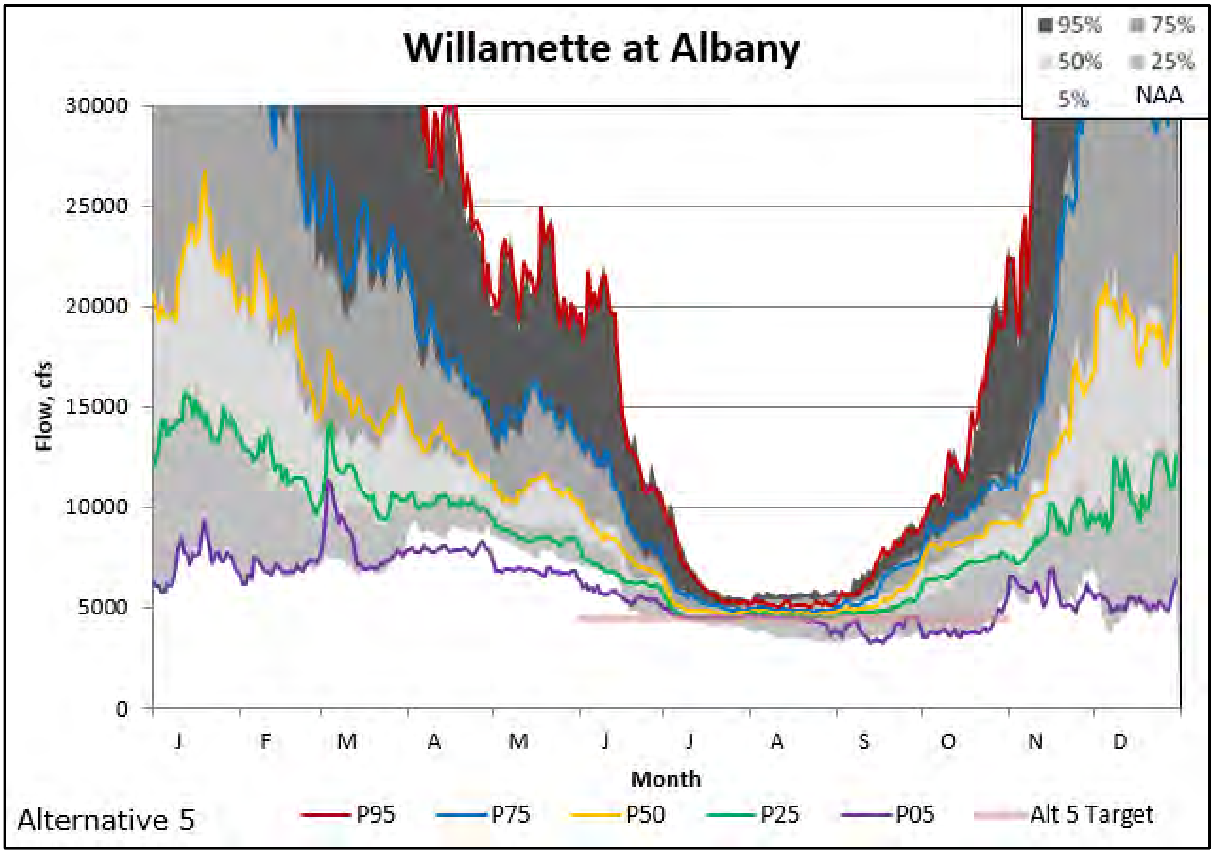

**Figure 3.2-172. Alternative 5 Willamette River at Albany flow non-exceedance compared with NAA**

Like the Albany control point, the Willamette River at Salem (Figure 3.2-173) would show reduced flows from April to June of dry years, while meeting the refined integrated temperature and habitat flow regime target. Summer and fall flows would increase across all years as compared to the NAA. The effect of reduced storage at Cougar would be much less evident at Salem due to the contributions of the Santiam WVS reservoirs. Compared to Alterative 2B, flows in dry springs would be slightly higher reflecting the higher flow targets and fall flows in dry years would be slightly lower after the higher spring targets exhaust storage at key reservoirs.

The increased flows from September to November would be due to the deeper fall reservoir drawdown at Green Peter. These increases would be within the river channel (bankfull is at 90,000 cfs), meaning they would not impact flood risk.

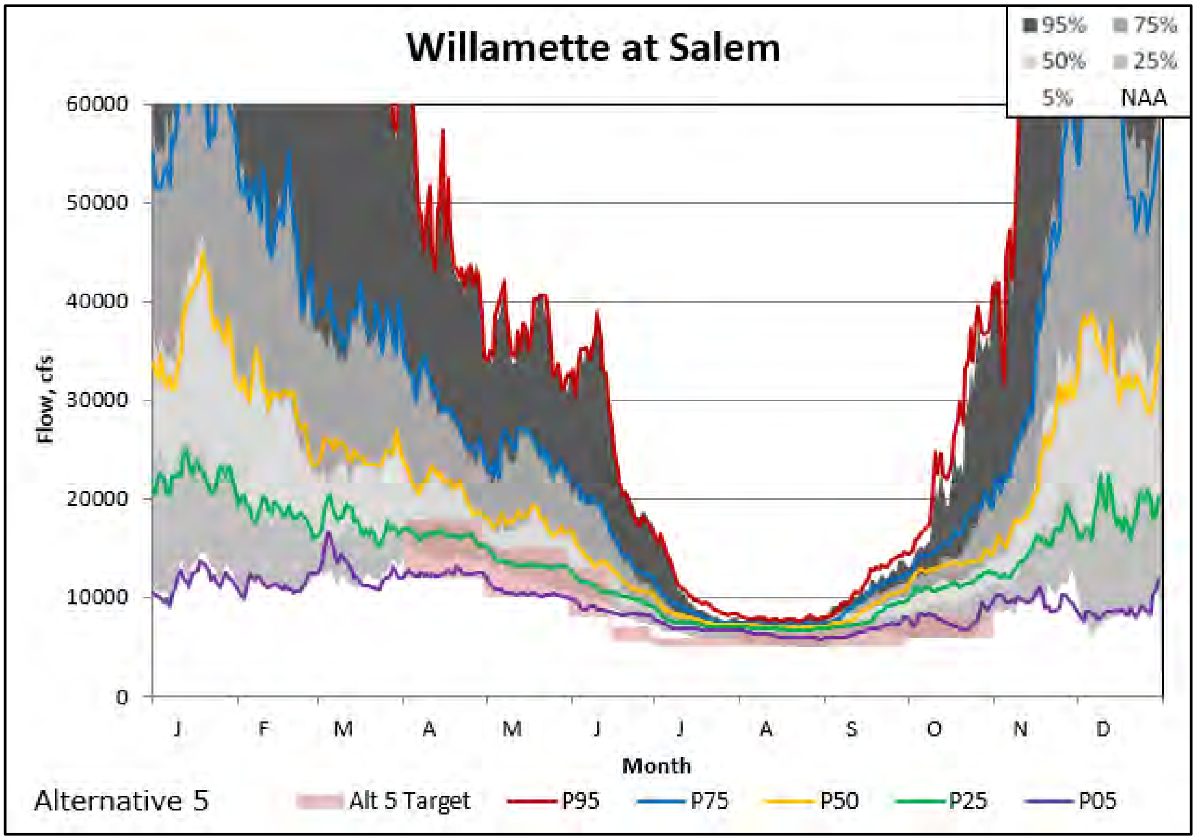

**Figure 3.2-173. Alternative 5 Willamette River at Salem flow non-exceedance compared with NAA**

### *3.2.2.10.7 Near-Term Operations Measure*

See Alternative 2A, Section 3.2.2.4.7, for description of effects due to the Near-Term Operations Measure.

### *3.2.2.10.8 Climate Change*

The WVS will likely experience increasing wintertime flow volumes in the future. Some flood magnification (increased severity during flood season) is also likely. Because the WVS system storage would not increase substantially, it's likely that FRM operations will face future challenges. An upward shift in winter median future project inflows may increase both the average reservoir water surface elevation as well as outflows downstream of the WVS dams. Both Green Peter and Cougar would refill to their conservation pool elevation later in the year after their deeper fall reservoir drawdowns. However, the overall potential benefit may be minimal to future FRM operations. While the lower reservoir elevation at Cougar at the start of flood season is potentially helpful, the storage volume below the minimum conservation elevation is much less than that above it and climate-driven conversion from snowfall to rain may be more impactful than the additional storage. At Green Peter, projections for flow changes are more muted than the higher elevation basins, meaning that it may diminish in importance relative to other WVS reservoirs for FRM operations.

Reservoirs located within higher elevation subbasins, such as Detroit, are likely to see higher rainfall and runoff volumes in the winter. Higher projected temperatures in the future will mean less snowpack than currently experienced. Lower snowpack would also reduce spring volume as the snow melts. Lower elevation subbasin projects such as Fern Ridge and Cottage Grove, with little or no snowpack, are projected to experience higher wintertime flow volumes, but similar peak runoff timing compared to historical baselines.

During conservation season, climate change will affect Alternative 5 similar to Alternative 2B. The refined integrated temperature and habitat flow regime targets allow for lower releases in the spring than the NAA BiOp requirements in the driest years. As a result, some WVS reservoirs can store more water during conservation season as compared to the NAA. However, those reservoirs will have to use more of this stored water to meet downstream flow targets with projected increased variability in the spring shoulder months, drier hotter summers, and lower summer baseflow. Outside of flood season, Cougar Reservoir would likely never fill to minimum conservation elevation due to decreased inflow after its spring reservoir drawdown. Hills Creek and Lookout Point would have to release more water to meet the Albany flow target, substituting for the lack of releases available from Cougar, which would not occur under the NAA.

Across the WVS, reservoirs are projected to have lower water surface elevations as compared to the NAA, though Cougar, Hills Creek, and Lookout Point are most affected. Reservoirs in Alternative 5 would sometimes draft to minimum targeted elevation during the summer, but less often than the NAA, meaning they would be able to augment summer flows for longer than the NAA even with projected decline in late spring and summer flows. The lowest reservoir water surface elevations would occur in the driest years, which would be drier than the WVS currently encounters, as the reservoirs are drafted more to meet downstream flow targets. In addition, increased reservoir evaporation would marginally decrease available water across all reservoirs. Climate change effects, and potential implications as discussed above, draw on the climate change projection and trend information provided in the climate change appendices (F1 and F2).

## 3.3 RIVER MECHANICS AND GEOMORPHOLOGY

### 3.3.1 Affected Environment

#### *3.3.1.1 Introduction*

The River Mechanics and Geomorphology description of the affected environment is divided into two primary portions: 1) the rivers downstream of the WVS and, 2) the dams and reservoirs themselves. In this section, river mechanics refers to the flow levels in the river and closely associated phenomena, such as sediment movement. The floodplain geomorphology refers to the geometry and features of the area that interact with the river. There are many factors that contribute to both, including the basin geology, hydrology, and riparian vegetation. The river and floodplain both shape and interact with each other. For example, the seasonal variability of flow velocity would erode or deposit sediment and change the shape of the channel and floodplain, leading to changed river velocities in a continuous process.

In the downstream portions of the WRB, riverine processes help shape the morphology of the terrain. The WVS substantially affects the hydraulics and morphology of rivers in the WRB. During all seasons, the dams and reservoirs remove sediment and energy from the system and the revetments along the river retard its movement. During the major flood season, peak flows are reduced to decrease damage from flood inundation. All these actions – and others outside of the WVS control – have the effect of reducing the width of the floodplain engaged by the river.

The reservoir elevations vary throughout the year, changing the ponded storage and shoreline with it. In the winter, these changes are for FRM operations. In spring and summer, the reservoirs store water for use during the conservation season and fill up to their full pools as conditions allow. The water surface elevations in the reservoirs and the outflows from dam outlet works have significant effects on the immediate surroundings.

#### *3.3.1.2 System*

There are approximately 465 River Miles (RMs) along the Willamette River and its regulated subbasins below the WVS. Two subbasins, the Clackamas and Molalla rivers, contain revetments but are not downstream of any WVS reservoirs, so they are 'unregulated' by USACE flood damage reduction storage projects

The WVS is multipurpose and the operational goals change throughout the year based on the season. During the major flood season, the goal is to decrease flood damages by reducing the peak flow downstream of the WVS. These operations are readily apparent in the historic record. The WVS was constructed starting in 1942 with Fern Ridge on the Long Tom River and was fully operational for water year (WY) 1969. The peak flows at Albany were reduced substantially after this date. Figure 3.3-1 shows the annual peak from each WY at a long-term flow gaging site on the Willamette River downstream of the WVS reservoirs. Annual peak flows are reduced, but the WVS also reduces potentially damaging flows that are lower than the peak flows shown in Figure 3.3-1.

The high flows, both annual peaks and lesser large flows, from before the construction of the WVS, formed the geomorphic floodplain in the WRB. The amount of energy and peak flows available to the rivers downstream of the WVS is reduced and the area of influence around the main channel has narrowed as an effect of flood damage reduction operations. In other words, the many floodplain terraces, swales, and other geomorphic formations along the Willamette Basin rivers are no longer regularly connected to the channel as they were before the construction of the WVS.

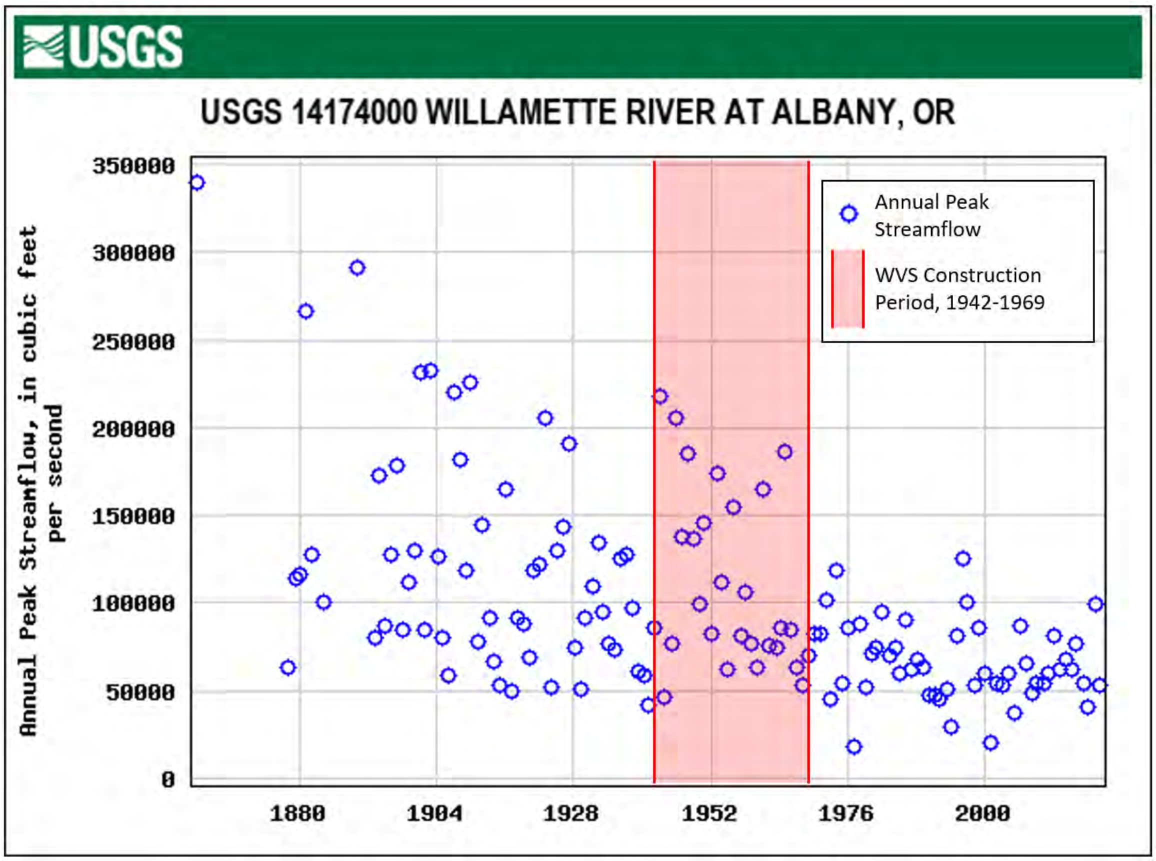

**Figure 3.3-1. Annual observed maximum flow at Albany, OR.**

The rivers are generally steeper further upstream toward the headwaters of the WRB. While the Willamette River above Willamette Falls is nearly flat during low water periods, the upper portions of the North Santiam River and McKenzie River have quite steep average channel slopes of up to 10 feet per mile. Figure 3.3-2 shows the Willamette Valley basin layout. A general geomorphic and hydraulic description of the downstream reaches (Wallick et al. 2013), is included later in this section moving from downstream to upstream.

All regulated tributaries in the WRB except Blue River, South Fork McKenzie, Fall Creek, and Row River contain constructed bank protection revetments, embankments or levees. These structures are part of the WVS and generally constrain the movements of river channels.

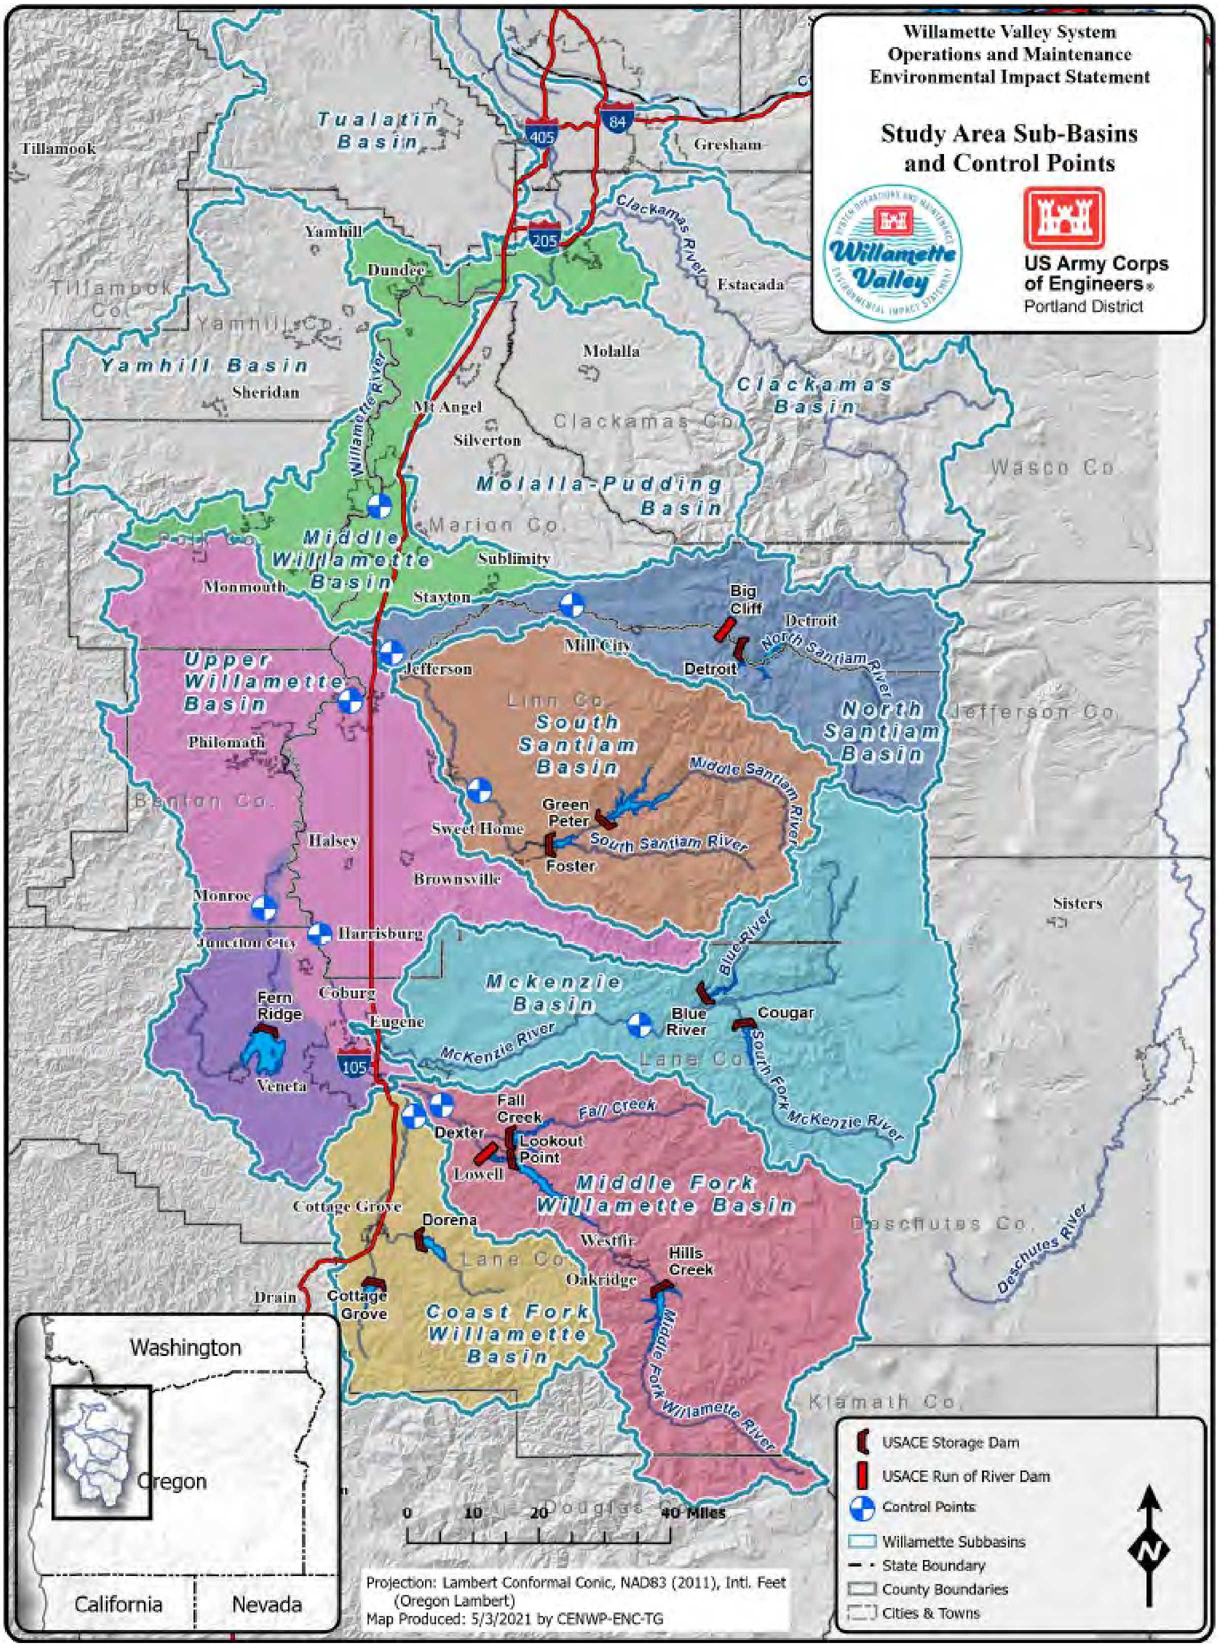

**Figure 3.3-2. Willamette Basin subbasins and WVS layout**

### *3.3.1.3 Willamette Basin Sediment Movement*

Sediment movement in the system is significantly altered by the WVS, both in the reservoirs themselves and in the downstream rivers due to the construction of revetments and hydrologic modifications for flood damage reduction.

#### *3.3.1.3.1 Reservoir Sediment Mechanics*

Coarse sediments (sand and gravel) entering a reservoir typically settle out and deposit as a delta in the upstream end of reservoirs and along the upstream river channels as the flow of the river encounters the reservoir pool. Sediment in the delta (commonly referred to as head of reservoir deposits) can be remobilized farther downstream when the reservoir operating pool lowers (e.g., for seasonal management changes). In dams that operate over a wide range of elevations throughout the year, the upstream extent of reservoir backwater and the location where coarse sediments deposit may shift considerable distances. Reservoirs with larger changes in water surface elevation and shallower slopes near the head of reservoir would have larger coarse sediment deltas. Coarse sediments rarely pass a dam with a significant pool impounded.

Fine suspended silts and clays tend to transport past the delta and slowly settle out of the water column along the reservoir bottom as a lakebed deposit. Finer sediment would typically travel further in the reservoir: the smallest sediment particles may never reach the bottom of the reservoir and would pass through the dam with the outflow. Reservoirs with large storage volumes relative to the annual volume of water passing through tend to trap more suspended sediment than reservoirs with smaller relative storage volumes. The geometry of the reservoir can also affect fine sediment trapping: sediment would take longer to travel to the bottom of a reservoir that is relatively long and deep as compared to a similar volume reservoir that is wide and shallow. Figure 3.3-3 shows a conceptual diagram of sediment trapping in a reservoir.

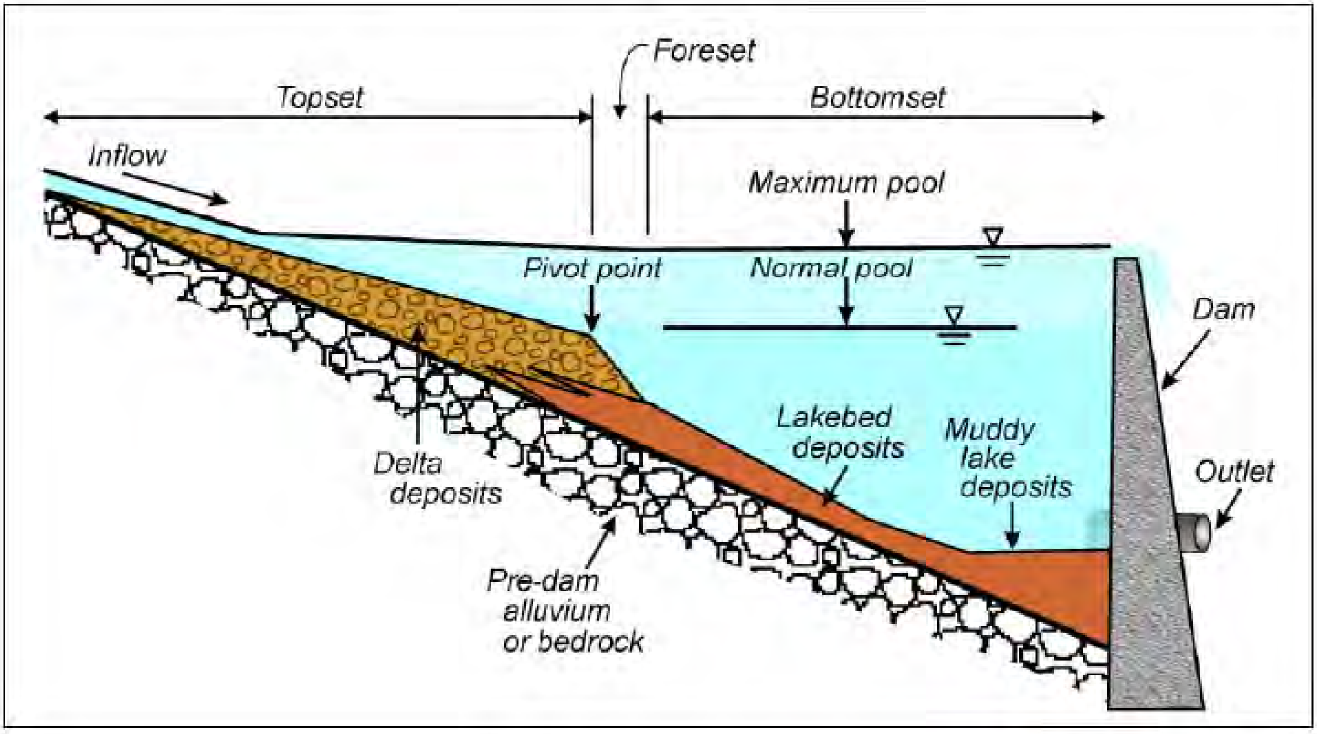

**Figure 3.3-3. Idealized sediment profile within a dam-controlled reservoir**

The estimated median sediment trapping efficiencies for the WVS (excluding the reregulating projects Big Cliff and Dexter) are shown below. These calculations use the WVS PEIS hydrology inflow dataset for storage and inflow volume (see appendix C). This target elevation generates useful comparison of median trapping efficiency across the WVS as most sediment generated from upstream sources transports into the reservoirs during the flood season flows. More broadly, since the trapping efficiency is based on a log-scale comparison of water volumes, the estimated trapping efficiency would not change significantly if the actual amount of impounded water is somewhat different than the rule curve target.

Estimated Trapping Efficiency of WVS:

- Blue River – 81%
- Cottage Grove – 81%
- Cougar – 91%
- Detroit – 91%
- Dorena – 81%
- Fall Creek – 82%
- Fern Ridge – 80%
- Foster – 67%

- Green Peter – 93%
- Hills Creek – 94%
- Lookout Point – 88%

It is important to note that these values are estimates based on comparing water volumes and not measured sedimentation. Also, as noted above, every reservoir in the WVS traps nearly all coarse sediments (gravels and sands) in the pool (O'Connor et al. 2014). These are included in the values above, and generally the only sediment passing a reservoir would be fines (silt and clay sized sediments).

There are two existing reservoir sediment mobilization models in the WVS, at Detroit (USACE 2016a) and Lookout Point/Dexter (USACE 2015c). The intent of both studies was to assess the movement of accumulated sediments in and out of the reservoir during a deep drawdown reduction in the pool elevation to the lowest outlet in each dam. In addition, USACE has lowered the reservoir elevation at Fall Creek during the fall in recent years with a deep drawdown.

Figure 3.3-4 shows the results of the scour analysis during a modeled drawdown of Lookout Point. The Lookout Point model was designed to investigate sediment movement in and out of the reservoir in preparation to replace the spillway gates which required a lowering of the reservoir.

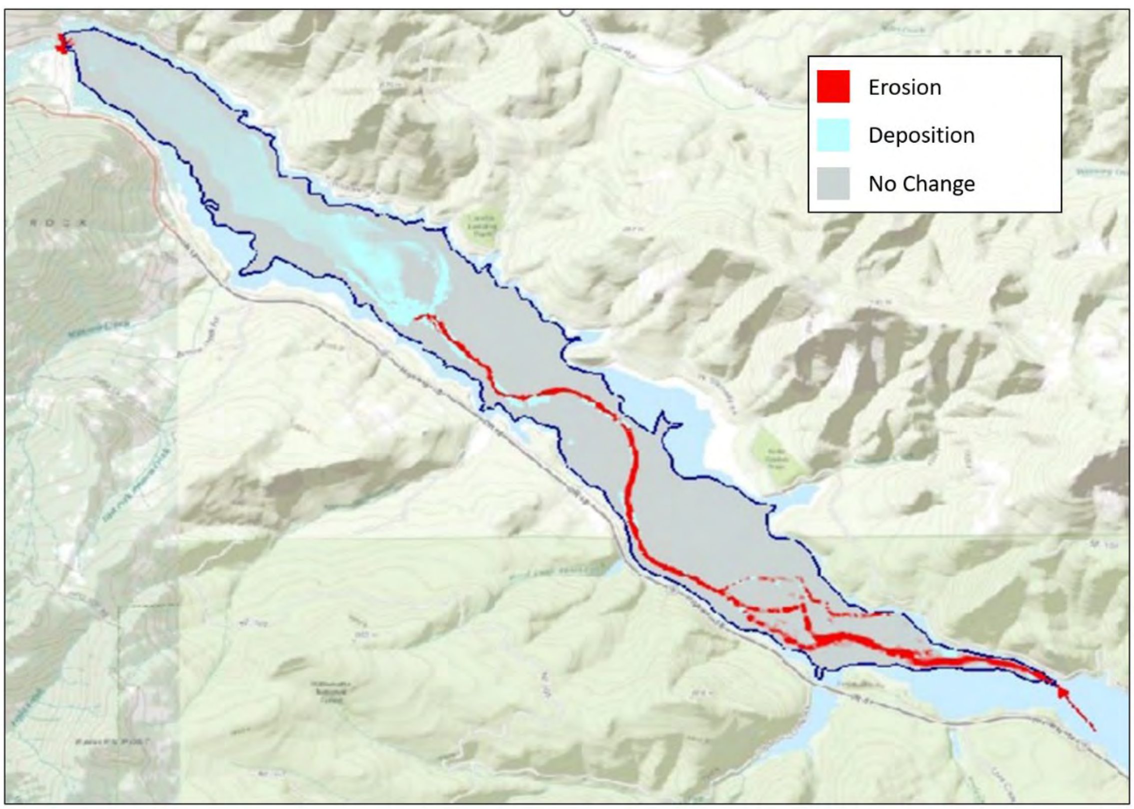

**Figure 3.3-4. Modeled sediment mobility during modeled Lookout Point drawdown**

The results show that the sediment accumulated at the upstream end of Lookout Point since construction (bottom right in the figure) moving closer to the Dam (top left) and a limited amount of sediment passing through to Dexter Reservoir downstream.

*3.3.1.3.2 River Sediment Mechanics*

Most coarse sediments in the WRB are from the Cascade Mountains, which primarily supplies volcanic basalts. This material degrades relatively slowly and typically disappears from river channels due to coarse sediments being broken into smaller particles as they are carried downstream (O'Connor et al. 2014). The McKenzie and North Santiam Rivers currently contribute the highest amount of sediment to the mainstem Willamette (Wallick et al. 2013). These two rivers have larger portions of their drainage basins that are both relatively steep and outside the control of any WVS dam and reservoir. Although the Coast Range does contribute substantial sediments, the soft sedimentary sandstone of the lower mountains rapidly degrades to silt and clay (O'Connor et al. 2014) and is transported as suspended and wash load. (The "wash load" is the portion of sediments that remains suspended even without water flow, thereby contributing to turbidity.) Figure 3.3-5 shows gravel bar formation in the North Santiam River south of Stayton, Oregon. The side channels and various ages of vegetation and gravel bars are evidence that the river channel is mobile within its immediate floodplain in this area.

**Figure 3.3-5. Gravel bars and side channel morphology in North Santiam River south of Stayton, OR.**

Most sediment transport capacity in riverine environments occurs during near channel bankfull water conditions. Bankfull refers to the water level stage that just begins to spill water out of the channel into the floodplain. As noted in Section 3.2, Hydrologic Processes, the frequency of these events has been reduced by the upstream storage operations of the WVS. Combined with the sediment capture in the reservoir pools, the basin modifications have had the effect of reducing sediment load in the Willamette Valley. In total, the WVS is estimated to reduce the estimated coarse sediment flux in the WRB by about two-thirds, from about 199,000 to 72,000 cubic meters per year (Wallick et al. 2013).

As with hydrology and peak flows, the sediment movement in the rivers closest to the dams and reservoirs is most heavily affected by their construction. Generally, the streambed in these areas coarsens (or 'armors') over time as the water from the dam outlets erode the fine material in the downstream channel. In a natural system, this material would be replaced by incoming transporting sediments, but these sediments are instead trapped in the reservoir itself. This coarsening effect is not limited to river reaches directly downstream of reservoirs and, over time, the regulated rivers in the WRB have coarsened (Klingeman 1987; Minear 1994). Simultaneously, the regulation of the peak flow in the main reaches reduces the transport capacity for coarse sediment load. The sediment coming into the main reaches from downstream rivers still contains the coarse sediment, in contrast to the water from the reservoirs. The reduced peak flows leave the incoming coarse sediment behind as finer material moves downstream. The combined effect of these two riverine processes is an overall coarsening of riverbeds in the regulated portions of the WRB.

Coarse sediment availability and mobilization and large changes in flow all contribute to river channel migration. The segments of the mainstem Willamette River that currently experience the most migration due to these factors are the areas downstream of the confluences with the McKenzie River and Santiam River. As the river flows away from these confluences, the river adjusts to its larger flow, the coarse sediment is lost to attrition and the river is more incised in the sections between Corvallis until the confluence with the Santiam – farthest away from the McKenzie River – and downstream of Salem – furthest away from the Santiam River (Wallick et al. 2013).

##### *3.3.1.3.3 Bank Stabilization by Revetments*

USACE, private landowners, and others have built revetments along the historically mobile river reaches of the WRB. Figure 3.3-6 shows a picture and cross section of a revetment north of Salem, OR – individual revetments vary in geometry based on the local river and bank conditions. These structures typically consist of large stones (riprap) placed along the river to prevent the bank from eroding further and protect adjacent property. The stone revetments often have accessory structures like drift barriers, which are placed at the mouth of high-water overflow channels to collect debris and reduce the velocity of flows into the channel; and groins, which extend into the channel diagonally or perpendicularly to the riverbank in order to reduce near-bank velocities. Revetments are typically placed on the outside of a river bend where erosion is most likely to occur but are sometimes also used to realign or straighten the main channel.

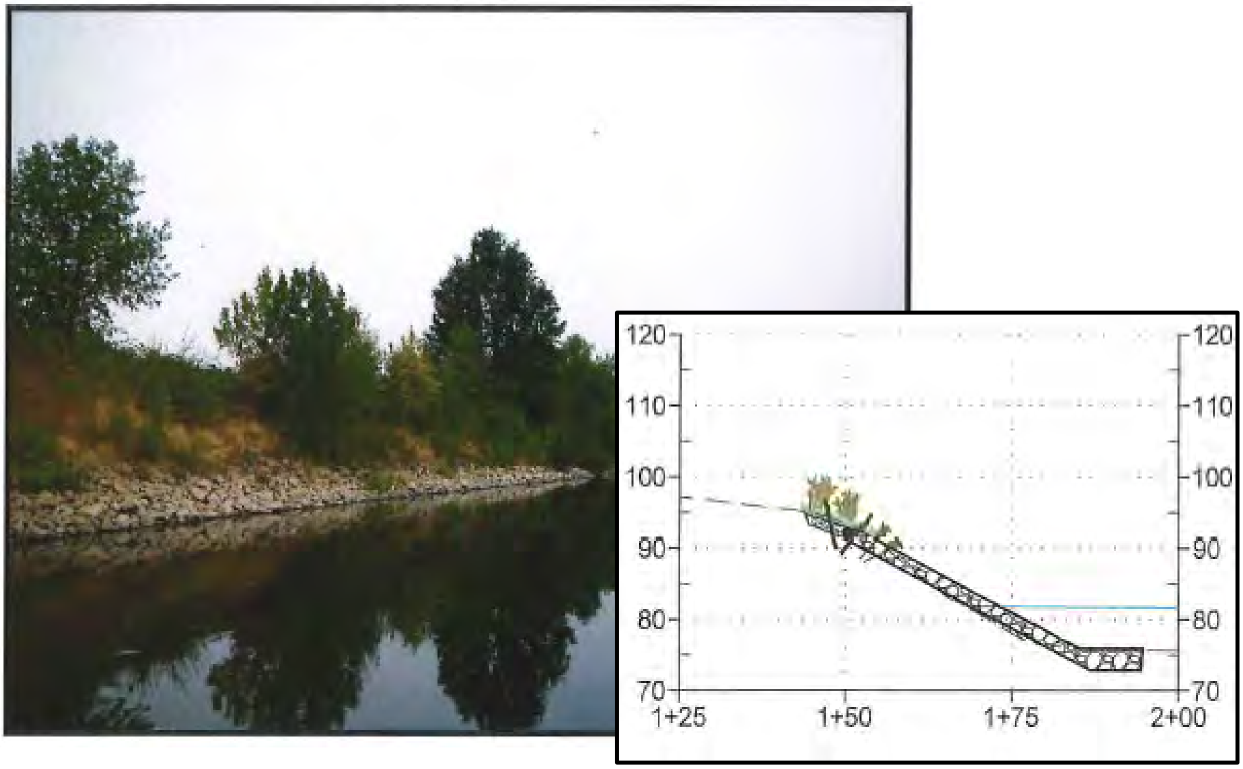

**Figure 3.3-6. Example Willamette River revetment north of Salem, OR, with typical cross section**

USACE has frequently constructed two other types of hydraulic structures: levees and embankments. Levees are designed to protect an area from high flood waters and typically connect to high ground on either side. There would necessarily be a water surface elevation differential inside and outside of the levee. USACE has also constructed hydraulic embankments in some locations. These linear structure appear like levees but can be perforated with culverts or may not connect to high ground. Often, these structures increase channel flow capacity (as along the Long Tom River downstream of Fern Ridge Dam) but can be designed for other purposes. Importantly, neither embanclipkments or revetments are designed to protect an area against flooding. In summary, levees mitigate flooding, revetments mitigate erosion, and embankments can increase channel capacity, redirect flow or serve other functions as necessary. There are projects that incorporate aspects of each into their design.

Revetments are most common in river reaches with the most historic channel migration, such as the McKenzie, upper mainstem Willamette, and South Santiam rivers. Currently, about 26% of the banks of the mainstem Willamette between Eugene and Portland have revetments. A significant portion of the rest is geologically stable (e.g., bedrock canyon, banks made of compacted gravels resistant to erosion, etc.), so approximately 25% of the river is able migrate freely through erodible soils, down from 80% in 1932 (Wallick et al. 2007).

Along with the lower water levels due to flood damage reduction operations, revetment projects can have the effect of partially restricting previously active floodplain interaction with the main channel. Riprap is typically placed on a slope with no associated embankment. Some revetments have placed earthen embankments or plugs where the existing bank is uneven in elevation or planform. Typically, any embankment that is part of a revetment project only provides a consistent surface for facing with riprap and does not stop water from moving behind them like a levee. Riprap on the landward side of an embankment slope prevents erosion when floodwaters flow over the embankment into the floodplain. Where revetment projects with embankments isolate previously connected low areas, suspended sediments passing into the floodplain over the revetments would then fall out of suspension in the lower energy areas behind the structure and, over the course of years, fill in previously active areas with fine sediment.

Since the revetments constrain lateral movement of the river, the material in the banks is no longer available to be eroded and transported downstream as bed and suspended sediment load. The accumulated material is lost to the floodplain from the river as the revetments reduce bank erosion in the system.

#### *3.3.1.4 Lower Willamette River*

The Lower Willamette River – below Willamette Falls at RM 26 – is not included in the WVS PEIS. It is tidally influenced by the Columbia River and the hydrology of that reach is better suited in a discussion of the Lower Columbia River estuary. Please refer to the Columbia River System Operations EIS for information on this reach (USACE et al. 2020).

#### *3.3.1.5 Middle Willamette River*

The Middle Willamette River, from Willamette Falls to the Santiam confluence, is divided into two parts. The Willamette Falls backwater, commonly referred to as the Newberg Pool, extends up to about RM 50. The channel slope is about 1.2 ft/mile and the water surface can be nearly flat during the summer, though higher flows steepen the water surface profile somewhat. The river is confined by canyons and high terraces in some areas and the geomorphic floodplain is narrow: generally, between 1,000 to 3,500 feet across. The natural backwater associated with the Willamette Falls means there is less energy available for channel movement. The Willamette River has few side channels and limited floodplain interaction downstream of RM 50.

Upstream of Newberg Pool, the river increases in slope somewhat (1.8 ft/mile) but remains a very low gradient river. There are gravel bars with the material supplied by the Santiam River and occasional side channels, but the river is predominately a single-threaded channel. The river still has relatively steep banks, between 10 and 20 feet high. High flows are required for floodplain interaction. The river is geologically constrained in certain places – such as south of Salem, Oregon – but the geomorphic floodplain is generally wider in this stretch at 1 to 4 miles across. The furthest downstream WVS revetments are in this reach.

### *3.3.1.6 Upper Willamette River*

Upstream of the supply from the Santiam River, gravel bars are much less prevalent. The largely single-thread channel, up until the Corvallis area, remains low gradient, (1.5 ft/mile) and the geomorphic floodplain is between 3000 feet and 3.5 miles. The river channel is relatively stable due to geographic constraints. Fewer revetments were constructed in this reach than upstream, primarily due to the natural stability of the reach.

Upstream of Corvallis is the most active and varied portion of the mainstem Willamette River. Previous work (Wallick et al. 2007) has described this area as a "wandering gravel-bed river". The overall channel slope steepens considerably to 4-5 ft/mile and the channel is unconstrained by geography like it is downstream. This is the widest geomorphic floodplain in the mainstem Willamette (upper, middle and lower), at up to 5 miles. Gravel bars are frequent and larger flows can sometimes realign the channel in a relatively short period of time. However, these events, called river avulsions, have decreased by about 70% in the 20th Century (Wallick et al. 2007). Figure 3.3-7 shows one such location south of Peoria, Oregon, comparing August 2005 and August 2006, where a flood in January 2006 cut off an existing meander, straightening the channel. The historic response to the Willamette River's ability to wander was to construct revetments, so this area of the mainstem has the greatest number and longest total length of them.

**Figure 3.3-7. Willamette River realignment before and after January 2006 flood, south of Peoria, OR**

### *3.3.1.7 North Santiam River*

The North Santiam River is the steepest reach downstream of any WVS, with an average slope of 14 ft/mile, with the highest slopes as it approaches Big Cliff Reregulating Dam. There are many secondary channels and gravel bars. Channel movement and avulsions (where a river channel shifts location) are relatively common in the North Santiam as compared to other rivers in the WRB. The North Santiam is the source for much of the sediment in the mainstem Willamette River downstream of the confluence. The geomorphic floodplain is a still relatively narrow with widths between 3500 feet to 1.5 miles due to bedrock and other hardened geologic features.

#### *3.3.1.8 South Santiam and Mainstem Santiam Rivers*

The South and mainstem Santiam rivers have wide geomorphic floodplains, up to 3 miles across. This is due to a combination of moderate overall channel grades – ranging from 4-6 ft/mile – and unconstrained geology. Historically, this would have resulted in an active channel, but most of the river is single thread currently due to the construction of revetments. Vegetation has colonized previously active gravel bars, further hardening the modified morphology. Since the area surrounding the river channel is relatively flat across the floodplain, the inundated area can expand quite quickly once floodwaters overtop the riverbanks.

#### *3.3.1.9 Long Tom River*

The Long Tom River is lined with embankments along nearly its entire length downstream of Fern Ridge Reservoir to its confluence with the Willamette River. These embankments were designed so that the highly modified channel can pass the output from Fern Ridge Dam. There is limited interaction between the channel and its historic floodplain because of the embankments, but culverts in the embankments allow for regular inundation of floodplain regions.

The river was shortened from 36.5 miles to 23.6 miles. A series of seven drop structures were also built with the intent to reduce channel velocity and decrease erosion, while still moving water downstream efficiently.

#### *3.3.1.10 McKenzie and Blue Rivers*

Near the confluence with the mainstem Willamette River (north of Eugene and south of Coburg), the McKenzie River floodplain is up to 2 miles wide, but the channel is single thread due to modifications such as revetments and gravel mining along the banks. The floodplain is lower with respect to the channel than most other rivers in the WRB and inundation is possible at levels as low as the 50% Annual Exceedance Probability flow (commonly referred to as the 2-year flood).

The McKenzie River steepens upstream of Hayden Bridge (about RM 10, upstream of the confluence with the Mohawk River) to 10 ft/mile, with the geomorphic floodplain narrowing, intermittent multithread sections, and increasing prevalence of gravel bars. Further upstream, near Blue River and Cougar dams (Figure 3.3-8), the river is increasingly single thread in a canyon and the banks are generally forested.

There is about 1.6 miles of river between Blue River Dam and the confluence with the McKenzie River. The channel is modified to accommodate the outlet works of the dam, but there are no revetments on Blue River.

**Figure 3.3-8. Winter Drawdown on Cougar Reservoir**

### *3.3.1.11 Middle Fork of the Willamette River and Fall Creek*

The Middle Fork between the mainstem Willamette and Dexter Reservoir has little inflow that is not controlled by the upstream WVS (Hills Creek, Lookout Point, Dexter and Fall Creek). The geomorphic floodplain is constrained by the foothills of the Cascade mountains and is between 3500 feet and 1.5 miles wide. The proximity of the WVS reducing peak flow and sediment supply, and construction of revetments in the most mobile areas, means that the Middle Fork is largely stable through this reach. Historic gravel bars have forested, further hardening the banks against movement.

There are about 7 RM of Fall Creek below the Fall Creek Dam. The geomorphic floodplain is confined by hills on each side and ranges from 1000 to 4000 feet across. Upstream of Little Fall Creek (RM 3), the effects of the reservoir predominate. The channel is oversized for its current reduced peak flows and lack of sediments. From Little Fall Creek to the confluence with the Middle Fork, there are a few side channels and more sediment as the two floodplains interact and merge.

#### *3.3.1.12 Coast Fork of the Willamette and Row Rivers*

Near the confluence with the Middle Fork to form the mainstem Willamette, the Coast Fork has several secondary channels and swales. This area also has significant developed areas and historic gravel mines. Upstream of the Highway 58 bridge (RM 6), the geomorphic floodplain progressively narrows and is more confined by the hills up to the WVS (Cottage Grove and Dorena). The channel is single thread for most of its length, modified with both revetments and channel capacity straightening through urbanized areas. Trees have stabilized most historic gravel bars.

### 3.3.2 Environmental Consequences

#### *3.3.2.1 Methodology*

Environmental consequences are identified for each of five river mechanics metrics based on thresholds of relative change (Action Alternative versus NAA) normalized to four levels (None/Negligible, Minor, Moderate, and Major). To facilitate interpretation, the results for the estimated environmental consequences are presented in the following sections organized by each alternative and grouped by sub-basin and then hydraulic operation (storage projects or run-of-river reservoirs and free flowing reaches).

Both quantitative and qualitative assessment methods were used to assess relative potential changes to river hydraulics, sediment supply and geomorphology for each PEIS alternative. Five quantitatively informed, but fundamentally qualitative metrics were developed to represent various physical characteristics and processes that could affect storage reservoirs, run-of-river reservoirs, and free-flowing reaches.

Environmental consequences related to river mechanics processes were evaluated in a comparative nature between and the action alternatives and the NAA. The general approach for evaluating system response for river processes was to use the historical period of record (POR) daily output from the quantitative Hydrologic Engineering Center Reservoir Simulation System (HEC-ResSim) as analysis inputs to compute or inform a suite of five metrics as described in this section and in further detail in Appendix C. Details of the HEC-ResSim model and analysis are located in section 3.2.

Note that in order to accurately represent spatiotemporal effects, the HEC-ResSim model analyses were applied using daily average values over the entire WVS basin and metrics presented herein are limited to the previously identified WVS projects. Due to a number of limitations associated with the H&H modeling process (see Appendix B), the baseline conditions established by the NAA results may not necessarily completely characterize the actualized conditions. Nonetheless, considering the size of the study area, the NAA and action alternative results were deemed sufficiently representative to adequately describe the hydrology and hydraulics as required to establish a general baseline of the study area for trend and departure analysis.

For a detailed description of the integrated operations and their effects to flows and reservoir stages throughout the WVS, see chapter 3.2, Hydrologic Processes.

##### *3.3.2.1.1 Alternative Comparison Thresholds*

The analysis method for river mechanics and geomorphology is qualitative, driven by quantitative storage and flow metrics. Visible or measurable expected change to a field observer drives the analysis. The basis for the quantitative metrics and the resulting qualitative descriptions is the hydrology and HEC-ResSim outputs for each alternative, as compared to the NAA. There are four levels of magnitude of effects, three levels of duration and three levels of extents when comparing the NAA to the others as shown in Table 3.3-1 below.

**Table 3.3-1. Evaluation Criteria for Potential Effects to River Mechanics and Geomorphology**

| Effect Magnitude | Criteria |
|---|---|
| None/Negligible | The resource area would not be affected, or changes or benefits would be either nondetectable or, if detected, would have effects that would be slight and localized. The area extent of effects would be small (limited) and would not require additional consideration or mitigation. |
| Minor | Changes to the resource would be measurable, although the changes would be small and localized. The duration of effects may vary. |
| Moderate | Changes to the resource would be measurable and have either localized or regional-scale adverse effects/benefits. |
| Major | Changes would be readily measurable and would have substantial consequences on a local or regional level. |
| **Effect Duration** | **Criteria** |
| Short-term | Changes to river mechanics and/or geomorphology would last less than two years. |
| Medium-term | Changes to river mechanics and/or geomorphology would last between two and five years. |
| Long-term | Changes to river mechanics and/or geomorphology would last throughout the duration of the project (2050). |
| **Effect Extents** | **Criteria** |
| Local | Changes to river mechanics and/or geomorphology would be confined to the dam/reservoir or river. |
| Regional | Changes to river mechanics and/or geomorphology would be perceived throughout a single county, multiple counties, or the entire WVS. |
| State-wide | Changes to river mechanics and/or geomorphology would be perceived throughout the entire state. |

As an example, a newly implemented deep fall drawdown of a reservoir would likely result in a major effect as it alters the accumulation point of coarse sediments and exposes more shoreline and lake-bottom fine sediments to potential movement. The deep fall drawdown operation would be in effect through the project life and therefor long-term in duration. Effects within the reservoir would be local to the reservoir. A smaller alteration in the rule curve, such as refill at a later calendar date, would likely be negligible or minor effects, long-term in duration and local to the reservoir.

There are no new hydraulic or sediment models (e.g., HEC-RAS) run as part of the analysis. Existing hydraulic models inform the professional engineering judgment wrapped into the qualitative levels of change listed above. Furthermore, the measures under consideration are primarily about operational changes outside of the major flood season. New potential hydraulic and sediment models would differentiate the alternatives significantly more during the high flows of the flood season, in contrast to the relatively lower-flow late spring, summer and fall.

##### *3.3.2.1.2 Storage Project Metrics*

There are eleven WVS dams that are designed and operated for flood, irrigation, or other storage purposes: Blue River, Cottage Grove, Cougar, Detroit, Dorena, Fall Creek, Fern Ridge, Foster, Green Peter, Hills Creek and Lookout Point. Note that while Foster can be operated as a run-of-river project, it also includes a small amount of storage, and thus, was also evaluated for the storage project metrics. Operators change the pool elevation at these storage projects over large ranges throughout the year to capture and release water in to meet specific water management goals.

**Shoreline Exposure**

Shoreline erosion of bank sediments along reservoir margins is a complex process that is influenced by the cumulative effects of: wind and boat wave erosion, reservoir currents, precipitation runoff, freeze-thaw, soil properties, exposure, and vegetation density and type. One commonly observed process is that, during times of extended reservoir drawdown, exposed un-vegetated shoreline soils that were previously saturated are prone to erosion and localized slope failures (slumping). The shoreline exposure metric was developed as a surrogate for shoreline erosion processes. This metric compares the number of days that the reservoir water surface spends at any elevation to identify change in shoreline exposure and indicate the potential for change in shoreline erosion in the WVS storage projects. Shoreline processes leave long-term marks on the land, reworking soils and exposing underlying layers.

The simplest metric is a reservoir elevation exceedance percentage analysis. Comparison of the reservoir elevation exceedance percentage between alternatives would demonstrate the range of reservoir operations. If the range and duration of the reservoir elevations changes, there is a potential that the shoreline erosion rates, or patterns, may change. While the shoreline exposure metric does not directly consider reservoir draft rate, it does represent the duration effects that could result from draft rate operational measures. See Appendix C, Section 1.3.1 for additional details on the shoreline exposure metric calculation and magnitude thresholds.

Shoreline exposure effects may vary in magnitude, but would be long-term, as long as the alternative operation set remains in effect, and local to the reservoir where the draft is occurring.

**Head of Storage Reservoir Sediment Mobilization**

The head-of-reservoir sediment mobilization metric is designed to indicate the potential for changes in sediment scour and deposition patterns in the most upstream portion of storage reservoirs. In dams that use large amounts of storage volume and operate over a wide range of elevations throughout the year, the transition from riverine to reservoir conditions can shift upstream and downstream considerable distances. If reservoir drawdown leaves the delta exposed during high-flow periods, the upper layers of delta would be eroded and transported further into the reservoir, potentially increasing turbidity within the reservoir and thickness of lakebed deposits. Changes in storage project elevations or changes to the flow of water and sediment into the reservoir can result in changes to the head-of-reservoir erosion and deposition patterns. This metric compares the paired relationships of flow and stage over time to indicate the potential for change in sediment mobilization at the head-of-reservoir for each alternative. Changes in delta sediment mobilization could alter the sediment load farther downstream within the reservoir and potentially the amount of sediment passing a dam, particularly during high-flow periods. See Appendix C, Section 1.3.2 for additional details on the head of reservoir sediment mobilization metric calculation and magnitude thresholds.

Head of reservoir sediment mobilization effects may vary in magnitude, but would be long-term, as long as the alternative operation set remains in effect, and local to the reservoir where the change in the metric is occurring.

**Sediment Trap Efficiency**

The sediment trap efficiency metric estimates the potential for changes in the amount of sediment that can deposit within or pass through the storage reservoirs. Trap efficiency is the proportion of inflowing sediment deposited in the reservoir relative to the total incoming sediment load. The trap efficiency is computed based on the ratio of reservoir storage volume to annual inflow. Because the volume of water stored at any given time in the storage projects can vary between alternatives, there is potential for the amount of material being deposited in the reservoir to change between alternatives. This metric compares the paired relationship of flow and reservoir storage to indicate the potential for changes in the amount of sediment being trapped by the storage projects for each action alternative relative to the NAA. The actual amount of sediment trapped is dependent not only on trap efficiency but also the incoming sediment load. See Appendix C, Section 1.3.3 for additional details on the sediment trap efficiency metric calculation and impact thresholds.

Sediment trap efficiency effects may vary in magnitude, but would be long-term, as long as the operation set remains in effect, and local to the reservoir where the change in the metric is occurring. Indirect effects of sediment being transported downstream of a dam are expressed in the run-of-river reservoir and free-flowing reach metric, potential changes in sediment supply.

#### *3.3.2.1.3 Run-of-River Reservoirs and Free-Flowing Reach Metrics*

Run-of-river reservoirs and free-flowing reaches include all the river reaches downstream of WVS storage projects. Run-of-river reservoirs are formed by dams that are operated to discharge water downstream at rates that generally match the upstream inflows. Big Cliff, and Dexter dams are run-of-river projects that operate in a small range of pool elevations for daily or weekly hydropower purposes but do not attempt to store water for release in later seasons. Foster Dam is considered both a storage and a run-of-river project in this analysis as it is partially operated to re-regulate the outflows from Green Peter. Free-flowing reaches are portions of the river downstream of WVS storage reservoirs that are not influenced by the backwater of a downstream reservoir. The run-of-river and free-flowing reach metrics are necessarily qualitative due to a lack of continuous bed material sediment data or lack of continuous and integrated hydraulic modeling.

**Potential for Change in Sediment Supply**

This metric estimates the potential for changes in sediment passing WVS projects relative to NAA. This can occur when WVS storage projects experience large changes in sediment trapping efficiency. This can also occur where there is a change in operational range of the WVS reservoirs that can potentially re-entrain sediment currently stored in the reservoir or induce slope failures and introduce new sediment to the system. This metric also addresses the gravel augmentation below dams (#384) measure where sediment supply would be actively augmented.

The sediment supply analysis assumes that sediment supply from rivers upstream of WVS projects, or tributaries to WVS impacted reaches that are not downstream of a WVS reservoir, would be unchanged relative to the NAA.

The sediment trap efficiency metric integrates coincident daily reservoir inflow with storage to estimate trapping efficiency. This calculation focuses on sediment delivered to the reservoir from the watershed with the sediment load assumed to be correlated to inflow. Decreases in sediment trapping efficiency indicate that the reservoir would have the potential to deliver more sediment downstream and is considered in the potential for change in sediment supply metric.

A separate potential source of sediment to the reservoir can come from bank erosion or bank failures within the reservoir itself. Drafts deeper than those historically experienced have the potential to re-suspend stored sediments or induce landslides (USACE 2003) introducing new sediment to the reservoir. The timing of these deep drawdowns is not correlated to reservoir inflow and are not fully captured in the sediment trap efficiency metric. Deeper drafts are assumed to increase the potential for sediment re-entrainment supplying additional suspended sediment to the reservoir. Whether this sediment would settle within the reservoir or pass downstream would depend on sediment particle size and hydraulics within the reservoir. Lacking detailed data for both factors, reduction in minimum pool storage relative to the NAA, which is coincident with drafts, is used to indicate if there is a change in potential for sediment to pass the reservoir.

Sediment augmentation though spawning gravel nourishment or geomorphic process-based sediment nourishment below target WVS projects in included in the gravel augmentation below dams (#384) measure. A direct introduction of bed material to the system would change sediment supply in a known and controlled manner.

See Appendix C, Section 1.4.1 for additional details on the potential for change in sediment supply metric calculation and magnitude thresholds.

Potential for changes in sediment supply effects may vary in magnitude, but would be long-term, as long as the alternative operation set or gravel augmentation below dams (#384) measure remains in effect. Potential for changes in sediment supply effects would be local to regional with fine grained sediments capable of passing from an upstream reach to downstream reaches. Changes in sediment supply from WVS projects due to changes in system operations are indirect effects, while gravel augmentation below dams (#384) effects would be direct.

**Potential for Geomorphic Change**

This metric estimates the potential for changes in river character due to operations proposed by the action alternatives. System wide morphological change, away from the NAA, would be dependent on changes to flood flow frequency, changes to bank stabilization, or changes in sediment supply. The Proposed Action is not proposing any measures or a suite of measures that change flood flow frequency and as such, morphologic changes or processes that are driven by high flows would be unchanged from the NAA. Measure 9, maintain revetments considering nature-based engineering or alter revetments for aquatic ecosystem restoration, does propose to implement maintenance actions that incorporate nature-based engineering options. This would locally change habitat but maintain the river stabilization purposes and geomorphic trajectory of the revetment. Also proposed in measure 9 also seeks opportunities for working with non-federal sponsors to study and work through processes for substantial alternation. These project would be brought under the Continuing Authority Program Section 1135 and would be require analysis a compliance actions consistent with the authority. While there is opportunity for localized or potentially larger geomorphologic effects due to revetment alternation, the location and scale are unknown at this time and would be analyzed for effects in future planning. The remaining actions that could impact geomorphic trends are those that change sediment supply to the system. See Appendix C, Section 1.4.2 for additional details on the potential for geomorphic change metric calculation and magnitude thresholds.

Potential for geomorphic change effects may vary in magnitude but would be long-term as geomorphic effects manifest over long periods of time and persist beyond immediate action. Potential for geomorphic change would be local to regional with change in sediment supply effecting both the immediate reach below a WVS dam and downstream reaches. Potential for geomorphic change due to changes in system operations are indirect effects, while gravel augmentation below dams (#384) effects would be direct.

#### *3.3.2.1.4 Construction*

This PEIS discusses general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure would be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects.

Direct effects to sediment supply associated with many construction activities (such as fish facility construction and revetment modifications) would include releases of fine-grained sediment during installation and removal of coffer dams, fish exclusions or water management activities. Sediment management limiting sediment releases would occur during the construction period. Following the completion of construction actions, local sediment supply would return to existing conditions.

Construction of the WTC towers at Detroit, Lookout Point, Green Peter, and Hills Creek may require reservoir drawdowns and pool restrictions over several years. A long drawdown may also be necessary at Cougar to construct the outlet works for the routine use of the diversion tunnel. During the construction activities, a lower pool at each of these reservoirs would mean notably reduced conservation season water storage. In the winter, each reservoir could be subject to pool restrictions over the construction period, which may impact flood risk management operations. Deeper reservoir drafts have the potential change head of reservoir sediment deposition patterns and mobilize stored sediment within the reservoir, increasing suspended sediment concentrations within and downstream of the reservoir. Winter pool restrictions would have the potential to decrease sediment trapping efficiency of the reservoir, increasing fine-grained sediment releases from the stage restricted reservoirs during high flow winter events.

#### *3.3.2.1.5 Climate Change*

Supplemental Climate Change Information- Appendix F2 and Willamette Basin Climate Change Qualitative Assessment-Appendix F1, describe projected climate change trends likely to be experienced in the WVS. The supplemental appendix also identifies relevant climate factors or hydrology and climate variables that may change and have a consequential impact to the PEIS resource areas. The climate change factors of most importance to the hydraulics resource area are projected future changes in precipitation (rainfall and snow), rates of peak and average streamflow, snowpack and flow volumes, and wildfire intensity/frequency.

There is a causal relationship between wildfires and increased sediment supply observed in the Pacific Northwest and elsewhere. The dominant processes for increased supply in the Pacific Northwest are dry ravel in the short-term following fire and hillslope failure with associated debris flows in the longer-term (Alden Research Laboratory Inc. 2021). Ravel occurs when wildfires disturb or eliminate vegetation and other organic structures that hold loose material on steep slopes. This material can lead to debris flows during the wet season in the Pacific Northwest as material collected in valley and channel bottoms is moved downstream during high peak flow events. Hillslope failure is exacerbated in the years post wildfire by the loss of shear strength in the soils as tree roots decay, typically 5-10 years post-fire (Wondzell and King 2003Surface erosion and shallow channels cut into the soil by the erosive action of flowing water (rilling) during direct runoff in a minor factor in sediment supply changes in the Pacific Northwest due to low rainfall intensity and high infiltration rates (Alden Research Laboratory Inc. 2021). Increases in annual very high fire danger days are assumed to be directly related to an increase in acres burned by severe forest fires, and therefore, an increase in basin sediment supply, particularly in portions of the basin with steeper topography.

Sediment transport and many geomorphic processes associated with river and streams are dominated by high flows and associated high energies in the river. Changes in peak flows or changes in the duration of high flow can both increase the sediment transport capability of a river and increase the potential for larger scale geomorphic change (such as bar growth, bank erosion or avulsions). It is assumed that higher peak flows or longer durations of high flow are correlated to increases in sediment transport and geomorphic change. With the presence of flood storage projects that can trap sediment and regulate peak flood flows in the basin, the expected changes in the regulated reaches would be largely mitigated. Unregulated rivers and would more directly show the potential sediment supply, transport and geomorphic changes associated with climate change.

These climate change factors as well as the climate change analysis performed in the Hydrologic Processes, section 3.2, were used to qualitatively assess the expected effects to the system under NAA and all Alternatives.

#### *3.3.2.2 No Action Alternative*

Environmental consequences under the NAA are defined as the geomorphology and sediment transport conditions that would be expected within the WVS study area, without any changes in system configuration, maintenance, or operation. For this NAA assessment, future geomorphology and sediment transport conditions are evaluated for the next 30 years. River mechanics metrics related to the NAA are generally described below from a process-based perspective.

Under the NAA, climatic conditions, land use patterns, and the amount of sediment entering the reservoirs from upstream are all expected to remain the same as historically experienced. Climatic conditions, land use, and precipitation are major drivers for sediment erosion and yield into the river system. The range of precipitation is expected to be within the historical range experienced, including some very wet and some very dry years. Land use is anticipated to follow similar patterns as currently experienced, with discrete population centers in some areas, but with a large portion of the watershed held as public lands. Sources of sediment such as agricultural fields are expected to continue cultivation in a manner similar to the current conditions. Under the NAA, the sediment loading throughout the basin is not expected to change from the historical range experienced.

Under the NAA, water storage patterns are expected to be generally within the same range as historically experienced. There is a wide range in the water elevation in the storage reservoirs depending on the season and precipitation, and this variation would continue to control the location of the transition between riverine and reservoir conditions. The flow rates and project operating stages within the system are expected to remain within the historical range of variations. The incoming flow rate and downstream stage within a river segment or reservoir directly affect the hydraulic grade, which is the primary driver of sediment transport and suspension.

Shoreline erosion occurs to varying degrees in the storage reservoirs, depending on water level, wind (wave erosion), ice, currents, and other processes. Under the NAA, the duration and timing of reservoir water levels are not expected to change compared to the historical range. Similarly, it is anticipated that winds, freeze-thaw patterns, and flow rates within the reservoir would be within the historically experienced range.

Sediment would continue to deposit at the head of reservoirs (deltas) due to the slow-velocity backwater zone caused by the dams. Erosion and transport of head of reservoir sediment is expected to continue as a result of fluctuating reservoir pools. The transport of sediment from the head of the reservoir (delta) further downstream are expected to remain within the historically experienced range.

Reservoirs would continue to trap incoming sediment due to the slow-velocity backwater pool created by the dams. The amount of sediment trapped in storage reservoirs is expected to be within historical levels, since the reservoir operations and sediment loading are not expected to change. A portion of the incoming sediment load would continue to pass run-of-river reservoirs and free-flowing reaches at magnitudes and rates similar to those historically experienced.

Bed material erosion and deposition patterns, bank erosion and avulsion rates and overall geomorphic character would continue to be altered by the WVS, since flow rates, operational stages, and sediment loading to the system are expected to be similar to historical ranges. Federal revetments would continue to function to limit bank erosion and avulsion. Rates of change and process would continue as described in the affected environment. Deposition and finer bed-material gradation in run-of-river reservoir downstream of storage projects is expected to continue in areas backwatered by dams.

##### *3.3.2.2.1 Lower Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the Lower Willamette, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.4). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic regime, sediment sources and loading, and sediment properties while the operations stay unchanged.

##### *3.3.2.2.2 Middle Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the Middle Willamette, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.5). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

##### *3.3.2.2.3 Upper Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the Upper Willamette, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.6). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

##### *3.3.2.2.4 North Santiam*

**Storage Projects – Detroit Dam**

Under the NAA in Detroit Reservoir, negligible change is expected in storage project metrics for head of reservoir sediment mobilization, trap efficiency, and shoreline exposure, indicating that these processes would continue as generally described in the Affected Environment (Section 3.3.1.3). The negligible change in these metrics results from negligible change in water storage patterns, seasonal reservoir elevations, sediment loading, and sediment properties.

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the North Santiam, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.7). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

#### *3.3.2.2.5 South Santiam and Mainstem Santiam*

**Storage Projects – Green Peter and Foster**

Under the NAA in Green Peter and Foster reservoirs, negligible change is expected in Storage Project metrics for head of reservoir sediment mobilization, trap efficiency, and shoreline exposure, indicating that these processes would continue as generally described in the Affected Environment (Section 3.3.1.3). The negligible change in these metrics results from negligible change in water storage patterns, seasonal reservoir elevations, sediment loading, and sediment properties.

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the South Santiam and Mainstem Santiam, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.8). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

#### *3.3.2.2.6 Long Tom River*

**Storage Projects – Fern Ridge**

Under the NAA in Fern Ridge Reservoir, negligible change is expected in storage project metrics for head of reservoir sediment mobilization, trap efficiency, and shoreline exposure, indicating that these processes would continue as generally described in the Affected Environment (Section 3.3.1.3). The negligible change in these metrics results from negligible change in water storage patterns, seasonal reservoir elevations, sediment loading, and sediment properties.

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the Long Tom, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.9). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

#### *3.3.2.2.7 McKenzie and Blue Rivers*

**Storage Projects – Cougar and Blue River**

Under the NAA in Cougar and Blue River reservoirs, negligible change is expected in storage project metrics for head of reservoir sediment mobilization, trap efficiency, and shoreline exposure, indicating that these processes would continue as generally described in the Affected

Environment (Section 3.3.1.3). The negligible change in these metrics results from negligible change in water storage patterns, seasonal reservoir elevations, sediment loading, and sediment properties.

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the McKenzie and Blue River, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.10). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

##### *3.3.2.2.8 Middle Fork of the Willamette River and Fall Creek*

**Storage Projects – Fall Creek, Lookout Point and Hills Creek**

Under the NAA in Fall Creek, Lookout Point and Hills Creek reservoirs, negligible change is expected in storage project metrics for head of reservoir sediment mobilization, trap efficiency, and shoreline exposure, indicating that these processes would continue as generally described in the Affected Environment (Section 3.3.1.3). The negligible change in these metrics results from negligible change in water storage patterns, seasonal reservoir elevations, sediment loading, and sediment properties.

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the Middle Fork of the Willamette and Fall Creek, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.11). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

##### *3.3.2.2.9 Coast Fork of the Willamette River and Row Rivers*

**Storage Projects – Cottage Grove and Dorena**

Under the NAA in Cottage Grove and Dorena reservoirs, negligible change is expected in storage project metrics for head of reservoir sediment mobilization, trap efficiency, and shoreline exposure, indicating that these processes would continue as generally described in the Affected Environment (Section 3.3.1.3). The negligible change in these metrics results from negligible change in water storage patterns, seasonal reservoir elevations, sediment loading, and sediment properties.

**Run-of-River Reservoir and Free-Flowing Reaches**

Under the NAA in the Coast Fork of the Willamette, negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment (Sections 3.3.1.3 and 3.3.1.12). The negligible change in these metrics results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

*3.3.2.2.10 Climate Change*

Site specific variation is described in the climate change technical appendices (F1 and F2). However, the following climate trends are applicable to the wider WRB. Temperatures in the region are expected to warm relative to the historic period 1970-1999 by another 1.5 to 3 deg F by about mid-century and 2 to 5 deg F by the end. Already scarce winter snowpack is likely to decline over time as more winter precipitation falls as rain instead of snow. The projections are for future precipitation to trend upward for the rest of the century, particularly in the winter months. Already dry summers could become drier. Overall, the climate change assessments point to fall and winter flows likely increasing.

Additionally, the number of days with very high fire danger in any given year are projected to increase in all of the WVS subregions. Supplemental Climate Change Information Appendix F2 shows a consistent trend across all WVS subbasins, with a projected increase in median "Annual Very High Fire Danger Day" from 36 days in 1971-2020 to 49 days by 2040-2069. This increase in fire danger days is expected to correlate to increased land area impacted by wildfire and increased sediment supply from dry ravel, slope failure, and debris flows as described in Section 3.3.1.3.

The transition toward increased wintertime flow volumes, and potentially flood magnification, along with reduced snowpack and increased potential for wildfires, create the conditions for increased sediment supply to the Willamette River and its tributaries. Sediment transport throughout the system is correlated with flow, with higher flows moving more sediment. However, sediment must be available to the river for it to be transported. Sediment supply, for both coarse- and fine-grained sediment, is expected to increase generally in the system due to reduction in snow cover, which protects lands from erosion and wildfires that further destabilize soil and slopes. Morphological change, in the forms of bed and bank erosion, deposition, or even avulsion, is dominated by flood hydraulics. The potential for increase flood magnitude, along with increased sediment supply, increases the potential for morphological change.

The WVS dams would continue to trap sediment and effectively trap all coarse-grained material (with the exception of Fall Creek which currently experiences run-of-river depth drafts) and a large proportion of the fine-grained sediment. The volume of trapped sediment would likely increase under climate change but is not expected to change the flood storage volume of the system through deposition. Additional coarse sediment supplied to the reservoirs would predominately deposit at the head of reservoir while the fine sediment would distribute throughout the reservoir.

Turbidity in the system would likely increase as unregulated streams experience increased sediment supply; however, the WVS dams would continue to moderate peak suspended sediment concentrations in the regulated reaches downstream from the dams due to continued high rates of sediment trapping.

Flood regulation is expected to continue at similar magnitudes, effectively reducing peak flows downstream of the WVS projects. Morphological trends related to dam operations in the system are expected to be minorly effected from non-climate change scenarios. Unregulated steams may increase winter flow and sediment supply to the system under climate change, resulting in moderate effects with more dynamic morphology, particularly at unregulated tributary confluences.

##### *3.3.2.2.11 Summary of Effects of the No Action Alternative*

Under the NAA, negligible change is expected in storage project metrics for head of reservoir sediment mobilization, trap efficiency, and shoreline exposure, indicating that these processes would continue as generally described in the Affected Environment throughout the WVS. The negligible effect results from negligible change in water storage patterns, seasonal reservoir elevations, sediment loading, and sediment properties.

Negligible change is expected in the run-of-river reservoir and free-flowing reach metrics for potential changes in sediment supply or geomorphic change, indicating that these processes would continue at magnitudes and rates similar to those described in the Affected Environment. The negligible effect results from negligible change in flow rates, operating levels, hydraulic energy regime, sediment sources and loading, and sediment properties.

#### ***3.3.2.3 Alternative 1***

See Section 2.4.3 for a complete description of Alternative 1. Alternative 1 effects would be relative to the NAA and are summarized by impact type in this section. See Appendix C, Chapter 2 for metric calculations and supporting figures.

##### *3.3.2.3.1 Lower Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Lower Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Lower Willamette free-flowing reach.

#### *3.3.2.3.2 Middle Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Middle Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Middle Willamette free-flowing reach.

#### *3.3.2.3.3 Upper Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Upper Willamette free-flowing reach from the Coast Fork Willamette when compared to the NAA. Increased sediment supply would be due to deeper drafts in Cottage Grove and Dorena reservoirs that have the potential to induce bank erosion, and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is negligible potential for geomorphic change relative to the NAA in the Upper Willamette free-flowing reach.

#### *3.3.2.3.4 North Santiam*

**Storage Projects – Detroit Dam**

Alternative 1 would have negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at Detroit Reservoir compared to the NAA. Alternative 1 would have a major change in shoreline exposure relative to NAA at Detroit Reservoir due to changes in operational range. Deeper drafts would expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts would also allow access to reservoir banks that were previously inundated.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into Big Cliff run-of river reservoir compared to the NAA. Increased sediment supply is due to deeper drafts in Detroit Reservoir increasing the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Big Cliff Reservoir may partially settle in the reservoir.

There would be a major change in coarse-grained bed material sediment supply to the North Santiam free-flowing reach due to direct placement of bed material sized sediment through an adaptively managed sediment nourishment program compared to the NAA. Additionally, there is potential for a minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply would be due to deeper drafts in Detroit Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Big Cliff run-of-river reservoir.

***Geomorphic Change Below Big Cliff***

There is major potential for geomorphic change in the North Santiam downstream of Big Cliff Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Sediment augmentation into the North Santiam River below Big Cliff Dam is proposed to improve the quality and quantity of habitat for Spring Chinook and Winter Steelhead. The North Santiam below Big Cliff has been largely scoured of appropriately sized spawning gravels and has developed an armored bed between bedrock grade control. Gravel augmentation below dams (#384) would annually place an appropriate quantity of specifically sized and graded sediments into the river prior to seasonal high flows and spawning. The placed material would be distributed by the river during high flows into bank attached bars and bed patches and would transiently fill existing pools. This sediment augmentation would likely deposit on top of existing armored river features and be mobile during high water events and water years, with gravels scouring and cleaning themselves as they pulse downstream.

Since the North Santiam River is capable of scouring out these size classes of sediment and armoring its bed in the existing condition, placed gravel would be expected to transport, abrade to smaller material, and deposit for longer term storage in bars and backwaters over time. An ongoing program of annual or semiannual sediment placement is proposed to maintain long term spawning gravel bars and beds downstream of the dam.

Placed sediment would be screened for only bed material, therefore transport rates and distances would be limited in any given water year. Gravel pulses are expected to transport downstream at a rate of approximately 1 mile per year as observed in the long running gravel augmentation project below Howard Hansen Dam in the Green River (USACE 2018).

Sediment placement would partially fill the channel and replace a portion of the sediment that has scoured since Dam development and regulation. Channel aggradation, to the extent that it occurs, is based on sediment augmentation quantity and sizing. It is expected that aggradation would occur as bed material pulses move downstream and becomes quasi-stable as augmentation sediment is scoured and replaced in roughly the same quantities. Flood capacity of the channel may be impacted by placed sediments, however the placed sediment and resulting transient river features are only expected to replace a portion of historical sediment that has scoured from the river.

River condition and water surface monitoring, along with gravel augmentation below dams (#384) that may change the quantity, size or injection location of sediment augmentation, would identify and respond to river changes to improve targeted river feature creation and limit adverse effects.

#### *3.3.2.3.5 South Santiam and Mainstem Santiam*

**<u>Storage Projects – Green Peter and Foster</u>**

Alternative 1 would have negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at Green Peter and Foster reservoirs as compared to the NAA. Alternative 1 would have a negligible change in shoreline exposure relative to NAA at Foster Reservoir.

Alternative 1 would have a major change in shoreline exposure relative to NAA at Green Peter Reservoir due to changes in operational range. Deeper drafts would expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts would also allow access to reservoir banks that were previously inundated under the NAA.

**<u>Run-of-River Reservoir and Free-Flowing Reaches</u>**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into Foster Reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Green Peter Reservoir increasing the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Foster Reservoir may partially settle in the reservoir.

There is a major change in coarse-grained bed material sediment supply to the South Santiam free-flowing reach due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a minor change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Green Peter Dam and partially through Foster Reservoir.

***Geomorphic Change Below Foster Dam***

There is major potential for geomorphic change in the South Santiam downstream of Foster Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Sediment augmentation into the South Santiam River below Foster Dam is proposed to improve the quality and quantity of habitat for Spring Chinook and Winter Steelhead. The South Santiam below Foster has been largely scoured of appropriately sized spawning gravels and has developed an armored bed between bedrock grade control. Gravel augmentation below dams (#384) would annually place an appropriate quantity of specifically sized and graded sediments into the river prior to seasonal high flows and spawning. The placed material would be distributed by the river during high flows into bank attached bars and bed patches and would transiently fill existing pools. This sediment augmentation would likely deposit on top of existing armored river features and be mobile during high water events and water years, with gravels scouring and cleaning themselves as they pulse downstream.

Since the South Santiam River is capable of scouring out these size classes of sediment and armor its bed in the existing condition, placed gravel would be expected to transport, abrade to smaller material, and deposit for longer term storage in bars and backwaters over time. An ongoing program of annual or semiannual sediment placement is proposed to maintain long term spawning gravel bars and beds downstream of the Dam.

Placed sediment would be screened for only bed material, therefor transport rates and distances would be limited in any given water year. Gravel pulses are expected to transport downstream at a rate of approximately 1 mile per year as observed in the long running gravel augmentation project below Howard Hansen Dam in the Green River (USACE 2018a).

Sediment placement would partially fill the channel and replace a portion of the sediment that has scoured since Dam development and regulation. Channel aggradation, to the extent that it occurs, is based on sediment augmentation quantity and sizing. It is expected that aggradation would occur as bed material pulses move downstream and then become quasi-stable as augmentation sediment is scoured and replaced in roughly the same quantities. Flood capacity of the channel may be impacted by placed sediments, however the placed sediment and resulting transient river features are only expected to replace a portion of historical sediment that has scoured from the river.

River condition and water surface monitoring, along with gravel augmentation below dams (#384) that may change the quantity, size or injection location of sediment augmentation, would identify and respond to river changes to improve targeted river feature creation and limit adverse effects.

##### *3.3.2.3.6 Long Tom River*

**Storage Projects – Fern Ridge**

Alternative 1 would have negligible change in the potential for shoreline exposure, head-of-reservoir sediment mobilization and sediment trap efficiency at Fern Ridge Reservoir as compared to the NAA.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Long Tom River free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Long Tom River free-flowing reach.

##### *3.3.2.3.7 McKenzie and Blue Rivers*

**Storage Projects – Cougar and Blue River**

Alternative 1 would have major changes in shoreline exposure relative to NAA due to changes in operational range at Cougar and Blue River reservoirs. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 1 would have negligible potential for changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Cougar and Blue River reservoirs.

Alternative 1 would have negligible potential for changes in sediment trap efficiency relative to NAA at Cougar and Blue River reservoirs.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is a major change in coarse-grained bed material sediment supply to the McKenzie River free-flowing reach below Cougar Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a minor change compared to the NAA in fine-grained sediment supply to the McKenzie River downstream of Cougar Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Cougar Reservoir increasing the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is a major change in coarse-grained bed material sediment supply to the Blue River free-flowing reach below Blue River Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a moderate change compared to the NAA in fine-grained sediment supply to the Blue River downstream of Blue River Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Blue River Reservoir increasing the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

***Geomorphic Change Below Cougar Dam***

There is major potential for geomorphic change in the South Fork McKenzie downstream of Cougar Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Sediment augmentation in the South Fork McKenzie River below Cougar Dam is proposed to maintain and enhance the existing high quality and quantity of habitat for Spring Chinook and Winter Steelhead developed in the reach since 2018. Gravel augmentation below dams (#384) would annually place an appropriate quantity of specifically sized and graded sediments into the river prior to seasonal high flows and spawning. The placed material would be distributed by the river during high flows and integrate itself into the existing anastomosing mosaic downstream established during prior river restoration activities. Sediments are expected to move slowly through the restoration reach and potentially store for longer periods of time as normative river process occur.

Because the armored plane bed condition of the river has already been addressed by restoration actions, the goal of the augmentation is to supply required sediment into an existing process-based floodplain reengagement action. The gradation classes of the augmentation would necessarily be more varied and smaller than a typical confined valley spawning gravel augmentation project.

River condition monitoring, along with gravel augmentation below dams (#384) that may change the quantity, size or injection location of sediment augmentation, would identify and respond to river changes to improve targeted habitat maintenance goals and limit adverse effects.

***Geomorphic Change Below Blue River Dam***

There is major potential for geomorphic change compared to the NAA in the Blue River and potentially in the mainstem McKenzie downstream of Blue River Dam due to the gravel augmentation below dams (#384) measure. Sediment augmentation into the Blue River below Blue River Dam is proposed to improve the quality and quantity of habitat for Spring Chinook and Winter Steelhead. The Blue River below the dam has been largely scoured of appropriately sized spawning gravels and has developed an armored bed between bedrock grade control. Gravel augmentation below dams (#384) would annually place an appropriate quantity of specifically sized and graded sediments into the river prior to seasonal high flows and spawning. The placed material would be distributed by the river during high flows into bank attached bars and bed patches and would transiently fill existing pools. This sediment augmentation would likely deposit on top of existing armored river features and be mobile during high water events and water years, with gravels scouring and cleaning themselves as they pulse downstream.

Since the South Santiam River and sediment starved reaches of the McKenzie are capable of scouring out these size classes of sediment and armor their bed in the existing condition, placed gravel would be expected to transport, abrade to smaller material, and deposit for longer term storage in bars and backwaters over time. An ongoing program of annual or semiannual sediment placement is proposed to maintain long term spawning gravel bars and beds downstream of the Dam.

Placed sediment would be screened for only bed material, therefor transport rates and distances would be limited in any given water year. Gravel pulses are expected to transport downstream at a rate of approximately 1 mile per year as observed in the long running gravel augmentation project below Howard Hansen Dam in the Green River (USACE 2018a). Due to the relatively short length of the Blue River below the dam, augmentation is expected to work its way into the mainstem McKenzie within a few years of initiation.

Sediment placement would partially fill the channel and replace a portion of the sediment that has scoured since Dam development and regulation. Channel aggradation, to the extent that it occurs, is based on sediment augmentation quantity and sizing. It is expected that aggradation would occur as bed material pulses move downstream and then become quasi-stable as augmentation sediment is scoured and replaced in roughly the same quantities. Flood capacity of the channel may be impacted by placed sediments, however the placed sediment and resulting transient river features are only expected to replace a portion of historical sediment that has scoured from the river.

River condition and water surface monitoring, along with gravel augmentation below dams (#384) that may change the quantity, size or injection location of sediment augmentation, would identify and respond to river changes to improve targeted river feature creation and limit adverse effects.

##### *3.3.2.3.8 Middle Fork of the Willamette River and Fall Creek*

**Storage Projects – Fall Creek, Lookout Point and Hills Creek**

Alternative 1 would have a negligible change in shoreline exposure relative to NAA at Fall Creek Reservoir as compared to the NAA. Alternative 1 would have a major change in shoreline exposure relative to NAA at Lookout Point and Hills Creek reservoirs due to changes in operational range. Deeper drafts expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts also allow access to reservoir banks that were previously inundated.

Alternative 1 would have negligible potential for changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Fall Creek, Hills Creek and Lookout Point reservoirs.

Alternative 1 would have negligible potential for changes in sediment trap efficiency relative to NAA at Fall Creek, Hills Creek and Lookout Point reservoirs.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing out of Hills Creek dam into the Middle Fork of the Willamette above Lookout Point Reservoir free-flowing reach as compared to the NAA. Increased sediment supply is due deeper drafts that have the potential to induce bank erosion and pass fine-grained sediment out of Hills Creek Dam. This fine-grained sediment is expected to pass into Lookout Point Reservoir and deposit.

There is potential for a minor change compared to the NAA in sediment supply with additional fine-grained sediment passing into Dexter run-of-river reservoir. Increased sediment supply is due to deeper drafts in Lookout Point Reservoir increasing the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Dexter Reservoir may settle in the reservoir.

There is negligible potential for change in sediment supply downstream of Dexter Dam.

There is negligible potential for geomorphic change relative to the NAA in the Middle Fork of the Willamette River and Fall Creek free-flowing reach.

*3.3.2.3.9 Coast Fork of the Willamette River and Row River*

**Storage Projects – Cottage Grove and Dorena**

Alternative 1 would have a major change in shoreline exposure relative to NAA at Cottage Grove and Dorena reservoirs due to changes in operational range. Deeper drafts expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts also allow access to reservoir banks that were previously inundated.

Alternative 1 would have negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at Cottage Grove and Dorena reservoirs as compared to the NAA.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Coast Fork Willamette and Row River free-flowing reaches from Cottage Grove and Dorena River as compared to the NAA. Increased sediment supply is due deeper drafts in Cottage Grove and Dorena reservoirs that have the potential to induce bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is negligible potential for geomorphic change relative to the NAA in the Coast Fork of the Willamette River and Row River free-flowing reach.

*3.3.2.3.10 Climate Change*

Alternative 1 would have negligible potential for change in sediment conditions due to climate change relative to the NAA.

*3.3.2.3.11 Summary of Effects of Alternative 1*

Table 3.3-2 shows the summary of effects under Alternative 1.

**Table 3.3-2. Summary of effects for River Mechanics and Geomorphology under Alternative 1 as Compared to the NAA**

| Subbasin | Alternative 1 |
|---|---|
| **General** | Effects to river mechanics and geomorphology metrics are none/negligible except those stated below. |
| **Santiam Subbasin** | Detroit and Green Peter storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts.<br><br>Downstream of the storage projects, there is potential for a moderate effects with an increase in fine grained sediment supply |

| | |
|---|---|
| | into the Big Cliff and Foster re-regulation projects which in turn may pass a minor increase in fine grained sediment downstream into the free-flowing reaches.<br><br>Gravel augmentation below dams (#384) measure will have major effects to geomorphology downstream of Big Cliff and Foster dams and would modify the geomorphology of the North Fork Santiam and South Fork Santiam respectively. |
| **Long Tom Subbasin** | Negligible effects |
| **McKenzie Subbasin** | Cougar and Blue River storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts.<br><br>Downstream of the storage projects, there is potential for a minor effects with an increase in fine grained sediment supply into the South Fork McKenzie and a moderate increase of fine-grained sediment supply into Blue River.<br><br>Gravel augmentation below dams (#384) measure would have major effects to geomorphology downstream of the South Fork McKenzie and Blue River dams and would modify the geomorphology of the South Fork McKenzie and Blue River respectively. |

| **Coast Fork of the Willamette Subbasin** | Dorena and Cottage Grove storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts.<br><br>Downstream of both storage projects, there is potential for a moderate effect with an increase in fine grained sediment supply into the Row River and Coast Fork Willamette. |
| **Mainstem Willamette River** | Negligible effects |

### 3.3.2.4 Alternative 2A

See Section 2.4.4 for a complete description of Alternative 2A. Alternative 2A effects are relative to the NAA and are summarized by impact type in this section. See Appendix C, Chapter 2 for metric calculations and supporting figures.

#### *3.3.2.4.1 Lower Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There would be negligible potential for changes in sediment supply relative to the NAA in the Lower Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Lower Willamette free-flowing reach.

#### *3.3.2.4.2 Middle Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Middle Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Middle Willamette free-flowing reach.

#### *3.3.2.4.3 Upper Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Upper Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Upper Willamette free-flowing reach.

#### *3.3.2.4.4 North Santiam*

**Storage Projects – Detroit Dam**

Alternative 2A would have negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at Detroit Reservoir as compared to the NAA. Alternative 2A would have a major change in shoreline exposure relative to NAA at Detroit Reservoir due to changes in operational range. Deeper drafts expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts also allow access to reservoir banks that were previously inundated.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into Big Cliff run-of river reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Detroit Reservoir increasing the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Big Cliff Reservoir may partially settle in the reservoir.

There is a major change compared to the NAA in coarse-grained bed material sediment supply to the North Santiam free-flowing reach due to direct placement of bed material sized sediment through gravel augmentation below dams (#384). Additionally, there is potential for a minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Detroit Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Big Cliff run-of-river reservoir.

***Geomorphic Change Below Big Cliff***

There is major potential for geomorphic change in the North Santiam downstream of Big Cliff Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Geomorphic effects below Big Cliff Dam as the same as Alternative 1. See the Section 3.3.2.3.4 for description of effects.

*3.3.2.4.5 South Santiam and Mainstem Santiam*

**Storage Projects – Green Peter and Foster**

Alternative 2A would have major changes in shoreline exposure relative to NAA due to changes in operational range at Green Peter Reservoir. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated. Alternative 2A would have negligible change in shoreline exposure at Foster Reservoir as compared to the NAA.

Alternative 2A would have the potential for a major change in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Green Peter Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 2A would have the potential for minor change in head-of-reservoir sediment mobilization relative to NAA in Foster Reservoir. This is due to changes in operations at Green Peter Reservoir upstream. Peak flows entering Foster Reservoir when the pool is drawn down are decreased, however there is an increase in fall flows when the reservoir is full. There is minor potential for future head-of-reservoir deposition to occur higher in the reservoir relative to NAA.

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 2A would have the potential for moderate changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Green Peter Reservoir. Alternative 2A would have negligible potential for changes in sediment trap efficiency relative to NAA at Foster Reservoir. Potential changes in reservoir sediment trap efficiency in all cases are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a major change in sediment supply with additional fine-grained sediment passing into Foster reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Green Peter Reservoir. The primary mechanism that is causing the effect determination is deeper drafts create major potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. Additionally, there is a moderate decrease in trapping efficiency at Green Peter Reservoir where the dam passes additional inflowing sediment during high flow events. These additional fine-grained sediments that enter Foster Reservoir may partially settle in the reservoir.

There is a major change, compared to the NAA, in coarse-grained bed material sediment supply to the South Santiam free-flowing reach due to direct placement of bed material sized sediment through gravel augmentation below dams (#384). Additionally, there is potential for a moderate change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Green Peter Dam and partially through Foster Reservoir.

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Mainstem Santiam free-flowing reach from the both the North Fork and South Fork Santiam Rivers as compared to the NAA. Increased sediment supply is due deeper drafts in Green Peter and Detroit reservoirs that have major potential pass additional fine-grained sediment downstream of the dams.

***Geomorphic Change in Foster Run-of-River Reservoir***

Due to the potential for a major change in fine-grained sediment supply into Foster Reservoir from Green Peter draw downs, observable changes in sedimentation rates in Foster Reservoir compared to the NAA are likely. Trapping efficiency for Foster is calculated to be 67% meaning that a portion of the increased fine-grained sediment supply would likely get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Foster reservoir.

***Geomorphic Change Below Foster Dam***

There is major potential for geomorphic change in the South Santiam downstream of Foster Dam due the gravel augmentation below dams (#384) measure as compared to the NAA. Geomorphic effects below Foster Dam as the same as Alternative 1. See Section 3.3.2.3.5 for description of effects.

*3.3.2.4.6 Long Tom River*

**Storage Projects – Fern Ridge**

Alternative 2A would have negligible change from the NAA in the potential for shoreline exposure, head-of-reservoir sediment mobilization and sediment trap efficiency at Fern Ridge Reservoir.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Long Tom River free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Long Tom River free-flowing reach.

*3.3.2.4.7 McKenzie and Blue Rivers*

**Storage Projects – Cougar and Blue River**

Alternative 2A would have major changes in shoreline exposure relative to NAA due to changes in operational range at Cougar and Blue River reservoirs. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 2A would have negligible potential for changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Cougar and Blue River reservoirs.

Alternative 2A would have negligible potential for changes in sediment trap efficiency relative to NAA at Cougar and Blue River reservoirs.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is a major change in coarse-grained bed material sediment supply to the McKenzie River free-flowing reach below Cougar Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a minor change in fine-grained sediment supply to the McKenzie River downstream of Cougar Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Cougar Reservoir increasing the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is a major change, compared to the NAA, in coarse-grained bed material sediment supply to the Blue River free-flowing reach below Blue River Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384). Additionally, there is potential for a moderate change in fine-grained sediment supply to the Blue River downstream of Blue River Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Blue River Reservoir increasing the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

***Geomorphic Change Below Cougar Dam***

There is major potential for geomorphic change in the South Fork McKenzie downstream of Cougar Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Geomorphic effects of gravel augmentation below Cougar Dam as the same as Alternative 1. See the Geomorphic Change Below Cougar Dam discussion in Alternative 1 for description of effects.

***Geomorphic Change Below Blue River Dam***

There is major potential for geomorphic change compared to the NAA in the Blue River and potentially in the mainstem McKenzie downstream of Blue River Dam due to the gravel augmentation below dams (#384) measure. Geomorphic effects of gravel augmentation below Blue River Dam as the same as Alternative 1. See Section 3.3.2.3.7 for description of effects.

#### *3.3.2.4.8 Middle Fork of the Willamette River and Fall Creek*

**<u>Storage Projects – Fall Creek, Lookout Point and Hills Creek</u>**

Alternative 2A would have negligible change relative to the NAA in shoreline exposure at Fall Creek Reservoir. Alternative 2A would have major changes in bank exposure relative to NAA due to changes in operational range at Hills Creek and Lookout Point reservoirs. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 2A would have negligible potential for changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Fall Creek, Hills Creek and Lookout Point reservoirs.

Alternative 2A would have negligible potential for changes in sediment trap efficiency relative to NAA at Fall Creek, Hills Creek and Lookout Point reservoirs.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing out of Hills Creek dam into the Middle Fork of the Willamette above Lookout Point Reservoir free-flowing reach relative to the NAA. Increased sediment supply is due deeper drafts that have the potential to induce bank erosion and pass fine-grained sediment out of Hills Creek Dam. This fine-grained sediment is expected to pass into Lookout Point Reservoir and deposit.

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into Dexter run-of-river reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Lookout Point Reservoir increasing the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Dexter Reservoir may settle in the reservoir.

There is negligible potential for change in sediment supply downstream of Dexter Dam.

There is negligible potential for geomorphic change relative to the NAA in the Middle Fork of the Willamette River and Fall Creek free-flowing reaches.

*3.3.2.4.9 Coast Fork of the Willamette River and Row Rivers*

**Storage Projects – Cottage Grove and Dorena**

Alternative 2A would have negligible change in the potential for shoreline exposure, head-of-reservoir sediment mobilization and sediment trap efficiency at Cottage Grove and Dorena reservoirs relative to the NAA.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Coast Fork of the Willamette River and Row River free-flowing reaches. There is negligible potential for geomorphic change relative to the NAA in the Coast Fork of the Willamette River and Row River free-flowing reaches.

*3.3.2.4.10 Evaluation of Near-Term Operations Measure*

**Lower Willamette**

***Run-of-River Reservoir and Free-Flowing Reaches***

There is negligible potential for changes in sediment supply relative to the NAA in the Lower Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Lower Willamette free-flowing reach.

**<u>Middle Willamette</u>**

***Run-of-River Reservoir and Free-Flowing Reaches***

There is negligible potential for changes in sediment supply relative to the NAA in the Middle Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Middle Willamette free-flowing reach.

**<u>Upper Willamette</u>**

***Run-of-River Reservoir and Free-Flowing Reaches***

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Upper Willamette free-flowing reach from the Middle Forks of the Willamette and the McKenzie River as compared to the NAA. Increased sediment supply is due to deeper drafts in Fall Creek, Lookout Point, Blue River and Cougar reservoirs that have the potential to pass additional fine-grained sediment downstream. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

There is negligible potential for geomorphic change relative to the NAA in the Upper Willamette free-flowing reach.

**<u>North Santiam</u>**

The near-term operations measure within the North Santiam Basin includes Fall/Winter downstream fish passage through the upper regulating outlets and spring fish passage through strategic use of spillway and turbines at Detroit Dam and spreading spill to reduce total dissolved gas at Big Cliff Dam.

***Storage Projects – Detroit Dam***

The Near-Term operations measure would have negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at Detroit Reservoir as compared to the NAA. Although the Near-term Operation at Detroit do not affect reservoir levels, the assumed flow under the "Integrated Temperature and Habitat Flow Regime" measure would impact reservoir levels and would result in a major change in shoreline exposure relative to NAA at Detroit Reservoir due to changes in operational range. Deeper drafts expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts also allow access to reservoir banks that were previously inundated. Changes in shoreline exposure would last as long at the Near-Term operations measure is in effect.

***Run-of-River Reservoir and Free-Flowing Reaches***

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into Big Cliff run-of river reservoir relative to the NAA. Increased sediment supply is due to deeper drafts in Detroit Reservoir increasing the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Big Cliff Reservoir may partially settle in the reservoir. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

There is potential for a minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff Dam with additional fine-grained sediment passing the dam relative to the NAA. Increased fine-grained sediment supply is due deeper drafts in Detroit Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Big Cliff run-of-river reservoir. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

**South Santiam and Mainstem Santiam**

The near-term operations measure within the South Santiam Subbasin include outplanting of adult Chinook above Green Peter Reservoir, downstream fish passage at Green Peter Dam via the spillway in the spring and fall, and downstream fish passage at Foster via the spillway in the spring and fall.

***Storage Projects – Green Peter and Foster***

The Near-Term operations measure would have major changes in shoreline exposure relative to NAA due to changes in operational range at Green Peter Reservoir. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated. The Near-Term operations measure would have negligible change in shoreline exposure at Foster Reservoir as compared to the NAA. Changes in shoreline exposure would last as long at the Near-Term operations measure is in effect.

The Near-Term operations measure would have the potential for a major change in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Green Peter Reservoir relative to the NAA. Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. The Near-Term operations measure would have negligible change in head-of-reservoir sediment mobilization relative to NAA at Foster Reservoir. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Potential for Head-of-Reservoir Sediment Mobilization would last as long at the Near-Term operations measure is in effect.

The Near-Term operations measure would have the potential for moderate changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Green Peter Reservoir. The Near-Term operations measure would have minor potential for changes in sediment trap efficiency relative to NAA at Foster Reservoir. Potential changes in reservoir sediment trap efficiency in all cases are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream. Potential for changes in sediment trap efficiency would last as long at the Near-Term operations measure is in effect.

***Run-of-River Reservoir and Free-Flowing Reaches***

There is potential for a major change in sediment supply with additional fine-grained sediment passing into Foster Reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Green Peter Reservoir. The primary mechanism that is causing the effect determination is that deeper drafts create major potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. Additionally, there is a moderate decrease in trapping efficiency at Green Peter Reservoir where the dam passes additional inflowing sediment during high flow events relative to the NAA. These additional fine-grained sediments that enter Foster Reservoir may partially settle in the reservoir. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

There is potential for a moderate change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster Dam with additional fine-grained sediment passing the dam as compared to the NAA. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Green Peter Dam and partially through Foster Reservoir. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Mainstem Santiam free-flowing reach from the both the North Fork and South Fork Santiam Rivers relative to the NAA. Increased sediment supply is due deeper drafts in Green Peter and Detroit reservoirs that have major potential pass additional fine-grained sediment downstream of the dams. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

<u>Geomorphic Change in Foster Run-of-River Reservoir</u>

Due to the potential for a major change in fine-grained sediment supply into Foster Reservoir from Green Peter draw downs, observable changes in sedimentation rates in Foster Reservoir are likely relative to the NAA. Trapping efficiency for Foster is calculated to be 67% meaning that a portion of the increased fine-grained sediment supply would likely get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Foster reservoir.

**Long Tom River**

There are no local operations proposed under the near-term operations measure within the Long Tom subbasin

***Storage Projects – Fern Ridge***

The Near-Term operations measure would have negligible change from the NAA in the potential for shoreline exposure, head-of-reservoir sediment mobilization and sediment trap efficiency at Fern Ridge Reservoir.

***Run-of-River Reservoir and Free-Flowing Reaches***

There is negligible potential for changes in sediment supply relative to the NAA in the Long Tom River free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Long Tom River free-flowing reach.

**McKenzie and Blue Rivers**

The near-term operations measure within the McKenzie Subbasin includes spring and fall drawdown for fish passage at Cougar Reservoir to a target elevation of 1505 feet.

***Storage Projects – Cougar and Blue River***

The Near-Term operations measure would have major changes in shoreline exposure relative to NAA due to changes in operational range at Cougar and Blue River reservoirs. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated. Potential for changes in shoreline exposure would last as long at the Near-Term operations measure is in effect.

The Near-Term operations measure would have the potential for minor changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Cougar Reservoir. There is minor potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream. The Near-Term operations measure would have the potential for negligible changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Blue River Reservoir.

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir. Potential for Head-of-Reservoir Sediment Mobilization would last as long at the Near-Term operations measure is in effect.

The Near-Term operations measure would have the potential for minor changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Cougar Reservoir. The Near-Term operations measure would have the potential for negligible changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Blue River Reservoir. Potential changes in reservoir sediment trap efficiency in all cases are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream. Potential for changes in sediment trap efficiency would last as long at the Near-Term operations measure is in effect.

***Run-of-River Reservoir and Free-Flowing Reaches***

There is potential for a moderate change in fine-grained sediment supply to the McKenzie River downstream of Cougar Dam, and the Blue River downstream of Blue River Dam, with additional fine-grained sediment passing the dam as compared to the NAA. Increased fine-grained sediment supply is due deeper drafts in Cougar Reservoir increasing the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

**Middle Fork of the Willamette River and Fall Creek**

The near-term operations measure within the Middle Fork Willamette Subbasin includes use of the regulating outlet for downstream fish passage at Hills Creek, deep drafts for fish passage at Lookout Point in winter, use of the spillway for fish passage at Lookout Point in the spring, use of the Lookout Point regulating outlets for temperature management in the summer and fall, and deep drafts for fish passage in the fall at Fall Creek. For the operations at Lookout Point, storage at Hills Creek would be used for refilling Lookout Point in early March.

***Storage Projects – Fall Creek, Lookout Point and Hills Creek***

The Near-Term operations measure would have the potential for major changes in bank exposure relative to NAA due to changes in operational range at Lookout Point and Hills Creek reservoirs. The Near-Term operations measure would have the potential for major changes in bank exposure relative to NAA due to changes in operations that hold the pool lower for longer periods of time at Fall Creek Reservoir. Potential for changes in shoreline exposure would last as long at the Near-Term operations measure is in effect.

The Near-Term operations measure would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Fall Creek and Lookout Point reservoirs. At Fall Creek there is major potential for transient and longer-term head of reservoir sediment to deposit lower in the reservoir due to operations that hold the reservoir lower during high inflow periods. At Lookout Point there is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

The Near-Term operations measure would have the potential for minor changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Hills Creek Reservoir. There is minor potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir. Potential changes in Head-of-Reservoir Sediment Mobilization would last as long at the Near-Term operations measure is in effect.

The Near-Term operations measure would have the potential for major changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Fall Creek Reservoir. The Near-Term operations measure would have the potential for moderate changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Lookout Point Reservoir. The Near-Term operations measure would have negligible changes in sediment trap efficiency relative to NAA at Hills Creek Reservoir. Potential changes in reservoir sediment trap efficiency are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream. Potential for changes in sediment trap efficiency would last as long at the Near-Term operations measure is in effect.

#### *Run-of-River Reservoir and Free-Flowing Reaches*

There is moderate potential for changes in sediment supply relative to the NAA in the Middle Fork of the Willamette above Lookout Point Reservoir free-flowing reach. This potential increase in fine-grained sediment supply is due to deeper drafts in Hills Creek Reservoir that create major potential for bank erosion and sloughing, generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

There is potential for a major change in sediment supply into Dexter Reservoir with additional fine-grained sediment passing out of Lookout Point Dam run-of-river reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Lookout Point Reservoir. The primary mechanism that is causing the effect determination is deeper drafts in Lookout Point Reservoir that create major potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Dexter Reservoir may partially settle in the reservoir. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Middle Fork of the Willamette below Dexter Dam free-flowing reach and from Fall Creek relative to the NAA. Increased sediment supply is due deeper drafts in Lookout Point Reservoir that have potential pass additional fine-grained sediment downstream and partially through Dexter Reservoir as well as deeper draft in Fall Creek Reservoir that increase fine grained sediment supply to Fall Creek. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

There is major potential for changes in sediment supply relative to the NAA in the Fall Creek free-flowing reach downstream of Fall Creek Dam. This potential increase in fine-grained sediment supply is due to deeper drafts in Fall Creek Reservoir during higher flows that reduce trapping efficiency. Potential for changes in sediment supply due to changes in reservoir operation would last as long at the Near-Term operations measure is in effect.

Geomorphic Change in Dexter Run-of-River Reservoir

Due to the potential for a major change in fine-grained sediment supply into Dexter Reservoir from Lookout Point draw downs, observable changes in sedimentation rates in Dexter Reservoir are likely as compared to the NAA. Trapping efficiency for Dexter is calculated to be 51% meaning that a portion of the increased fine-grained sediment supply would likely get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Dexter reservoir.

**Coast Fork of the Willamette River and Row Rivers**

There are no local operations proposed under the near-term operations measure within the Coast Fork subbasin.

***Storage Projects – Cottage Grove and Dorena***

The Near-Term operations measure would have negligible change from the NAA in the potential for shoreline exposure, head-of-reservoir sediment mobilization and sediment trap efficiency at Cottage Grove and Dorena reservoirs.

***Run-of-River Reservoir and Free-Flowing Reaches***

There is negligible potential for changes in sediment supply relative to the NAA in the Coast Fork of the Willamette River and Row River free-flowing reaches. There is negligible potential for geomorphic change relative to the NAA in the Coast Fork of the Willamette River and Row River free-flowing reaches.

*3.3.2.4.11 Climate Change*

Alternative 2A would have negligible potential for change in sediment conditions due to climate change relative to the NAA in all reservoirs and reaches except Green Peter and Foster dams. Deeper drafts at Green Peter Dam have to potential to pass increased climate change driven fine grained sediment into Foster Reservoir resulting in increased deposition in Foster Reservoir and increased fine-grained sediment supply to the South Santiam downstream of Foster Dam.

*3.3.2.4.12 Summary of Effects of Alternative 2A*

Table 3.3-3 shows the summary of effects under Alternative 2A.

**Table 3.3-3. Summary of effects for River Mechanics and Geomorphology under Alternative 2A as Compared to the NAA**

| Subbasin | Alternative 2A |
|---|---|
| **General** | Effects to river mechanics and geomorphology metrics are none/negligible except those stated below. |
| **Santiam Subbasin** | Detroit and Green Peter storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts. Additionally, Green Peter would have moderate effects with decreases in sediment trap efficiency and major changes in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir.<br><br>Downstream of the storage projects, there is potential for a moderate effects with an increase in fine grained sediment supply into the Big Cliff re-regulation project which in turn may pass a minor |

### ***3.3.2.5 Alternative 2B***

See Section 2.4.5 for a complete description of Alternative 2B. Alternative 2B effects are relative to the NAA and are summarized by impact type in this section. See Appendix C, Chapter 2 for metric calculations and supporting figures.

Alternative 2B effects are the same as Alternative 2A for all geographical subregions and metrics with the exception of the Middle Willamette, Upper Willamette and the McKenzie and Blue River subregion. See section 3.3.2.4, Alternative 2A, for description of effects other than those described below.

#### *3.3.2.5.1 Middle Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Middle Willamette free-flowing reach from the Upper Willamette as compared to the NAA. Increased sediment supply is due deeper drafts in Cougar and Blue River reservoirs Reservoir that would have the potential pass additional fine-grained sediment downstream.

There is negligible potential for geomorphic change relative to the NAA in the Middle Willamette free-flowing reach.

#### *3.3.2.5.2 Upper Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Upper Willamette free-flowing reach from the McKenzie River relative to the NAA. Increased sediment supply is due deeper drafts in Cougar and Blue River reservoirs that would have the potential pass additional fine-grained sediment downstream.

There is negligible potential for geomorphic change relative to the NAA in the Upper Willamette free-flowing reach.

#### *3.3.2.5.3 McKenzie and Blue Rivers*

**Storage Projects – Cougar and Blue River**

Alternative 2B would have major changes in shoreline exposure relative to NAA due to changes in operational range at Cougar and Blue River reservoirs. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 2B would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Cougar Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Alternative 2B would have negligible potential for changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Blue River Reservoir.

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 2B would have the potential for major changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Cougar Reservoir. Potential changes in reservoir sediment trap efficiency are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream. Alternative 2B would have negligible potential for changes in sediment trap efficiency relative to NAA at Blue River Reservoir.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is a major change in coarse-grained bed material sediment supply to the McKenzie River free-flowing reach below Cougar Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) relative to the NAA. Additionally, there is potential for a major change in fine-grained sediment supply to the McKenzie River downstream of Cougar Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper draft in Cougar Reservoir that cause a major decrease in trapping efficiency and a major increase in the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is a major change in coarse-grained bed material sediment supply to the Blue River free-flowing reach below Blue River Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a moderate change in fine-grained sediment supply to the Blue River downstream of Blue River Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper draft in Blue River Reservoir that cause a moderate increase in the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

***Geomorphic Change Below Cougar Dam***

There is major potential for geomorphic change in the South Fork McKenzie downstream of Cougar Dam due to the gravel augmentation below dams (#384) measure and fine-grained passing Cougar Dam relative to the NAA. Sediment augmentation in the South Fork McKenzie River below Cougar Dam is proposed to maintain and enhance the existing high quality and quantity of habitat for Spring Chinook and Winter Steelhead developed in the reach since 2018. Gravel augmentation below dams (#384) would annually place an appropriate quantity of specifically sized and graded sediments into the river prior to seasonal high flows and spawning. The placed material would be distributed by the river during high flows and integrate itself into the existing anastomosing mosaic downstream established during prior river restoration activities. Sediments are expected to move slowly through the restoration reach and potentially store for longer periods of time as normative river process occur.

Because the armored plane bed condition of the river has already been addressed by restoration actions, the goal of the augmentation is to supply required sediment into an existing process-based floodplain reengagement action. The gradation classes of the augmentation would necessarily be more varied and smaller than a typical confined valley spawning gravel augmentation project.

River condition monitoring, along with gravel augmentation below dams (#384) that may change the quantity, size or injection location of sediment augmentation, would identify and respond to river changes to improve targeted habitat maintenance goals and limit adverse effects.

Due to the potential for a major change in fine-grained sediment supply from Cougar Dam draw downs, observable turbidity and deposition of fines is expected in the South Fork McKenzie and potentially main stem McKenzie downstream of the South Fork confluence.

***Geomorphic Change Below Blue River Dam***

There is major potential for geomorphic change in the Blue River and potentially in the mainstem McKenzie downstream of Blue River Dam due to the gravel augmentation below dams (#384) measure relative to the NAA. Geomorphic effects of gravel augmentation below Blue River Dam as the same as Alternative 1. See Section 3.3.2.3.7 for description of effects.

#### *3.3.2.5.4 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.3.3.3, for description of effects due to the Near-Term Operations Measure.

#### *3.3.2.5.5 Climate Change*

Alternative 2B would have negligible potential for change in sediment conditions due to climate change relative to the NAA in all reservoirs and reaches except Green Peter, Foster and Cougar dams and the McKenzie downstream of Cougar Dam. Deeper drafts at Green Peter Dam have to potential to pass increased climate change driven fine grained sediment into Foster Reservoir resulting in increased deposition in Foster Reservoir and increased fine-grained sediment supply to the South Santiam downstream of Foster Dam. Deeper drafts at Cougar Dam have to potential to pass increased climate change driven fine grained sediment in the South Fork McKenzie downstream of the dam.

#### *3.3.2.5.6 Summary of Effects of Alternative 2B*

Table 3.3-4 shows the summary of effects under Alternative 2B.

**Table 3.3-4. Summary of effects for River Mechanics and Geomorphology under Alternative 2B Compared to the NAA**

| Subbasin | Alternative 2B |
|---|---|
| **General** | Effects to river mechanics and geomorphology metrics are none/negligible except those stated below. |
| **Santiam Subbasin** | Detroit and Green Peter storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts. Additionally, Green Peter would have moderate effects with decreases in sediment trap efficiency and major changes in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir.<br><br>Downstream of the storage projects, there is potential for a moderate effects with an increase in fine grained sediment supply into the Big Cliff re-regulation project which in turn may pass a minor increase in fine grained sediment downstream into the North Santiam free-flowing reach. There is potential for a major effects with an increase in fine grained sediment supply to Foster reservoir from Green Peter which in partially settle in the Foster pool and in turn may pass a moderate increase in fine grained sediment supply downstream into the South Santiam.<br><br>Gravel augmentation below dams (#384) measure would have major effects to geomorphology downstream of Big Cliff and Foster dams and would modify the geomorphology of the North Fork Santiam and South Fork Santiam respectively. |
| **Long Tom Subbasin** | Negligible effects |
| **McKenzie Subbasin** | Cougar and Blue River storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts. Additionally, the Cougar storage project would have major effects with decreased sediment trapping efficiency and changes in head of reservoir sediment mobilization with sediment deposition deeper in the reservoir. |

| Subbasin | Alternative 2B |
|---|---|
| | Downstream of the storage projects, there is potential for a major effects with an increase in fine grained sediment supply into the South Fork McKenzie and a moderate effects with an increase of fine-grained sediment supply into Blue River from the reservoirs.<br><br>Gravel augmentation below dams (#384) measure would have major effects to geomorphology downstream of the South Fork McKenzie and Blue River dams and would modify the geomorphology of the South Fork McKenzie and Blue River respectively. |
| **Middle Fork of the Willamette Subbasin** | Hills Creek and Lookout Point storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts.<br><br>Downstream of the storage projects, there is potential for a moderate effect with an increase in fine grained sediment supply below Hills Creek and a minor increase in fine-grained sediment supply below Lookout Point entering Dexter Reservoir. |
| **Coast Fork of the Willamette Subbasin** | Negligible effects |
| **Mainstem Willamette River** | There is potential for a moderate effect with an increase in fine grained sediment supply entering the mainstem Willamette from the McKenzie River due to changes in operations at Cougar Dam. |

#### *3.3.2.6 Alternative 3A*

See Section 2.4.6 for a complete description of Alternative 3A. Alternative 3A effects are relative to the NAA and are summarized by impact type in this section. See Appendix C, Chapter 2 for metric calculations and supporting figures.

##### *3.3.2.6.1 Lower Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Lower Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Lower Willamette free-flowing reach.

*3.3.2.6.2 Middle Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Middle Willamette free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Middle Willamette free-flowing reach.

*3.3.2.6.3 Upper Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Upper Willamette free-flowing reach from the Coast and Middle Forks of the Willamette and the McKenzie River as compared to the NAA. Increased sediment supply is due deeper drafts in Cottage Grove, Dorena, Lookout Point, Blue River and Cougar reservoirs that have the potential pass additional fine-grained sediment downstream.

There is negligible potential for geomorphic change relative to the NAA in the Upper Willamette free-flowing reach.

*3.3.2.6.4 North Santiam*

**Storage Projects – Detroit Dam**

Alternative 3A would have the potential for major changes in shoreline exposure relative to NAA due to changes in operational range at Detroit Reservoir. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 3A would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Detroit Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoirs. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3A would have the potential for major changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Detroit Reservoir. Potential changes in reservoir sediment trap efficiency are due to operations holding the reservoir lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a major change in sediment supply with additional fine-grained sediment passing into Big Cliff run-of-river reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Detroit Reservoir. The primary mechanism that is causing the effect determination is a major decrease in trapping efficiency at Detroit Reservoir where the dam passes additional inflowing sediment during high flow events. Additionally, deeper drafts moderately increase the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Big Cliff Reservoir may partially settle in the reservoir.

There is a major change in coarse-grained bed material sediment supply to the North Santiam free-flowing reach due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) relative to the NAA. Additionally, there is potential for a moderate change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Detroit Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Big Cliff run-of-river reservoir.

***Geomorphic Change in Big Cliff Run-of-River Reservoir***

Due to the potential for a major change in fine-grained sediment supply into Big Cliff Reservoir from Detroit draw downs, observable changes in sedimentation rates in Big Cliff Reservoir are likely relative to the NAA. Trapping efficiency for Big Cliff is calculated to be 96% meaning that a large portion of the increased fine-grained sediment supply would get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Big Cliff reservoir.

***Geomorphic Change Below Big Cliff***

There is major potential for geomorphic change in the North Santiam downstream of Big Cliff Dam due to the gravel augmentation below dams (#384) measure relative to the NAA. Geomorphic effects below Big Cliff Dam as the same as Alternative 1. See the Section 3.3.2.3.4 for description of effects.

*3.3.2.6.5 South Santiam and Mainstem Santiam*

**Storage Projects – Green Peter and Foster**

Alternative 3A would have major changes in shoreline exposure relative to NAA due to changes in operational range at Green Peter Reservoir. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated. Alternative 3A would have negligible change in shoreline exposure at Foster Reservoir.

Alternative 3A would have the potential for a major change in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Green Peter Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3A would have the potential for minor change in head-of-reservoir sediment mobilization relative to NAA in Foster Reservoir. This is due to changes in operations at Green Peter Reservoir upstream. Peak flows entering Foster Reservoir when the pool is drawn down are decreased, however there is an increase in fall flows when the reservoir is full. There is minor potential for future head-of-reservoir deposition to occur higher in the reservoir relative to NAA.

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 3A would have the potential for moderate changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Green Peter Reservoir. Alternative 3B would have negligible potential for changes in sediment trap efficiency relative to NAA at Foster Reservoir. Potential changes in reservoir sediment trap efficiency in all cases are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a major change in sediment supply with additional fine-grained sediment passing into Foster Reservoir relative to the NAA. Increased sediment supply is due to deeper drafts in Green Peter Reservoir. The primary mechanism that is causing the effect determination is deeper drafts create major potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. Additionally, there is a moderate decrease in trapping efficiency at Green Peter Reservoir where the dam passes additional inflowing sediment during high flow events. These additional fine-grained sediments that enter Foster Reservoir may partially settle in the reservoir.

There is a major change in coarse-grained bed material sediment supply to the South Santiam free-flowing reach due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a moderate change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Green Peter Dam and partially through Foster Reservoir.

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Mainstem Santiam free-flowing reach from the both the North Fork and South Fork Santiam Rivers. Increased sediment supply is due deeper drafts in Green Peter and Detroit reservoirs that have major potential pass additional fine-grained sediment downstream of the dams.

***Geomorphic Change in Foster Run-of-River Reservoir***

Due to the potential for a major change in fine-grained sediment supply into Foster Reservoir from Green Peter draw downs, observable changes in sedimentation rates in Foster Reservoir are likely as compared to the NAA. Trapping efficiency for Foster is calculated to be 67%, meaning that a portion of the increased fine-grained sediment supply would likely get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Foster Reservoir.

***Geomorphic Change Below Foster Dam***

There is major potential for geomorphic change in the South Santiam downstream of Foster Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Geomorphic effects below Foster Dam as the same as Alternative 1. See Section 3.3.2.3.5 for description of effects.

*3.3.2.6.6 Long Tom River*

**Storage Projects – Fern Ridge**

Alternative 3A would have negligible change from the NAA in the potential for shoreline exposure, head-of-reservoir sediment mobilization and sediment trap efficiency at Fern Ridge Reservoir.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Long Tom River free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Long Tom River free-flowing reach.

### *3.3.2.6.7 McKenzie and Blue Rivers*

**Storage Projects – Cougar and Blue River**

Alternative 3A would have the potential for major changes in shoreline exposure relative to NAA due to changes in operational range at Cougar and Blue River reservoirs. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 3A would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Cougar Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3A would have the potential for minor changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Blue River Reservoir. There is minor potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 3A would have the potential for moderate changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Cougar Reservoir. Alternative 3A would have the potential for minor changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Blue River Reservoir. Potential changes in reservoir sediment trap efficiency in all cases are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is a major change in coarse-grained bed material sediment supply to the McKenzie River free-flowing reach below Cougar Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a moderate change in fine-grained sediment supply to the McKenzie River downstream of Cougar Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper draft in Cougar Reservoir that cause a moderate decrease in trapping efficiency and a minor increase in the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is a major change in coarse-grained bed material sediment supply to the Blue River free-flowing reach below Blue River Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) relative to the NAA. Additionally, there is potential for a moderate change in fine-grained sediment supply to the Blue River downstream of Blue River Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper draft in Blue River Reservoir that cause a minor decrease in trapping efficiency and a moderate increase in the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

***Geomorphic Change Below Cougar Dam***

There is major potential for geomorphic change in the South Fork McKenzie downstream of Cougar Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Geomorphic effects of gravel augmentation below Cougar Dam as the same as Alternative 1. See Section 3.3.2.3.7 for description of effects.

***Geomorphic Change Below Blue River Dam***

There is major potential for geomorphic change in the Blue River and potentially in the mainstem McKenzie downstream of Blue River Dam due to the gravel augmentation below dams (#384) measure relative to the NAA. Geomorphic effects of gravel augmentation below Blue River Dam as the same as Alternative 1. See Section 3.3.2.3.7 for description of effects.

*3.3.2.6.8 Middle Fork of the Willamette River and Fall Creek*

**Storage Projects – Fall Creek, Lookout Point and Hills Creek**

Alternative 3A would have the potential for major changes in bank exposure relative to NAA due to changes in operational range at Lookout Point Reservoir. The proposed operational range change at Hills Creek Reservoir is to lower the minimum pool by 1 foot which is well withing the typical daily fluctuation and wave height condition. The calculated shoreline exposure metric shows a potential for minor change in Hills Creek shoreline exposure. A minor change in shoreline exposure at Hills Creek with the reservoir being drawn deeper more frequently is an appropriate effect given the small minimum pool change. Alternative 3A would have negligible change in shoreline exposure at Fall Creek Reservoir.

Alternative 3A would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Lookout Point Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3A would have the potential for minor changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Hills Creek Reservoir. There is minor potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream

Alternative 3A would have negligible potential for changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Falls Creek Reservoir.

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 3A would have the potential for major changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Lookout Point Reservoir. Alternative 3A would have negligible potential for changes in sediment trap efficiency relative to NAA Fall Creek and Hills Creek reservoirs. Potential changes in reservoir sediment trap efficiency are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes in sediment supply relative to the NAA in the Middle Fork of the Willamette above Lookout Point Reservoir free-flowing reach.

There is potential for a major change in sediment supply into Dexter Reservoir with additional fine-grained sediment passing out of Lookout Point Dam run-of-river reservoir as compared to the NAA. Increased sediment supply is due to deeper drafts in Lookout Point Reservoir decreasing trap efficiency and increasing the potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. There is major potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. Additionally, there is a major decrease in trapping efficiency at Lookout Point Reservoir where the dam passes additional inflowing sediment during high flow events. These additional fine-grained sediments that enter Dexter Reservoir may partially settle in the reservoir.

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Middle Fork of the Willamette below Dexter Dam free-flowing reach. Increased sediment supply is due deeper drafts in Lookout Point Reservoir that have potential pass additional fine-grained sediment downstream and partially through Dexter Reservoir.

There is negligible potential for changes in sediment supply relative to the NAA in the Fall Creek free-flowing reach downstream of Fall Creek Dam.

***Geomorphic Change in Dexter Run-of-River Reservoir***

Due to the potential for a major change in fine-grained sediment supply into Dexter Reservoir from Lookout Point drafts, observable changes in sedimentation rates in Dexter Reservoir are likely. Trapping efficiency for Dexter is calculated to be 51%, meaning that a portion of the increased fine-grained sediment supply would likely get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Dexter Reservoir.

##### *3.3.2.6.9 Coast Fork of the Willamette River and Row Rivers*

**Storage Projects – Cottage Grove and Dorena**

Alternative 3A would have a major change in shoreline exposure relative to NAA at Cottage Grove and Dorena reservoirs due to changes in operational range. Deeper drafts expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts also allow access to reservoir banks that were previously inundated.

Alternative 3A would have negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at Cottage Grove and Dorena reservoirs relative to the NAA.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Coast Fork Willamette and Row River free-flowing reaches from Cottage Grove and Dorena River from the NAA. Increased sediment supply is due deeper drafts in Cottage Grove and Dorena reservoirs that have the potential to induce bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is negligible potential for geomorphic change relative to the NAA in the Coast Fork of the Willamette River and Row River free-flowing reach.

#### *3.3.2.6.10 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.3.2.4.10, for description of effects due to the Near-Term Operations Measure.

#### *3.3.2.6.11 Climate Change*

Alternative 3A would have negligible potential for change in sediment conditions due to climate change relative to the NAA in all reservoirs and reaches except Lookout Point, Dexter, Green Peter, Foster, Cougar, Detroit and Big Cliff dams. There are also potential climate change driven sediment effects in the McKenzie River downstream of Cougar Dam.

Deeper drafts at Lookout Point Dam have the potential to pass increased climate change driven fine-grained sediment into Dexter Reservoir, resulting in increased deposition in Dexter Reservoir and increased fine-grained sediment supply into the Middle Fork Willamette downstream of Dexter Dam.

Deeper drafts at Green Peter Dam have the potential to pass increased climate change driven fine-grained sediment into Foster Reservoir resulting in increased deposition in Foster Reservoir and increased fine-grained sediment supply into the South Santiam downstream of Foster Dam.

Deeper drafts at Cougar Dam have the potential to pass increased climate change driven fine-grained sediment into the South Fork McKenzie downstream of the dam.

Deeper drafts at Detroit Dam have the potential to pass increased climate change driven fine-grained sediment into Big Cliff Reservoir resulting in increased deposition in Big Cliff Reservoir and increased fine-grained sediment supply into the North Santiam downstream of Big Cliff Dam.

#### *3.3.2.6.12 Summary of Effects of Alternative 3A*

Table 3.3-5 shows the summary of effects under Alternative 3A.

**Table 3.3-5. Summary of effects for River Mechanics and Geomorphology under Alternative 3A Compared to the NAA**

| Subbasin | Alternative 3A |
|---|---|
| **General** | Effects to river mechanics and geomorphology metrics are none/negligible except those stated below. |
| **Santiam Subbasin** | Detroit storage project would have a major effect with a decrease in sediment trapping efficiency, major effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and major effect in shoreline exposure with more shoreline |

| Subbasin | Alternative 3A |
|---|---|
| | exposed due to changes in operational range and deeper drafts. Green Peter storage project would have a moderate effects with a decrease in sediment trapping efficiency, major effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and major effect in shoreline exposure with more shoreline exposed due to changes in operational range and deeper drafts.<br><br>Downstream of the storage projects, there is potential for a major effect with an increase in fine grained sediment supply into the Big Cliff and Foster re-regulation projects which would partially settle in the pools and in turn may pass a moderate increase in fine grained sediment downstream into the North and South Santiam free-flowing reaches.<br><br>Gravel augmentation below dams (#384) measure would have major effects to geomorphology downstream of Big Cliff and Foster dams and would modify the geomorphology of the North Fork Santiam and South Fork Santiam respectively. |
| **Long Tom Subbasin** | Negligible effects |
| **McKenzie Subbasin** | Cougar storage project would have a moderate effect with a decrease in sediment trapping efficiency, major effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and major effect in shoreline exposure with more shoreline exposed due to changes in operational range and deeper drafts. Blue River storage project would have a minor effects with decrease in sediment trapping efficiency, minor effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and major effect in shoreline exposure with more shoreline exposed due to changes in operational range and deeper drafts.<br><br>Downstream of the storage projects, there is potential for a moderate effect with an increase in fine grained sediment supply into the South Fork McKenzie and Blue Rivers from the reservoirs.<br><br>Gravel augmentation below dams (#384) measure would have major effects to geomorphology downstream of Big Cliff and Foster dams and would modify the geomorphology of the North Fork Santiam and South Fork Santiam respectively. |

| Subbasin | Alternative 3A |
|---|---|
| **Middle Fork of the Willamette Subbasin** | Lookout Point storage project would have a major effect with a decrease in sediment trapping efficiency, major effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and major effect in shoreline exposure with more shoreline exposed due to changes in operational range and deeper drafts. Hills Creek storage project would have minor effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and minor effect in shoreline exposure with more shoreline exposed due to deeper drafts.<br><br>Downstream of the storage projects, there is potential for a major effects with an increase in fine grained sediment supply into the Dexter re-regulation project which would partially settle in the pool and in turn may pass a moderate increase in fine grained sediment downstream into the Middle Fork Willamette free-flowing reach. |
| **Coast Fork of the Willamette Subbasin** | Dorena and Cottage Grove storage projects would have major effects in shoreline exposure due to changes in operational range and deeper drafts.<br><br>Downstream of both storage projects, there is potential for a moderate effect with an increase in fine grained sediment supply into the Row River and Coast Fork Willamette. |
| **Mainstem Willamette River** | There is potential for a minor effects with an increase in fine grained sediment supply into the Mainstem Willamette River coming from changes in operation in the Middle and Coast Forks of the Willamette and McKenzie subbasins. |

### *3.3.2.7 Alternative 3B*

See Section 2.4.7 for a complete description of Alternative 3B. Alternative 3B effects are relative to the NAA and are summarized by impact type in this section. See Appendix C, Chapter 2 for metric calculations and supporting figures.

#### *3.3.2.7.1 Lower Willamette*

**<u>Run-of-River Reservoir and Free-Flowing Reaches</u>**

There is negligible potential for changes in sediment supply relative to the NAA in the Lower Willamette free-flowing reach relative to the NAA. There is negligible potential for geomorphic change relative to the NAA in the Lower Willamette free-flowing reach.

#### *3.3.2.7.2 Middle Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Middle Willamette free-flowing reach from the Upper Willamette as compared to the NAA. Increased sediment supply is due deeper drafts in Cougar Reservoir that would have the potential pass additional fine-grained sediment downstream.

There is negligible potential for geomorphic change relative to the NAA in the Middle Willamette free-flowing reach.

#### *3.3.2.7.3 Upper Willamette*

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Upper Willamette free-flowing reach from both the Coast Fork and Middle Fork Willamette relative to the NAA. Increased sediment supply is due deeper drafts in Cottage Grove, Dorena and Lookout Point reservoirs that have the potential pass additional fine-grained sediment downstream.

There is negligible potential for geomorphic change relative to the NAA in the Upper Willamette free-flowing reach.

#### *3.3.2.7.4 North Santiam*

**Storage Projects – Detroit Dam**

Alternative 3B would have the potential for major changes in shoreline exposure relative to NAA due to changes in operational range at Detroit Reservoir. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 3B would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Detroit Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoirs. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3B would have the potential for minor changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Detroit Reservoir. Potential changes in reservoir sediment trap efficiency are due to operations holding the reservoir lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into Big Cliff run-of-river reservoir relative to the NAA. Increased sediment supply is due to deeper drafts in Detroit Reservoir. The primary mechanism that is causing the effect determination is deeper drafts in Detroit Reservoir that creates moderate potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. Additionally, there is a minor decrease in trapping efficiency at Detroit Reservoir where the dam passes additional inflowing sediment during high flow events. These additional fine-grained sediments that enter Big Cliff Reservoir may partially settle in the reservoir.

There is a major change in coarse-grained bed material sediment supply to the North Santiam free-flowing reach due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) relative to the NAA. Additionally, there is potential for a minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Detroit Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Big Cliff run-of-river reservoir.

***Geomorphic Change Below Big Cliff***

There is major potential for geomorphic change in the North Santiam downstream of Big Cliff Dam due to the gravel augmentation below dams (#384) measure as compared to the NAA. Geomorphic effects below Big Cliff Dam as the same as Alternative 1. See the Section 3.3.2.3.4 for description of effects.

*3.3.2.7.5 South Santiam and Mainstem Santiam*

**Storage Projects – Green Peter and Foster**

Alternative 3B would have major changes in shoreline exposure relative to NAA due to changes in operational range at Green Peter Reservoir. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated. Alternative 3B would have negligible change in shoreline exposure at Foster Reservoir.

Alternative 3B would have the potential for a major change in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Green Peter Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3B would have the potential for minor change in head-of-reservoir sediment mobilization relative to NAA in Foster Reservoir. This is due to changes in operations at Green Peter Reservoir upstream. Peak flows entering Foster Reservoir when the pool is drawn down are decreased, however there is an increase in fall flows when the reservoir is full. There is minor potential for future head-of-reservoir deposition to occur higher in the reservoir relative to NAA.

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 3B would have the potential for major changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Green Peter Reservoir. Alternative 3B would have negligible potential for changes in sediment trap efficiency relative to NAA at Foster Reservoir. Potential changes in reservoir sediment trap efficiency in all cases are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a major change in sediment supply with additional fine-grained sediment passing into Foster Reservoir as compared to the NAA relative to the NAA. Increased sediment supply is due to deeper drafts in Green Peter Reservoir. Deeper drafts in Green Peter Reservoir create major potential for bank erosion and sloughing, generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. Additionally, there is a major decrease in trapping efficiency at Green Peter Reservoir where the dam passes additional inflowing sediment during high flow events. These additional fine-grained sediments that enter Foster Reservoir may partially settle in the reservoir.

There is a major change in coarse-grained bed material sediment supply to the South Santiam free-flowing reach due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a moderate change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Foster run-of-river reservoir.

There is potential for a minor change in sediment supply with additional fine-grained sediment passing into the Mainstem Santiam free-flowing reach from the both the North Fork and South Fork Santiam Rivers. Increased sediment supply is due deeper drafts in Green Peter and Detroit reservoirs that have major potential pass additional fine-grained sediment downstream of the dams.

***Geomorphic Change in Foster Run-of-River Reservoir***

Due to the potential for a major change in fine-grained sediment supply into Foster Reservoir from Green Peter draw downs, observable changes in sedimentation rates in Foster Reservoir are likely as compared to the NAA. Trapping efficiency for Foster is calculated to be 67% meaning that a portion of the increased fine-grained sediment supply would likely get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Foster reservoir.

***Geomorphic Change Below Foster Dam***

There is major potential for geomorphic change in the South Santiam downstream of Foster Dam due to the gravel augmentation below dams (#384) measure. Geomorphic effects below Foster Dam as the same as Alternative 1. See Section 3.3.2.3.5 for description of effects.

*3.3.2.7.6 Tom River*

**Storage Projects – Fern Ridge**

Alternative 3B would have negligible change in the potential for shoreline exposure, head-of-reservoir sediment mobilization and sediment trap efficiency at Fern Ridge Reservoir.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is negligible potential for changes from the NAA in sediment supply relative to the NAA in the Long Tom River free-flowing reach. There is negligible potential for geomorphic change relative to the NAA in the Long Tom River free-flowing reach.

*3.3.2.7.7 McKenzie and Blue Rivers*

**Storage Projects – Cougar and Blue River**

Alternative 3B would have the potential for major changes in shoreline exposure relative to NAA due to changes in operational range at Cougar and Blue River reservoirs. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 3B would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Cougar Reservoir. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3B would have the potential for minor changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Blue River Reservoir. There is minor potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 3B would have the potential for major changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Cougar Reservoir. Alternative 3B would have the potential for minor changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Blue River Reservoir. Potential changes in reservoir sediment trap efficiency in all cases are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is a major change in coarse-grained bed material sediment supply to the McKenzie River free-flowing reach below Cougar Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) relative to the NAA. Additionally, there is potential for a major change in fine-grained sediment supply to the McKenzie River downstream of Cougar Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper draft in Cougar Reservoir that cause a major decrease in trapping efficiency and a major increase in the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is a major change in coarse-grained bed material sediment supply to the Blue River free-flowing reach below Blue River Dam due to direct placement of bed material sized sediment through gravel augmentation below dams (#384) as compared to the NAA. Additionally, there is potential for a moderate change in fine-grained sediment supply to the Blue River downstream of Blue River Dam with additional fine-grained sediment passing the dam. Increased fine-grained sediment supply is due deeper draft in Blue River Reservoir that cause a minor decrease in trapping efficiency and a moderate increase in the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

***Geomorphic Change Below Cougar Dam***

There is major potential for geomorphic change in the South Fork McKenzie downstream of Cougar Dam due to the gravel augmentation below dams (#384) measure and fine-grained passing Cougar Dam relative to the NAA. Sediment augmentation in the South Fork McKenzie River below Cougar Dam is proposed to maintain and enhance the existing high quality and quantity of habitat for Spring Chinook and Winter Steelhead developed in the reach since 2018. Gravel augmentation below dams (#384) would annually place an appropriate quantity of specifically sized and graded sediments into the river prior to seasonal high flows and spawning. The placed material would be distributed by the river during high flows and integrate itself into the existing anastomosing mosaic downstream established during prior river restoration activities. Sediments are expected to move slowly through the restoration reach and potentially store for longer periods of time as normative river process occur.

Because the armored plane bed condition of the river has already been addressed by restoration actions, the goal of the augmentation is to supply required sediment into an existing process-based floodplain reengagement action. The gradation classes of the augmentation would necessarily be more varied and smaller than a typical confined valley spawning gravel augmentation project.

River condition monitoring, along with gravel augmentation below dams (#384) that may change the quantity, size or injection location of sediment augmentation, would identify and respond to river changes to improve targeted habitat maintenance goals and limit adverse effects.

Due to the potential for a major change in fine-grained sediment supply from Cougar Dam draw downs, observable turbidity and deposition of fines is expected in the South Fork McKenzie and potentially main stem McKenzie downstream of the South Fork confluence as compared to the NAA.

***Geomorphic Change Below Blue River Dam***

There is major potential for geomorphic change in the Blue River and potentially in the mainstem McKenzie downstream of Blue River Dam due to the gravel augmentation below dams (#384) measure relative to the NAA. Geomorphic effects of gravel augmentation below Blue River Dam as the same as Alternative 1. See Section 3.3.2.3.7 for description of effects.

#### *3.3.2.7.8 Middle Fork of the Willamette River and Fall Creek*

**Storage Projects – Fall Creek, Lookout Point and Hills Creek**

Alternative 3B would have the potential for major changes in bank exposure relative to NAA due to changes in operational range at Lookout Point and Hills Creek reservoirs. Alternative 3B would have negligible change in shoreline exposure at Fall Creek Reservoir. Deeper drafts expose additional shoreline to potential bank erosion, sediment entrainment or even slope failures. Deeper drafts also allow access to banks that were previously inundated.

Alternative 3B would have the potential for major changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Lookout Point and Hills Creek reservoirs. There is major potential for stored head-of-reservoir sediment to be re-mobilized and transported further into the reservoir. Future head-of-reservoir deposition would likely deposit further into the reservoir than NAA. Potential changes in head-of-reservoir deposits are due to operations holding the reservoirs lower than NAA during higher inflow where sediment is mobilized and brought into the reservoir from upstream.

Alternative 3B would have negligible potential for changes in head-of-reservoir sediment mobilization relative to NAA due to changes in operations at Falls Creek Reservoir.

Head-of reservoir deposits are typically composed of the coarse-grained sediment supply (sand, gravels and any cobbles that may be in transport) but may also contain some of the coarser silts that can readily settle in the transition from flowing river to quiescent reservoir.

Alternative 3B would have the potential for minor changes in sediment trap efficiency with reduced trap efficiency relative to NAA at Lookout Point and Hills Creek reservoirs. Alternative 3B would have negligible potential for changes in sediment trap efficiency relative to NAA Fall Creek Reservoir. Potential changes in reservoir sediment trap efficiency are due to operations holding the reservoirs lower than NAA, resulting in sufficiently lower reservoir storage volumes, during higher inflow where sediment is mobilized and brought into the reservoir from upstream. Reductions in trap efficiency would mean that a larger fraction of easily suspended, fine-grained sediment may stay in transport and pass these dams. This results in less deposition of these fine-grained sediments in the reservoir and conversely, large quantities of easily suspended, fine-grained sediments passing the reservoir downstream.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is minor potential for changes in sediment supply relative to the NAA in the Middle Fork of the Willamette above Lookout Point Reservoir free-flowing reach. This potential increase in fine-grained sediment supply is due to deeper drafts in Hills Creek Reservoir during higher flows that reduce trapping efficiency.

There is potential for a major change in sediment supply into Dexter Reservoir with additional fine-grained sediment passing out of Lookout Point Dam run-of-river reservoir relative to the

NAA. Increased sediment supply is due to deeper drafts in Lookout Point Reservoir. The primary mechanism that is causing the effect determination is deeper drafts create major potential for bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume. These additional fine-grained sediments that enter Dexter Reservoir may partially settle in the reservoir.

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Middle Fork of the Willamette below Dexter Dam free-flowing reach as compared to the NAA. Increased sediment supply is due deeper drafts in Lookout Point Reservoir that would have potential pass additional fine-grained sediment downstream and partially through Dexter Reservoir.

There is negligible potential for changes in sediment supply relative to the NAA in the Fall Creek free-flowing reach downstream of Fall Creek Dam.

***Geomorphic Change in Dexter Run-of-River Reservoir***

Due to the potential for a major change in fine-grained sediment supply into Dexter Reservoir from Lookout Point draw downs, observable changes in sedimentation rates in Dexter Reservoir are likely relative to the NAA. Trapping efficiency for Dexter is calculated to be 51% meaning that a portion of the increased fine-grained sediment supply would likely get trapped in the reservoir. This deposition would likely appear as a thicker silt drape within the reservoir and areas along on the banks of Dexter reservoir.

*3.3.2.7.9 Coast Fork of the Willamette River and Row Rivers*

**Storage Projects – Cottage Grove and Dorena**

Alternative 3B would have a major change in shoreline exposure relative to NAA at Cottage Grove and Dorena reservoirs due to changes in operational range as compared to the NAA. Deeper drafts expose additional shoreline to potential bank erosion and sediment entrainment. Deeper drafts also allow access to reservoir banks that were previously inundated.

Alternative 3B would have negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at Cottage Grove and Dorena reservoirs.

**Run-of-River Reservoir and Free-Flowing Reaches**

There is potential for a moderate change in sediment supply with additional fine-grained sediment passing into the Coast Fork Willamette and Row River free-flowing reaches from Cottage Grove and Dorena River. Increased sediment supply is due deeper drafts in Cottage Grove and Dorena reservoirs that have the potential to induce bank erosion and sloughing generating sediment that may pass the dam due to a concurrent reduction in reservoir storage volume.

There is negligible potential for geomorphic change relative to the NAA in the Coast Fork of the Willamette River and Row River free-flowing reach.

##### *3.3.2.7.10 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.3.2.4.10, for description of effects due to the Near-Term Operations Measure.

##### *3.3.2.7.11 Climate Change*

Alternative 3B would have negligible potential for change from the NAA in sediment conditions due to climate change relative to the NAA in all reservoirs and reaches except Hills Creek, Lookout Point, Dexter, Green Peter, Foster, Cougar, Detroit and Big Cliff dams. There are also potential climate change driven sediment effects in the McKenzie River downstream of Cougar Dam and Middle Fork Willamette downstream of Hills Creek Dam.

Deeper drafts at Hills Creek Dam have the potential to pass increased climate change driven fine grained sediment in the Middle Fork Willamette downstream of the dam.

Deeper drafts at Lookout Point Dam have the potential to pass increased climate change driven fine-grained sediment into Dexter Reservoir, resulting in increased deposition in Dexter and increased fine-grained sediment supply to the Middle Fork Willamette downstream of Dexter Dam.

Deeper drafts at Green Peter Dam have the potential to pass increased climate change driven fine-grained sediment into Foster Reservoir, resulting in increased deposition in Foster Reservoir and increased fine-grained sediment supply into the South Santiam downstream of Foster Dam.

Deeper drafts at Cougar Dam have the potential to pass increased climate change driven fine grained sediment into the South Fork McKenzie downstream of the dam.

Deeper drafts at Detroit Dam have the potential to pass increased climate change driven fine-grained sediment into Big Cliff Reservoir, resulting in increased deposition in Big Cliff Reservoir and increased fine-grained sediment supply to the North Santiam downstream of Big Cliff Dam.

##### *3.3.2.7.12 Summary of Effects of Alternative 3B*

Table 3.3-6 shows the summary of effects under Alternative 3B.

**Table 3.3-6. Summary of effects for River Mechanics and Geomorphology under Alternative 3B Compared NAA**

| Subbasin | Alternative 3B |
|---|---|
| **General** | Effects to river mechanics and geomorphology metrics are none/negligible except those stated below. |
| **Santiam Subbasin** | Detroit storage project would have a minor effects with a decrease in sediment trapping efficiency, major effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and major effect in shoreline exposure with more shoreline exposed due to changes in operational range and deeper drafts. Green Peter storage project would have a major effect with a decrease in sediment trapping efficiency, major effect in head-of-reservoir sediment mobility with more sediment depositing further into the reservoir and major effect in shoreline exposure with more shoreline exposed due to changes in operational range and deeper drafts.<br><br>Downstream of the storage projects, there is potential for a moderate effect with an increase in fine grained sediment supply into the Big Cliff re-regulation project which would partially settle in the pools and in turn may pass a minor increase in fine grained sediment downstream into the North Santiam free-flowing reach. | **Mainstem Willamette River** | There is potential for a moderate effect with an increase in fine grained sediment supply entering the mainstem Willamette from the McKenzie River due to changes in operations at Cougar Dam. |

## 3.4 GEOLOGY

### 3.4.1 Affected Environment

The affected environment for geology includes dam foundations, the areas around dams and reservoirs, and all relevant features that were described in each dam's periodic inspection. It also includes the active channel of the river up to the 1% and 0.2% Annual Exceedance Probability (AEP) flood elevation (100 and 500-year flood zones, respectively) for all reaches in the Willamette Valley that contain levees and bank protection works (Figure 3.4-1).

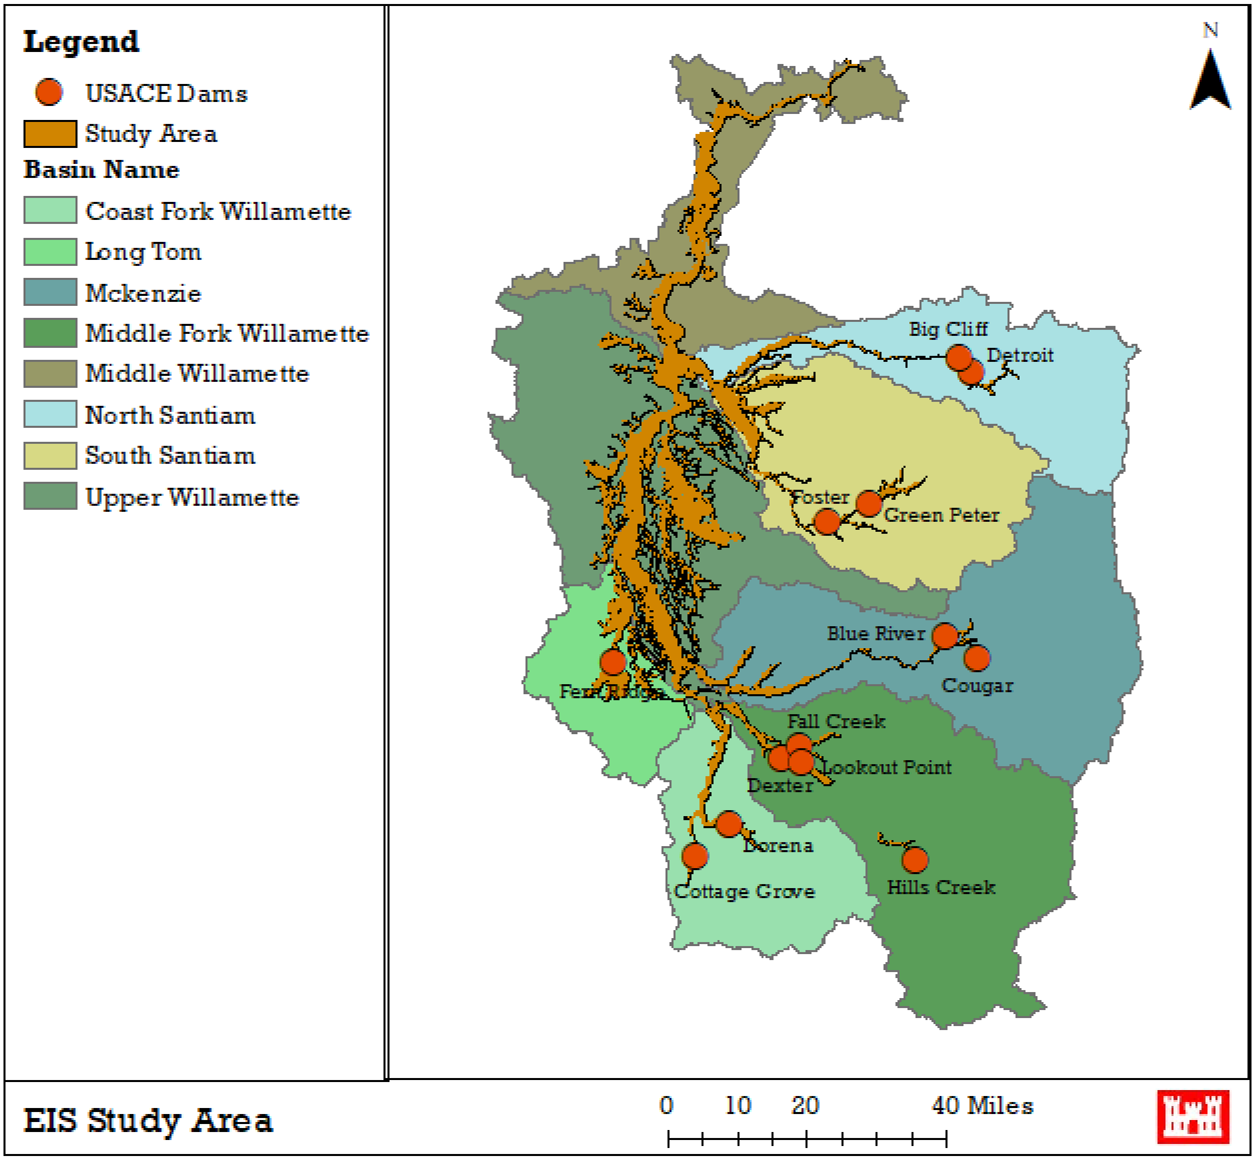

**Figure 3.4-1. Study Areas for the Willamette Valley PEIS**

### *3.4.1.1 Basin Wide*

#### *3.4.1.1.1 Geologic Physiographic Regions*

Western Oregon geology is the product of the Cascadia Subduction Zone (CSZ) and associated arc volcanism, which forms the major geologic regions in the area. The Willamette Valley hosts two provinces and three regions that have common topography, rock types and structure, and geologic and geomorphic history. These include the Middle Cascade Mountains region of the Cascade-Sierra mountains province and the Pacific Border province that is subdivided into the Puget Trough section (Willamette Valley) and Oregon Coast Range section (Fenneman and Johnson, 1946).

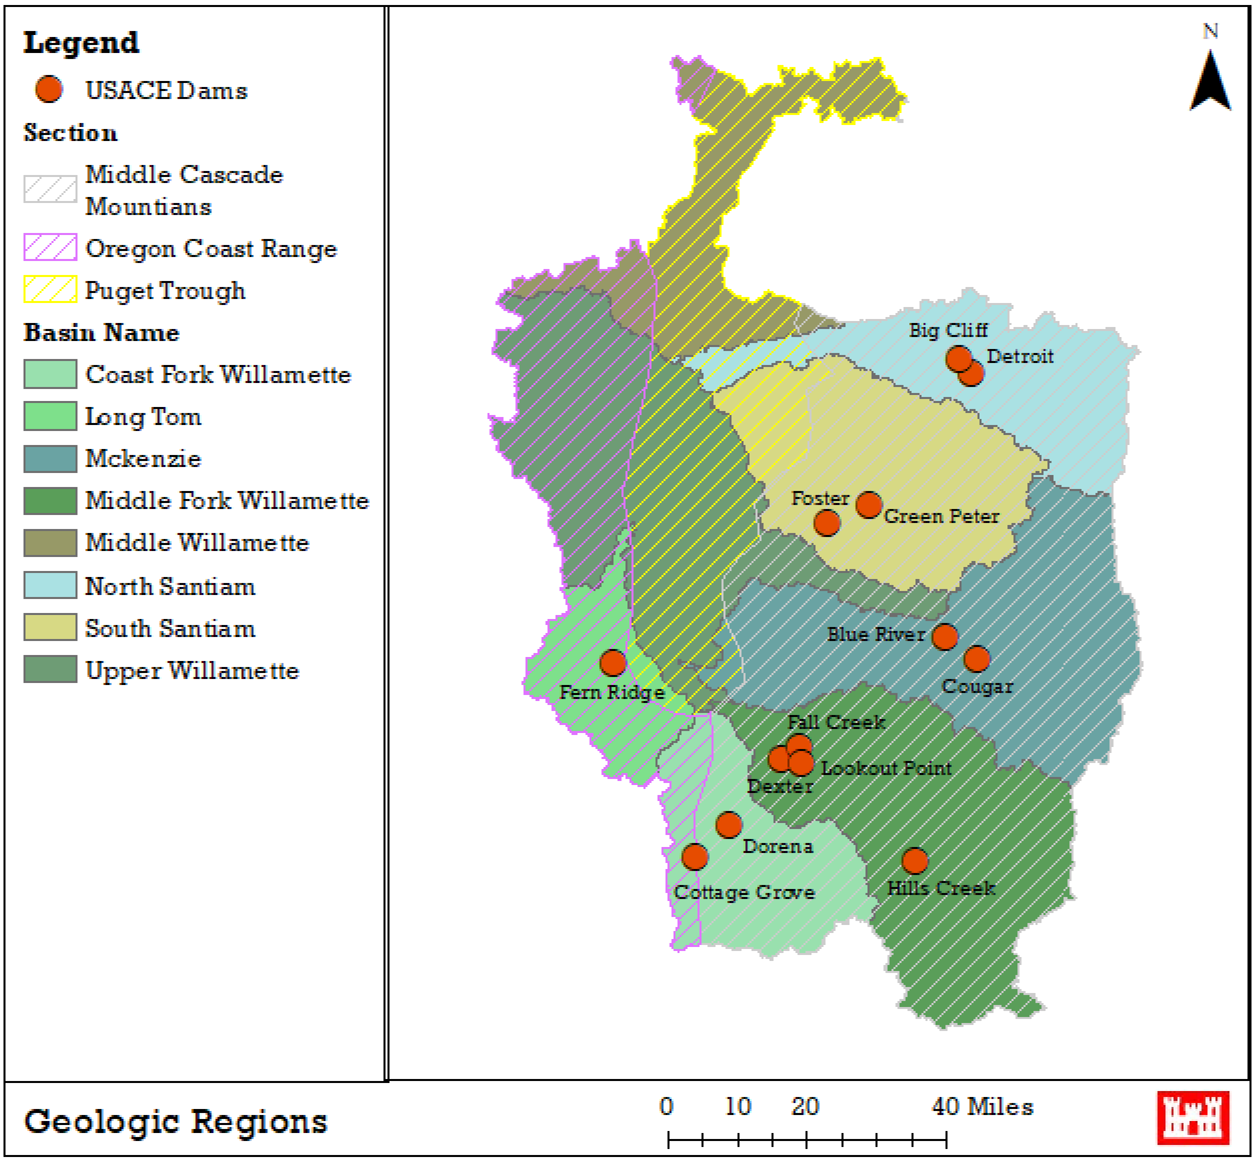

**Figure 3.4-2. Geologic Physiographic Regions of the Willamette Basin**

Source: Fenneman and Johnson, 1946

**Cascades**

The Cascades is a volcanic belt of rocks that extend from the Sierra Nevada in northern California to the Coast Mountains in British Columbia. The volcanic belt is about 80 miles wide in Washington and northern Oregon, but it narrows to about 40 to 50 miles in California. As shown in Figure 3.4-3, the range is frequently subdivided to two subprovinces, the Western Cascades and the High Cascades (Sherrod and Smith, 2000; **Error! Reference source not found.**). The Western Cascades is the older Tertiary inactive volcanic belt and forms the base of the range. The second subprovince is the High Cascades which is an active volcanic belt. The Cascades is a thick sequence 15,000 to 30,000 feet of volcanic rock. The composition of volcanic rocks ranges from basaltic to rhyolitic lava flows which are interbedded with explosive pyroclastic fragmental rocks (tuffs, breccias, lapilli tuffs, tuffaceous, ashflows, sandstone, siltstone and conglomerate). Most of the rocks in the Western Cascades have a slight hydrothermal alteration from the intrusion of monzonitic and dioritic sills and dikes in the late Miocene. The volcanic rocks are broken into numerous formations based on similar lithologic characteristics (USACE, 2017b).

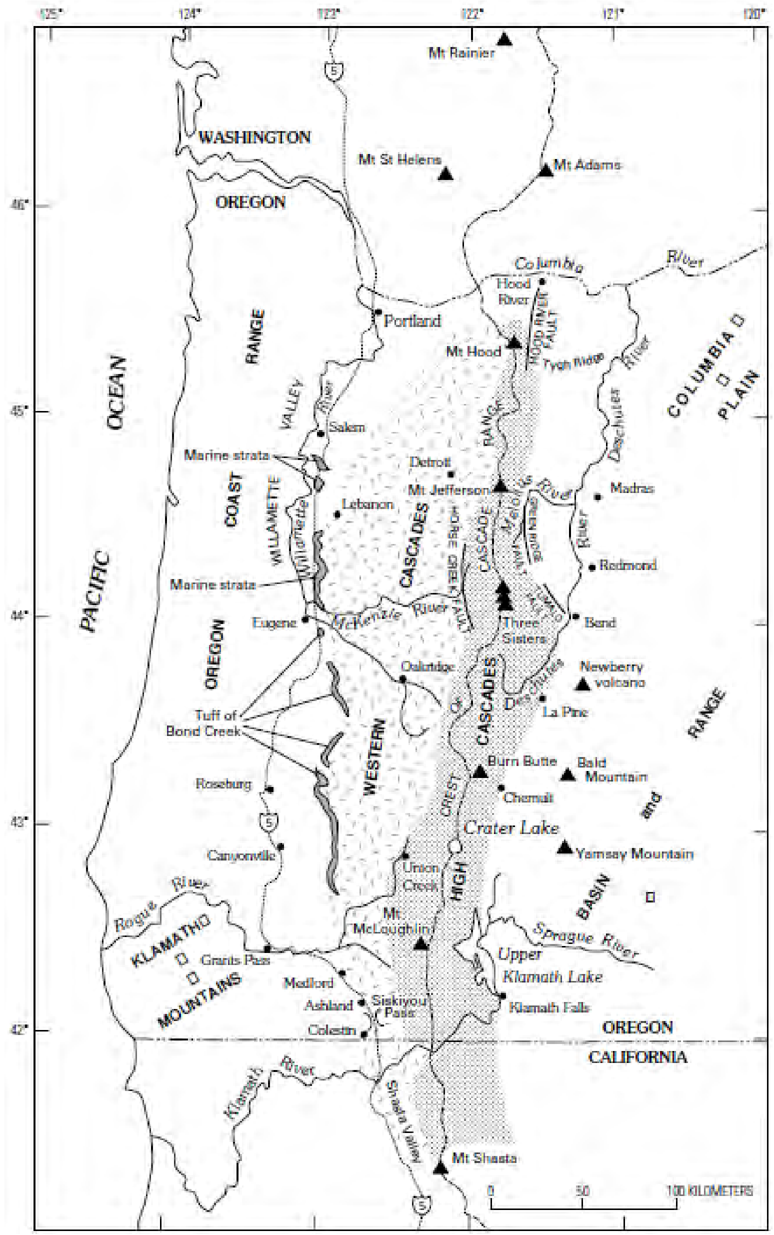

**Figure 3.4-3. Distribution of the Western and High Cascades**
Source: Sherrod and Smith, 2000)

## Oregon Coast Range and Puget Trough

The Oregon Coast Range is derived from continental arc volcanism and the accretion of marine rocks and sediments along the CSZ (McClaughry et al., 2010). Along with the volcanic rocks of the Western Cascades, it forms the basement of the Puget Trough, which is an elongated forearc basin that extends from the Puget Sound Lowland in Washington south to central Oregon (Vaccaro, 1997).

The Paleocene and Eocene mid-ocean ridge pillow basalts of the Siletz River formation form the basement of the Coast Range. The Kings Valley Formation is a siltstone containing volcanic grains from the Siletz River Formation and is interbedded in places with Siletz River volcanics.

The Eocene age Tyee Formation unconformably overlays the Siletz River Formation and contains sandstone turbidites deposited in a submarine fan and slope environment. The middle Eocene Spencer Formation includes marine sediments ranging in size from sandstone and conglomerate to sandstone and siltstone higher in the formation. It fines northward from near shore marine delta and shelf deposits near Eugene to deep water siltstone and claystone facies. The shallow-water marine deposits of the upper Eocene and Oligocene Eugene Formation overlay the Spencer Formation and contain marine sandstone, tuffaceous sandstone and siltstone, and pebbly conglomerate.

Both the Spencer and Eugene formations are interlayered with middle and upper Eocene aged nonmarine volcaniclastic sedimentary rocks, silicic tuff, and mafic lava strata of the Fisher Formation. The Eugene Formation also interfingers with the upper Eocene and lower Oligocene Keasy Formation which is composed of marine siltstone and tuffaceous siltstone and mudstone formed from volcanic lithics. The Paleocene- to lower Miocene-aged rocks are cut by a series of upper Eocene to middle-upper Miocene mafic to intermediate composition intrusive bodies including the Oligocene-aged gabbro and diorite dikes and sills of the Mary's Peak Intrusives, which form the highest peak in the coast range (McClaughry et al., 2010).

Tectonic activity during the Miocene and Pliocene uplifted the Coast Range and depressed the Puget Trough, forming a back-arc basin. During the Miocene the Columbia River Basalt Group (CRBG) lava flows entered the basin, forming the bedrock of the valley. Sediments from both the Coast and Cascade Mountain ranges and the Columbia River filled the depression.

Sediment from the Coast Range is generally clay, silt, and fine sand from weathering and erosion of marine sedimentary rocks. Sediment from the Cascades is composed of coarse sand and gravel-sized volcanic clasts. Sediments from the Columbia River are predominately derived from glacial outwash floods and include exotic quartzite, and granitic and metamorphic clasts lithologies. The Missoula Flood deposits are thicker and more extensive in the Portland Basin, but extend south past Eugene within the Willamette Basin.

Volcanic activity near Portland in the late Pliocene to early Pleistocene formed the Boring Lava Field, which contains shield volcanoes that are typically 100 to 200 feet thick but can be more than 600 feet thick. Holocene-aged alluvium in the floodplains of major streams of the foothills in the southern and central Willamette Valley predominantly contain tens of feet of sand and gravel-sized grains with some silt- and clay-sized particles. Smaller tributaries consist primarily of sand-to-clay size alluvial material. Along the Willamette River alluvium becomes progressively finer grained and thicker downstream, consisting primarily of 50-100 feet of sand and silt near Portland (Vaccaro, 1997).

#### *3.4.1.1.2 Seismicity*

The CSZ is a convergent boundary between the North America plate and the Juan de Fuca/Gorda plates from northernmost California to southernmost British Columbia. A major subduction zone “interplate” earthquake with a magnitude ($M_W$) between 8.5 and 9.2 on the Richter scale is believed to have occurred about once every 450 to 550 years (USACE, 2017d). More frequent events of smaller magnitudes (8.0 $M_W$) could occur every 200 years along the southern Oregon coast, resulting in strong ground shaking extending inland to the Willamette Valley. The last event occurred over 300 years ago on 26 January, 1700 (USACE, 2016b). The CSZ represents the main seismic source hazard for the Willamette Valley projects.

Other types of seismic events that may occur in western Oregon are deep subcrustal earthquakes that occur in the subducting slab typically at depths between 25 and 62+ miles, and crustal sources occurring within the North American plate (both along known faults and random seismicity not associated with any known faults).

The other type of earthquakes associated with the CSZ include “intraplate” earthquakes which occur within the subducting Juan de Fuca Plate. These earthquakes are generally quite deep with focal depths of 25 miles or more. The largest historical intraplate earthquakes recorded in the Pacific Northwest were the $M_W$ 7.1 Olympia earthquake in 1949, the $M_W$ 6.8 Nisqually earthquake northeast of Olympia in 2001, and the $M_W$ 6.5 Seattle-Tacoma earthquake in 1965. An intraplate event would likely have an epicenter located along the eastern margin of the Coast Range and possibly beneath the Willamette Valley (USACE, 2017d).

### *3.4.1.2 Coast Fork Willamette River*

#### *3.4.1.2.1 Basin Overview*

The Coast Fork Willamette River study area straddles the Cascades and Coast Range south of the Puget Trough. Unconsolidated deposits make up 81% of the surface area within the 1% AEP floodplain and 99% of the surface area within the 0.2% AEP floodplain. The majority of bedrock in the study area belongs to the Colestin Formation, which is the exposed oldest unit and is typically interfingered with the Eugene Formation; both are overlayed by the Little Butte Volcanics. The Colestin Formation is Eocene- and Oligocene-aged Early Western Cascade Volcanics including the andesite and volcanoclastic sedimentary rocks and tuff of the Fisher Formation and basalt (Hoover, 1963). The upper Eocene and Oligocene Eugene Formation is shallow-water marine deposits containing marine sandstone within the Coast Fork Willamette subbasin study area (McClaughry et al, 2010). The Little Butte Volcanics unit are composed of tuffs and basalt and andesite flows within the study area (Peck, 1964). There are no major quaternary faults or folds recorded in the study area.

#### *3.4.1.2.2 Dorena Dam*

In the immediate vicinity of Dorena Dam (Figure 3.4-4), the ground surface elevations range from approximately 1,200 to 2,000 feet. Lithologies near the reservoir consist of a varied and complex stratified volcanic sequence which includes basalt flows, well-bedded tuffaceous sandstones, tuffaceous pebble to cobble conglomerates, andesite flows and intrusions, tuffs, tuff breccias, and conglomeratic tuffs. Bedrock dips generally 30 degrees towards the east (upstream) and is cut by small basaltic andesite dikes, irregular intrusions and a large northwest trending fault zone.

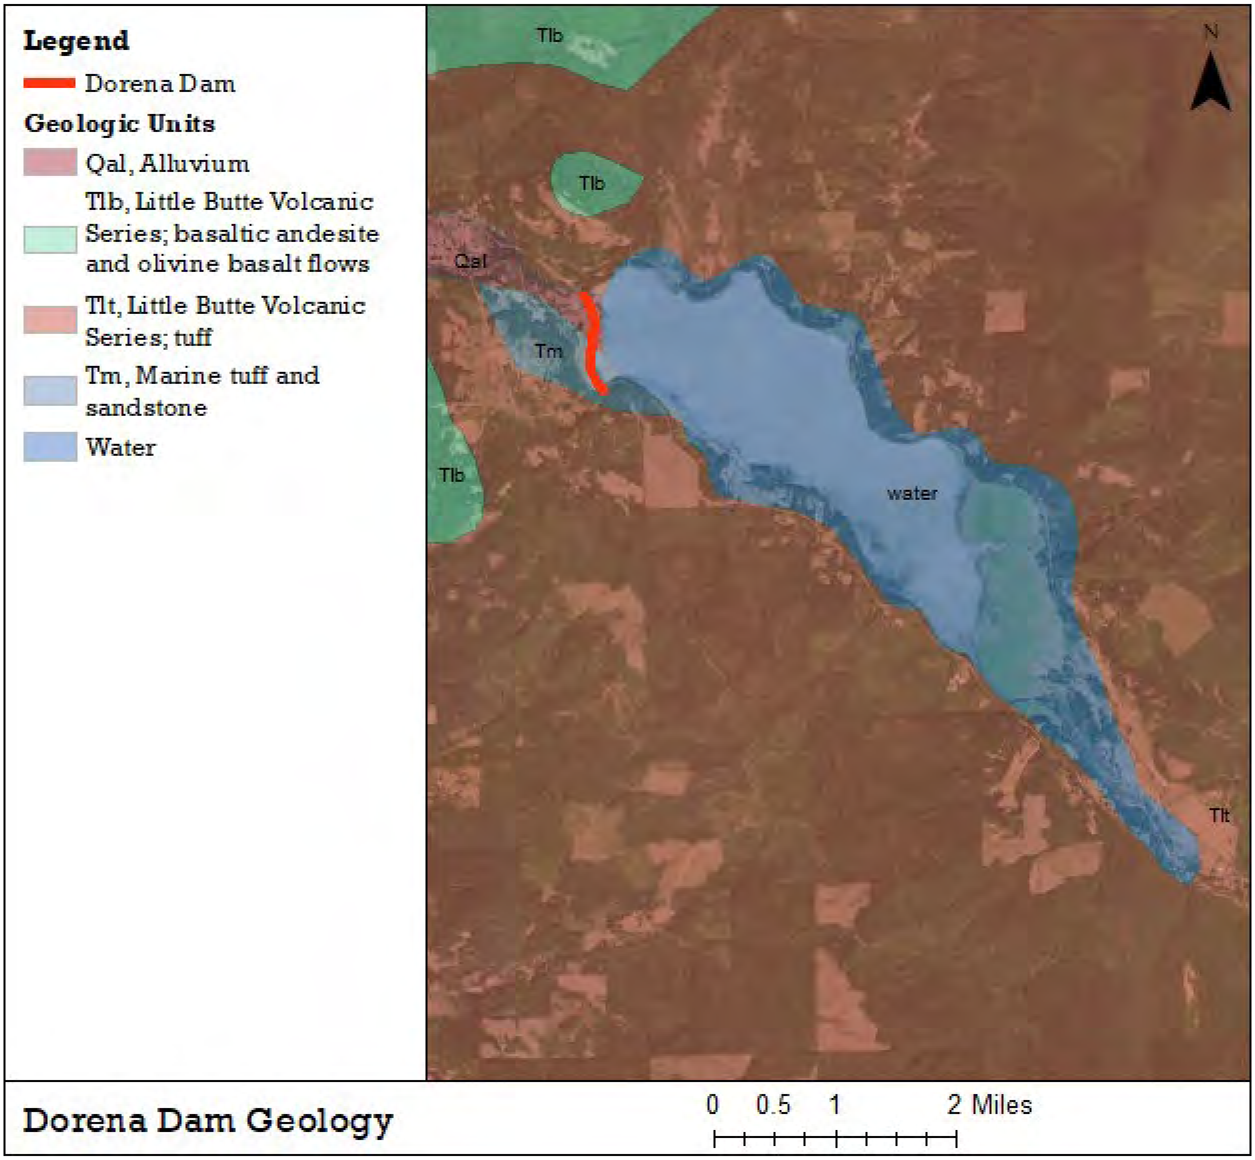

**Figure 3.4-4. Geologic Formations and Alluvial Deposits around Dorena Dam**

Source: Peck, 1964)

The valley floor is composed of approximately 10 to 20 feet of Quaternary river-deposited alluvium overlying bedrock. The upper layer of alluvium near the damsite is an average of 4 feet of low strength plastic clay and silt, underlain by approximately 15 feet of stratified alluvium containing 3-inch minus fraction gravel with 10-20% clay and silt with boulders. The foundation rock beneath the dam is predominantly andesite with some lapilli tuff and coarse tuff breccia. Foundation bedrock below the concrete structures consists almost entirely of massive andesite flow rock (USACE, 2017d). A large (32 million square feet) landslide is located immediately upstream of the dam (Walker, 2002).

### *3.4.1.2.3 Cottage Grove*

Cottage Grove Dam (Figure 3.4-5) and reservoir is located within the Middle Cascades physiographic section near the boundary with the Oregon Coast Range. The foothills of the Cascade Range are to the east of the dam and the Coast Range to the west. Relief ranges up to about 1500 feet on both sides of the lake. The immediate lake area has eroded terrain with gently sloping to partially rounded hills. The closest mapped Quaternary fault to the site is an unnamed fault located near Sutherlin, approximate 12 miles east of the site. The Cascadia Subduction Zone is 45 to 75 miles west of Cottage Grove Dam (USACE, 2017b).

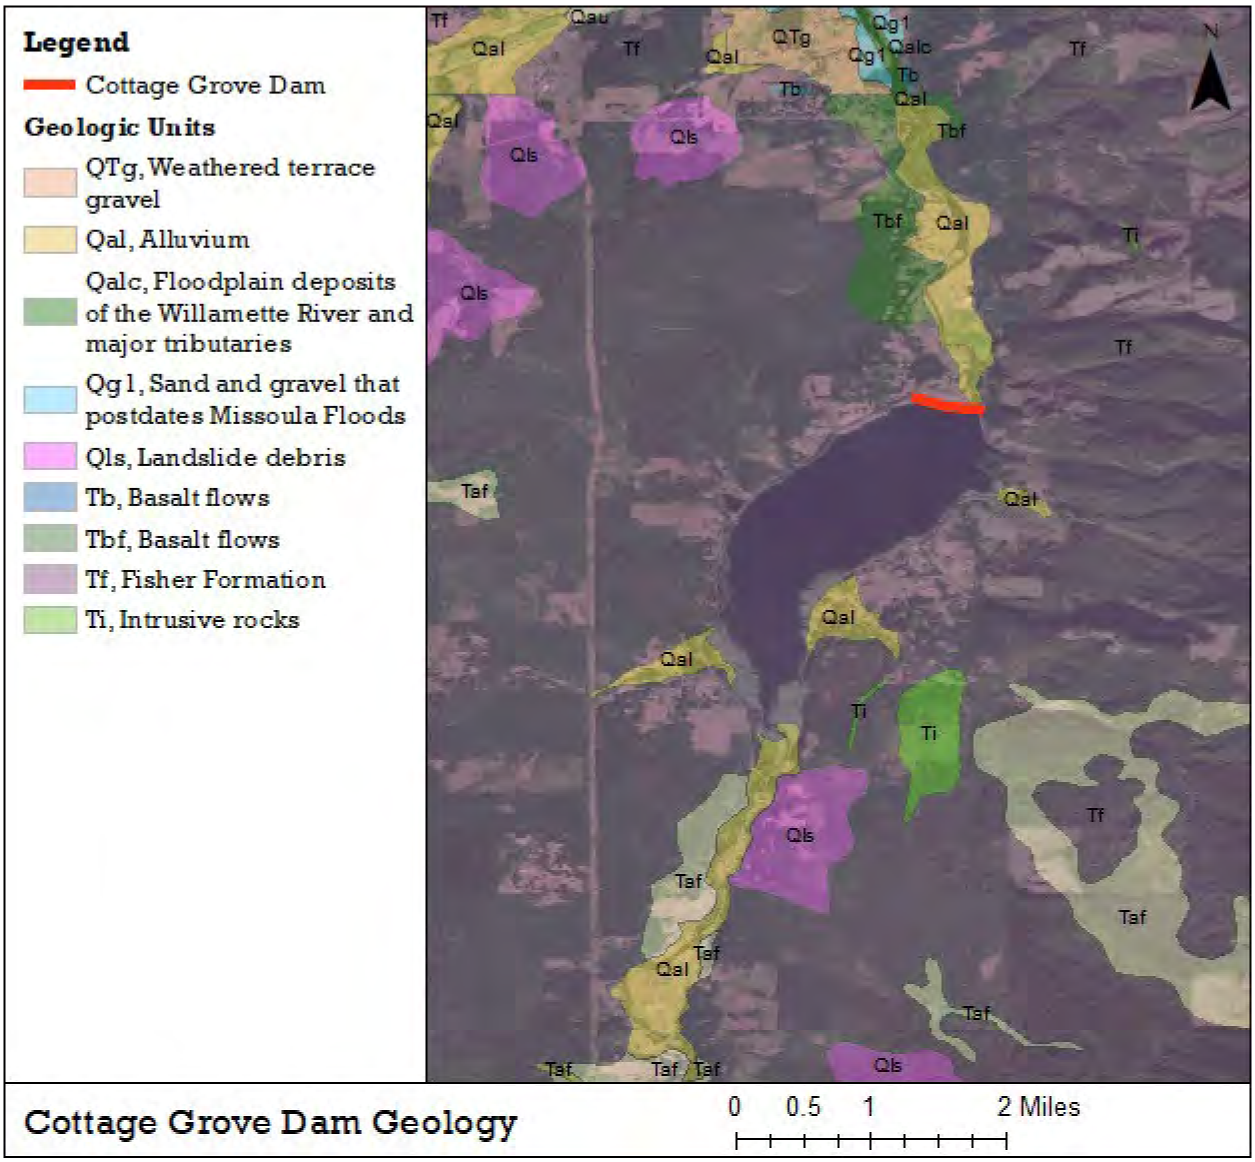

**Figure 3.4-5. Geologic Formations and Alluvial Deposits around Cottage Grove Dam**

Source: Hoover, 1963

#### *3.4.1.3 Long Tom*

##### *3.4.1.3.1 Basin Overview*

The Long Tom Basin is an elongated structural basin filled with thick accumulations of silt-clay, fresh sand, gravel and cobble deposits, and partly decomposed sand, gravel and cobbles (USACE, 2015e). The 1% AEP and 0.2% AEP floodplains are dominated by quaternary-aged unconsolidated deposits, which make up 99% of the 1% AEP floodplain and 100% of the 0.2% AEP floodplain. Eocene-aged deltaic sandstones of the Spencer Formation make up 1% of the 100-year floodplain within the study area and minor areas (<15 acres) of the Eugene Formation and Colestin Formations are present (McClaughry et al., 2010). There are no major quaternary faults or folds recorded in the study area.

##### *3.4.1.3.2 Fern Ridge*

Fern Ridge Dam (Figure 3.4-6) is located in the Oregon Coast Range physiographic section near the southern end of the Puget Trough (Willamette Valley). Rock formations underlying Fern Ridge Lake are exposed in adjacent foothills. Rock strata typically have low eastward dips of 10 to 20 degrees. Foundation materials beneath the Fern Ridge embankment consists of a thin clay blanket, underlain by a thin layer of silty sand, which overlies clayey gravels that extend 80 to 100 feet to bedrock. Foundation rocks are primarily marine tuffaceous sandstones and agglomerates that are intruded by diabase sills and dikes; there are some inter-bedded continental clastic tuffs and breccias to the southeast. West of the spillway, the embankment sits on highly weathered diabase. The spillway is founded on diabase rock (USACE, 2015e).

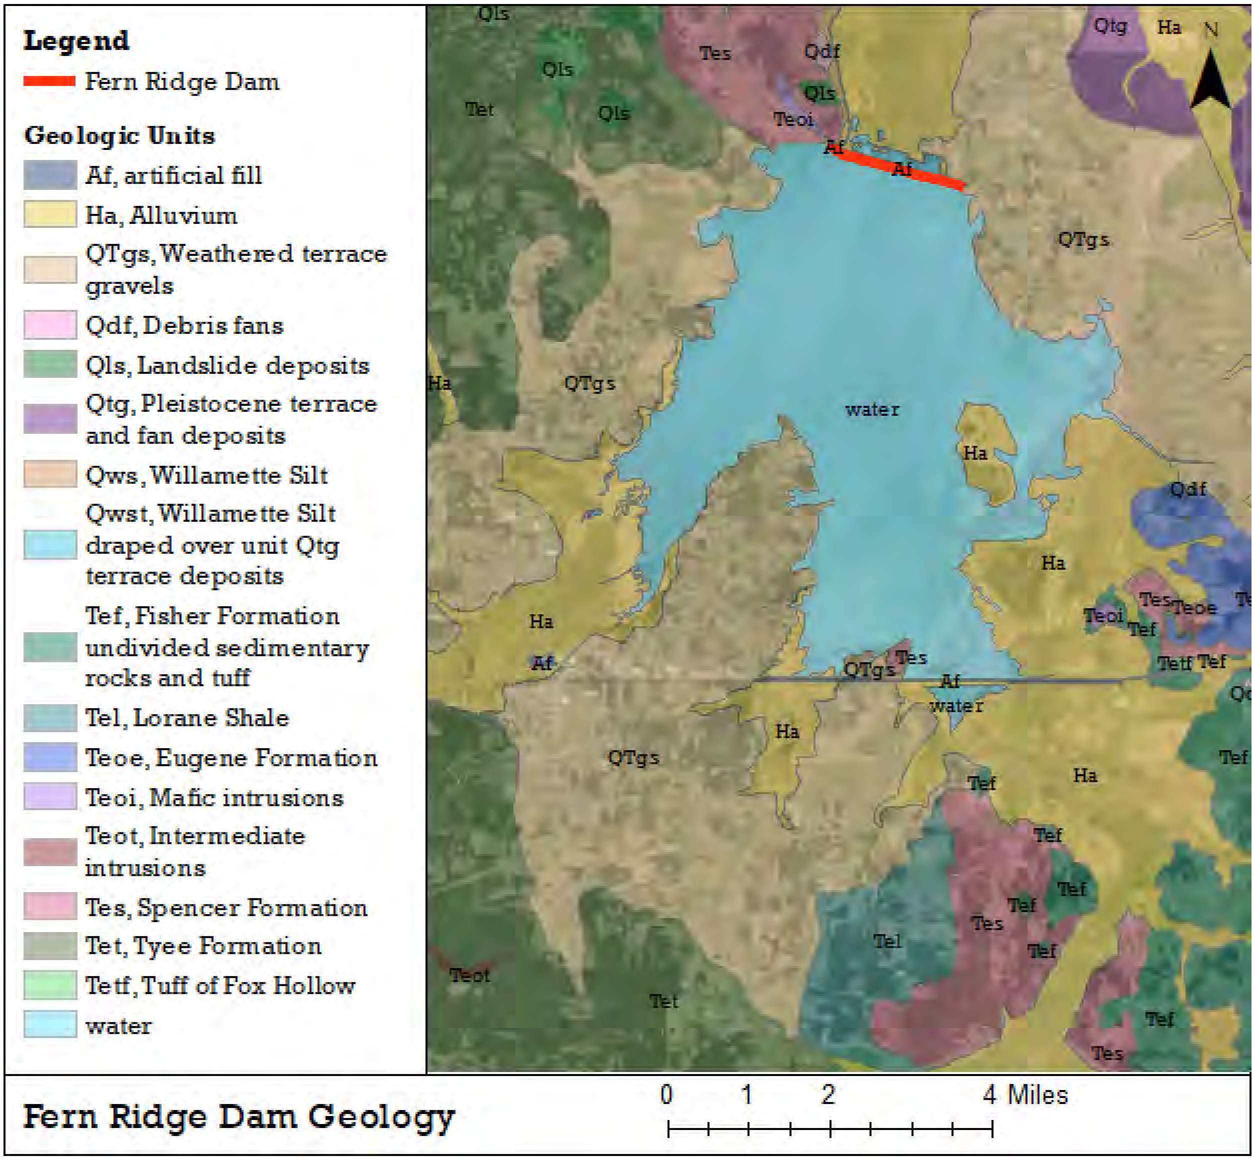

**Figure 3.4-6. Geologic Units in the Vicinity of Fern Ridge Dam**

Source: McClaughry et al., 2010

### *3.4.1.4 McKenzie Subbasin*

#### *3.4.1.4.1 Basin Overview*

In the McKenzie River subbasin unconsolidated deposits make up 95% of the 1% AEP floodplain and 70% of the 0.2% AEP floodplain. Primary surficial bedrock within the floodplain is the Little Butte Volcanic series, including the tuffs of the Mohawk River Caldera and basalts of the Mt. Tom formations (McClaughry et al., 2010). Miocene-aged granitic intrusions from Late Western Cascade Volcanics are also present in the study area. Small areas (<15 acres) of the Eugene Formation and Eocene/Oligocene-aged basaltic intrusive rocks of the Early Western Cascade Volcanics are also present in the 1% AEP study area (McClaughry et al., 2010). The White

Branch fault zone is a N-S striking normal fault located 13 miles east of Cougar Dam and 17 miles east of Blue River Dam (Personius, 2002d).

### *3.4.1.4.2 Cougar*

Cougar Dam (Figure 3.4-7) lies near the fault-controlled boundary between the Western Cascades and the High Cascade geologic provinces. Important geologic features near the dam include Horse Creek fault, which is about 12 miles east and the major strato-volcano South Sister, which is 20 miles west of the project and has volcanism that is less than 1,000 years old.

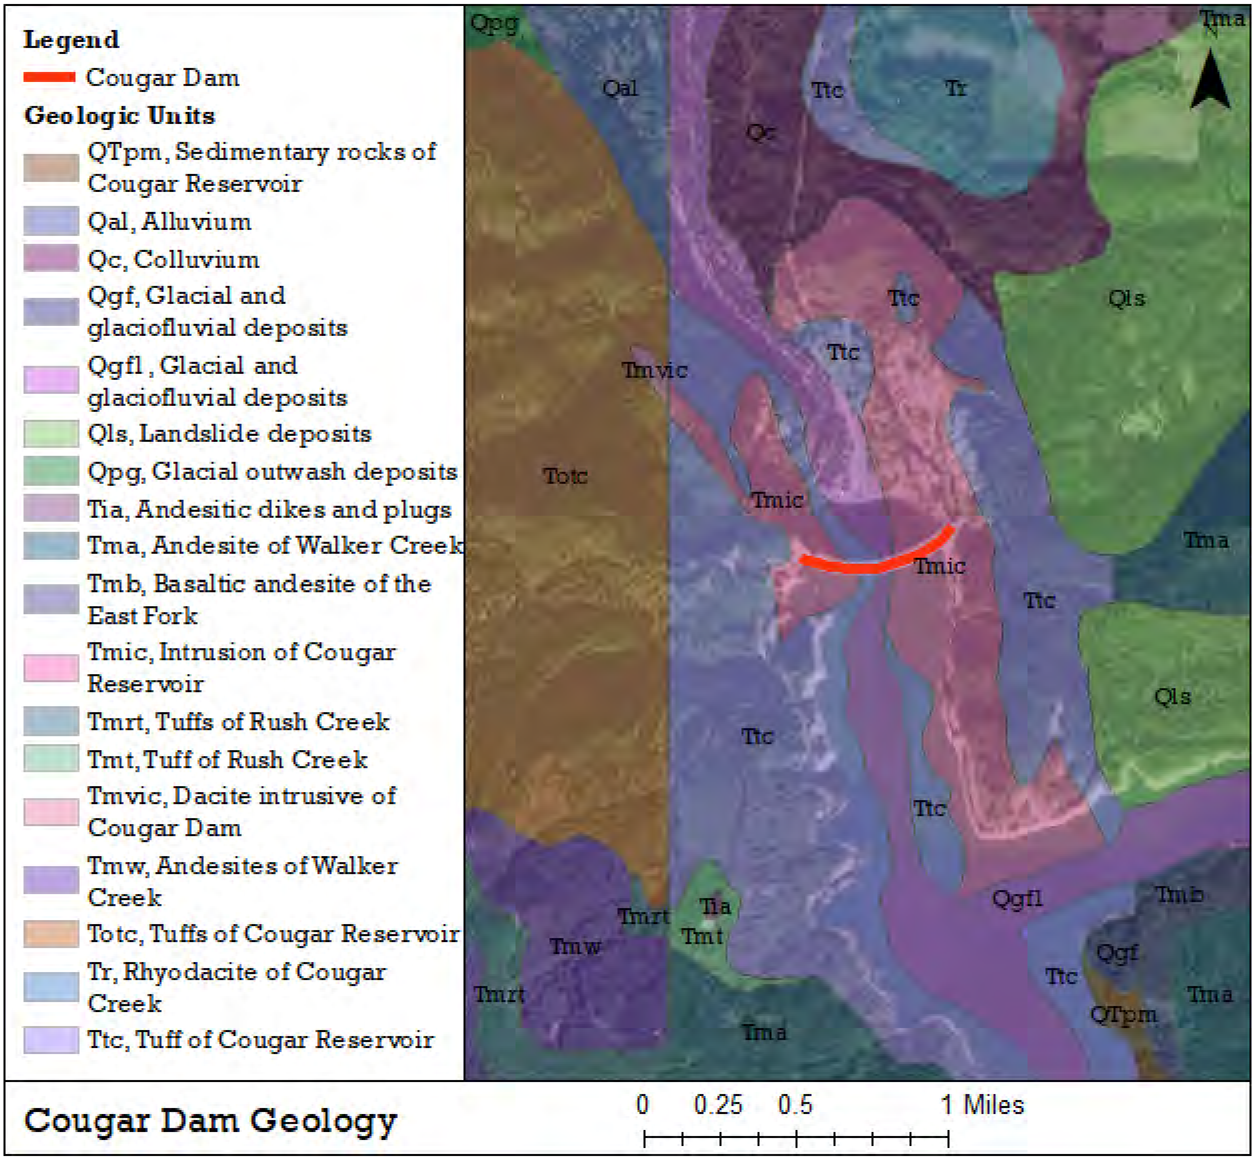

**Figure 3.4-7. Geologic Units in the Vicinity of Cougar Dam**

Source: Priest and Woller, 1983 and Priest et al., 1988

The oldest rock unit in the dam and reservoir area is the series of bedded pyroclastic deposits of the tuff of Cougar Reservoir, which are dacitic tuffs interbedded with ash flows, rhyodacite, andesites, and fine-grained bedded tuffs referred to as “mudstone” in the original design memorandum. The pyroclastics form a massive rock unit which is both faulted and gently folded. The tuffs have been intruded by dikes and other irregular basalt or dacite. The largest intrusion at the site follows the foot print of the dam. The lower contact of the intrusion has been eroded through by the river (USACE, 2017c). A 6 million square foot landslide is located 1.3 miles upstream of the dam and extends into the reservoir (Priest et al., 1988).

##### *3.4.1.4.3 Blue River*

Blue River Dam (Figure 3.4-8) is located in the Western Cascade physiographic subprovince. The reservoir area is dominated by thick, deformed sequences of Tertiary rocks (Oligocene to Miocene); including pyroclastics, lava flows and minor intrusions that resulted from several periods of intense volcanism. The oldest rock units in the area are mudflow (lahar) deposits, massive to bedded fine-to coarse-grained tuffaceous sedimentary rocks, and volcanic conglomerates which exhibit low grade metamorphism. Basaltic dikes intruded the older volcanic deposits. Both the volcanic deposits and dikes are cut by quartz veins associated with the Blue River Mining District hydrothermal system.

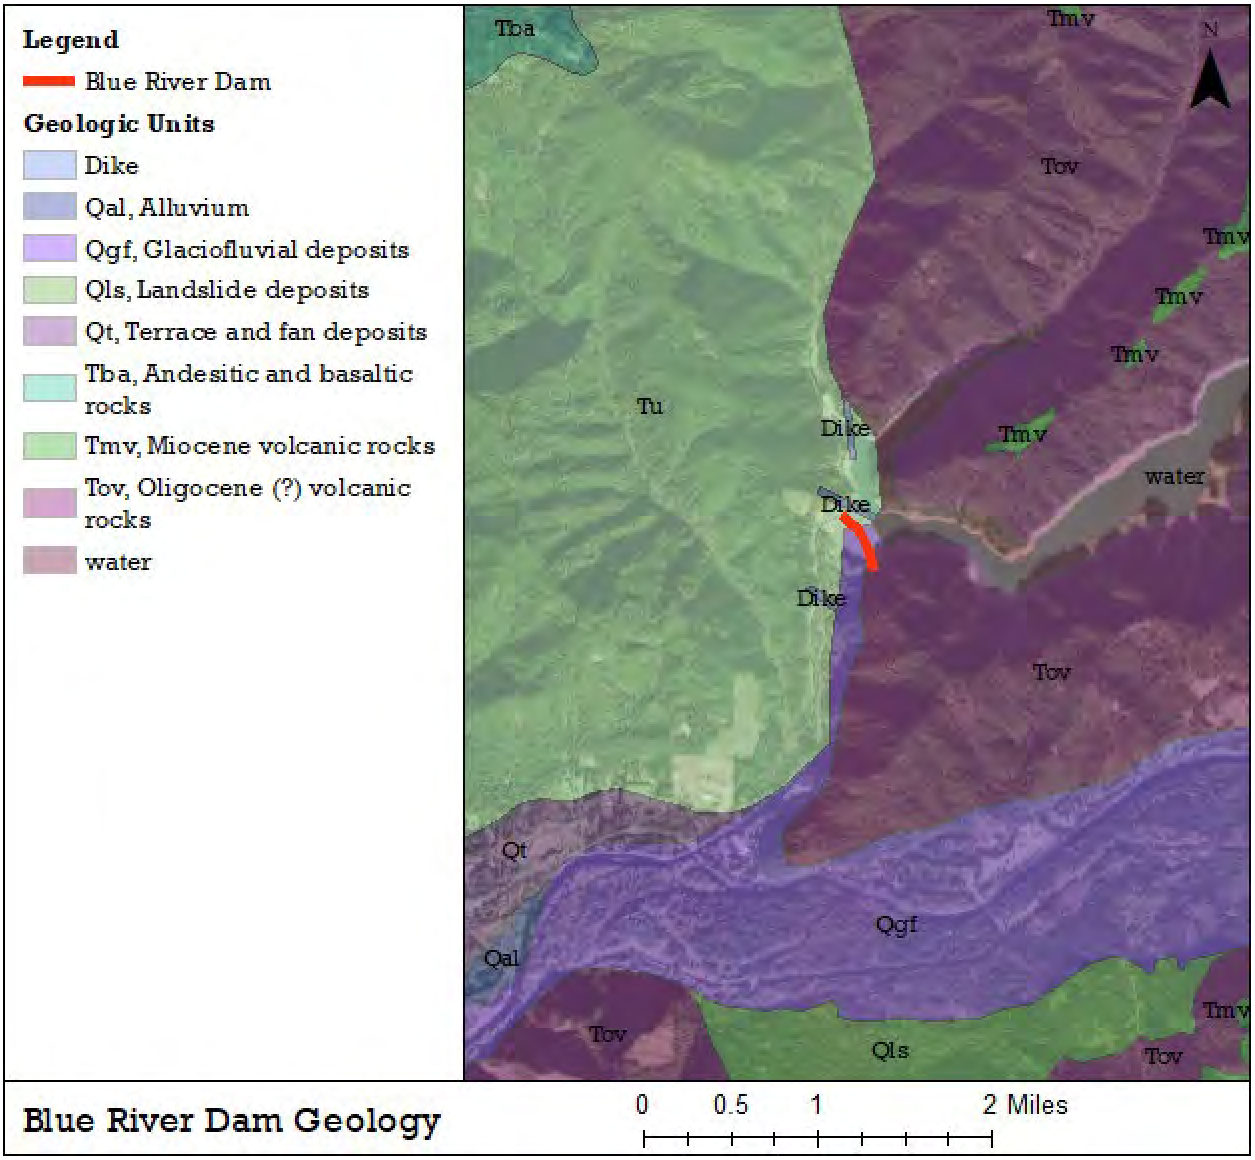

**Figure 3.4-8. Geologic Units in the Vicinity of Blue River Dam**

Source: Brown et al., 1980a and Walker and Duncan, 1989

Ridges adjacent to the dam and reservoir are relatively narrow and have a maximum relief of approximately 2,000 feet. About 40,000 years ago the McKenzie River valley was occupied by an alpine glacier created by the merging of three glaciers from the Three Sisters volcanic mounts. The glacier periodically advanced up the original Blue River drainage, blocked the drainage and formed a glacial lake. In the Quaternary, glacial-influenced stream action, developed narrow canyons with steep side slopes in the main dam area and a wider canyon with steep side slope in the middle and upper reservoir area. Final retreat of the glacier deposited thick sediments in the area of the auxiliary dam resulting in permanent diversion of the river over bedrock near the mouth of Scout Creek, and establishment of current drainage past the area of the main Blue River dam. The foundation rock is predominantly hard and fresh andesite, contact breccia and lapilli tuff. The auxiliary dam foundation is primarily composed of stratified glacial lake and alluvial materials with depths of up to 150 feet (USACE, 2016b).

#### *3.4.1.5 Middle Fork Willamette River*

##### *3.4.1.5.1 Basin Overview*

The Middle Fork Willamette River is located within the Western Cascades physiographic subprovince. Sedimentary deposits make up 70% of the 1% AEP floodplain and 99% of the 0.2% AEP floodplain. The Little Butte Volcanic Series, including the Mohawk River Caldera and Mt. Tom formations, form the majority of bedrock (Peck, 1964; McClaughry et al., 2010). Minor areas (<15 acres) of Early Western Cascade Volcanics, including intrusive rocks and volcanoclastic sediments of the Mehama Formation, are present. Between Lookout Point and Hills Creek Dam the Middle Fork Willamette River traces the path of the Upper Willamette River fault zone, which strikes NW-SE to the east of Hills Creek Reservoir (Personius, 2002h).

##### *3.4.1.5.2 Lookout Point*

The rocks found in the vicinity of Lookout Point Dam (Figure 3.4-9) range in age from Eocene to Miocene, and consist of tilted sediments, pyroclastic beds, and lava flows. The topography is characterized by narrow valleys and sharp ridges that are mostly unrelated to the underlying bedrock structure. Localized folds within the region form short anticlines and synclines. All bedrock in the Western Cascades has experienced low grade metamorphism.

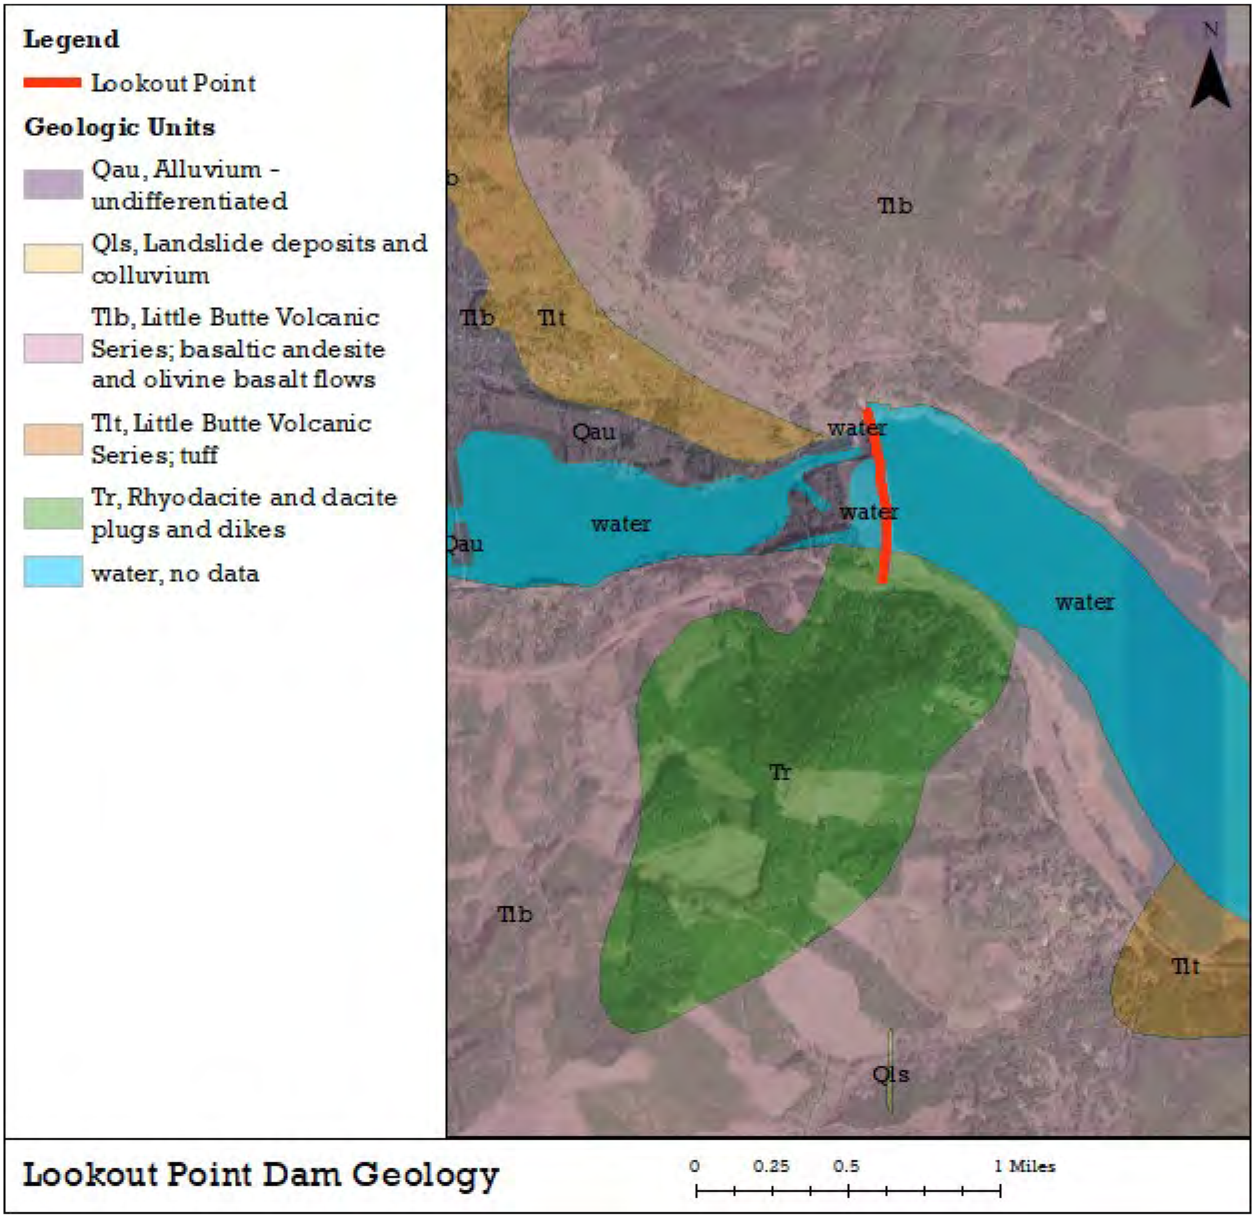

**Figure 3.4-9. Geologic Units in the Vicinity of Lookout Point Dam**

Source: O'Connor et al. and Peck, 1964

Overburden in the valley floor consists of a 10- to 20-foot thick deposit of boulders, cobbles, gravels, sands, silt, and deeply weathered clay talus. The left abutment of the dam is tied into an ancient landslide complex (USACE, 2019d). Two slides extend into the reservoir and are influenced by fluctuations in the Lost Creek Reservoir. The Minnow slide deposit is located on the left bank of Lookout Point Lake, approximately 0.8 to 1.8 miles upstream from the dam and the slide mass extends below the minimum pool (elevation 819 NAVD88). Relocation of the highway and railroad during early construction of Lookout Point Dam reactivated the slide. The Voss slide is 3 miles upstream of the dam on the left bank. The toe is approximately at elevation 859 feet NAVD88 (75 feet below full pool). The Voss slide formed during the first pool drawdown in 1955. Measures were taken to stabilize both slopes, but periodic movements of the slide masses have continued to occur (USACE, 1981). Deposits of clay and talus are prevalent throughout the valley, and large masses were present on both abutments of the dam site.

Volcanic rocks that form the foundation area fall into two main groups, a porphyritic andesite group and a porphyritic augite basalt group. The porphyritic andesite group is the main lithology in the project area. There are three dominate bedrock joint systems at the site, many of which are also open and contain colloidal clay. The main large fault at the dam site cuts diagonally across the stilling basin (USACE, 2019d).

###### *3.4.1.5.3 Hills Creek*

The Hills Creek Project (Figure 3.4-10) is located in the central Western Cascade Range. The dam occupies a steep-sided canyon at the confluence of Hills Creek and the Middle Fork of the Willamette River, where the original valley was about 700 feet wide. Overburden at the dam site is mainly a gravel-cobble-boulder alluvium that increases in depth from the right abutment to the left abutment. The upper 10 to 15 feet of the gravel is mostly unweathered, hard, and unconsolidated. Deeper alluvium contains a high percentage of weathered and compacted gravel that is permeable. Outside the original river channel, the floodplain has a blanket of 3 to 8 feet of silty sand. Overburden on the left abutment includes deeply weathered Lapilli Tuff and shallower landslide deposits (USACE, 2019c). An 18 million square foot landslide is located 0.4 miles SW of the dam (Walker, 2002) and several large landslides are mapped 1 mile east of the dam (Sherrod, 1991 and Brown et al., 1980b). Both landslides extend into the reservoir.

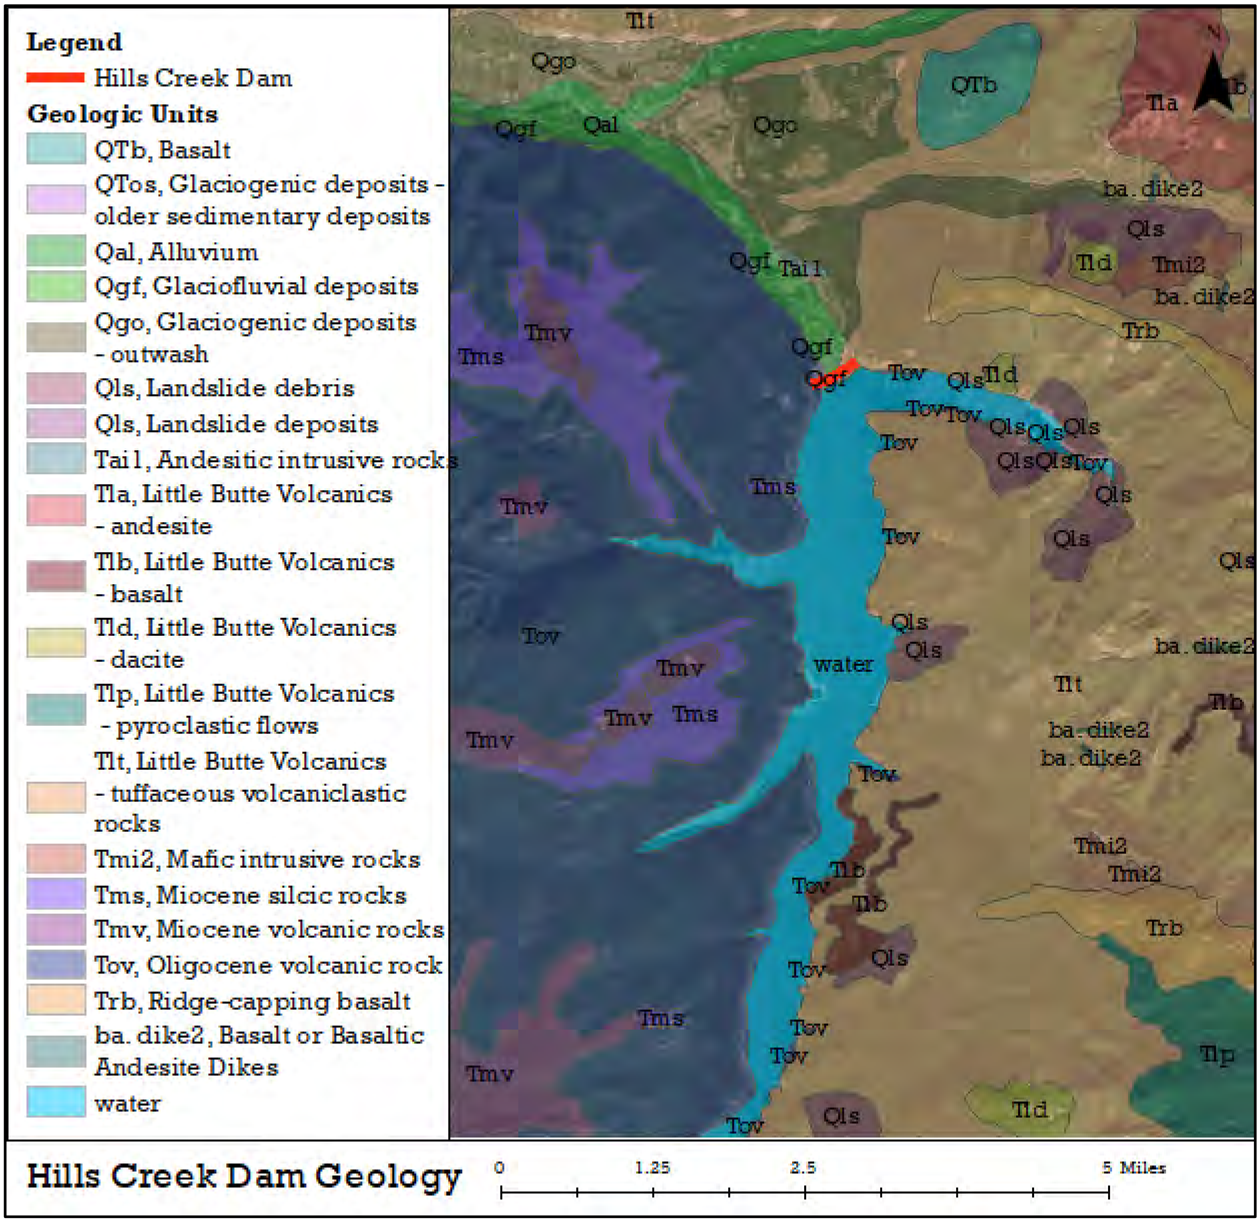

**Figure 3.4-10. Geologic Units in the Vicinity of Hills Creek Dam**

Source: Brown et al., 1980b and Sherrod, 1991

Hills Creek Dam is founded in Oligocene-Miocene-age tuffs of the Little Butte Volcanic Series. The tuffs have been hydrothermally altered, sheared, and displaced by intrusive rocks. Near the dam, intrusive rocks include small localized sills, a massive hornblende andesite intrusion in the left abutment, a large dacite dike downstream of the dam centerline and in the right abutment, and a large diabase dike downstream of the dacite dike.

The Hills Creek Project coincides with the intersection of two major fault zones, the Middle Fork and Hills Creek Faults. The faults are associated with widespread shearing, clay-filled rock joints and fractures, and deep weathering in the project site vicinity. These faults are believed to be inactive based on USGS mapping, and pre-construction geologic mapping provides no evidence of recent fault activity (USACE, 2019c).

*3.4.1.5.4 Dexter*

Most of the overburden in the Dexter Dam (Figure 3.4-11) area is shallow, consisting of loose, sandy gravel containing cobbles and occasional boulders. Cemented gravel and boulders were encountered in the fault-controlled channel beneath the upstream training wall. The base of the right abutment and the west end of the fishway have shallow residual clays and talus (USACE, 2015d). No modern landslides are mapped within the reservoir area (Walker, 2002).

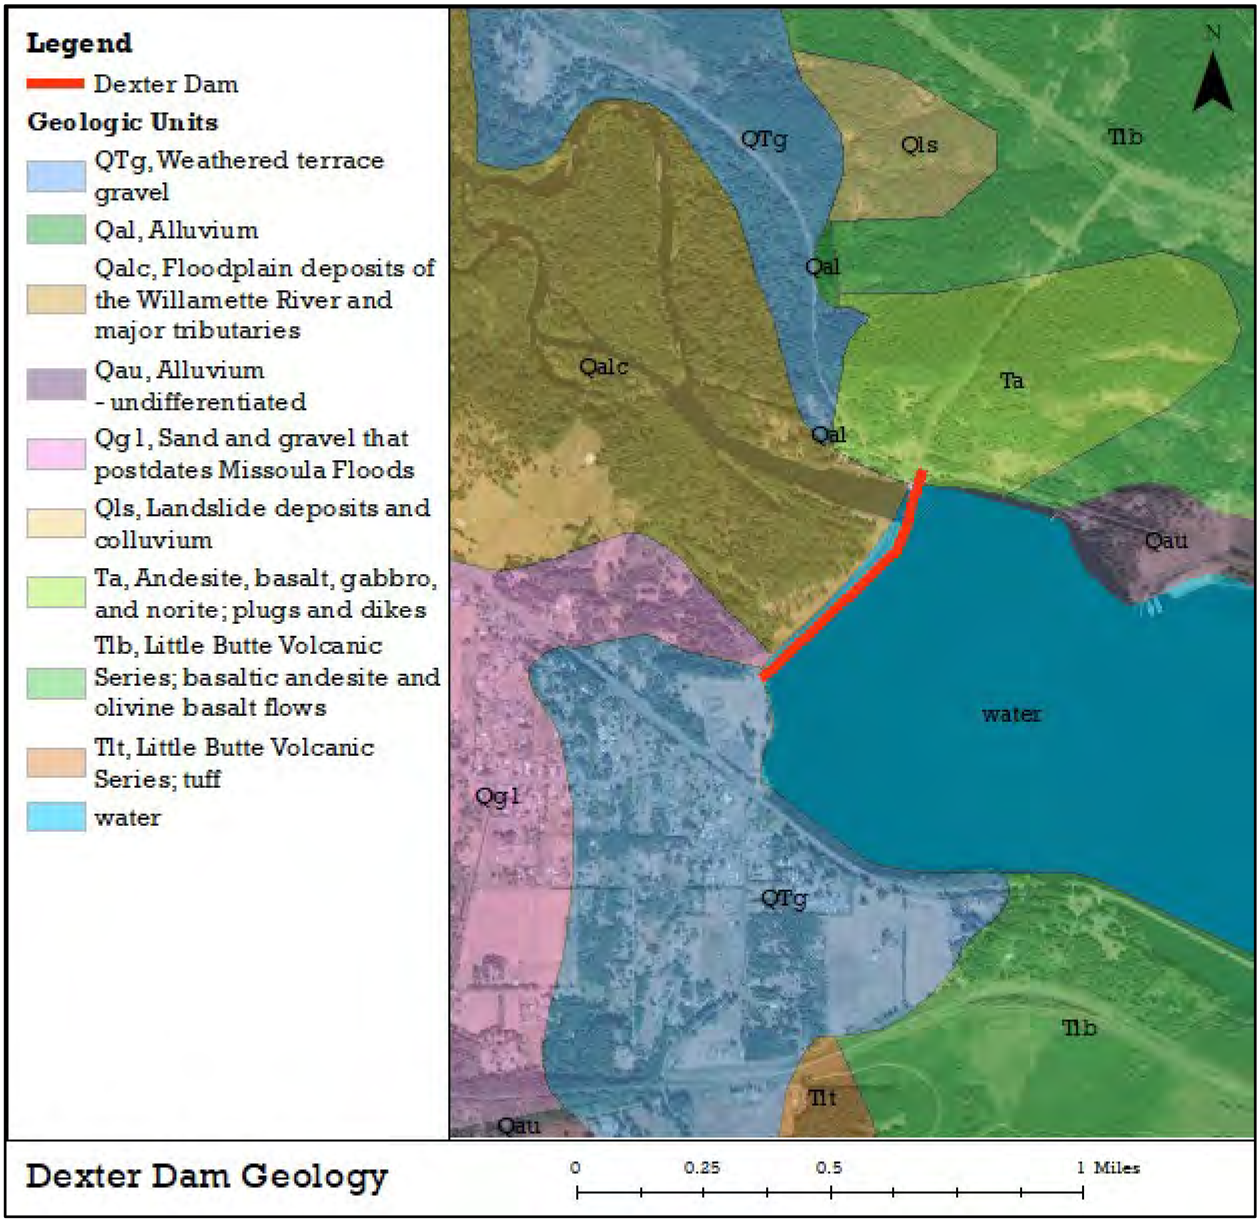

**Figure 3.4-11. Geologic Units in the Vicinity of Dexter Dam**

Source: O'Connor et al., 2001 and Peck, 1964)

Bedrock in the concrete structure area consists of a series of pyroclastic tuffs and tuff breccia that have been intruded by dense, hard basalt. The surface of the foundation is for the most part a remnant of a basalt flow or flows which has been eroded deeply enough in places to expose the underlying pyroclastics. There are numerous faults in the embankment foundation, some of which are responsible for steep to near vertical slopes in the foundation surface. The most prominent and extensive fault in the concrete portion of the dam is the Powerhouse Fault, which follows the contact of the pyroclastics and the main body of intrusive basalt. This fault movement was probably produced in the late stages of intrusion after solidification of the magma. Foundation rock beneath the embankment area is a composite series of pyroclastic rocks and basalt flows with occasional intruding fingers of basalt. One important fault that was uncovered during construction was a fault zone that transects the embankment dam. The Foundation Report states that indicators of frictional movement between rocks along the two sides of a fault were observed within the alluvial gravels overlying bedrock. USACE initiated a geologic reconnaissance of this fault/lineament in the early 1980s which suggests that the last activity was Early Pleistocene (>100,000 years). There is no confirmed activity on this geologic fault in the last 10,000 years. (USACE, 2015d).

##### *3.4.1.5.5 Fall Creek*

The topography within the Fall Creek Drainage Basin is irregular with much variation observed in slope steepness around the lake. Fall Creek Dam (Figure 3.4-12) is located along the lowermost foothills of the Cascade Range and discharges to the southern extent of the Willamette Valley. The valley slopes extend approximately 500 feet to nearly 1,400 feet above the lake elevation.

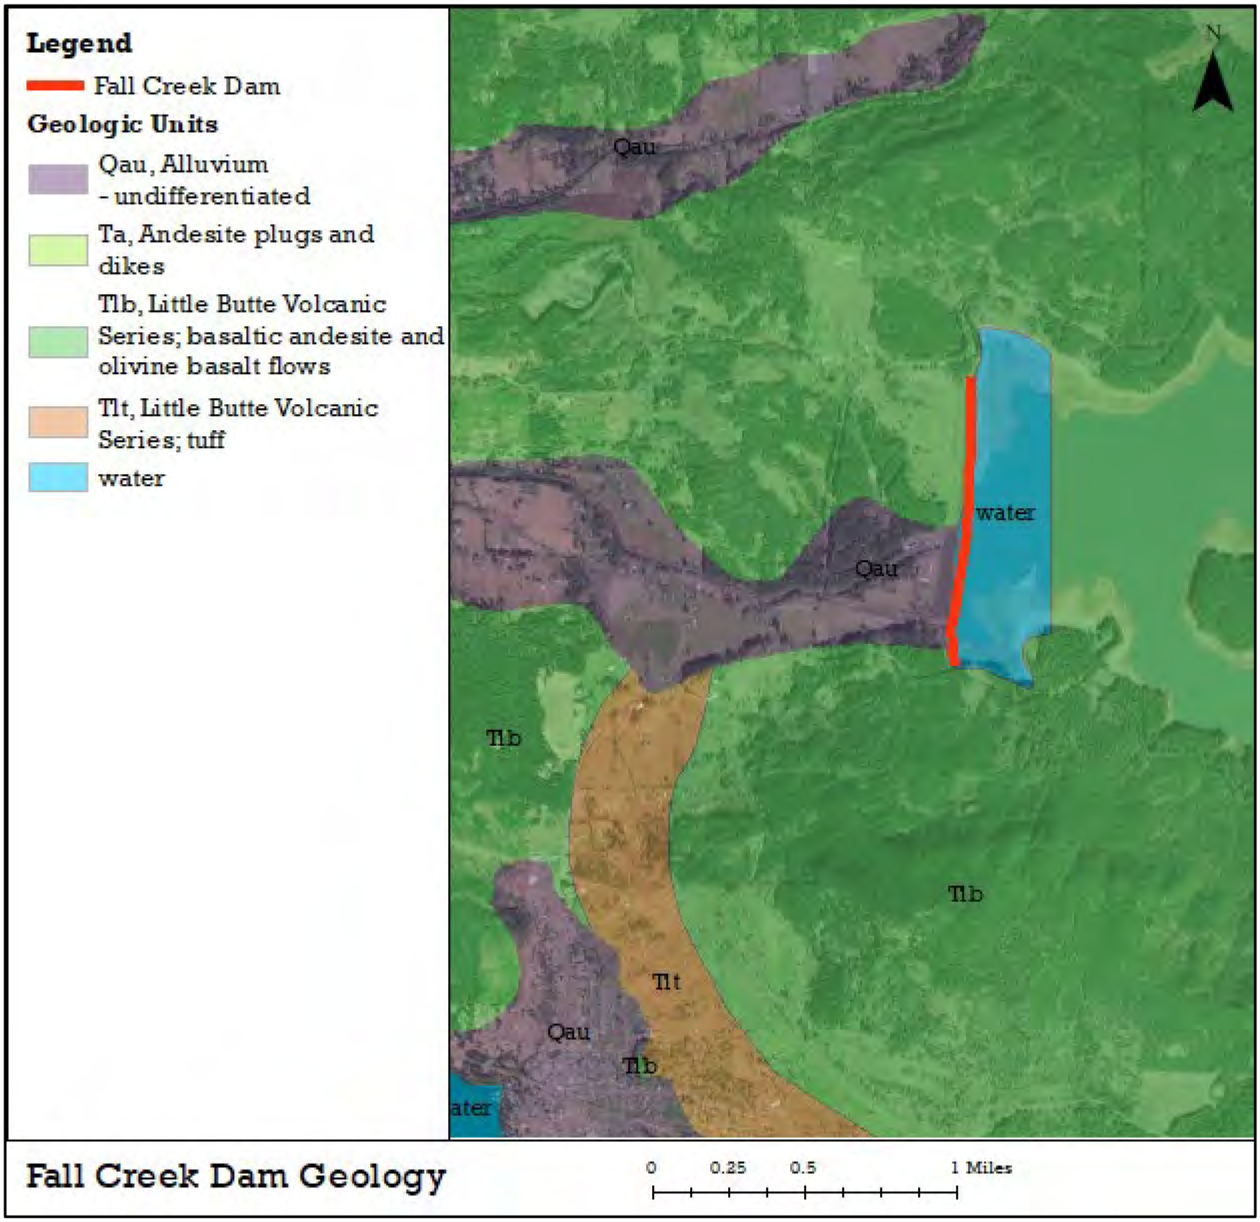

**Figure 3.4-12. Geologic Units in the Vicinity of Fall Creek Dam**

Source: O'Connor et al., 2001 and Peck, 1964

Historically, downcutting of the Fall Creek and Winberry Creek valleys was periodically interrupted by valley deposition and infilling, as indicated by deeply weathered terrace deposits along the valley walls. Numerous landslide deposits are present along the slopes around Fall Creek Lake in deep overburden and/or intensively weathered rocks (USACE, 2014b), but no modern landslides are mapped within the reservoir area (Walker, 2002). The right abutment is located on an old alluvium-filled river channel. The residual soil consists of sandy silty clay and silty gravel. The decomposed terrace gravels consist of dense, silty, gravelly sand. Left abutment overburden was mostly shallow residual silty soil and slopewash between scattered rock outcrops, with some small local talus deposits. An old gravel terrace is located upstream on the left abutment.

The foundation material in the area of Fall Creek Dam consists of lava flows, intrusive rock masses, fragmental pyroclastic materials, and the lowest member of the stratigraphic sequence is volcanic derived sandstone. The pyroclastic- and volcanic-derived sandstone materials are the dominate rock types. In the dam foundation area, the resistant andesite rock materials are intrusive in origin and form the blufflike abutments, especially on the right abutment.

An intrusive contact zone separates andesite that extends from the intake of the regulating outlet to the dam axis and sandstone that extends to the downstream end of the discharge channel. The dam foundation alignment generally follows this contact. Major rock fractures and joint sets generally trend approximately NE and NW with minor fractures and joint sets trending north and east. (USACE, 2014b).

#### *3.4.1.6 Middle Main Stem Willamette River*

##### *3.4.1.6.1 Basin Overview*

The study area for the Middle Main Stem Willamette River is within western half of the Puget Trough. More than 99% of the study area is unconsolidated deposits and bedrock is composed primarily of the Miocene-aged Columbia River Basalt Group, including the Grande Ronde and Wanapum formations, and Eocene-aged marine sedimentary rocks of the Keasey Formation (O'Connor et al., 2001; Yeats et al., 1996). Major faults that intersect the study area include the Salem-Eola homocline (Personius, 2002b), Newberg fault (Personius, 2002c), Canby-Molalla fault (Personius, 2002e), and Bolton fault (Personius, 2002a).

#### *3.4.1.7 North Santiam Subbasin*

##### *3.4.1.7.1 Basin Overview*

In the North Santiam subbasin unconsolidated sediments cover 99% of the 1% AEP and 100% of the 0.2% AEP. The majority of the surficial bedrock in the area is from the Little Butte Volcanics and the intermediate rocks of the Late Western Cascade Volcanics, including the andesite volcanic rocks of the Sardine Formation. A small area (<16 acres for each formation) of the 1% AEP study area contains the Columbia River Basalt Group, the Eugene Formation, and the Keasey Formation. The Salem-Eola Hills homocline is mapped at the downstream end of the basin (Personius, 2002b).

##### *3.4.1.7.2 Detroit*

Overburden at Detroit Dam (Figure 3.4-13) consisted of 0 to 70 feet of talus, river alluvium, glacial debris, and remnants of old cemented terrace river gravels (USACE, 2016c). Many 1-10 million square foot landslides are mapped extending into the water along the right bank of the reservoir about 4 miles upstream of the dam (Calhoun et al, 2020). These areas are shown as active landslides showing active movement since completion of the reservoir in the Detroit DM 4 (USACE, 1983). Detroit Dam is founded on Hall Diorite near the roof and northern margin of a 2 to 3 square mile pluton. It is intruded into the Lower Member of the Sardine volcanic country rock, which is composed of stratified tuffs, tuff breccias, andesite flows, and volcanic sedimentary rocks. In order of abundance, bedrock at the dam consists of the following: andesite breccia, diorite, aplite, andesite porphyry, hydrothermally altered phases of these rocks, and vein material composed of crushed vein matter, quartz and traces of hematite, lead, and zinc minerals. The andesite breccia is a hard and brittle rock mass that occurs along the northwestern and western margin of the intrusion and has been altered.

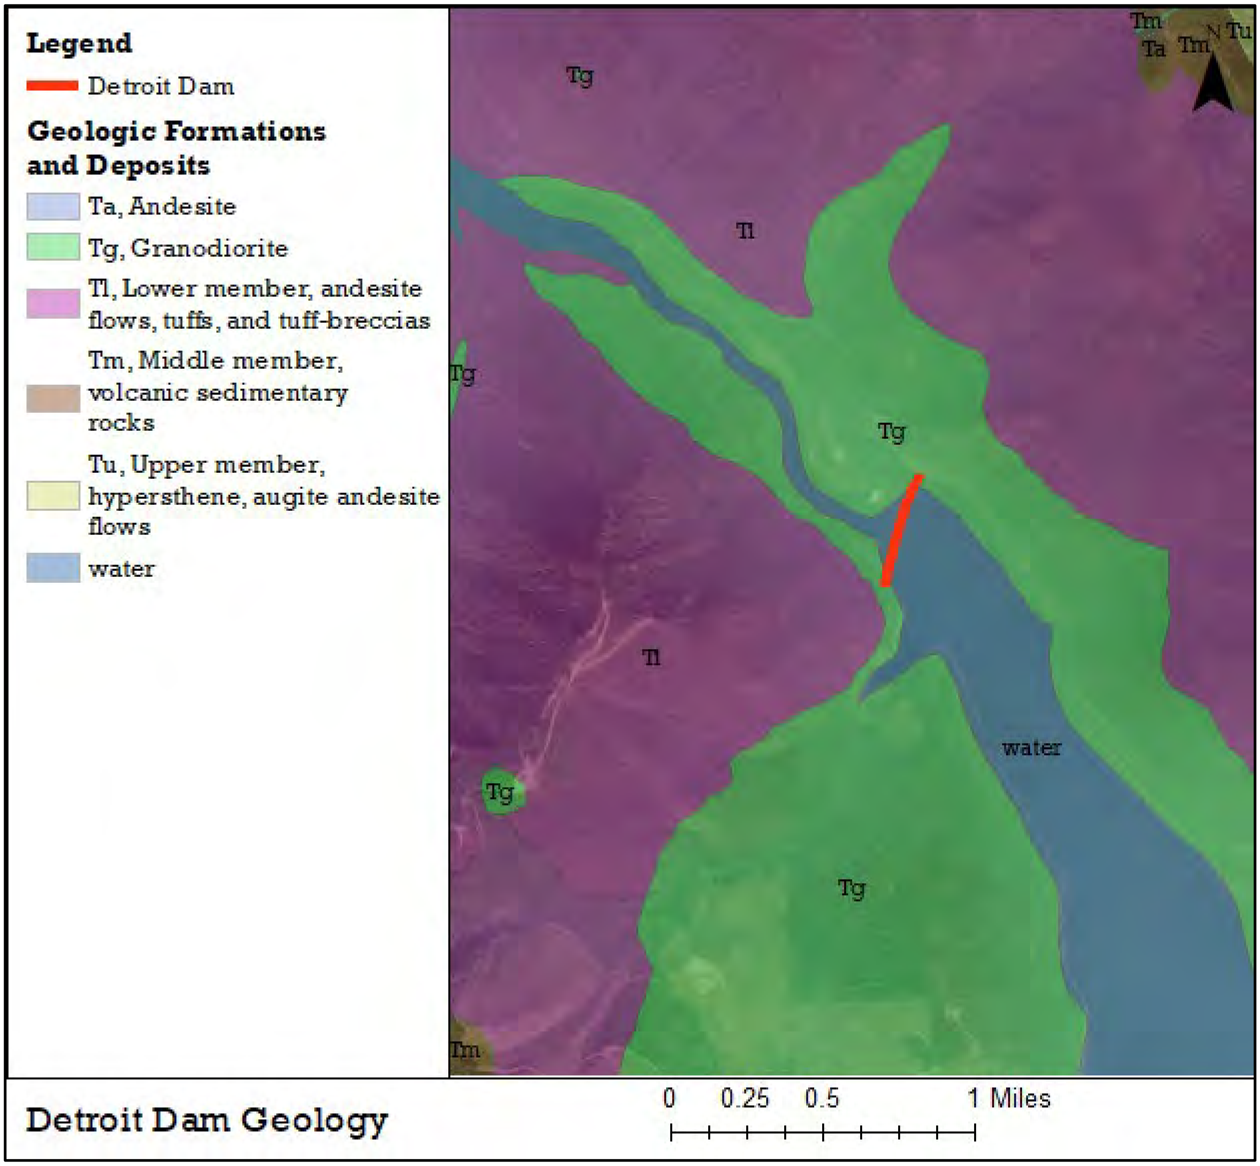

**Figure 3.4-13. Geologic Units in the Vicinity of Detroit Dam**

Source: Pungrassami, 1969

Primary direction of faults, fissures, shears and joints in the foundation strike NW, nearly parallel to the dikes of andesite porphyry and the Hall Diorite. The larger northwest striking shears have been mineralized and presently consist of a few inches to nearly 5 feet of shattered rock in a hard matrix of quartz and epidote. Northeast striking faults and shears exposed in the foundation were generally tight and fresh. Joints higher up on the abutments and above the dam typically were deeply weathered to clay (USACE, 2016c).

### *3.4.1.7.3 Big Cliff*

Big Cliff Dam (Figure 3.4-14) is in located in a steep V-shaped canyon, the sides of which reach heights from 1,500 to 2,500 feet above the stream channel. The channel is little more than 50 feet wide, and there is no floodplain. The left abutment is a vertical cliff from which the site derives its name. The entire site is underlain by massive, sound, andesite lava flows, tuffs, and lapilli tuffs. The tuffs are overlain by a dense porphyritic andesite flow that reaches a maximum thickness of 200 feet, strikes northwesterly, and dips 20 degrees southwest. The lower 50 feet of this flow is highly brecciated.

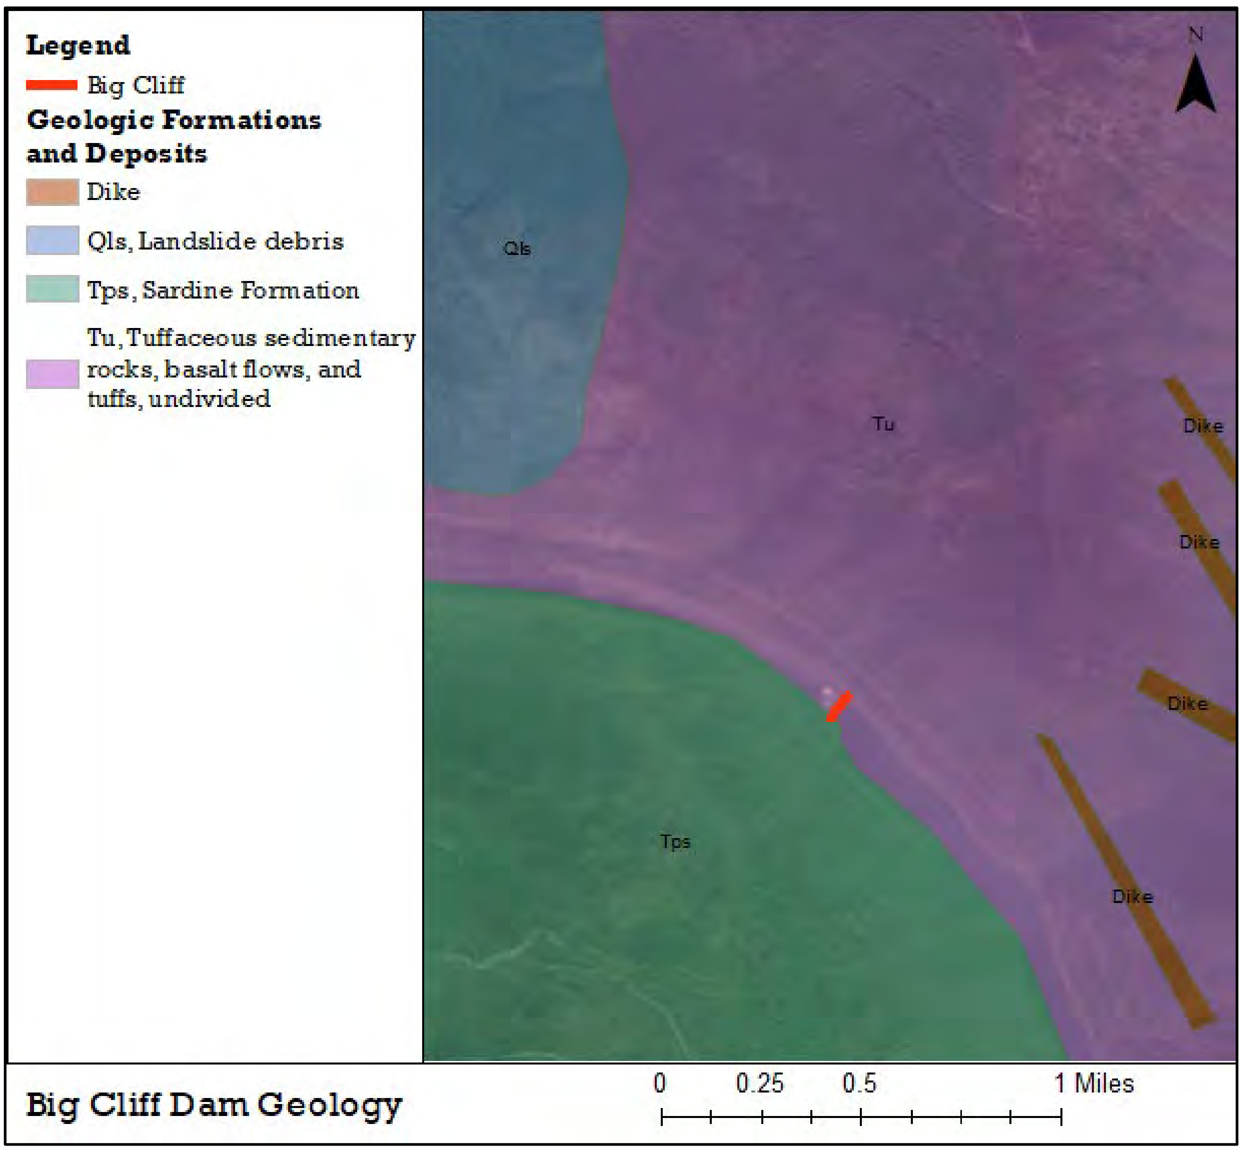

**Figure 3.4-14. Geologic Units in the Vicinity of Big Cliff Dam**

Source: Beaulieu, 1947

### *3.4.1.8 South Santiam Subbasin*

#### *3.4.1.8.1 Basin Overview*

Unconsolidated deposits in the South Santiam River study area make up 73% of the 1% AEP floodplain and 100% of the 0.2% AEP floodplain. Little Butte Volcanics, including the Mt. Tom and Scorpion Mountain Formations form the majority of bedrock in the area, with a lesser surface area of the Mehama Formation. Miocene/Pliocene age terrestrial sedimentary rocks of the Early High Cascade Volcanics and Grande Ronde Basalt are also present (Beaulieu, 1971; McClaughry et al., 2010; Yeats et al., 1996). There are no major quaternary faults or folds recorded in the study area.

#### *3.4.1.8.2 Foster*

Foster Dam (Figure 3.4-15) is located in the deeply eroded valley that was formed by the confluence of the Middle Santiam and South Santiam Rivers. Slopes around Foster Lake were formed by rapid down-cutting into alternating layers of strong and weak volcanic rocks. Oversteepened lower valley slopes have a potential for slides, but most slope failures are limited to local overburden accumulations. Below the juncture of the two rivers the valley is much wider and is marked by a sequence of five well-developed, contiguous alluvial terraces consisting of discontinuous layers, lenses, and mixtures of gravel and sand sized clasts and low plasticity silt. Valley overburden is primarily deposits of poorly graded, clean gravels near the surface and well graded silty sandy gravel at depths below 15 ft.

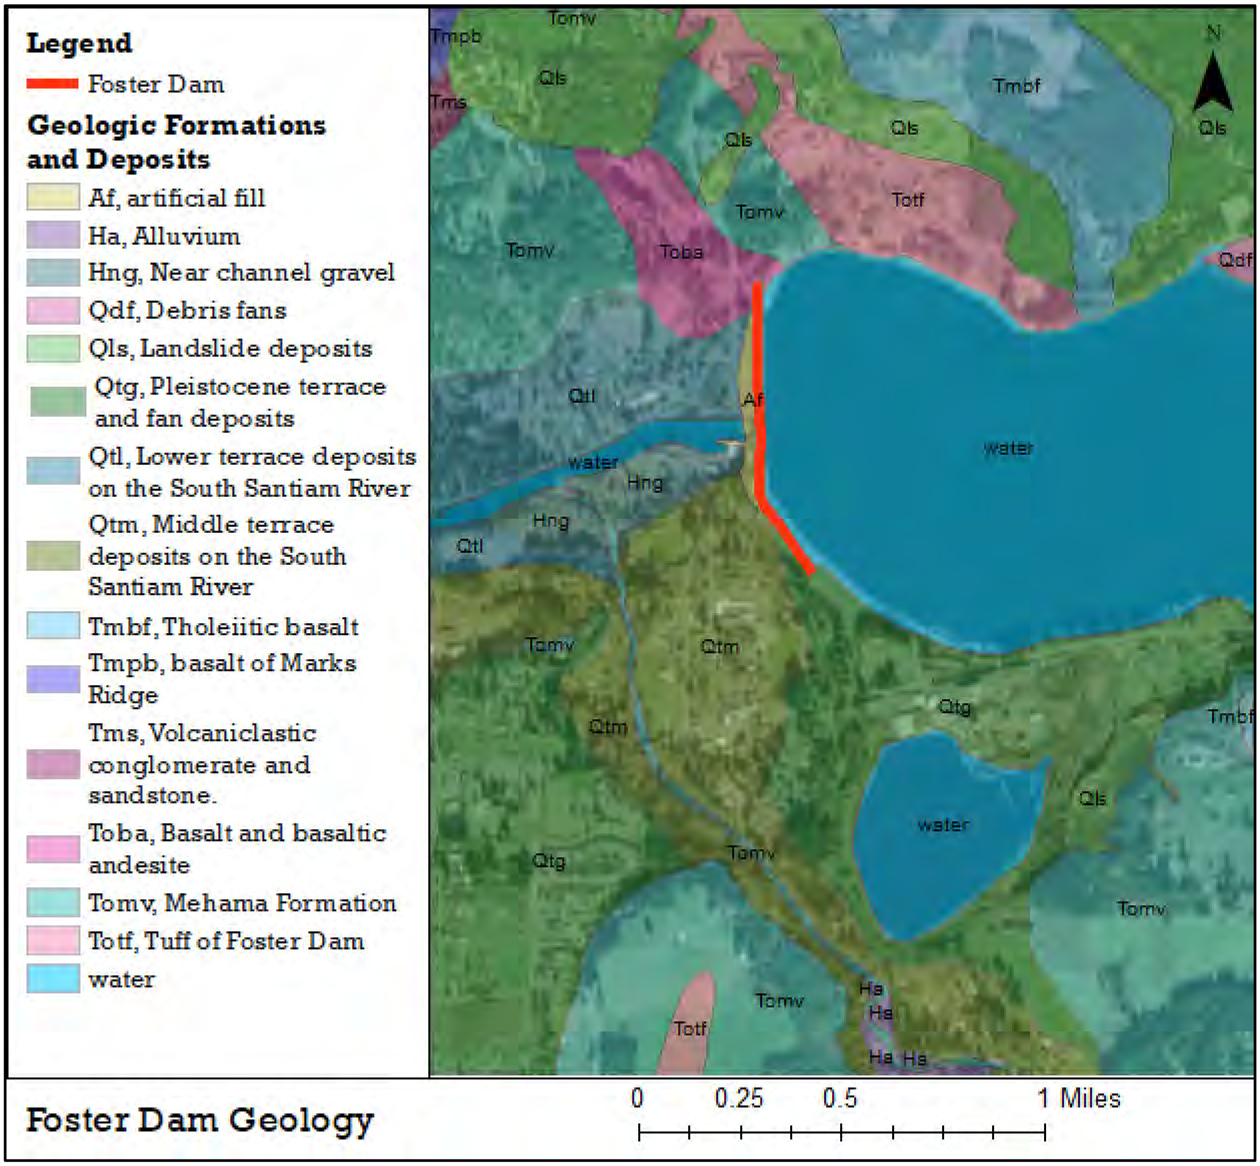

**Figure 3.4-15. Geologic Units in the Vicinity of Foster Dam**

Source: McClaughry et al., 2010

The Mehama Formation is exposed in outcrops along the right dam embankment and is capped by basaltic rock units. It is part of the Little Butte Volcanics and consists of undifferentiated sedimentary rocks and tuffs. The sedimentary rocks are mainly indurated, non-marine volcaniclastic conglomerate, breccias, sandstone, and mudstone. Bedrock in the dam foundation area consists of two major rock units and three subunits. The major rock units are the Wiley Creek Tuff and the Foster Basalt. Subunits comprising the Wiley Creek Tuff within the dam site area are the upper Ashy Tuff Member, the middle Sandy Tuff Member, and the lower Lapilli Tuff Member. Stratigraphic boundaries between these members are not always distinct and individual members have considerable lateral variation.

Foster Dam is situated between two northeast trending tertiary aged geologic structures: (1) Foster Lake Anticline, and (2) an unnamed syncline. Folded strata in the area are cut by a series of conjugate northwest- and northeast-trending normal faults and several northwest-trending strike-slip faults. Two other normal faults have been mapped near the site: an east-northeast trending fault approximately 0.5 miles southeast of the site and a north-northeast trending fault approximately 0.7 miles east of the site associated with Hogback Ridge. Both these faults are downdropped to the northwest, cut Oligocene- to Miocene-aged rock units, and have been mapped trending through Foster Lake (USACE, 2015f).

##### *3.4.1.8.3 Green Peter*

The USGS interprets geologic bedrock at the Green Peter Dam site as predominantly sedimentary (Figure 3.4-16). However, detailed geological investigations at the dam site show bedrock is predominantly volcanic andesite and basaltic lava flows; Tertiary Andesite Lavas approximately 17-25 million years old (labeled as Ta3) would be a more appropriate characterization (Figure 3.4-17). Green Peter Dam is most likely located on the flanks of an old shield volcano where the individual lava flows may be separated by volcanic ash/cinders and occasionally by bedded volcanic sediments (Figure 3.4-18).

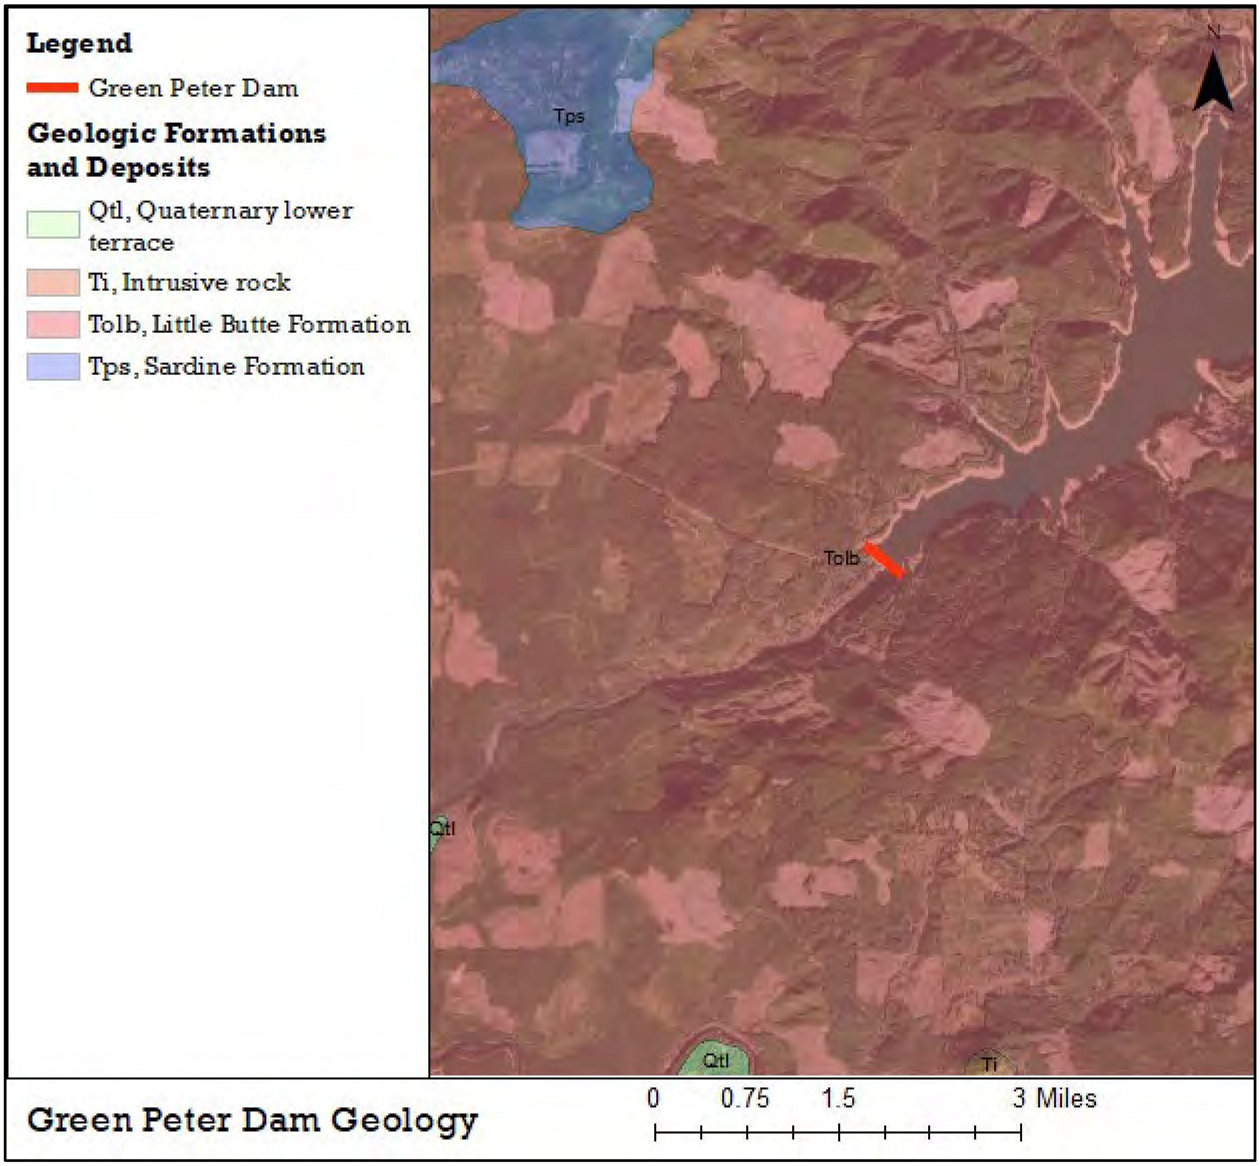

**Figure 3.4-16. Geologic Units in the Vicinity of Green Peter Dam**

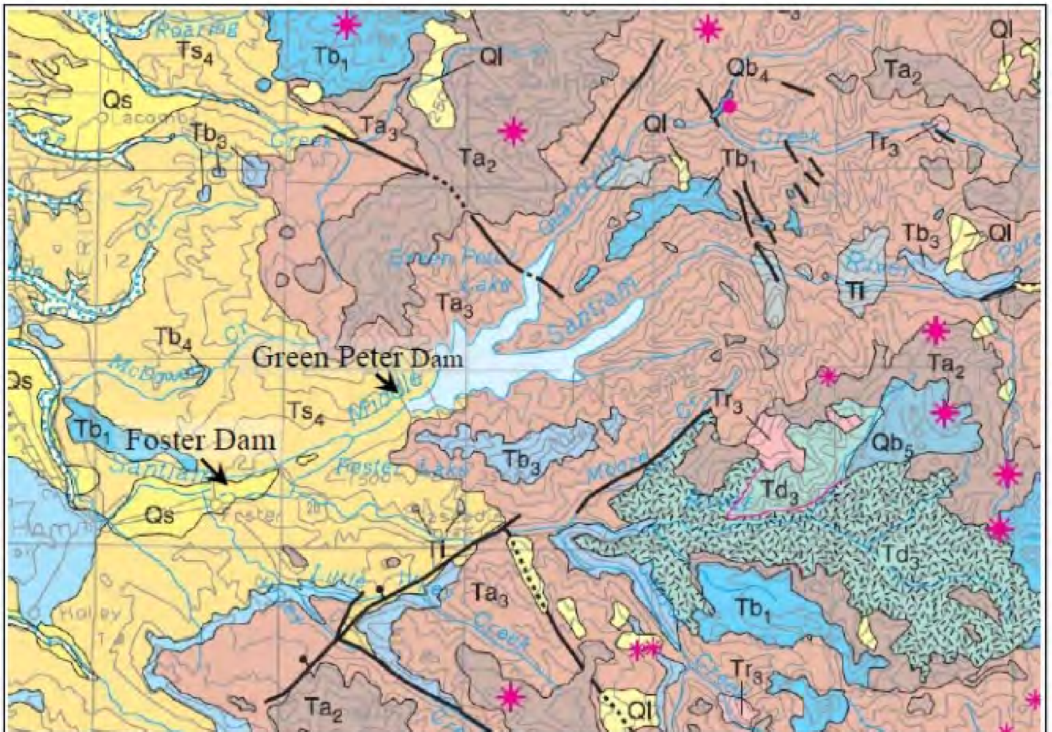
Source: Beaulieu, 1947



Legend:

| Geologic Epic | | Lithology | | Age (million years) | |
|---|---|---|---|---|---|
| Q | Quaternary | l | Landslide | 1 | 2 to 7 |
| T | Tertiary | s | Sediment | 2 | 7 to 17 |
| | | a | Andesite Lavas | 3 | 17 to 25 |
| | | b | Basalt Lavas | 4 | 25 to 35 |
| | | d | Dacite Lavas | 5 | 35 to 45 |
| | | r | Rhyolite Lavas | | |

Example: $Ta_3$ = Tertiary - Andesite Lava Flows - 17 to 25 million years old

**Figure 3.4-17. USACE Interpretation of the Regional Geologic Map around Green Peter and Foster Dams**

USACE, 2015d

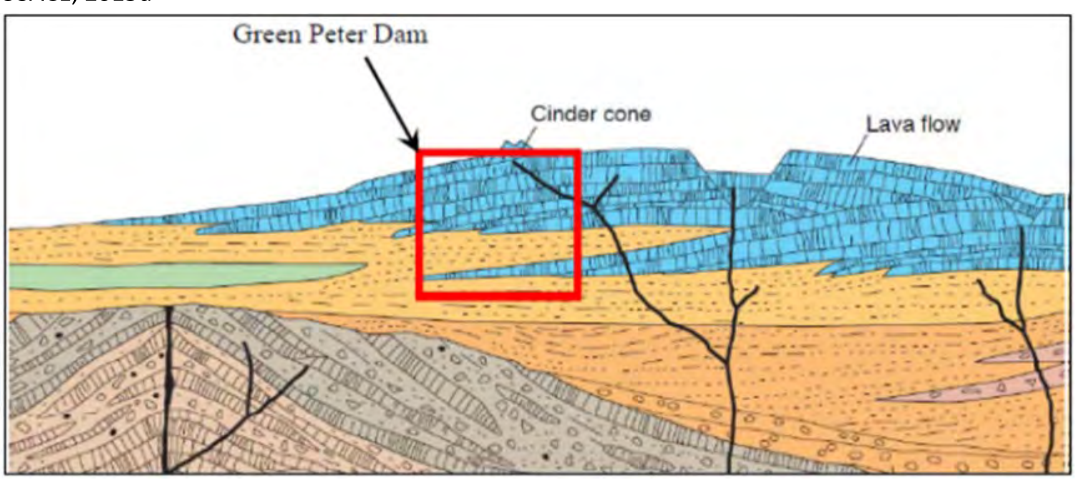


**Figure 3.4-18. Cross Section of the USACE Interpretation of the Regional Geologic Map around Green Peter and Foster Dams**

USACE, 2015d

The dam foundation is constructed in a relatively narrow portion of the Middle Santiam River where the river is downcutting through a layered series of 15 lava flows and 5 interbeds of pyroclastics. The geology through this stretch consists of extensive terrain of ancient landslides. Numerous smaller historic landslides have occurred downstream along the Middle Santiam River. Overburden at the site consists of 7 to 53 feet of soil underlain by up to 24 feet of decomposed rock on both abutments. The dam abuts into rock on both abutments. However, there remains a remnant of an ancient buried river channel further to the east on the left abutment that is separated from the dam by a bedrock high (USACE, 2015d). A 2.5 million square foot landslide is mapped directly upstream of the dam on the left abatement, but it is difficult to tell from the available information whether it is in contact with the reservoir (Beaulieu, 1974). During construction of Green Peter the flood of December 1963 - January 1964 caried landslide debris down Big Alder Creek into the right abutment working area (USACE, 1969). The main body of the Big Alder Creek slide is mapped on the right embankment hillslope above the reservoir (Beaulieu, 1974).

#### ***3.4.1.9 Upper Main Stem Willamette River***

##### *3.4.1.9.1 Basin Overview*

The Upper Willamette Subbasin spans all three physiographic sections within the Willamette Valley, so bedrock includes marine Coast Range formations, volcanics of the Western Cascades, and large amounts of unconsolidated deposits, which make up 99.7% of both the 1% and 0.2% AEP floodplains in the study area. Coast Range formations include Eocene-aged marine pillow lavas and sediments of the Siletz River Volcanics, turbidite-derived sedimentary rocks of the Tyee Formation, deltaic sandstones of the Spencer Formation, slope mudstone of the Yamhill Formation, continental shelf sandstone of the Eugene Formation, and Eocene- to Oligocene-aged intermediate intrusions of the Coastal Intrusives Group. Early Western Cascade Volcanics within the study area include mafic intrusions, the Mehama Formation, and the Eocene-aged, welded, Tuff of Bond Creek (McClaughry et al., 2010; Yeats et al., 1996). The Owl Creek fault (Personius, 2002f) strikes N-S paralleling the Willamette River and the Corvallis fault zone strikes NE-SW along the western edge of the study area (Personius, 2002g).

### 3.4.2 **Environmental Consequences**

#### ***3.4.2.1 Methodology***

This evaluation is based on review of existing geologic reports and qualitative geologic and engineering judgement using known mechanisms of geologic hazards. No new geotechnical or seismic models were developed as part of the analysis. Sediment transport associated with the revetments measure and small-scale impacts to sediment transport from mechanisms like slumping and erosion is discussed in Section 3.3 – River Mechanics and Geomorphology. Environmental consequence impacts are identified for the activation of landslides due to deep drawdown and removal of geologic material metrics based on thresholds of relative change (Alternative versus NAA) normalized to four levels (Negligible, Minor, Moderate, and Major).

Geologic processes develop over the span of hundreds to millions of years and the influence of operational changes from a dam to the geologic environment is limited. Only environmental consequences that are likely to cause impacts in the near future were considered in this analysis.

#### *3.4.2.1.1 Activation of Landslides Due to Deep Drawdown*

The activation of landslides due to deep drawdown metric indicates the potential for the reduction of the minimum pool elevation to induce landslides for the following measures: deeper fall reservoir drawdowns for fish passage (#40), augment instream flows by using the power pool (#304), augment instream flows by using the inactive pool (#718), and spring reservoir drawdown for downstream fish passage (#720). Currently withdrawal from the inactive pool is rare and only occurs during times of extreme drought or during special operations.

When a reservoir level drops more quickly than the pore water can drain, the water remaining in the unconsolidated bank material that was at a steady state with the reservoir water has pore pressures that exceed atmospheric pressure. If water cannot drain quickly enough for pore water pressures to dissipate, for example if the slope is composed of clay or silt, the slope experiences higher shear stress and there is the potential for slope instability (Wieczorek, 1996). For example, it was observed during the intentional breach of Condit Dam that exposure of unvegetated slopes during the full drawdown of the reservoir resulted in slumping of the bank that progressed upstream and caused slope failures through the lower ~2100 feet of the reservoir (Wilcox, et al., 2014). There is no proposed change to reservoir drawdown rates that would result in drawdowns as rapid as those experienced at Condit Dam, but the progressive failure of exposed un-vegetated shoreline soils that were previously saturated and are prone to erosion and slumping due to extended reservoir drawdown is of concern.

Additionally, there is concern that small scale erosion and slumping of the newly exposed, unvegetated reservoir slopes that is assessed in Section 3.3 could progressively destabilize areas of existing weakness, like historic landslides. The presence of historic landslides is used as a proxy for the potential of slope failure in this assessment. Most types of landslide have a high probability of reoccurring in areas that have experienced previous landslides (Highland and Bobrowsky, 2008).

Small scale landslides (defined in this assessment as the resulting landslide body having a surface area extent of <100,000 square feet) are commonly caused by heavy rains and are part of the normal geotechnical regime. It would be difficult to detect whether a small-scale landslide is induced by the change in reservoir operation or other natural processes. Moderate (100,000 square feet - 10,000,000 square feet) and large (>10,000,000 square feet) landslides are likely to have a greater impact on dam safety and critical infrastructure than small scale landslide. For this reason, the presence of moderate and large landslides was used to indicate a higher likelihood of environmental consequences occurring. Typically, the most dangerous time for reservoir slope failure is at initial filling and the period of refilling after the first two cycles of rapid drawdown because the increase in water pressure within the slope increases poor water pressure and reduces the effective strength of the reservoir slope, allowing slopes that are already vulnerable to movement to fail (Wieczorek, 1996). Landslides that experienced movement during or since initial filling are considered more likely to have environmental consequences than historic landslides that have not shown indications of failure vulnerability in this assessment.

Over the lifetime of the Willamette Valley projects there has not been a case of a deep drawdown causing initiation of an existing landslide resulting in a moderate or large earth movement. Cougar was drawn down to below elevation 1510 feet NAVD88 without incident between December 20, 2012 and January 12, 2013 (USACE, 2013b), which is 4 feet above the minimum drawdown elevation recommended under Alternative 2A. Fall Creek was drawn down to the elevation of the original river channel (680 feet NAVD88) during a 2015 fish operation without incident (USACE, 2016d). Although the Willamette Valley projects do not have a history of poor performance during drawdown the presence of landslides that extend into the reservoir mean that the potential for failure cannot be eliminated.

There are four levels of change when comparing the No Action Alternative (NAA) to the others (Table 3.4-1):

**Table 3.4-1. Evaluation Criteria for Activation of Landslides Due to Deep Drawdown**

| Effect Scale | Criteria |
|---|---|
| **None/negligible** | No or only small landslides are mapped in contact with the reservoir pool or the surface exposure metric calculated in Section 3.3 has an effect rating of “none/negligible” or “minor.” |
| **Minor** | The surface exposure metric calculated in Section 3.3 has a “major” effect rating and landslides of moderate or large surface area mapped in connection with the reservoir that do not have a history of movement since the beginning of reservoir operation and engineering judgement indicates that the probability of slope failure due to deep drawdown cannot be eliminated. |
| **Moderate** | The surface exposure metric calculated in Section 3.3 has a “major” effect rating and landslides of moderate or large surface area are mapped in connection with the reservoir that have a history of movement since the beginning of reservoir operation. And no site-specific study that indicates failure is likely to occur due to deep drawdown is available, but, based on engineering judgement, initiation of landslides by deep drawdown cannot be ruled out. |
| **Major** | The surface exposure metric calculated in Section 3.3 has a “major” effect rating and landslides of moderate or large surface area mapped in connection with the reservoir that have a history of movement since |

| Effect Scale | Criteria |
|---|---|
| | the beginning of reservoir operation. And a site-specific study has shown that the reduction in minimum pool elevation is likely to induce failure of the slope. |

*3.4.2.1.2 Removal of Geologic Material*

Construction of water temperature control towers (#105) and structural downstream fish passages (#392) may necessitate some permanent removal of a non-negligible volume (more than 12 cubic yards) of sediment and bedrock for construction of the temperature control tower foundation and outlets.

There are four levels of change when comparing the NAA to the others (Table 3.4-2):

**Table 3.4-2. Evaluation Criteria for Potential Effects for Removal of Geologic Material**

| Effect Scale | Criteria |
|---|---|
| **None/negligible** | No measures would result in removal of geologic materials. |
| **Minor** | Geologic materials would be removed from the dam site or reservoir as the result of a measure, but these changes would be small and localized. |
| **Moderate** | Geologic materials would be removed from the dam site or reservoir as the result of a measure at a scale that will be measurable and have either localized or regional-scale adverse effects/benefits. |
| **Major** | Geologic materials will be removed from the dam site or reservoir as the result of a measure at a scale that would have substantial consequences on a local or regional level. |

*3.4.2.1.3 Construction*

The Draft PEIS will discuss general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects during the implementation phase.

Direct effects from construction on geology and soils include local removal of geologic materials permanently due to excavation and temporally due to dredging. Drawdowns to construct water temperature control towers at Detroit, Lookout Point, Green Peter, and Hills Creek and a long drawdown at Cougar to construct the outlet works for the routine use of the diversion tunnel. Indirect effects from the drawdowns include the potential for slope stability issues from excess pore pressure if the initial drawdown is too rapid and increased shoreline exposure that could allow small scale slope stability issues and erosion to synergistically oversteepen slopes, which could lead to further slope instability issues during post-construction refilling. It is also possible for removal of materials during excavation and dredging to oversteepen the toe of an existing plain of weakness, indirectly leading to failure, but this is usually mitigated by good geotechnical design.

### *3.4.2.2 No Action Alternative*

#### *3.4.2.2.1 Santiam Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under normal operational conditions the Detroit and Green Peter reservoirs do not go below the minimum conservation pool even in the driest years. Big Cliff and Foster primarily reregulate Detroit and Green Peter during conservation season, smoothing power peaking flow from the upstream dam, and therefore follow the rule curve very closely in all years under the NAA. Large and moderate sized historic landslides are present at Detroit Dam and large landslides that have experienced small-scale movement, causing road maintenance problems, since completion of the project are present at Foster. All four dams have small-scale landslides that are currently active and cause short term damage to infrastructure that must be repaired.

**Removal of Geologic Material**

Under the NAA, removal of geologic materials is not expected at any project in this subbasin.

#### *3.4.2.2.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Fern Ridge reservoir remains above the minimum pool elevation in even dry years. There are no mapped landslides around the reservoir.

**Removal of Geologic Material**

Under the NAA, removal of geologic materials is not expected at any project in this subbasin.

#### *3.4.2.2.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Even in dry years the reservoir elevation does not go below the minimum pool elevation at Cougar and Blue River. Large and moderate size landslides are present around the Cougar reservoir and have experienced small scale movements resulting in minor rock fall and slumping since completion of the project.

**Removal of Geologic Material**

Under the NAA, removal of geologic materials is not expected at any project in this subbasin.

#### *3.4.2.2.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Due to the injunction the Fall Creek pool is drawn down to elevation 680 ft NAVD88, which is below the rule curve minimum pool, annually in autumn. Hills Creek and Lookout Point reach the bottom of the conservation pool in about 5% of years, but does not go below the minimum pool elevation. Dexter is a run of river dam and has minimal storage. Hills Creek and Lookout Point have historic landslides around their reservoirs and Hills Creek has moderate sized landslides that have displayed small scale activity, resulting in road damage, since project completion. Hills Creek and Lookout Point have active small-scale landslides that have caused temporary damage to infrastructure that must be repaired and Fall Creek has small-scale ancient landslides around the reservoir.

**Removal of Geologic Material**

Under the NAA, removal of geologic materials is not expected at any project in this subbasin.

#### *3.4.2.2.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Dorena and Cottage Grove reach the bottom of their conservation pool in the driest 5% of years but are not drafted below their minimum pool. Dorena has large ancient landslides mapped around the reservoir rim as well as several active small landslides that have damaged infrastructure and resulting in the need for periodic repairs to the roads and railroad around the Dorena reservoir. Cottage Grove does not have any landslides mapped around the reservoir rim.

**Removal of Geologic Material**

Under the NAA, removal of geologic materials is not expected at any project in this subbasin.

#### *3.4.2.2.6 Climate Change*

Increased variability in the spring precipitation may result in less reliable reservoir refill. Additionally, due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently. Drawdown may be more rapid to meet downstream minimum flow targets, which presents some landslide risk to reservoirs that have existing plains of weakness. Deep drafts due to climate change may result in increased shoreline exposure, which may allow small-scale failures of newly exposed, unvegetated, erodible sediment to propagate into existing failures, resulting in reactivation of large-scale material movements. These effects are particularly present in the Santiam and Middle Fork subbasins because they may be drafted more than other WVS reservoirs.

##### *3.4.2.2.7 Summary of Effects of the No Action Alternative*

Under the NAA, negligible change is expected for the activation of landslides due to deep drawdown. The current regime of small-scale landslides being activated at roads and rail lines during wet weather will continue as described in the affected environments section. The negligible change in these metrics results from negligible change in water storage patterns, seasonal reservoir elevations, and loading of slopes due to seasonal precipitation.

#### ***3.4.2.3 Alternative 1 – Project Storage Alternative***

##### *3.4.2.3.1 Santiam Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 1, augmenting instream flows by using the power pool (#304) is proposed for Green Peter and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Due to the moderate sized landslides that do not have a history of movement, environmental consequences at Green Peter Dam are expected to be minor. Based on the large landslides at Detroit Dam that do have a history of movement since the beginning of dam operations, the indirect adverse environmental effect from this measure is moderate compared to the NAA.

**Removal of Geologic Material**

This alternative includes constructing a water temperature control tower (#105) at Green Peter and Detroit, and constructing a structural downstream fish passage (#392) for Detroit, Foster, and Green Peter. These structures would likely require small-scale and localized rock excavation, which would have a minor direct effect on local geology compared to the NAA which does not include these structures.

##### *3.4.2.3.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included for Fern Ridge under this alternative. The effect of this alternative on local geology is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

#### *3.4.2.3.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 1 includes augmenting instream flows by using the power pool (#304) at Cougar and augmenting instream flows by using the inactive pool (#718) for Blue River, both of which result in an increase to shoreline exposure. Compared to the NAA there is the potential for moderate, indirect, adverse, local effects from large landslides that have a history of movement along the upstream reservoir rims at Cougar due to increased shoreline exposure from augmented instream flows from the power pool (#304). The effects from increased surface exposure augmenting instream flows by using the inactive pool (#718) at Blue River are expected to be negligible because only small-scale landslides are mapped in contact with the reservoir.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

#### *3.4.2.3.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 1 includes augmenting instream flows by using the power pool (#304) at Lookout Point and Hills Creek and augmenting instream flows by using the inactive pool (#718) at Fall Creek. Augmentation of instream flows by using the inactive pool (#718) is not expected to result in a difference from the NAA at Fall Creek, but augmented instream flows from the power pool (#304) results in reservoir drawdowns below the NAA rule curve elevations and therefore an increase to shoreline exposure at Lookout Point and Hills Creek.

Due to the increase in shoreline exposure and presence of large landslides that do not have a history of movement there is potential for minor, indirect, adverse, local effects at Lookout Point from augmented instream flows from the power pool (#304). Hills Creek has moderate sized landslides with a history of movement so there is the potential for moderate indirect, adverse, local effects from landslides along the upstream reservoir rims due to augmented instream flows from the power pool (#304) compared to the NAA.

**Removal of Geologic Material**

Alternative 1 includes constructing a water temperature control tower (#105) at Lookout Point and Hills Creek and constructing structural downstream fish passage (#392) at Lookout Point which would require small-scale and localized rock excavation. This would have a minor direct effect on local geology compared with the NAA that does not include a WTC.

#### *3.4.2.3.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 1 includes augmenting instream flows by using the inactive pool (#718) which results in reservoir drawdowns below the normal rule curve elevations at Cottage Grove and Dorena. Because there are large landslides mapped at Dorena that have no history of movement, this measure would have a minor, indirect, adverse, local effect on landslides compared to the NAA. No landslides are mapped around Cottage Grove, so the effect of drawdown would be negligible.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

#### *3.4.2.3.6 Climate Change*

Climate change would increase the probability of landslides due to deep drawdown under this alternative by three mechanisms: increasing the annual probability that a deep drawdown would occur, increasing the annual probability that major precipitation events would occur coincident with deep drawdown, and increasing the frequency of wildfires. Under Alternative 1, climate change is likely to enhance landslide risk at Cougar, Detroit, Dorena, Green Peter, Hills Creek, and Lookout Point compared with the NAA.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently and sooner in the year, which would increase the duration of shoreline exposure. This would increase the potential for erosion to undercut and destabilize slopes, which could result in an increased risk of slope failure during the next refill/drawdown cycle. Drawdown also may be more rapid to meet downstream minimum flow targets, which would mean a higher pore pressure differential between the slope and atmosphere could occur, increasing the risk of slope failure.

The WVS will likely experience increasing wintertime flow volumes in the future because of larger precipitation events and more precipitation falling as rain instead of snow. Intense rainfall is a triggering event for shallow landslides (Wieczorek, 1996). If large events were to occur coincident with deep drawdowns the exposed shoreline may saturate and cause shallow landslides that progress into larger debris flows and reactivate larger landslides in vulnerable slopes.

Increased variability in the spring rainfall, drier hotter summers, and lower summer baseflow mean that there is more potential for wildfires to impact the reservoir rim. Wildfire can produce a water repellent soil layer that increases overland flow through burnt forested areas (Wieczorek, 1996), and may lead to erosive undercutting of the exposed shoreline and saturation of unvegetated soils, which could lead to slope failure.

*3.4.2.3.7 Summary of Effects of Alternative 1*

**Table 3.4-3. Summary of effects for Geology and Soils under Alternative 1 as compared to the No Action Alternative**

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Cottage Grove | Augmentation from the inactive pool to meet flow targets at Cottage Grove would have a **negligible** effect on the activation of landslides due to no mapped landslides being in connection with the reservoir. |
| Coast Fork Willamette - Dorena | Augmentation from the inactive pool to meet flow targets at Dorena would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate mapped landslides that do not have a history of movement. |
| Long Tom - Fern Ridge | No measures that effect landslide formation are proposed for at Fern Ridge that would increase shoreline exposure, therefore effects are **negligible**. |
| McKenzie - Blue River | Augmentation from the inactive pool to meet flow targets at Blue River would increase shoreline exposure but would have a **negligible** effect on the activation of landslides because only small landslides are mapped around the reservoir. |
| McKenzie - Cougar | Augmentation from the power pool to meet flow targets at Cougar would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction |
| Middle Fork Willamette - Dexter | No measures that effect landslide formation are proposed at Dexter that would increase shoreline exposure, therefore effects are **negligible**. |
| Middle Fork Willamette - Fall Creek | Augmentation from the inactive pool to meet flow targets at Fall Creek would not increase shoreline exposure and would have a **negligible** effect on the activation of landslides |
| Middle Fork Willamette - Hills Creek | Augmentation from the power pool to meet flow targets at Hills Creek would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate mapped landslides that have a history of movement since project construction |
| Middle Fork Willamette - Lookout Point | Augmentation from the power pool to meet flow targets at Lookout Point would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate mapped landslides that do not have a history of movement. Construction of a temperature control tower and |

| Basin and Project | Summary |
|---|---|
| | structural downstream passage at Lookout Point would result in minor local removal of geologic materials. |
| Santiam - Big Cliff | No measures that effect landslide formation are proposed for at Big Cliff that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Detroit | Augmentation from the power pool to meet flow targets at Detroit would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction. Construction of a temperature control tower and structural downstream passage at Detroit would result in minor local removal of geologic materials. |
| Santiam - Foster | No measures that effect landslide formation are proposed at Foster that would increase shoreline exposure, therefore effects are **negligible**. Construction of a structural downstream passage at Foster would result in **minor** local removal of geologic materials. |
| Santiam - Green Peter | Augmentation from the power pool to meet flow targets at Green Peter would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate mapped landslides that do not have a history of movement since project completion. Construction of a temperature control tower and structural downstream passage at Green Peter would result in minor local removal of geologic materials. |

#### *3.4.2.4 Alternative 2A -- Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

##### *3.4.2.4.1 Santiam Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 2A, augmenting instream flows by using the power pool (#304) is proposed for Green Peter and Detroit, which would allow these projects to drawdown below the power pool to augment flows and which increases shoreline exposure relative to the NAA. Deeper fall reservoir drawdowns for fish passage (#40) under Alternative 2A would allow deep reservoir drawdown to within 25 feet of the RO invert at Green Peter, which also increases shoreline exposure.

Green Peter has moderate-sized landslides that have not experienced movement since project initiation. Therefore, the combined increase in shoreline exposure due to deep fall reservoir drawdown (#40) and augmented instream flows from the power pool (#304) have the potential to initiate minor, indirect, adverse, local effects from landslides around the reservoir's rim compared to the NAA. Based on the moderate-sized landslides at Detroit Dam that do have a history of movement since the beginning of dam operations, augmented instream flows from the power pool (#304) has some potential to initiate indirect, moderate, adverse, local effects from landslides around the reservoir's rim. Increases in shoreline exposure at Big Cliff would have a negligible effect on the activation of landslides due to only small landslides being present in connection to the reservoir compared to the NAA.

**Removal of Geologic Material**

This alternative includes constructing a water temperature control tower (#105) at Detroit and constructing structural downstream fish passage (#392) for Foster and Detroit. These structures would likely require small-scale and localized rock excavation. This would have a minor direct effect on local geology compared to the NAA.

*3.4.2.4.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included for Fern Ridge under this alternative. The effect of this alternative on local geology is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

*3.4.2.4.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 2A includes augmenting instream flows by using the power pool (#304) for Blue River and augmenting instream flows by using the inactive pool (#718) for Cougar. Both measures result in increased shoreline exposure compared with the NAA. Because of the presence of large landslides with a history of movement mapped around the Cougar reservoir, there is the potential for moderate, indirect, adverse, local effects from landslides at Cougar due to augmented instream flows from the power pool (#304) compared to the NAA. The effects from augmentation of instream flows by using the inactive pool (#718) at Blue River would be negligible because Blue River only has small-scale landslides mapped near the reservoir.

**Removal of Geologic Material**

This alternative includes constructing structural downstream fish passage (#392) for Cougar. These structures would likely require small-scale and localized rock excavation, which would have a minor local effect compared to the NAA.

#### *3.4.2.4.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 2A includes augmenting instream flows by using the power pool (#304) for Lookout Point and Hills Creek, which increases shoreline exposure compared with the NAA. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek, but would not increase shoreline exposure compared with the NAA so the effect of this measure is negligible. Due to the increase in shoreline exposure and presence of large landslides that do not have a history of movement at Lookout Point, there is some potential for minor, indirect, adverse, local effects due to this alternative. There is the potential for moderate, indirect, adverse, local effects from landslides that have a history of movement along the upstream reservoir rims at Hills Creek due to the increase in shoreline exposure under this alternative compared to the NAA.

**Removal of Geologic Material**

This alternative includes constructing structural downstream fish passage (#392) at Lookout Point which would require small-scale and localized rock excavation. This would have a minor direct effect on local geology.

#### *3.4.2.4.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included under this alternative. The effect of this alternative is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

#### *3.4.2.4.6 Evaluation of Near-Term Operations Measure*

#### *3.4.2.4.7 Santiam Subbasin*

The near-term operations (NTO) measure within the North Santiam Basin includes Fall/Winter downstream fish passage through the upper regulating outlets, spring fish passage through strategic use of spillway and turbines at Detroit Dam and spreading spill to reduce total dissolved gas at Big Cliff Dam. The near-term operations measure within the South Santiam Subbasin include outplanting of adult Chinook above Green Peter Reservoir, downstream fish passage at Green Peter Dam via the spillway in the spring and fall, deep drawdown and RO prioritization for downstream fish passage, and downstream fish passage at Foster via the spillway in the spring and fall.

**Activation of Landslides Due to Deep Drawdown**

The near-term operations measure involves allowing deep reservoir drawdown to within 35 feet of the RO invert at Green Peter. Green Peter has moderate-sized landslides that have not experienced movement since project initiation, therefore, the near-term operations measure has some potential to initiate minor, indirect, adverse, local effects from landslides around the reservoir's rim compared to the NAA. Although the near-term operations at Detroit themselves do not affect reservoir levels, their combined effect on outflow in drier years results in increased shoreline exposure, which would have a moderate, indirect, adverse, local effect from landslides around the reservoir rim that have experienced movement since project completion compared to the NAA.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under the near-term operations measure. There would be negligible effect resulting from this measure.

*3.4.2.4.8 Long Tom Subbasin*

There are no local operations proposed under the near-term operations measure within the Long Tom subbasin.

**Activation of Landslides Due to Deep Drawdown**

The near-term operations measure would not reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO, therefore, there would be negligible effect.

**Removal of Geologic Material**

The near-term operations measure would not result in excavation of geologic materials, therefore, there would be negligible effect.

*3.4.2.4.9 McKenzie Subbasin*

The near-term operations measures within the McKenzie Subbasin includes spring and fall drawdown for fish passage at Cougar Reservoir to a target elevation of 1505 feet and delayed reservoir refill and RO prioritization for improved downstream fish passage compared to the NAA.

**Activation of Landslides Due to Deep Drawdown**

Cougar has large- and moderate-sized landslides that have experienced movement since project initiation, therefore, increased shoreline exposure due to the near-term operation measures have some potential to initiate major, indirect, adverse, local effects from landslides around the reservoirs rim.

**Removal of Geologic Material**

The near-term operations measure would not result in excavation of geologic materials, therefore, there would be negligible effect.

#### *3.4.2.4.10 Middle Fork of the Willamette River Subbasin*

The near-term operations measure within the Middle Fork Willamette Subbasin includes use of the regulating outlet for downstream fish passage at Hills Creek , deep drawdown for fish passage at Lookout Point in winter, use of the spillway for fish passage at Lookout Point in the spring, use of the Lookout Point regulating outlets for temperature management in the summer and fall, and deep drawdown in the fall and delayed refill in the spring for fish passage at Fall Creek. For the operations at Lookout Point, storage at Hills Creek would be used for refilling Lookout Point in early March.

**Activation of Landslides Due to Deep Drawdown**

The near-term operations measure involves deep drawdown to a target elevation of 761 ft NAVD88, 50 ft over the top of the penstock at Lookout Point. Due to the presence of large landslides that do not have a history of movement at Lookout Point, there is some potential for minor, indirect, adverse, local effects due to the increased shoreline exposure from the near-term operations measure. The near-term operations require Detroit to prioritize refilling Lookout Point after fall drawdowns, so in winter after a dry year Hills Creek Reservoir may reach lower minimum elevations than under the NAA. The change the operating range of the reservoir results in increased shoreline exposure, which would have a moderate, indirect, adverse, local effect from landslides around the reservoir rim that have experienced movement since project completion at Hills Creek.

**Removal of Geologic Material**

The near-term operations measure would not result in excavation of geologic materials, therefore, there would be negligible effect.

#### *3.4.2.4.11 Coast Fork of the Willamette River Subbasin*

There are no local operations proposed under the near-term operations measure within the Coast Fork subbasin.

**Activation of Landslides Due to Deep Drawdown**

The near-term operations measure would not reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO, therefore, there would be negligible effect.

**Removal of Geologic Material**

The near-term operations measure would not result in excavation of geologic materials, therefore, there would be negligible effect.

*3.4.2.4.12 Climate Change*

Climate change would increase the probability of initiation of landslides due to deep drawdown under this alternative by three mechanisms: increasing the annual probability that a deep drawdown would occur, increasing the annual probability that major precipitation events would occur coincident with deep drawdown, and increasing the frequency of wildfires. Under Alternative 2A, climate change is likely to enhance landslide risk at Cougar, Detroit, Green Peter, and Hills Creek compared with the NAA.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently and sooner in the year, which would increase the duration of shoreline exposure. This would increase the potential for erosion to undercut and destabilize slopes, which could result in an increased risk of slope failure during the next refill/drawdown cycle. Drawdown also may be more rapid to meet downstream minimum flow targets, which would mean a higher pore pressure differential between the slope and atmosphere could occur, increasing the risk of slope failure.

The WVS will likely experience increasing wintertime flow volumes in the future because of larger precipitation events and more precipitation falling as rain instead of snow. Intense rainfall is a triggering event for shallow landslides (Wieczorek, 1996). If large events were to occur coincident with deep drawdowns, the exposed shoreline may saturate and cause shallow landslides that progress into larger debris flows and reactivate larger landslides in vulnerable slopes.

Increased variability in the spring rainfall, drier hotter summers, and lower summer baseflow mean that there is more potential for wildfires to impact the reservoir rim. Wildfire can produce a water repellent soil layer that increases overland flow through burnt forested areas (Wieczorek, 1996), and may lead to erosive undercutting of the exposed shoreline and saturation of unvegetated soils, which could lead to slope failure.

*3.4.2.4.13 Summary of Effects of Alternative 2A*

**Table 3.4-4. Summary of effects for Geology and Soils under Alternative 2A as compared to the No Action Alternative**

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Cottage Grove | No measures that effect landslide formation are proposed for at Cottage Grove that would increase shoreline exposure, therefore effects are **negligible**. |

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Dorena | No measures that effect landslide formation are proposed for at Dorena that would increase shoreline exposure, therefore effects are **negligible**. |
| Long Tom - Fern Ridge | No measures that effect landslide formation are proposed for at Fern Ridge that would increase shoreline exposure, therefore effects are **negligible**. |
| McKenzie - Blue River | Augmentation from the inactive pool to meet flow targets at Blue River would increase shoreline exposure, but would have a **negligible** effect on the activation of landslides because only small landslides are mapped around the reservoir. |
| McKenzie - Cougar | Augmentation from the power pool to meet flow targets at Cougar would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate mapped landslides that have a history of movement since project construction. Construction of a structural downstream passage at Cougar would result in **minor** local removal of geologic materials. |
| Middle Fork Willamette - Dexter | No measures that effect landslide formation are proposed at Dexter that would increase shoreline exposure, therefore effects are **negligible**. |
| Middle Fork Willamette - Fall Creek | Augmentation from the inactive pool to meet flow targets at Fall Creek would not increase shoreline exposure and would have a **negligible** effect on the activation of landslides |
| Middle Fork Willamette - Hills Creek | Augmentation from the power pool to meet flow targets at Hills Creek would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate mapped landslides that have a history of movement since project construction |
| Middle Fork Willamette - Lookout Point | Augmentation from the power pool to meet flow targets at Lookout Point would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate mapped landslides that do not have a history of movement. Construction of a structural downstream passage at Lookout Point would result in **minor** local removal of geologic materials. |
| Santiam - Big Cliff | No measures that effect landslide formation are proposed for at Big Cliff that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Detroit | Augmentation from the power pool to meet flow targets at Detroit would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and |

| Basin and Project | Summary |
|---|---|
| | moderate sized mapped landslides that have a history of movement since project construction. Construction of a temperature control tower and structural downstream passage at Detroit would result in **minor** local removal of geologic materials. |
| Santiam - Foster | No measures that effect landslide formation are proposed at Foster that would increase shoreline exposure, therefore effects are **negligible**. Construction of a structural downstream passage at Foster would result in **minor** local removal of geologic materials. |
| Santiam - Green Peter | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall at Green Peter would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement since project completion. |

#### *3.4.2.5 Alternative 2B -- Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

##### *3.4.2.5.1 Santiam Subbasin*

**<u>Activation of Landslides Due to Deep Drawdown</u>**

Augmenting instream flows by using the power pool (#304) is proposed for Green Peter and Detroit under Alternative 2B. Deeper fall reservoir drawdowns for fish passage (#40) would allow deep reservoir drawdown to within 25 feet of the RO invert in fall at Green Peter.

Green Peter has moderate-sized landslides that have not experienced movement since project initiation, therefore increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40) and augmented instream flows from the power pool (#304) have some potential to initiate minor, indirect, adverse, local effects from landslides around the reservoir's rim. Based on the moderate-sized landslides at Detroit Dam that have a history of movement since the beginning of dam operations, augmented instream flows from the power pool (#304) has some potential to initiate moderate, indirect, adverse, local effects from landslides around the reservoir's rim.

**<u>Removal of Geologic Material</u>**

This alternative includes constructing a water temperature control tower (#105) at Detroit and constructing structural downstream fish passage (#392) for Foster and Detroit. These structures would likely require small-scale and localized rock excavation. This would have a minor direct effect on local geology at both Foster and Detroit compared to the NAA.

#### *3.4.2.5.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included for Fern Ridge under this alternative. The effect of this alternative on local geology is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

#### *3.4.2.5.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

This alternative includes augmenting instream flows by using the power pool (#304) for Blue River and augmenting instream flows by using the inactive pool (#718) for Cougar both of which results in reservoir drawdowns below the normal rule curve elevations. At Cougar deeper fall reservoir drawdowns for fish passage (#40) would allow deep reservoir drawdown to within 10 feet of the RO invert during the fall season and spring reservoir drawdown for downstream fish passage (#720) proposes use of the diversion tunnel and drawdown to streambed. Based on the presence of landslides at Cougar that have shown some small-scale movement since project initiation there is the potential for moderate, indirect, adverse, local effects from landslides along the upstream reservoir rims because of increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40), augmented instream flows from the power pool (#304), and spring reservoir drawdown for downstream fish passage (#720) compared to the NAA. The effects from augmentation of instream flows by using the inactive pool (#718) at Blue River are expected to be negligible because no landslides are mapped in contact with the reservoir.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

#### *3.4.2.5.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point and Hills Creek and augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek. Augmentation from the inactive pool to meet flow targets (#718) at Fall Creek would not increase shoreline exposure and would have a negligible effect on the activation of landslides. Due to the presence of large landslides that do not have a history of movement, there is the potential for minor, indirect, adverse, local effects at Lookout Point due to increased shoreline exposure from augmented instream flows from the power pool (#304). Based on the presence of landslides at Hills Creek that have shown some small-scale movement since project initiation, there is the potential for moderate, indirect, adverse, local effects from increased shoreline exposure due to augmented instream flows from the power pool (#304) compared to the NAA.

**Removal of Geologic Material**

This alternative includes constructing structural downstream fish passage (#392) at Lookout Point which would require localized rock excavation. This would have a minor direct effect on local geology.

*3.4.2.5.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included under this alternative. The effect of this alternative is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

*3.4.2.5.6 Near Term Operations Measures*

See Alternative 2A, Section 0, for description of effects due to the Near-Term Operations Measure.

*3.4.2.5.7 Climate Change*

Climate change would increase the probability of initiation of landslides due to deep drawdown under this alternative by three mechanisms: increasing the annual probability that a deep drawdown would occur, increasing the annual probability that major precipitation events would occur coincident with deep drawdown, and increasing the frequency of wildfires. Under Alternative 2B climate change is likely to enhance landslide risk at Cougar, Detroit, Green Peter, and Hills Creek compared with the NAA.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently and sooner in the year, which would increase the duration of shoreline exposure. This would increase the potential for erosion to undercut and destabilize slopes, which could result in an increased risk of slope failure during the next refill/drawdown cycle. Drawdown also may be more rapid to meet downstream minimum flow targets, which would mean a higher pore pressure differential between the slope and atmosphere could occur, increasing the risk of slope failure.

The WVS would likely experience increasing wintertime flow volumes in the future because of larger precipitation events and more precipitation falling as rain instead of snow. Intense rainfall is a triggering event for shallow landslides (Wieczorek, 1996). If large events were to occur coincident with deep drawdowns, the exposed shoreline may saturate and cause shallow landslides that progress into larger debris flows and reactivate larger landslides in vulnerable slopes.

Increased variability in the spring rainfall, drier hotter summers, and lower summer baseflow mean that there is more potential for wildfires to impact the reservoir rim. Wildfire can produce a water repellent soil layer that increases overland flow through burnt forested areas (Wieczorek, 1996), and may lead to erosive undercutting of the exposed shoreline and saturation of unvegetated soils, which could lead to slope failure.

##### *3.4.2.5.8 Summary of Effects of Alternative 2B*

**Table 3.4-5. Summary of effects for Geology and Soils under Alternative 2B as compared to the No Action Alternative**

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Cottage Grove | No measures that effect landslide formation are proposed for at Cottage Grove that would increase shoreline exposure, therefore effects are **negligible**. |
| Coast Fork Willamette - Dorena | No measures that effect landslide formation are proposed for at Dorena that would increase shoreline exposure, therefore effects are **negligible**. |
| Long Tom - Fern Ridge | No measures that effect landslide formation are proposed for at Fern Ridge that would increase shoreline exposure, therefore effects are **negligible**. |
| McKenzie - Blue River | Augmentation from the inactive pool to meet flow targets at Blue River would increase shoreline exposure but would have a **negligible** effect on the activation of landslides because only small landslides are mapped around the reservoir. |
| McKenzie - Cougar | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall at Cougar would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate mapped landslides that have a history of movement since project construction. |
| Middle Fork Willamette - Dexter | No measures that effect landslide formation are proposed for Dexter that would increase shoreline exposure, therefore effects are **negligible**. |
| Middle Fork Willamette - Fall Creek | Augmentation from the inactive pool to meet flow targets at Fall Creek would not increase shoreline exposure and would have a **negligible** effect on the activation of landslides. |

| Basin and Project | Summary |
|---|---|
| Middle Fork Willamette - Hills Creek | Augmentation from the power pool to meet flow targets at Hills Creek would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction. |
| Middle Fork Willamette - Lookout Point | Augmentation from the power pool to meet flow targets at Lookout Point would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate mapped landslides that do not have a history of movement. Construction of a structural downstream passage at Lookout Point would result in **minor** local removal of geologic materials. |
| Santiam - Big Cliff | No measures that effect landslide formation are proposed for Big Cliff that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Detroit | Augmentation from the power pool to meet flow targets at Detroit would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction. Construction of a temperature control tower and structural downstream passage at Detroit would result in **minor** local removal of geologic materials. |
| Santiam - Foster | No measures that effect landslide formation are proposed at Foster that would increase shoreline exposure, therefore effects are **negligible**. Construction of a structural downstream passage at Foster would result in **minor** local removal of geologic materials. |
| Santiam - Green Peter | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall at Green Peter would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement since project completion. |

### *3.4.2.6 Alternative 3A – Operations-Focused Fish Passage Alternative*

#### *3.4.2.6.1 Santiam Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 3A, augmenting instream flows by using the power pool (#304) is proposed for Green Peter and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Under Alternative 3A, deeper fall reservoir drawdowns (#40) for Detroit and Green Peter and spring reservoir drawdowns (#720) for Detroit allow deep reservoir drawdown to within 25 feet of the RO.

Green Peter has moderate-sized landslides that have not experienced movement since project initiation, therefore increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40) and augmented instream flows from the power pool (#304) have some potential to initiate minor indirect adverse local effects. Based on the moderate sized landslides at Detroit Dam that have a history of movement since the beginning of dam operations, deeper fall reservoir drawdowns for fish passage (#40), augmented instream flows from the power pool (#304), and spring reservoir drawdown for downstream fish passage (#720) have some potential to initiate moderate, indirect, adverse, local effects compared to the NAA.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

#### *3.4.2.6.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included for Fern Ridge under this alternative. The effect of this alternative on local geology is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

#### *3.4.2.6.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 3A includes augmenting instream flows by using the inactive pool (#718) for Blue River and augmenting instream flows by using the power pool (#304) for Cougar both of which results in reservoir drawdowns below the normal rule curve elevations. Deeper fall reservoir drawdowns for fish passage (#40) would allow deep reservoir drawdown to within 25 feet of the RO invert in fall at Blue River. There is the potential for moderate, indirect, adverse, local effects from landslides along the upstream reservoir rims at Cougar from increased shoreline exposure due to augmented instream flows from the power pool (#304) due to the presence of large landslides that have a history of movement since project completion compared to the NAA. Because Blue River does not have landslides in contact with the reservoir, the effects from deeper fall reservoir drawdowns for fish passage (#40) and augmentation of instream flows by using the inactive pool (#718) are expected to be negligible.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative for this subbasin. The effect of this alternative on local geology is none.

##### *3.4.2.6.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 3A, augmenting of instream flows by using the power pool (#304) is proposed for Lookout Point and Hills Creek and augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek. Deeper fall reservoir drawdowns (#40) is proposed for both Lookout Point and Hills Creek and a spring reservoir drawdown (#720) is proposed for Lookout Point.

No increase in shoreline exposure is anticipated at Fall Creek under Alternative 3A, so the effect from augmentation of instream flows by using the inactive pool (#718) at Fall Creek would be negligible. Due to large landslides with no history of movement since project completion in contact with the reservoir at Lookout Point, there is the potential for minor, indirect, adverse, local effects from increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40), augmented instream flows from the power pool (#304), and spring reservoir drawdown for downstream fish passage (#720) compared to the NAA. Deeper fall reservoir drawdowns for fish passage (#40) and augmented instream flows from the power pool (#304) at Hills Creek would have moderate indirect adverse local effects due to large landslides that have a history of movement since project completion in contact with the reservoir.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative for this subbasin. The effect of this alternative on local geology is none.

##### *3.4.2.6.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 3A also includes augmenting instream flows by using the inactive pool (#718) at Cottage Grove and Dorena. Because there are large landslides mapped at Dorena that have no history of movement, this measure is expected to have a minor direct effect on landslides. No landslides are mapped around the reservoir at Cottage Grove, so the effects would be negligible compared to the NAA.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

*3.4.2.6.6 Near Term Operations Measures*

See Alternative 2A, Section 0, for description of effects due to the Near-Term Operations Measure.

*3.4.2.6.7 Climate Change*

Climate change would increase the probability of initiation of landslides due to deep drawdown under this alternative by three mechanisms: increasing the annual probability that a deep drawdown would occur, increasing the annual probability that major precipitation events would occur coincident with deep drawdown, and increasing the frequency of wildfires. Under Alternative 3A, climate change is likely to enhance landslide risk at Cougar, Detroit, Dorena, Green Peter, and Lookout Point compared with the NAA.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently and sooner in the year, which would increase the duration of shoreline exposure. This would increase the potential for erosion to undercut and destabilize slopes, which could result in an increased risk of slope failure during the next refill/drawdown cycle. Drawdown also may be more rapid to meet downstream minimum flow targets, which would mean a higher pore pressure differential between the slope and atmosphere could occur, increasing the risk of slope failure.

The WVS would likely experience increasing wintertime flow volumes in the future because of larger precipitation events and more precipitation falling as rain instead of snow. Intense rainfall is a triggering event for shallow landslides (Wieczorek, 1996). If large events were to occur coincident with deep drawdowns the exposed shoreline may saturate and cause shallow landslides that progress into larger debris flows and reactivate larger landslides in vulnerable slopes.

Increased variability in the spring rainfall, drier hotter summers, and lower summer baseflow mean that there is more potential for wildfires to impact the reservoir rim. Wildfire can produce a water repellent soil layer that increases overland flow through burnt forested areas (Wieczorek, 1996), and may lead to erosive undercutting of the exposed shoreline and saturation of unvegetated soils, which could lead to slope failure.

### *3.4.2.6.8 Summary of Effects of Alternative 3A*

**Table 3.4-6. Summary of effects for Geology and Soils under Alternative 3A as compared to the No Action Alternative**

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Cottage Grove | Augmentation from the inactive pool to meet flow targets at Cottage Grove would have a **negligible** effect on the activation of landslides due to no mapped landslides being in connection with the reservoir. |
| Coast Fork Willamette - Dorena | Augmentation from the inactive pool to meet flow targets at Dorena would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement since project completion. |
| Long Tom - Fern Ridge | No measures that effect landslide formation are proposed for Fern Ridge that would increase shoreline exposure, therefore effects are **negligible**. |
| McKenzie - Blue River | Augmentation from the inactive pool to meet flow targets and deep drawdowns to near the RO in fall at Blue River would increase shoreline exposure but would have a **negligible** effect on the activation of landslides because only small landslides are mapped around the reservoir. |
| McKenzie - Cougar | Augmentation from the power pool to meet flow targets at Cougar would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction |
| Middle Fork Willamette - Dexter | No measures that effect landslide formation are proposed at Dexter would increase shoreline exposure, therefore effects are **negligible**. |
| Middle Fork Willamette - Fall Creek | Augmentation from the inactive pool to meet flow targets at Fall Creek would not increase shoreline exposure and would have a **negligible** effect on the activation of landslides |
| Middle Fork Willamette - Hills Creek | Augmentation from the inactive pool to meet flow targets and deep drawdowns to near the RO in fall at Hills Creek would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction |
| Middle Fork Willamette - Lookout Point | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall and spring at Lookout Point would increase shoreline exposure and would have a |

| Basin and Project | Summary |
|---|---|
| | **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement. |
| Santiam - Big Cliff | No measures that effect landslide formation are proposed for at Big Cliff that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Detroit | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall and spring at Detroit would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction |
| Santiam - Foster | No measures that effect landslide formation are proposed at Foster that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Green Peter | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall at Green Peter would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement since project completion. |

#### *3.4.2.7 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)*

##### *3.4.2.7.1 Santiam Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 3B, augmenting instream flows by using the power pool (#304) is proposed for Green Peter and Detroit. Deep reservoir drawdown to within 25 feet of the RO at in fall at Green Peter (#40) and spring reservoir drawdown at Detroit (#720).

Green Peter has moderate-sized landslides that have not experienced movement since project initiation, therefore increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40), augmented instream flows from the power pool (#304), and spring reservoir drawdown for downstream fish passage (#720) have some potential to initiate minor, adverse, local effects from landslides around the reservoir's rim. Based on the moderate-sized landslides at Detroit Dam that do have a history of movement since the beginning of dam operations, increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40) and augmented instream flows from the power pool (#304) has some potential to initiate moderate, indirect, adverse, local effects from landslides around the reservoir's rim compared to the NAA.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

*3.4.2.7.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included for Fern Ridge under this alternative.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative.

*3.4.2.7.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 3B, augmenting instream flows by using the inactive pool (#718) is proposed for Blue River which results in reservoir drawdowns below the normal rule curve elevations. Deeper fall reservoir drawdowns (#40) is proposed at Cougar and Blue River, additionally spring reservoir drawdown (#720) at Cougar. Because large landslides that have history of movement since project construction are present at Cougar, there is the potential for moderate, indirect, adverse, local effects from increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40) and spring reservoir drawdown for downstream fish passage (#720) compared to the NAA. Only small landslides are mapped around the Blue River reservoir so effects from deeper fall reservoir drawdowns for fish passage (#40) and augmentation of instream flows by using the inactive pool (#718) would be negligible.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

*3.4.2.7.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 3B includes augmenting instream flows by using the power pool (#304) at Lookout Point and Hills Creek, and augmenting instream flows by using the inactive pool (#718) to at Fall Creek. Deeper fall reservoir drawdowns (#40) at Lookout Point and Hills Creek and spring reservoir drawdown for downstream fish passage (#720) at Hills Creek are proposed.

Because large landslides with a history of movement since project completion are present at Hills Creek, there is the potential for moderate, indirect, adverse, local effects from landslides along the upstream reservoir rims due to deeper fall reservoir drawdowns for fish passage (#40), augmented instream flows from the power pool (#304), and spring reservoir drawdown for downstream fish passage (#720) are expected compared to the NAA. Because large landslides without a history of movement since project completion are present at Lookout Point, there is the potential for minor, indirect, adverse, local effects from landslides along the upstream reservoir rims due to deeper fall reservoir drawdowns for fish passage (#40) and augmented instream flows from the power pool (#304) are expected compared to the NAA. No increase in shoreline exposure is anticipated at Fall Creek, so the effect from augmentation of instream flows by using the inactive pool (#718) at Fall Creek would be negligible.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative for this subbasin. The effect of this alternative on local geology is none.

*3.4.2.7.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 3B includes augmenting instream flows by using the inactive pool (#718), which results in reservoir drawdowns below the normal rule curve elevations at Cottage Grove and Dorena. Because there are large landslides mapped at Dorena that have no history of movement, this measure would have a minor, indirect, adverse, local effect on landslides. No landslides are mapped around Cottage Grove, so the effect of drawdown would be negligible compared to the NAA.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

*3.4.2.7.6 Near Term Operations Measures*

See Alternative 2A, Section 0, for description of effects due to the Near-Term Operations Measure.

*3.4.2.7.7 Climate Change*

Climate change would increase the probability of initiation of landslides due to deep drawdown under this alternative by three mechanisms: increasing the annual probability that a deep drawdown would occur, increasing the annual probability that major precipitation events would occur coincident with deep drawdown, and increasing the frequency of wildfires. Under Alternative 3B, climate change is likely to enhance landslide risk at Cougar, Detroit, Dorena, Green Peter, and Lookout Point compared with the NAA.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently and sooner in the year, which would increase the duration of shoreline exposure. This would increase the potential for erosion to undercut and destabilize slopes, which could result in an increased risk of slope failure during the next refill/drawdown cycle. Drawdown also may be more rapid to meet downstream minimum flow targets, which would mean a higher pore pressure differential between the slope and atmosphere could occur, increasing the risk of slope failure.

The WVS would likely experience increasing wintertime flow volumes in the future because of larger precipitation events and more precipitation falling as rain instead of snow. Intense rainfall is a triggering event for shallow landslides (Wieczorek, 1996). If large events were to occur coincident with deep drawdowns the exposed shoreline may saturate and cause shallow landslides that progress into larger debris flows and reactivate larger landslides in vulnerable slopes.

Increased variability in the spring rainfall, drier hotter summers, and lower summer baseflow mean that there is more potential for wildfires to impact the reservoir rim. Wildfire can produce a water repellent soil layer that increases overland flow through burnt forested areas (Wieczorek, 1996), and may lead to erosive undercutting of the exposed shoreline and saturation of unvegetated soils, which could lead to slope failure.

#### *3.4.2.7.8 Summary of Effects of Alternative 3B*

**Table 3.4-7. Summary of effects for Geology and Soils under Alternative 3B as compared to the No Action Alternative**

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Cottage Grove | Augmentation from the inactive pool to meet flow targets at Cottage Grove would have a **negligible** effect on the activation of landslides due to no mapped landslides being in connection with the reservoir. |
| Coast Fork Willamette - Dorena | Augmentation from the inactive pool to meet flow targets at Dorena would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement. |
| Long Tom - Fern Ridge | No measures that effect landslide formation are proposed for at Fern Ridge that would increase shoreline exposure, therefore effects are **negligible**. |
| McKenzie - Blue River | Augmentation from the inactive pool to meet flow targets and deep drawdowns to near the RO in fall at Blue River would increase shoreline exposure but would have a **negligible** effect on the activation of landslides because only small landslides are mapped around the reservoir. |

| Basin and Project | Summary |
|---|---|
| McKenzie - Cougar | Deep drawdowns to near the RO in fall and spring at Cougar would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction |
| Middle Fork Willamette - Dexter | No measures that effect landslide formation are proposed at Dexter would increase shoreline exposure, therefore effects are **negligible**. |
| Middle Fork Willamette - Fall Creek | Augmentation from the inactive pool to meet flow targets at Fall Creek would not increase shoreline exposure and would have a **negligible** effect on the activation of landslides |
| Middle Fork Willamette - Hills Creek | Augmentation from the inactive pool to meet flow targets and deep drawdowns to near the RO in fall and spring at Hills Creek would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate mapped landslides that have a history of movement since project construction. |
| Middle Fork Willamette - Lookout Point | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall and spring at Lookout Point would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement. |
| Santiam - Big Cliff | No measures that effect landslide formation are proposed for at Big Cliff that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Detroit | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall at Detroit would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction |
| Santiam - Foster | No measures that effect landslide formation are proposed at Foster that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Green Peter | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall and spring at Green Peter would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement since project completion. |

#### *3.4.2.8 Alternative 4 – Structures-Based Fish Passage Alternative*

##### *3.4.2.8.1 Santiam Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 4, augmenting instream flows by using the power pool (#304) is proposed for Green Peter and Detroit. Due to the moderate-sized landslides that do not have a history of movement mapped in contact with the reservoir, environmental consequences at Green Peter Dam would have minor, indirect, adverse, local effects. Based on the large landslides at Detroit Dam that do have a history of movement since the beginning of dam operations, the environmental effect from this measure is moderate.

**Removal of Geologic Material**

This alternative includes constructing a water temperature control tower (#105) at Detroit and the construction of a structural downstream fish passage (#392) for Foster and Detroit. These structures would likely require small-scale and localized rock excavation. This would have a minor effect on local geology.

##### *3.4.2.8.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included for Fern Ridge under this alternative.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative.

##### *3.4.2.8.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 4 includes augmenting instream flows by using the power pool (#304) for Cougar and augmenting instream flows by using the inactive pool (#718) for Blue River, both of which result in reservoir drawdowns below the NAA rule curve elevations. Based on the presence of landslides that have exhibited movement since project completion, there is the potential for moderate, indirect, adverse, local effects from landslides along the upstream reservoir rims at Cougar due to augmented instream flows from the power pool (#304). The effects from augmentation of instream flows by using the inactive pool (#718) at Blue River would be negligible because only small landslides are mapped in contact with the reservoir compared to the NAA.

**Removal of Geologic Material**

This alternative includes the construction of a structural downstream fish passage (#392) for Cougar. These structures would likely require small-scale and localized rock excavation, which would have a minor local effect.

*3.4.2.8.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 4 includes augmenting instream flows by using the power pool (#304) to augment flows at Lookout Point and Hills Creek, which both result in reservoir drawdowns below the NAA rule curve elevations.

At Fall Creek, augmenting instream flows by using the inactive pool (#718) would not result in a change in shoreline exposure compared with the NAA, so the effect of this measure is negligible. Due to the presence of large landslides that do not have a history of movement and an increase in shoreline exposure compared to the NAA, there is the potential for minor, indirect, adverse, local effects at Lookout Point due to augmented instream flows from the power pool (#304). Based on large landslides that have experienced movement since project completion, there is the potential for moderate, indirect, adverse, local effects from landslides with a history of movement along the upstream reservoir rims due the increase in shoreline exposure caused by augmented instream flows from the power pool (#304) at Hills Creek.

**Removal of Geologic Material**

This alternative includes constructing a water temperature control (WTC) tower (#105) at Hills Creek and constructing structural downstream fish passage (#392) at both Lookout Point and Hills Creek which would require small-scale and localized rock excavation. This would have a minor effect on local geology at both projects compared to the NAA.

*3.4.2.8.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 4 includes augmenting instream flows by using the inactive pool (#718), which results in reservoir drawdowns below the normal rule curve elevations at Cottage Grove and Dorena. Because there are large landslides mapped at Dorena that have no history of movement, this measure would have a minor, indirect, adverse, local effect on landslides. No landslides are mapped around Cottage Grove, so the effect of drawdown would be negligible compared to the NAA.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

*3.4.2.8.6 Near Term Operations Measures*

See Alternative 2A, Section 0, for description of effects due to the Near-Term Operations Measure.

*3.4.2.8.7 Climate Change*

Climate change would increase the probability of initiation of landslides due to deep drawdown under this alternative by three mechanisms: increasing the annual probability that a deep drawdown would occur, increasing the annual probability that major precipitation events would occur coincident with deep drawdown, and increasing the frequency of wildfires. Under Alternative 4 climate change is likely to enhance landslide risk at Cougar, Detroit, Dorena, Green Peter, Hills Creek, and Lookout Point compared with the NAA.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently and sooner in the year, which would increase the duration of shoreline exposure. This would increase the potential for erosion to undercut and destabilize slopes, which could result in an increased risk of slope failure during the next refill/drawdown cycle. Drawdown also may be more rapid to meet downstream minimum flow targets, which would mean a higher pore pressure differential between the slope and atmosphere could occur, increasing the risk of slope failure.

The WVS would likely experience increasing wintertime flow volumes in the future because of larger precipitation events and more precipitation falling as rain instead of snow. Intense rainfall is a triggering event for shallow landslides (Wieczorek, 1996). If large events were to occur coincident with deep drawdowns the exposed shoreline may saturate and cause shallow landslides that progress into larger debris flows and reactivate larger landslides in vulnerable slopes.

Increased variability in the spring rainfall, drier hotter summers, and lower summer baseflow mean that there is more potential for wildfires to impact the reservoir rim. Wildfire can produce a water repellent soil layer that increases overland flow through burnt forested areas (Wieczorek, 1996), and may lead to erosive undercutting of the exposed shoreline and saturation of unvegetated soils, which could lead to slope failure.

*3.4.2.8.8 Summary of Effects of Alternative 4*

**Table 3.4-8. Summary of effects for Geology and Soils under Alternative 4 as compared to the No Action Alternative**

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Cottage Grove | Augmentation from the inactive pool to meet flow targets at Cottage Grove would have a **negligible** effect on the activation of landslides due to no mapped landslides being in connection with the reservoir. |

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Dorena | Augmentation from the inactive pool to meet flow targets at Dorena would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement. |
| Long Tom - Fern Ridge | No measures that effect landslide formation are proposed for at Fern Ridge that would increase shoreline exposure, therefore effects are **negligible**. |
| McKenzie - Blue River | Augmentation from the inactive pool to meet flow targets at Blue River would increase shoreline exposure but would have a **negligible** effect on the activation of landslides because only small landslides are mapped around the reservoir. |
| McKenzie - Cougar | Augmentation from the power pool to meet flow targets at Cougar would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction. Construction of a structural downstream passage at Cougar would result in minor local removal of geologic materials. |
| Middle Fork Willamette - Dexter | No measures that effect landslide formation are proposed for at Dexter would increase shoreline exposure, therefore effects are **negligible**. |
| Middle Fork Willamette - Fall Creek | Augmentation from the inactive pool to meet flow targets at Fall Creek would not increase shoreline exposure and would have a **negligible** effect on the activation of landslides |
| Middle Fork Willamette - Hills Creek | Augmentation from the power pool to meet flow targets at Hills Creek would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction. Construction of a temperature control tower and structural downstream passage at Hills Creek would result in **minor** local removal of geologic materials. |
| Middle Fork Willamette - Lookout Point | Augmentation from the power pool to meet flow targets at Lookout Point would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement. Construction of a temperature control tower and structural downstream passage at Lookout Point would result in minor local removal of geologic materials. |

| Basin and Project | Summary |
|---|---|
| Santiam - Big Cliff | No measures that effect landslide formation are proposed for at Big Cliff that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Detroit | Augmentation from the power pool to meet flow targets at Detroit would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate mapped landslides that have a history of movement since project construction. Construction of a temperature control tower and structural downstream passage at Detroit would result in **minor** local removal of geologic materials. |
| Santiam - Foster | No measures that effect landslide formation are proposed at Foster that would increase shoreline exposure, therefore effects are **negligible**. Construction of a structural downstream passage at Foster would result in **minor** local removal of geologic materials. |
| Santiam - Green Peter | Augmentation from the power pool to meet flow targets at Green Peter would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate sized mapped landslides that do not have a history of movement since project completion. |

#### *3.4.2.9 Alternative 5 - Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

##### *3.4.2.9.1 Santiam Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Augmenting instream flows by using the power pool (#304) is proposed for Green Peter and Detroit under Alternative 5. Deeper fall reservoir drawdowns for fish passage (#40) would allow deep reservoir drawdown to within 25 feet of the RO invert at Green Peter.

Green Peter has moderate-sized landslides that have not experienced movement since project initiation, therefore increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40) and augmented instream flows from the power pool (#304) has some potential to initiate minor, indirect, adverse, local effects from landslides around the reservoir's rim. Based on the moderate-sized landslides at Detroit Dam that have a history of movement since the beginning of dam operations, augmented instream flows from the power pool (#304) has some potential to initiate moderate, indirect, adverse, local effects from landslides around the reservoir's rim compared to the NAA.

**Removal of Geologic Material**

Alternative 5 includes constructing a water temperature control tower (#105) at Detroit and constructing a structural downstream fish passage (#392) for Foster and Detroit. These structures would likely require small-scale and localized rock excavation. This would have a minor direct effect on local geology at both Foster and Detroit compared to the NAA.

*3.4.2.9.2 Long Tom Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included for Fern Ridge under this alternative. The effect of this alternative on local geology is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

*3.4.2.9.3 McKenzie Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Alternative 5 includes augmenting instream flows by using the power pool (#304) for Blue River and augmenting instream flows by using the inactive pool (#718) for Cougar. Both of these measures result in reservoir drawdowns below the normal rule curve elevations. At Cougar deeper fall reservoir drawdowns for fish passage (#40) would allow reservoir drawdown to within 10 feet of the RO invert and spring reservoir drawdown for downstream fish passage (#720) proposes use of the diversion tunnel and drawdown to streambed. Based on the presence of landslides at Cougar that have shown some small-scale movement since project initiation, there is the potential for moderate, indirect, adverse, local effects from landslides along the upstream reservoir rims because of increased shoreline exposure due to deeper fall reservoir drawdowns for fish passage (#40), augmented instream flows from the power pool (#304), and spring reservoir drawdown for downstream fish passage (#720) compared to the NAA. The effects from augmentation of instream flows by using the inactive pool (#718) at Blue River are expected to be negligible because no landslides are mapped in contact with the reservoir compared to the NAA.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative on local geology is none.

#### *3.4.2.9.4 Middle Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

Under Alternative 5, augmenting instream flows by using the power pool (#304) is proposed for Lookout Point and Hills Creek and augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek. Due to the presence of large landslides that do not have a history of movement, there is the potential for minor, indirect, adverse, local effects at Lookout Point due to increased shoreline exposure from augmented instream flows from the power pool (#304). Based on the presence of landslides at Hills Creek that have shown some small-scale movement since project initiation, there is the potential for moderate, indirect, adverse, local, effects from increased shoreline exposure due to augmented instream flows from the power pool (#304) compared to the NAA.

**Removal of Geologic Material**

Alternative 5 includes constructing structural downstream fish passage (#392) at Lookout Point which would require localized rock excavation. This would have a minor direct effect on local geology.

#### *3.4.2.9.5 Coast Fork of the Willamette Subbasin*

**Activation of Landslides Due to Deep Drawdown**

No measures that reduce the pool below the rule curve, active pool, or draft the reservoir down to the RO are included under this alternative. The effect of this alternative is none.

**Removal of Geologic Material**

No measures that would result in excavation of geologic materials are proposed under this alternative. The effect of this alternative is none.

#### *3.4.2.9.6 Near Term Operations Measures*

See Alternative 2A, Section 0, for description of effects due to the Near-Term Operations Measure.

#### *3.4.2.9.7 Climate Change*

Climate change would increase the probability of initiation of landslides due to deep drawdown under this alternative by three mechanisms: increasing the annual probability that a deep drawdown would occur, increasing the annual probability that major precipitation events would occur coincident with deep drawdown, and increasing the frequency of wildfires. Under Alternative 5, climate change is likely to enhance landslide risk at Cougar, Detroit, Green Peter, and Hills Creek compared with the NAA.

Due to decreasing future summer and fall inflows, WVS projects may reach their minimum water surface elevations more frequently and sooner in the year, which would increase the duration of shoreline exposure. This would increase the potential for erosion to undercut and destabilize slopes, which could result in an increased risk of slope failure during the next refill/drawdown cycle. Drawdown also may be more rapid to meet downstream minimum flow targets, which would mean a higher pore pressure differential between the slope and atmosphere could occur, increasing the risk of slope failure.

The WVS would likely experience increasing wintertime flow volumes in the future because of larger precipitation events and more precipitation falling as rain instead of snow. Intense rainfall is a triggering event for shallow landslides (Wieczorek, 1996). If large events were to occur coincident with deep drawdowns the exposed shoreline may saturate and cause shallow landslides that progress into larger debris flows and reactivate larger landslides in vulnerable slopes.

Increased variability in the spring rainfall, drier hotter summers, and lower summer baseflow mean that there is more potential for wildfires to impact the reservoir rim. Wildfire can produce a water repellent soil layer that increases overland flow through burnt forested areas (Wieczorek, 1996), and may lead to erosive undercutting of the exposed shoreline and saturation of unvegetated soils, which could lead to slope failure.

#### *3.4.2.9.8 Summary of Effects of Alternative 5*

**Table 3.4-9. Summary of effects for Geology and Soils under Alternative 5 as compared to the No Action Alternative**

| Basin and Project | Summary |
|---|---|
| Coast Fork Willamette - Cottage Grove | No measures that effect landslide formation are proposed for Cottage Grove that would increase shoreline exposure, therefore effects are **negligible**. |
| Coast Fork Willamette - Dorena | No measures that effect landslide formation are proposed for Dorena that would increase shoreline exposure, therefore effects are **negligible**. |
| Long Tom - Fern Ridge | No measures that effect landslide formation are proposed for Fern Ridge that would increase shoreline exposure, therefore effects are **negligible**. |
| McKenzie - Blue River | Augmentation from the inactive pool to meet flow targets at Blue River would increase shoreline exposure but would have a **negligible** effect on the activation of landslides because only small landslides are mapped around the reservoir. |
| McKenzie - Cougar | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall at Cougar would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped |

| Basin and Project | Summary |
|---|---|
| | landslides that have a history of movement since project construction |
| Middle Fork Willamette - Dexter | No measures that effect landslide formation are proposed for Dexter would increase shoreline exposure, therefore effects are **negligible**. |
| Middle Fork Willamette - Fall Creek | Augmentation from the inactive pool to meet flow targets at Fall Creek would not increase shoreline exposure and would have a **negligible** effect on the activation of landslides |
| Middle Fork Willamette - Hills Creek | Augmentation from the power pool to meet flow targets at Hills Creek would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate sized mapped landslides that have a history of movement since project construction |
| Middle Fork Willamette - Lookout Point | Augmentation from the power pool to meet flow targets at Lookout Point would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate mapped landslides that do not have a history of movement. Constructing a structural downstream fish passage at Lookout Point would have a **minor** effect on the removal of geologic materials. |
| Santiam - Big Cliff | No measures that effect landslide formation are proposed for Big Cliff that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Detroit | Augmentation from the power pool to meet flow targets at Detroit would increase shoreline exposure and would have a **moderate** effect on the activation of landslides due to large and moderate mapped landslides that have a history of movement since project construction. Construction of a WTC tower and fish passage structure would have a **minor** effect on removal of geologic material. |
| Santiam - Foster | No measures that effect landslide formation are proposed at Foster that would increase shoreline exposure, therefore effects are **negligible**. |
| Santiam - Green Peter | Augmentation from the power pool to meet flow targets and deep drawdowns to near the RO in fall at Green Peter would increase shoreline exposure and would have a **minor** effect on the activation of landslides due to large and moderate mapped landslides that do not have a history of movement since project completion. |

## 3.5 WATER QUALITY

### 3.5.1 Affected Environment

Water quality consists of chemical and physical properties that are an integral part in determining the health of a waterbody. Regulations and guidelines established to protect U.S. waters and species include the Federal Water Pollution Control Act (1948) which was amended and replaced by to the Clean Water Act (1972), as amended, and Endangered Species Act (1973).

In 2008, the National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service issued their respective Willamette Project Biological Opinion (BiOp) (NMFS 2008; USFWS 2008). Listed within the NMFS BiOp are Reasonable and Prudent Actions (RPAs) which address multiple interim and long-term water quality improvement objectives.

The Clean Water Act Section 303(d) requires each State to prepare a list of impaired water bodies that do not meet state water quality standards. Under the State of Oregon Administrative Rules (OAR) 340-041, the Oregon Department of Environmental Quality (ODEQ) implements the Water Quality Standards and Total Maximum Daily Loads (TMDL's) for Oregon waters. USACE was given Designated Management Agency status under the act by the Governor of Oregon. A TMDL is a load allocation of a pollutant implemented to reduce the impairment and meet water quality standards. Water Quality Standards in the state of Oregon are listed for pH, Bacteria, Dissolved Oxygen (DO), Temperature, Total Dissolved Gas (TDG), Total Dissolved Solids, Turbidity, Nuisance Phytoplankton and Toxic Substances.

ODEQ added Willamette Basin rivers and streams to the 303(d) list of impaired waters in 1998, for exceeding standards for biological criteria, temperature, and bacteria. A table adapted from the ODEQ 2022 Integrated Report of impaired water bodies downstream of USACE Willamette dams is listed below with water quality parameters (Table 3.5-1). The temperature criteria is listed as "period" in Table 3.5-1 and is associated with fish life stages, mercury criteria is within the water column and within fish tissue, turbidity is within the water column. In 2021 ODEQ and EPA revised the mercury TMDL criteria for the Willamette Basin (ODEQ 2019).

UWR Chinook and UWR steelhead All Willamette Basin sub-basins and the mainstem Willamette River have TMDL load allocations set by the State for mercury, and nine of the 12 sub-basins have load allocations for temperature and bacteria, dissolved oxygen and turbidity. USACE dams are in six of the 12 sub-basins within the Willamette Basin and TMDL load allocations were set by the State for temperature of water released below these dams. The Annual Willamette Basin Water Quality Reports, from 2009 to present, details implemented water quality measures describing reservoir temperature targets, temperature TMDL's, TDG and other water quality and water supply conditions.

Water quality parameters that will be covered include Temperature, TDG, Harmful Algae Blooms (HABs), Turbidity, and Mercury by sub-basin.

**Table 3.5-1. 303d listed Impaired Waterbodies downstream of the Willamette Valley dams. Adapted from ODEQ 2022 Integrated Report including Willamette Valley TMDL. Please refer to the website for full list of impairments: Department of Environmental Quality : TMDL Program: Willamette Basin : Total Maximum Daily Loads : State of Oregon; https://www.oregon.gov/deq/wq/Pages/epaApprovedIR.aspx**

| Name | Description | Pollutant | period | Parameter category | Rationale | Assessed 2022 | Year Assessed | Year Listed |
|---|---|---|---|---|---|---|---|---|

### *3.5.1.1 Temperature*

Downstream water temperatures affected by the dams disrupt fish spawning and rearing life stages because water is too warm in the fall/winter and too cool in the summer/spring (Figure 3.5-1, Figure 3.5-2). In the reservoirs, thermal stratification occurs in summer, with warmer water near the surface and cooler water at the bottom. In the winter a lake may "turnover" meaning surface water will cool to temperatures less than water at the bottom thereby displacing the water at the bottom. Currently, dam operations utilize various outlets and spillways to mix temperatures and provide more normative downstream temperatures.

State and resource agencies have implemented temperature TMDLs and temperature targets throughout the year to coincide with life cycle stages of Endangered Species Act (ESA) listed fish. Currently, ESA-listed fish, such as the Upper Willamette River (UWR) spring Chinook *Oncorhynchus tshawytscha*, UWR winter steelhead *Oncorhynchus mykiss*, and bull trout *Salvelinus confluentus* have been identified in the Willamette sub-basins (Oregon Chub de-listed in 2015) (USACE 2020a).

Construction of the Willamette Valley Project dams have disrupted the natural thermal and flow regimes of the rivers (Gregory et al, 2007). The water temperatures below Willamette Valley dams have been identified as one of the limiting factors preventing the recovery of UWR spring Chinook salmon and UWR steelhead (USACE 2000; Taylor et al. 2007; Angilletta et al 2008; NMFS 2008; ODFW and NMFS 2011). Water temperatures are monitored by U.S. Army Corps of Engineers (USACE)-funded U.S. Geological Survey (USGS) gages that may be located upstream (inflow) and downstream (outflow) of a project.

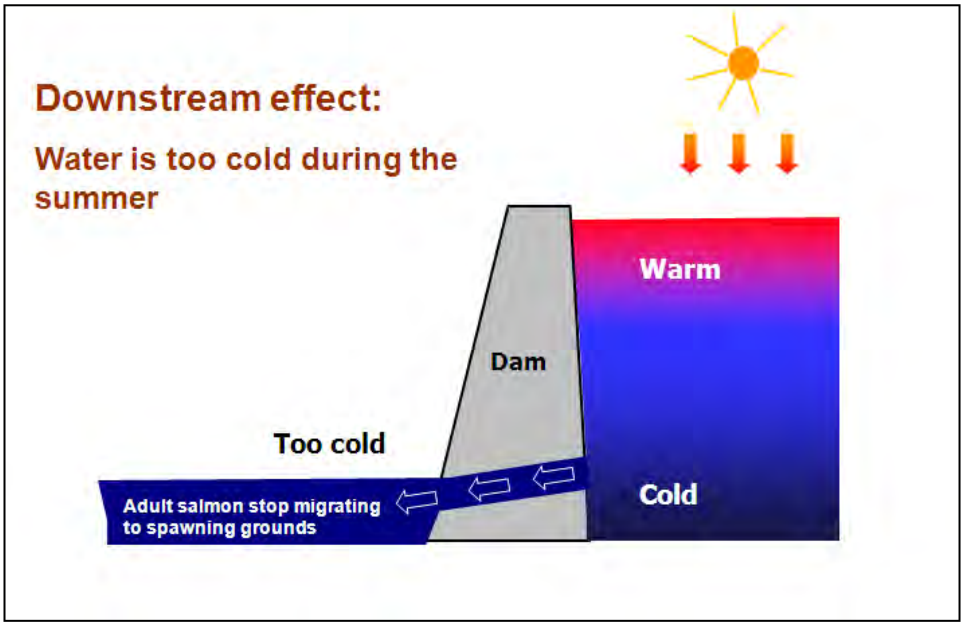

**Figure 3.5-1. Schematic Showing the Influence of Typical Dam Operations on Downstream Water Temperatures During the Conservation Season.** ***USACE, Willamette Fish Operations Plan 2020.***

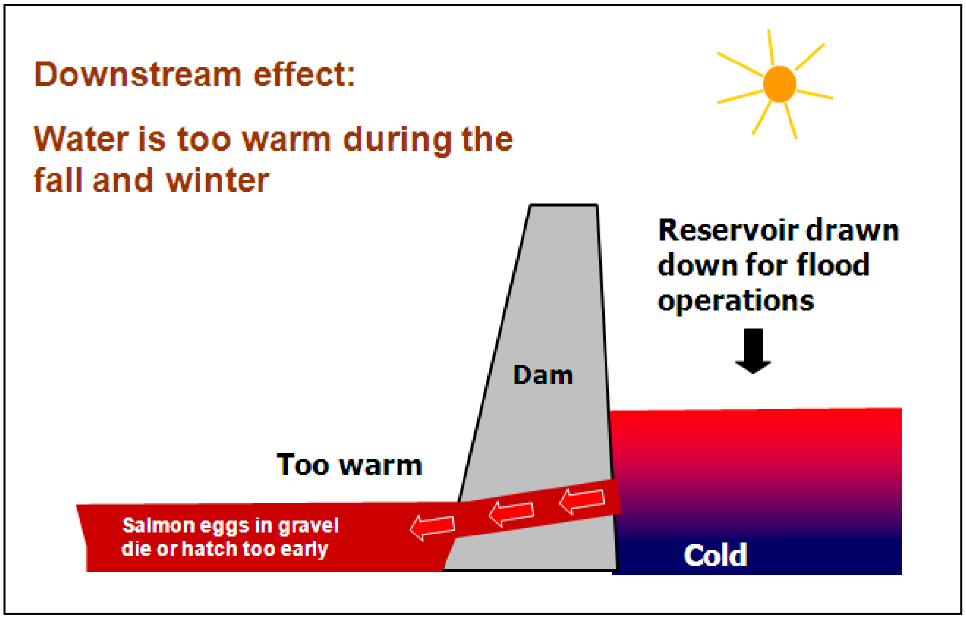

**Figure 3.5-2. Schematic Showing the Influence of Typical Dam Operations on Downstream Water Temperatures During Reservoir Drawdown for Flood Damage Reduction. *USACE, Willamette Fish Operations Plan 2020.***

*3.5.1.1.1 North Santiam Sub-basin*

Detroit Reservoir is a warm monomictic lake that thermally stratifies during the spring, summer and fall months. From June through mid-September the dam provides interim water temperature management downstream using a blend of releases from the spillway, regulating outlets and turbines. During the summer months, the upper layer of water warms due to radiative heating. Water is much cooler near the regulating outlets. The real-time reservoir temperature thermistor string can be accessed through the USACE public website (USACE 2022). The thermistor string data measures the reservoir's thermal stratification throughout the year and helps to inform temperature management operations.

The blending of the two water layers provides downstream temperature control. Water quality considerations shape operation of the reservoirs unless the system is being operated for Flood Risk. USACE-funded USGS gages for monitoring temperature are located above and below Detroit Reservoir for temperature and TDG monitoring (Figure 3.5-3). The State TMDL temperature targets for waters downstream of the Detroit and Big Cliff Dams (Table 3.5-1) were developed with basin experts in 2006. The State also established sub-basin Resource Agency (RA) working groups with specialists from ODFW, ODEQ, NMFS, USFWS and others. The RA's consider various factors like estimated fish emergence timing and spawning time variability, to generate yearly targets as shown in (Table 3.5-1).

Water of varying temperatures released from Detroit Dam mix in Big Cliff Reservoir. A gage is located 0.75 miles below Big Cliff Reservoir near Niagara, Oregon which is the compliance point for water temperature releases from both of the dams. In a typical year, water temperature targets are met during the summer and early fall months, but trend higher than targets in the late fall and early winter (Figure 3.5-4). Outflow temperatures are very close to the TMDL temperature targets, except for October and November (Figure 3.5-5; Figure 3.5-6). This is because Detroit Reservoir is a large body of water and takes longer to warm in the spring and cool in the fall as compared to unregulated river systems. Therefore, a thermal lag is produced resulting in late fall/early winter water temperature objectives not being met. It is not until mid-winter that the reservoir loses all heat gained from the summer season and downstream water temperatures are again achieved.

*3.5.1.1.2 South Santiam Sub-basin*

The NMFS 2008 Biological Opinion considers elevated water temperatures caused by dam operations a primary limiting factor for the egg/emergence component of the UWR spring Chinook salmon life stages in the South Santiam River due to premature hatching and emergency (NMFS 2008). Water temperatures can also affect other life stages including upstream migration of UWR spring Chinook salmon and UWR steelhead (USACE 2018b). There are no annual interim temperature control operations at Green Peter Reservoir.

In late-May 2020, a special study released warm water from Green Peter to increase temperatures and trigger a biological response for UWR spring Chinook salmon at the Foster Adult Fish Facility (AFF) ladder (USACE 2020b). Water temperatures increased by 4-5°F over a three-week period and high UWR spring Chinook salmon returns and collections at the AFF were observed. Additionally, there was an outage of an auxiliary water supply (AWS) pump during this period. The AWS acts to recirculate cool turbine water near the entrance of the Foster fish ladder. The outage also improved temperatures prompting an upstream migration response from fish in the tailrace (Figure 3.5-7). The results of the study indicated improved temperatures were needed to better operate the AFF at Foster.

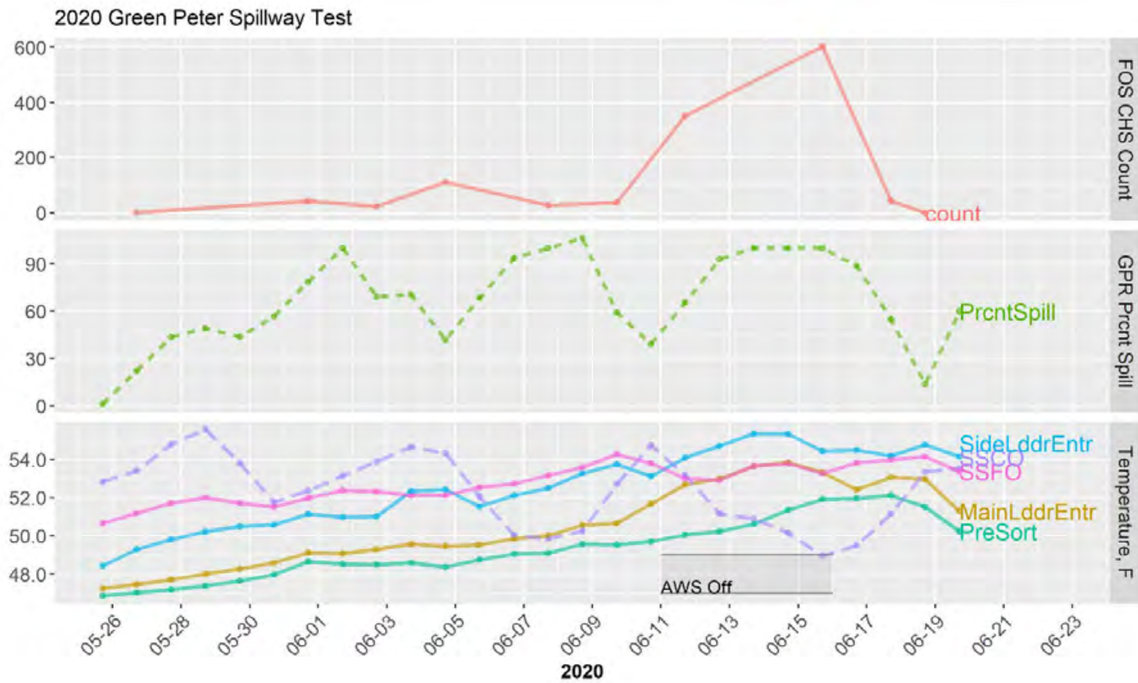

**Figure 3.5-7. 2020 Foster Fish Spring Chinook collection, Green Peter spill operation (percent of total flow), and Foster fish ladder water temperatures May 26 to June 16, 2020. Abbreviation definitions: FOS CHS Count (Foster AFF Chinook Return Fish Count; GPR Prcnt Spill (Green Peter Percent spillway flow as a percentage); SideLddrEntr (Water temperature at the entrance to the AFF on the Foster Spillway side); SSCO (Water temperature at South Santiam River below Cascadia, OR; SSFO (Water temperature at South Santiam River near Foster; MainLddrEntr (Water temperature at the main entrance to the AFF near penstock outfall; PreSort (Water temperature in the AFF fish ladder above the entrance, near holding tank).**

Currently there are three USACE-funded USGS gages that are located at Middle Santiam River upstream of Green Peter Reservoir, Quartzville Creek upstream of Green Peter Reservoir, and Middle Santiam downstream of Green Peter Reservoir (Figure 3.5-8). North Santiam and McKenzie Resource Agency (RA) utilized the targets developed for the for the South Santiam, as targets for this portion of the river have not been developed (Table 3.5-3). However, the South Santiam sub-basin has warmer upstream and cooler downstream temperatures as compared to the North Santiam. Historically, Green Peter temperatures meet RA targets and temperature TMDLs from February to May and tend to be cooler from June to September. Then from October to December temperatures are above the target (Figure 3.5-9 – 3.5-11). In-reservoir temperature thermistor strings were deployed in 2010 and continue to collect data and inform reservoir operations (USACE 2022).

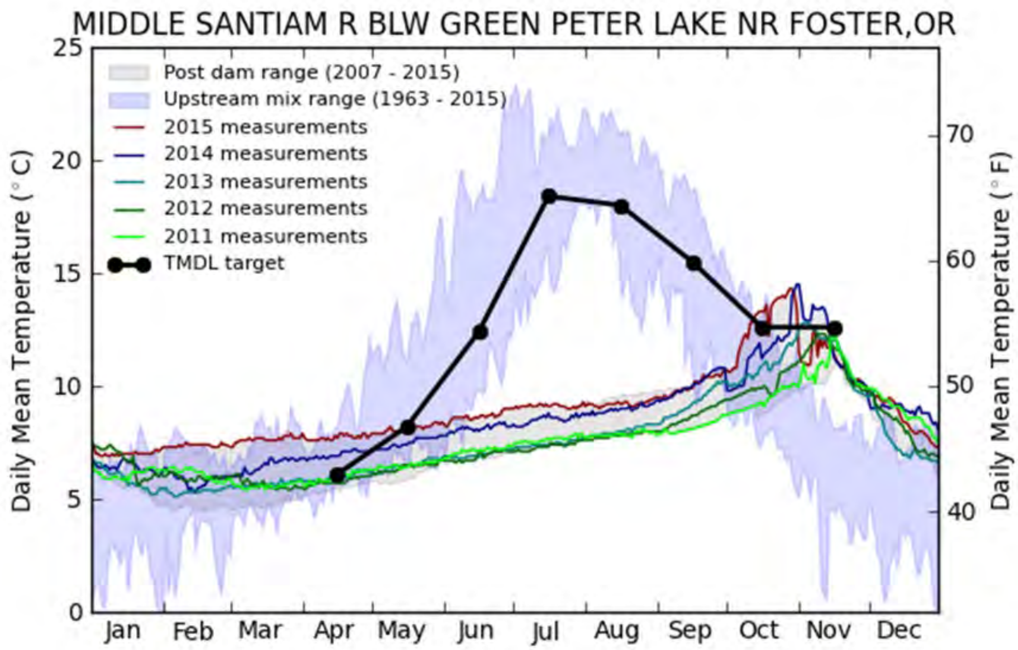

**Figure 3.5-11. Middle Santiam River Below Green Peter Lake near Foster, OR. Green Peter Reservoir Daily Mean Outflow Temperatures (2011 – 2015). Measured in the Middle Santiam River Compared to Upstream Mix Range (1963 – 2015), Post Dam Range (2007-2015), and ODEQ's TMDL Monthly Median Target Temperatures.**

Foster Reservoir is a re-regulating dam and smaller lake as compared to Green Peter Reservoir. Generally unregulated flow from the South Santiam River above Foster provides warmer water and Green Peter Reservoir provides cooler water from the powerhouse discharge. As such, Foster water temperatures stratify in the late Spring and Summer. The current Foster fish passage facility was modified in 2014 in response to the NMFS 2008 BiOp. As previous discussed in this section research in 2017 determined that water temperature from the AFF ladder entrance is too cold compared to historic or ambient river temperatures to attract UWR spring Chinook salmon from May through June, which delays collection and passage (Keefer et al. 2018).

Interim water temperature management operations are currently being conducted to improve water temperatures for upstream fish migration, attraction to the adult fish ladder, and the Foster Fish Facility. The operation uses the Foster Fish Weir to skim warm water off the surface of Foster Reservoir for release downstream. The USACE-funded USGS gages are located on the South Santiam River near the town of Cascadia and South Santiam River downstream of Foster Reservoir (Figure 3.5-8). These gages are used to monitor water temperature as well as other water quality parameters.

Foster temperatures are typically in range of the RA targets and temperature TMDLs from February through June and October through November, and lower from July until September (Figures 3.5-12 – 3.5-14), hence the need for temperature management operations.

In-reservoir thermistor strings were deployed in 2010 and continue to collect data which provides information on the thermal stratification of the reservoir (USACE 2022). The data provided by the gages are being used for water quality modeling efforts utilizing CE-QUAL-W2 to inform operational temperature management plans (USACE 2018b).

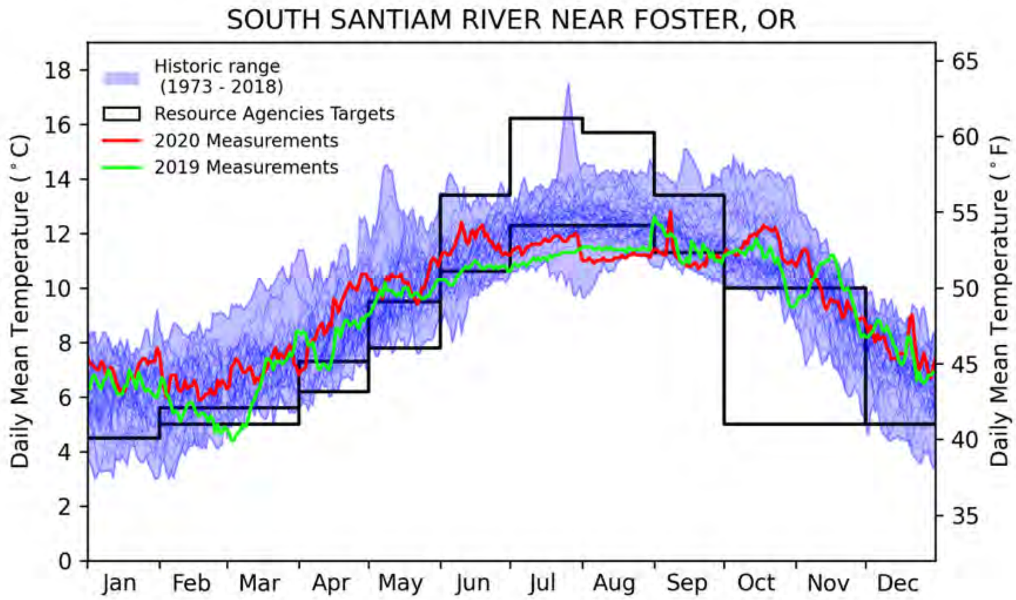

**Figure 3.5-12. South Santiam River near Foster. OR. Foster Reservoir Daily Mean 2019 and 2020 Outflow Temperatures compared to Resource Agencies Target Temperatures and Historical Temperature Ranges during 1973 - 2018.**

#### *3.5.1.1.3 McKenzie Sub-basin*

At Cougar Reservoir, the WTC enables the USACE to manage water elevations to regulate downstream temperatures for ESA listed species. USACE-funded USGS temperature gages are located upstream and downstream of the reservoir (Table 3.5-15). The data is available on the USGS' public website (https://or.water.usgs.gov/cgi-bin/grapher/table_setup.pl). There are no temperature management capabilities at Blue River Dam, as there is one set of regulating outlets and spillway. Temperature gages are located upstream and downstream of the dam, which are USACE-funded USGS gages (Figure 3.5-16).

Resource agency temperature targets were developed for Cougar and Blue River Dams (Table 3.5-4). McKenzie River estimated fish emergence times, which are generated yearly based on spawning time variability are also considered. Since 2005, the outflow water temperatures have generally met the RA targets utilizing the WTC at Cougar Reservoir as compared to pre-temperature-control-tower results (Figure 3.5-17). Outflow temperatures are closest to the TMDLs from April through June (Figure 3.5-18; Figure 3.5-19). Temperature thermistor strings are deployed in Cougar Reservoir and collect thermal stratification data. The real-time reservoir temperature thermistor string can be accessed through the USACE public website (USACE 2022). The thermistor string data measures the reservoir's thermal stratification throughout the year and helps to inform temperature management operations. Temperature thermistor strings are not deployed in Blue River reservoir. Historically, Blue River outflow water temperatures are nearest to the RA Targets and TMDLs from February through May and warmer from August through November (Figure 3.5-20 – 3.5-22).

#### *3.5.1.1.4 Middle Fork Willamette Sub-basin*

Currently, interim temperature management operations are not conducted at Hills Creek, Lookout Point or Dexter Reservoirs. However, informal temperature operations are implemented at Fall Creek from approximately March through October by utilizing the existing fish horns. Originally, the fish horns were constructed for fish to passage, however survivability was low. The nine fish horns are located at varying elevations (3-720 ft, 3-765 ft, 3-800 ft) and can provide water to the AFF. Although, with the fish horn elevations there is limited ability to affect the downstream temperatures. The primary use of the fish horns is to attract UWR spring Chinook salmon and UWR steelhead to the AFCF and secondarily for temperature. The Fall Creek spillway gates are not used for temperature management due to western pond turtle and Oregon chub habitat downstream.

Water temperature management operations were implemented at Lookout Point Dam from 2012 until 2014, by utilizing the spillway and powerhouse penstock to manage downstream water temperatures for UWR spring Chinook salmon. These operations and model simulations did not result in favorable downstream water temperatures. This is because inflow water temperatures are warmer, as compared to Detroit or Cougar Dams. Results from modeling analysis indicated only one day difference of egg emergence timing using the regulating outlet because it is 56 ft deeper than the powerhouse outlet (USACE 2015c). The Hills Creek spillway is used for emergency operations only, as its use would cause water to inundate the powerhouse below the dam. Therefore, no temperature management operations are currently conducted using the spillway.

In-reservoir thermistor temperature strings are deployed in Hills Creek, Lookout Point, Dexter, and Fall Creek Reservoirs. Hills Creek and Lookout Point temperature strings were deployed in 2010 and Dexter and Fall Creek Reservoirs were deployed in 2014 (USACE 2022). The thermistor string data measures the reservoir's thermal stratification throughout the year and helps to inform temperature management operations. USACE-funded USGS gages measure water temperature upstream and downstream of these reservoirs (Figure 3.5-23). RA temperature targets were developed for Hills Creek, Lookout Point, Dexter and Fall Creek Reservoirs (Table 3.5-6). The RA's consider estimated Middle Fork Willamette River fish emergence times which are generated yearly based on spawning time variability are also considered.

Historical temperature ranges at Hills Creek Reservoir have not exceeded 65°F in the summer, which is the optimal temperature for fish migration and holding (Figure 3.5-25). Figure 3.5-25 demonstrates the overlapping fish life cycle timeframe and temperature thresholds for holding, spawning, incubation, and migration. Temperatures at Hills Creek met most of the temperature targets from 2016 to 2020 but were lower than the TMDLs from 2011 to 2015 (Figure 3.5-25; Figure 3.5-26).

Outflow temperatures at Lookout Point/Dexter Dams can reach close to 70° F in the summer, optimal temperatures for fish migration and holding is approximately 50° F to 60 ° F (Figure 3.5-27). The outflow temperatures are generally close to the temperature TMDL targets for Lookout Point/Dexter, except from October through November when temperatures are higher

(Figure 3.5-28; Figure 3.5-29). At Fall Creek Reservoir the outflow temperatures are generally closest to the RA Targets and Temperature TMDLs from February through May (Figures 3.5-30; 3.5-31; 3.5-32).

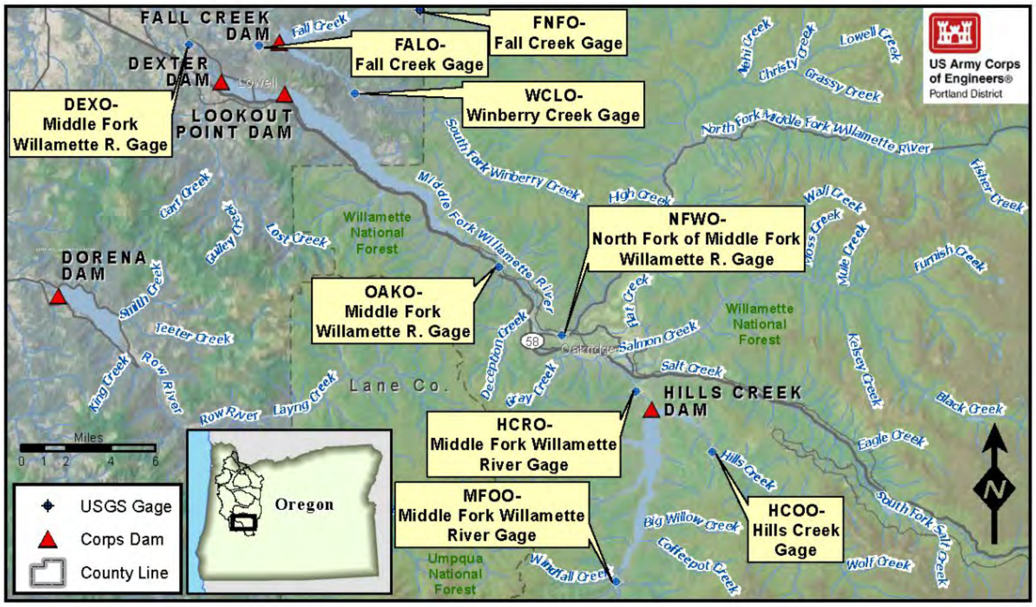

**Figure 3.5-23. Water Temperature USGS Gage Locations : Upstream and Downstream of Hills Creek, Lookout Point / Dexter, and Fall Creek Dams. USGS Data: http://or.water.usgs.gov/cgi-bin/grapher/table_setup.pl**

*3.5.1.1.5 Coast Fork and Long Tom Sub-basins*

Temperature control operations are not conducted at Cottage Grove, Dorena and Fern Ridge Reservoirs. USACE-funded USGS gages monitor temperature at inflow points and outflow points of Cottage Grove, Dorena, and Fern Ridge Reservoirs (Figure 3.5-33). There are no RA temperature targets implemented at these reservoirs, although there are Temperature TMDLs (Table 3.5-7). There are no temperature strings deployed at these reservoirs that provide thermal stratification data.

Historically, Cottage Grove outflow temperatures are warmest in August and begin to cool in late-September (Figure 3.5-34). Outflow temperatures at Cottage Grove have been closest to the TMDL targets from April through May and October through November. However, summer temperatures are generally cooler than the TMDL except in 2015 when the target was briefly met (Figure 3.5-35; Figure 3.5-36). Dorena Reservoir outflow temperatures are historically warmest in late-August and begin to cool by early October (Figure 3.5-37). Summer outflow temperatures at Dorena are cooler than the TMDL targets, as observed from 2011 – 2020 (Figure 3.5-38; Figure 3.5-39). Fern Ridge outflow temperatures are typically warmest in August and begin to cool in September (Figure 3.5-40). Outflow temperatures are warmer than the TMDL targets, as observed from 2011 – 2020 (Figure 3.5-41; Figure 3.5-42).

### *3.5.1.2 Total Dissolved Gas*

TDG is a measure of dissolved atmospheric gases in water. The primary gases that make up TDG are oxygen, nitrogen, and carbon dioxide. TDG levels are dependent on a variety of factors, including discharge rate (flow), pressure (depth) and water temperature. TDG is monitored by USACE-funded USGS gages. Elevated TDG can be created by the entrainment of air as the water is released through regulating outlets or spillway operations. Water released through dam outlets plunges into the tailrace, entraining and forcing air into solution, which can cause elevated TDG concentrations in the river below.

TDG levels above 110% saturation can adversely affect juvenile salmonids through gas bubble trauma (GBT), an effect similar to underwater diving decompression sickness or “the bends” in humans (Mesa et al, 2000). However there have been studies that indicate TDG levels up to 120% may not impact salmonids during less sensitive life stages, depending on depth compensation and other factors (McGrath et al. 2006). Fish residing in shallow or near-surface depths at certain stages of their life cycle are more at risk (Maynard 2008). As stated in the Oregon Administrative Rules (OAR) 340-041-0031:

> “Except when stream flow exceeds the ten-year, seven-day average flood, the concentration of total dissolved gas relative to atmospheric pressure at the point of sample collection may not exceed 110% of saturation. However, in hatchery-receiving waters and other waters of less than two feet in depth, the concentration of total dissolved gas relative to atmospheric pressure at the point of sample collection may not exceed 105% of saturation.”

#### *3.5.1.2.1 North Santiam Sub-basin*

TDG exceedances greater than Oregon standard of 110% can be observed downstream of Detroit and Big Cliff Dams when water is released through the non-turbine outlets of dams. TDG is monitored in real-time at the USGS gage (BCLO) located 0.75 miles below Big Cliff Reservoir near Niagara, Oregon (Figure 3.5-43).

A TDG study was conducted within the North Santiam River in 2010 (June - November) (USACE 2011). TDG saturation measurements were recorded at Detroit and Big Cliff Dam tailraces, Niagara, Minto Fish Facility and Mehama. This study determined that TDG produced by the USACE dams degasses as water moves downstream, typically returning to background levels by the time it reaches Mehama, Oregon, 20 miles downstream of the dams (Figure 3.5-43; USACE 2011).

Although TDG exceedances do occur on occasion from spill and maintenance operations at Detroit or Big Cliff Dams, elevated TDG is typically observed nearest the dams and is not found to persist downstream. Exceedances generally occur in the Fall and spring months when water is released for flood management due to precipitation events. For instance, in May 2013 TDG levels reached 120% TDG for 13 days due to high flows and spill at Detroit and Big Cliff dams for flood management. A compilation of TDG exceedances from 2012 to 2020 is provided with explanations (Figure 3.5-45).

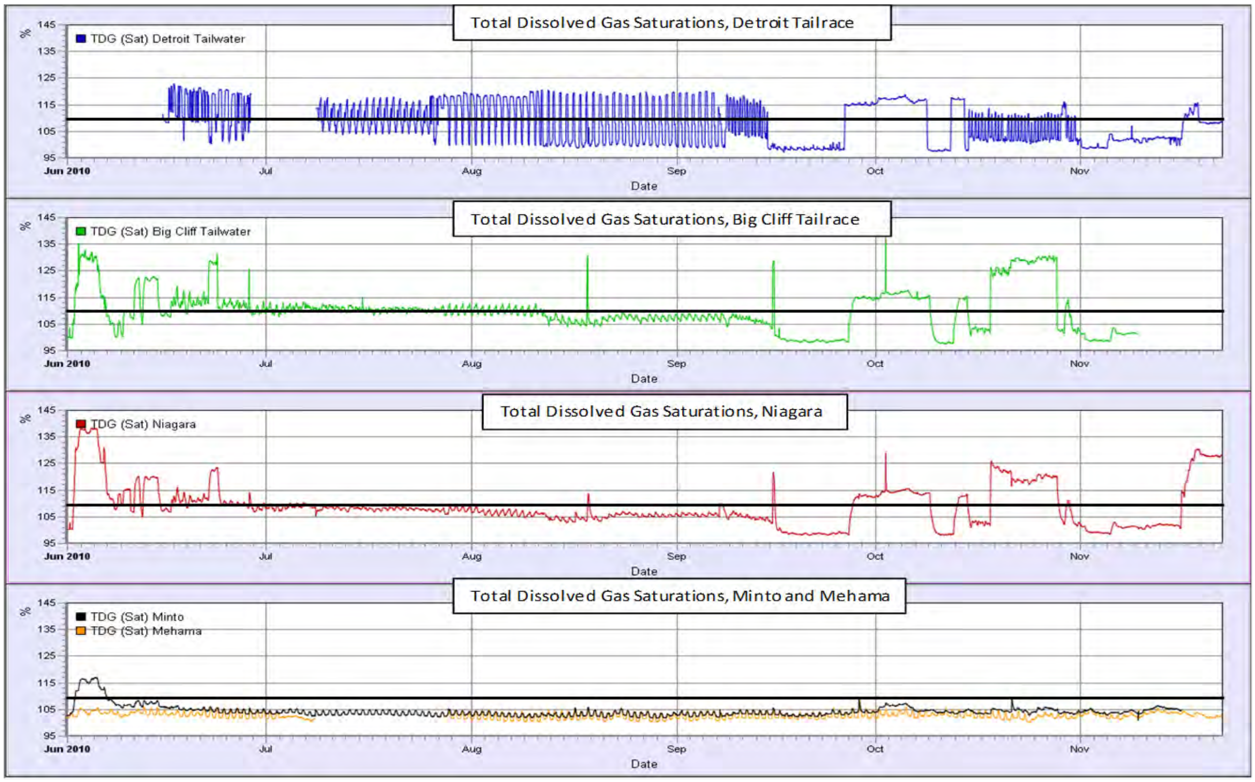

**Figure 3.5-44. Total Dissolved Gas Saturation Measured in the Detroit and Big Cliff Tailraces and Near Niagara, Minto and Mehama on the North Santiam River, June through November, 2010. Black line denotes Oregon criteria for TDG of 110% level. Excerpt from the *Willamette Basin Annual Water Quality Report for Water Year 2010, pg. 25***

#### *3.5.1.2.2 South Santiam Sub-basin*

TDG is not monitored downstream of Green Peter Dam, but Foster Dam instead. This sensor was installed in May 2015. Elevated TDG levels can occur when the outflow of water exceeds the powerhouse capacity and spillway discharge. A compilation of TDG exceedances from 2015 to 2020 is provided with explanations (Figure 3.5-46). For instance, in April 2019 TDG levels reached 121% for 10 days due to spill operations for flood management from a precipitation event. The USACE has updated TDG regression equations for tailwaters below Big Cliff Dam (and Cougar, Foster, and Dexter dams) using data from 2011 to 2020. These equations are based on System Total Dissolved Gas (SYSTDG) formulas used in the Columbia River system. The equations will assist in real-time Willamette Project operations and allow a quantified comparison of TDG resulting from operations in the Willamette Valley PEIS (refer to Technical Report for equation formula).

### *3.5.1.2.3 McKenzie Sub-basin*

The operation of Cougar Dam can lead to TDG exceedances above the state water quality standards when water is released through the regulating outlets of the dam. TDG is monitored at the USGS gaging station (CGRO) below Cougar Reservoir near Rainbow, Oregon (Figure 3.5-1). TDG is not monitored below Blue River Dam.

In 2006, the USACE conducted a two-day spill operation to study regulating outlets and powerhouse variable outflow discharges and TDG response (USACE 2007, *Draft*). The study measured TDG at 5 locations below Cougar Dam and one location in the forebay of Cougar Dam. Site locations were on the right bank of the powerhouse, right bank in the regulating outlet channel, right bank 590.5 ft (180m) below the confluence of powerhouse and regulating outlet releases, right bank adjacent to the USGS gage, right bank 2.8 mi (4.5 km) downstream of

Cougar Dam. The study concluded TDG was higher in the regulating outlet channel with flows higher than 575 cfs producing TDG above the state water quality standard (110%). Degassing and mixing of turbine and regulating outlet releases enabled TDG saturation to decrease downstream.

A compilation of TDG exceedances from 2012 to 2020 is provided with explanations (Figure 3.5-47). For instance, in April 2017 TDG levels reached 117% for 25 days due to spill and maintenance operations. The USACE has updated TDG regression equations for tailwaters below Cougar Dam (and Big Cliff, Foster, and Dexter dams) using data from 2011 to 2020. These equations, based on the SYSTDG formulas used in the Columbia River system, will assist in real-time Willamette Project operations, and allow a quantified comparison of TDG resulting from operations in the Willamette Valley PEIS.

#### *3.5.1.2.4 Middle Fork Sub-basin*

Since 2015 the Middle Fork Willamette River downstream of Dexter and Lookout Point Dams have been monitored for TDG (Figure 3.5-48). When outflows exceed the capacity of Lookout Point Dam's powerhouse, the spillway is used to pass the excess flow. This can lead to TDG exceedances above state water quality standards (110%) downstream.

The USACE conducted a TDG study from August 2012 until May 2013 at 12 sites in the Middle Fork Willamette River (Figure 3.5-48; USACE 2014). During the study Hills Creek Reservoir did not produce TDG levels (percent saturation) above the state criteria of 110% (Figure 3.5-49). The forebay of Lookout Point did not produce elevated TDG (>110%), however discharge from the regulating outlet, spillway, and powerhouse (backwater effect from spillway) resulted in TDG above 110% (Figure 3.5-50). Dexter Reservoir forebay TDG concentrations exceeded 110% when the Lookout Point spillway TDG concentrations were also exceeding the state standard. Comparable results were observed between the Dexter powerhouse and forebay concentrations. Flow through the Dexter spillway can increase TDG (>110%) and is dependent on spillway to powerhouse flow (Figure 3.5-51). The study concluded that excess TDG, generated from Lookout Point and Dexter Dams, generally dissipates to background levels within approximately 8 miles downstream of the Fall Creek confluence on the Middle Fork Willamette River. Currently, TDG is not monitored at Hills Creek, Lookout Point or Fall Creek.

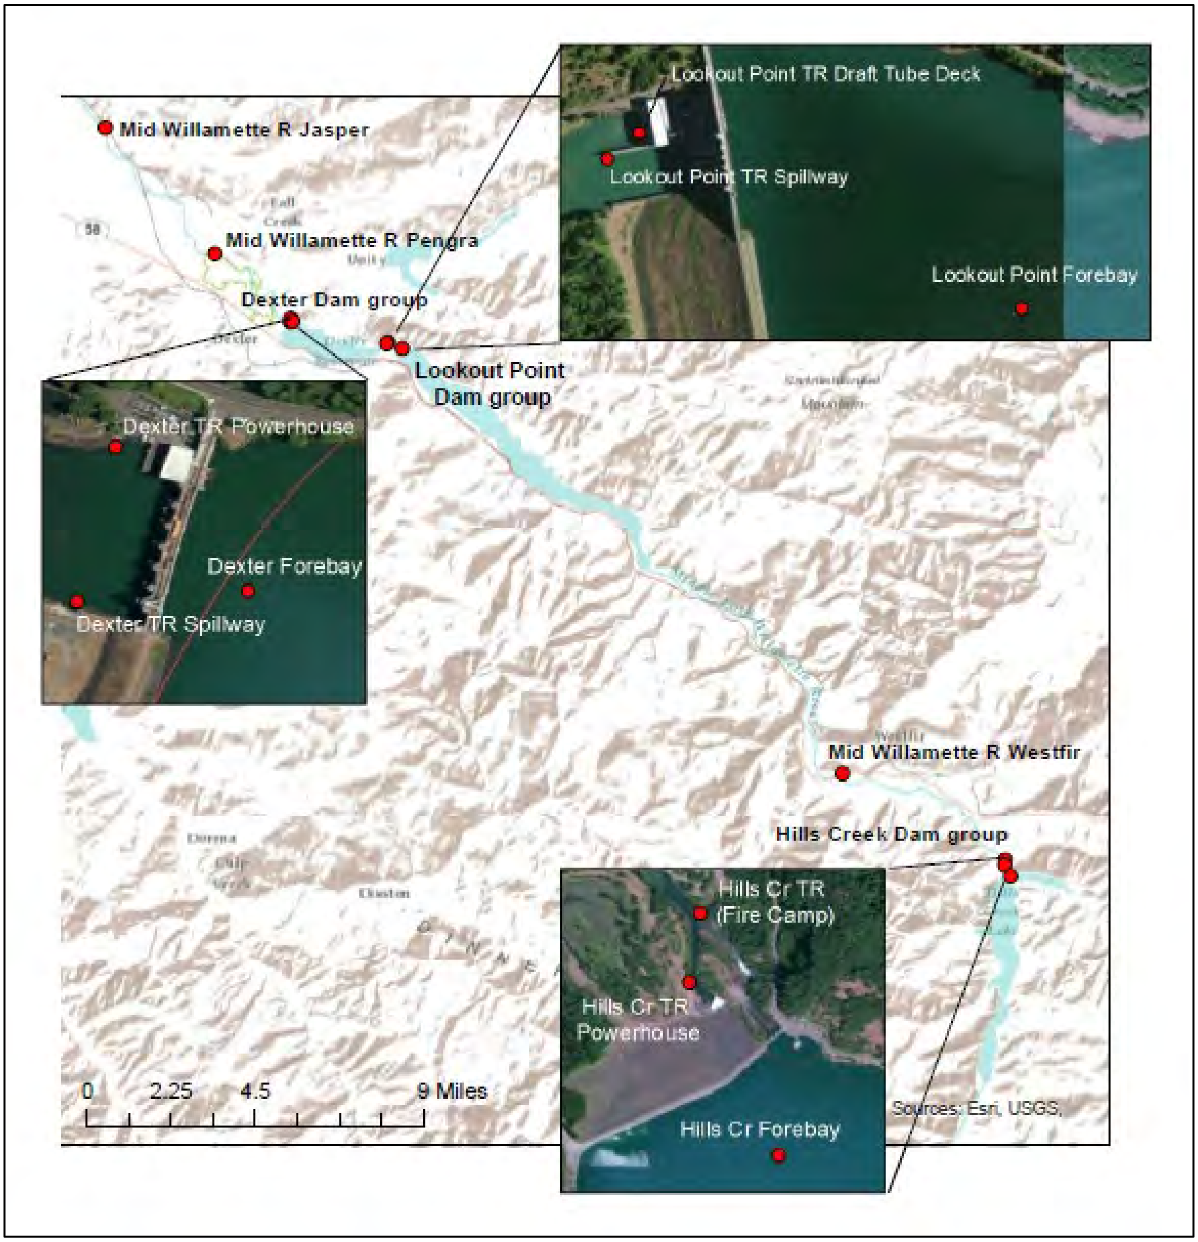

**Figure 3.5-48. Sampling locations for 2012 – 2013 Middle Fork Willamette TDG study (USACE 2014).**

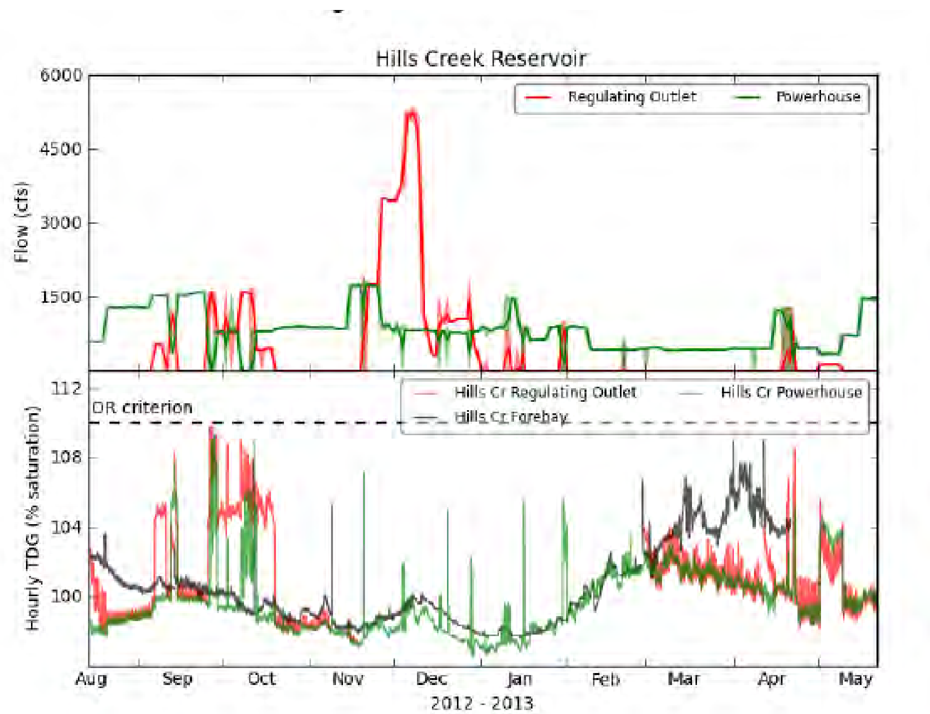

**Figure 3.5-49. Hills Creek Reservoir Operations and TDG Measurements, 2012 -2013 (USACE 2014)**

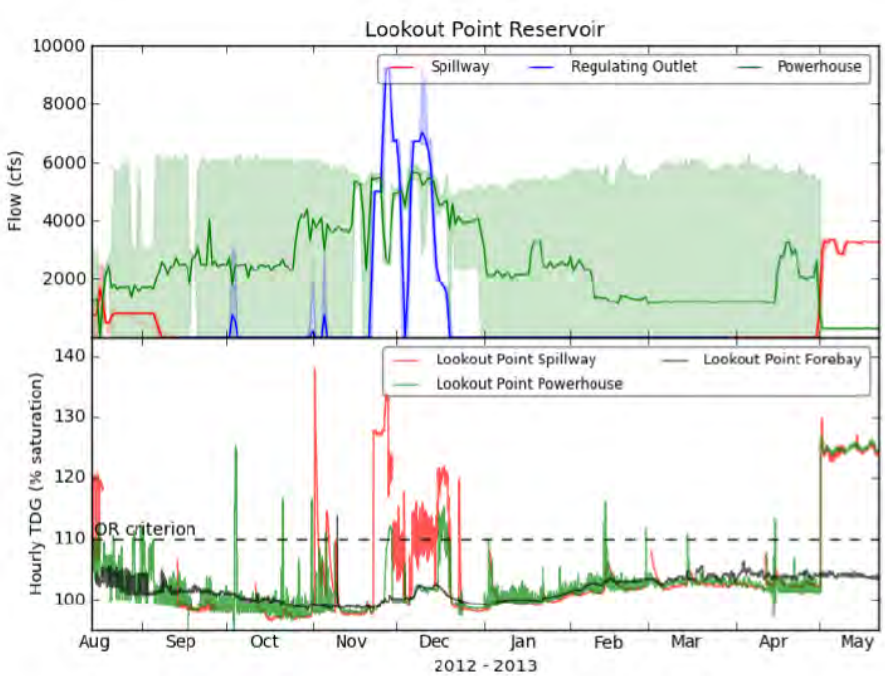

**Figure 3.5-50. Lookout Point Reservoir Operations and TDG Measurements, 2012 – 2013 (USACE 2014)**

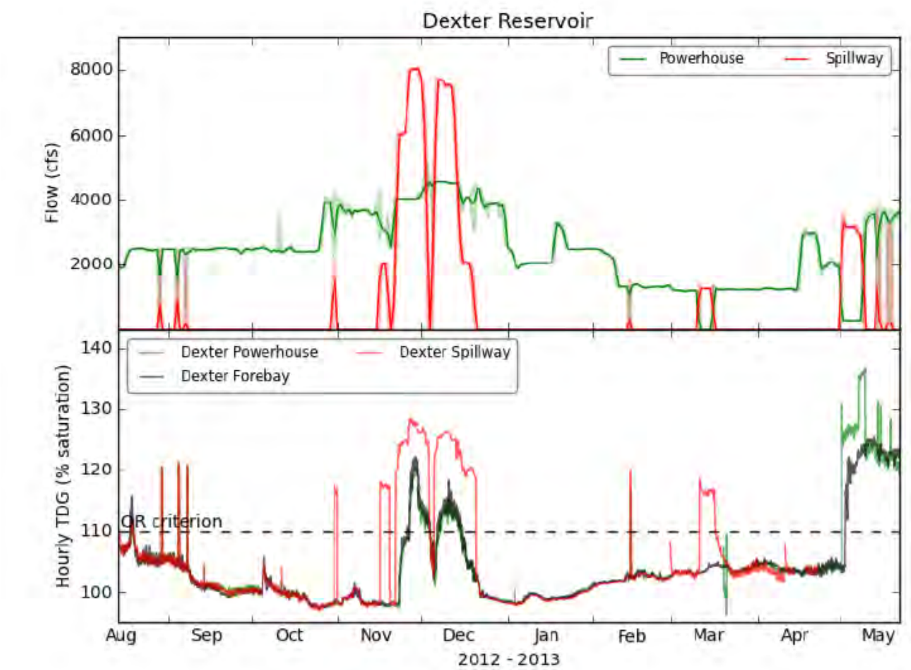

**Figure 3.5-51. Dexter Reservoir Operations and TDG Measurements, 2012 -2013 (USACE 2014)**

A compilation of TDG exceedances from 2015 to 2020 is provided with explanations (Table 3.5-52). For instance, in March 2017 TDG levels reached 118% for 18 days due to spill operations. The USACE has updated TDG regression equations for tailwaters below Dexter Dam (and Big Cliff, Foster, and Cougar Dam) using data from 2011 to 2020. These equations, based on the SYSTDG formulas used in the Columbia River system, will assist in real-time Willamette Project operations, and allow a quantified comparison of TDG resulting from operations in the Willamette Valley PEIS.

### *3.5.1.2.5 Coast Fork and Long Tom Sub-basins*

TDG is not monitored at Cottage Grove, Dorena and Fern Ridge Reservoirs. As stated in the 2008 BiOp: "The ODEQ 2004/2006 Integrated Report database does not identify any streams in the Coast Fork Willamette sub-basin that are water quality limited due to high TDG concentrations (ODEQ 2006b). However, a juvenile Salmonid study final report done for Dorena Lake Dam Hydroelectric Project by the firm Symbiotics (2005) measured TDG in the deep bottom waters of Dorena Reservoir as well as in the Row River just below the existing outlet gates at Dorena Dam. TDG levels deep in the reservoir exceeded ODEQ's 110% maximum saturation standard during February and March. Symbiotics also concluded that aeration through the dam's outlet gates causes TDG below the dam to exceed DEQ's standard in July and August. There are no other data on TDG concentrations in areas of the Coast Fork Willamette sub-basin used for listed anadromous salmonids" (NMFS 2008).

### *3.5.1.3 Harmful Algae Blooms or Cyanobacteria*

Harmful Algae Blooms (HABs) or blue-green algae are cyanobacteria that are commonly found in aquatic environments. Cyanobacteria occur naturally in aquatic environments and have the capability to produce toxins (cyanotoxins). Factors such as nutrient inputs, like nitrogen and phosphorous, and temperature can increase the likelihood of growth. Nutrients inputs can come from the natural environment or introduced as source pollution into waters. Cyanotoxins can affect the central nervous system or kidney/liver functions in humans, pets and livestock.

The Oregon Health Authority (OHA) implements cyanobacteria toxin guidelines and threshold levels for recreation and drinking waters for the public (OHA 2019). Information provided by OHA with current and archived algae bloom recreational advisory includes Willamette Valley reservoirs (Figure 3.5-53; OHA 2020). When USACE staff collect water samples that are sent for toxin analysis, OHA is notified if levels are above the toxin threshold. OHA then assesses the need for a public advisory for a particular water body.

Since 2005, OHA has been posting advisories based on sample results that exceed the cyanotoxin threshold levels (Figure 3.5-54). As shown in Figure 3.5-54 the criteria has evolved from 2005 to present. For instance, presently if Microcystin exceeds 8µg/L then OHA will post an advisory for the water body. The USACE has placed informational signage near boat ramp areas to bring awareness to the public. In addition, USACE staff review Landsat satellite imagery of reservoirs for potential algae bloom activity which is provided on the USACE Water Management Water Quality Reports public website (USACE 2022).

### *3.5.1.3.1 North Santiam Sub-basin*

Cyanobacteria blooms occur frequently in Blowout and Heater Creek arms of Detroit Reservoir. Detroit Reservoir has been listed on the OHA algae bloom advisory in 2018, 2017, 2015 and 2007. Big Cliff Reservoir has been listed on the OHA advisory in 2018 (Figure 3.5-53).

In May 2018 the City of Salem public water utility analyzed routine water samples within Detroit Reservoir, which resulted in high cyanotoxin levels. The City of Salem supplies drinking water daily to approximately 197,000 customers and draws water within the North Santiam River (City of Salem 2020). The City of Salem's water intake is located at Geren Island which is approximately 28 miles downstream of Detroit Reservoir. Due to the public health concern, water temperature control operations were delayed in 2018 for three weeks. During this event, rigorous field monitoring and sampling occurred by USACE and City of Salem until toxin levels were reduced to below the OHA toxin threshold (Figure 3.5-54). The dominant observed species was *Dolichospermum sp. (*previously *Anabaena sp.)* which can produce liver and nerve toxins.

Further research is needed to determine factors that assist in toxin production and toxin suppression. The City of Salem conducts routine monitoring and, in collaboration with the USACE and USGS, currently has a water quality platform deployed in Detroit Reservoir studying factors that may increase algae growth. The US Forest Service also collects water samples for cyanobacteria toxin analysis. In the future, these algae blooms may persist if nutrient inputs to the Reservoir remain the same or increase.

### *3.5.1.3.2 South Santiam Sub-basin*

There have been no known toxic algae blooms present in Green Peter and Foster Reservoirs; as such, no harmful algae bloom advisories have been issued by OHA (Figure 3.5-53). Species such as *Anabaena* sp., *Aphanizomenon* sp., and *Microcystis* sp. have been identified from water samples collected during the summer and early fall.

### *3.5.1.3.3 McKenzie Sub-basin*

Both Cougar and Blue River Reservoir have experienced harmful algae blooms (cyanobacteria). In general, water samples collected at these reservoirs have identified *Anabaena* sp. and *Aphanizomenon* sp. during the summer and early fall. These species have been known to produce toxins. Toxins produced by harmful algae blooms, such as Microcystin and Cylindrospermopsin, have been identified within Blue River and Cougar reservoirs, which prompted the OHA to include them on the advisory list in 2010 and 2011 (Figure 3.5-53).

USACE has posted algae bloom information signage at boat ramps near the reservoirs. When USACE staff collect water samples that are sent for toxin analysis, OHA is notified if levels are above the toxin threshold. Advisories are posted on the OHA Cyanobacteria (Harmful Algae) Blooms website and further water testing is conducted until the toxin levels are reduced below the OHA toxin threshold (OHA 2022). The Eugene Water Electric Board (EWEB) provides service to approximately 200,000 customers (includes electricity and water) and conducts routine sampling and laboratory analysis of water collected within both reservoirs and along the McKenzie River (EWEB 2017). The water intake for EWEB is located on River Mile 15 on the McKenzie River (OHA 2012). The USACE is collaborating with USGS, the City of Salem and EWEB to collect water quality information utilizing equipment housed on a floating platform within Cougar Reservoir. This study hopes to analyze data within Cougar Reservoir and compare with Detroit Reservoir results for algae bloom signatures and potential inputs.

### *3.5.1.3.4 Middle Fork Willamette Sub-basin*

Harmful algae bloom advisories have been documented for all four reservoirs, most recently at Dexter Reservoir in 2013 for 78 days (Figure 3.5-53). Fall Creek Reservoir was listed on the OHA advisory in 2011 for 101 days, Hills Creek for 58 days in 2009 and Lookout Point for 52 days in 2005. Historically, the dominant species identified include *Gloeotrichia* sp., *Dolichospermum* sp. and *Aphanizomenon* sp. which may produce Microcystin and Cylindrospermopsin toxins.

USACE contracted Portland State University to produce a CE-Qual-W2 model utilizing physical parameters and potential algae bloom response within Dexter Reservoir (Cervarich et al. 2020). Analysis included scenarios for structural changes (power intake, Lowell Covered Bridge, and curtain weir at bridge) and climate change. Results showed the simulated algae bloom was eliminated with structural changes and intensified with climate change scenarios. In the future, these results may be used to assist reservoir operations and management decisions. When USACE staff collect water samples that are sent for toxin analysis, OHA is notified if levels are above the toxin threshold. The USACE posts informational signage about algae blooms at reservoir boat ramps.

### *3.5.1.3.5 Coast Fork and Long Tom Sub-basins*

Cottage Grove, Dorena, and Fern Ridge Reservoirs have experienced algae blooms; however, not all blooms have been toxic and listed on the OHA advisory (Figure 3.5-53). Cottage Grove Reservoir has not been under an OHA Cyanotoxin advisory, although the USACE has collected samples in 2016 and 2019. Dorena Reservoir has been listed on the OHA advisory in 2018 for 9 days and Fern Ridge was last under an advisory for 125 days in 2013. Observed species in these reservoirs include *Gloetrichia* sp., *Aphanizomenon* sp., *Dolichospermum* sp., and *Microcystis* sp. The most common toxins have been Microcystin and Cylindrospermopsin which may produce nerve and liver damage. When USACE staff collect water samples that are sent for toxin analysis, OHA is notified if levels are above the toxin threshold. Lane County Parks also collects water samples analysis as necessary. USACE posted information signage at the reservoir boat ramps to educate the public about algae blooms.

### *3.5.1.4 Turbidity*

Increased turbidity levels can arise during storm events or maintenance operations of dams. During storm events bank erosion can increase sediment transport causing elevated turbidity. Turbidity monitoring is conducted ad-hoc and as necessary to ensure sediment load is minimal. At this time turbidity monitoring is not conducted year-round. As per OAR 340-041-0036:

> “No more than a ten percent cumulative increase in natural stream turbidities may be allowed, as measured relative to a control point immediately upstream of the turbidity causing activity”.

#### *3.5.1.4.1 Middle Fork Willamette Sub-basin*

At Fall Creek Reservoir, a deep reservoir drawdown to facilitate volitional downstream fish passage has occurred since 2012. Model results of drawdowns and influences on juvenile UWR spring Chinook salmon show the drawdown has minimal impacts to juvenile UWR spring Chinook salmon and incomplete refill may also reduce growth potential (Johnson et al. 2016). A USGS study, USACE-funded, was conducted at Fall Creek Lake to monitor and evaluate suspended sediment transport, bedload and dissolved oxygen in 2012 -2013. A calculated suspended sediment budget for 72 days concluded 16,300 tons of deposition occurred in the reaches of Fall Creek and the Middle Fork Willamette River (Schenk et al. 2014). The USACE has also funded USGS to conduct suspended sediment, turbidity, and DO studies for years 2012 – 2017. In general, turbidity levels increase as reservoir drawdown occurs (Figure 3.5-55). A summary was presented at the 2019 Willamette Fisheries Science Review on March 12 -14, 2019. The USGS will publish the report in 2021.

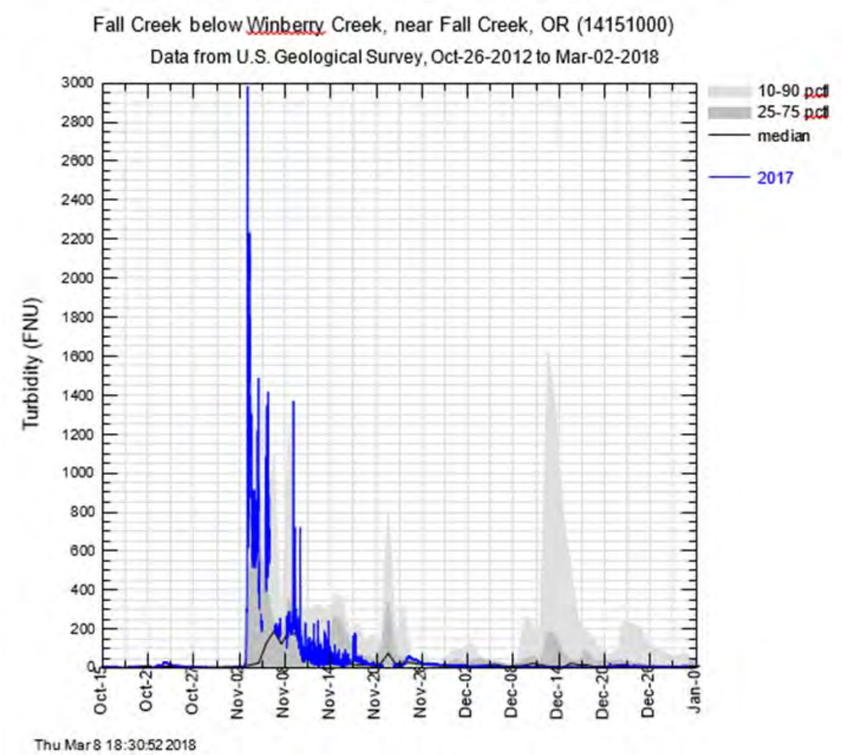

**Figure 3.5-55. Turbidity measured by USGS downstream of Fall Creek Reservoir during deep drawdown, 2012 – 2017.**

### *3.5.1.5 Mercury*

As discussed in section 1.8 the Willamette Valley System reservoirs operate for authorized purposes and follow a rule curve (Figure 1.8-3). Reservoir water elevations follow the rule curve based on operational requirements and time of year. A reservoir water drawdown operation for flood risk management can expose lakebed sediments. As the reservoir refills sediments will be covered with water and organic matter. The drying and rewetting of sediments from changing water levels may increase the methylation of mercury (Willacker et. al 2016; Eckley et. al. 2015).

Mercury can come from naturally occurring process such as deposits within volcanic rock or man-made processes such as atmospheric deposition and mining activities (Park et al. 1997; Ambers et al. 2001; Hammerschmidt et al. 2006). Main forms of Mercury are elemental, inorganic, and organic. Atmospheric deposited Mercury (elemental) can be converted to Methyl Mercury by microbial groups that are potential Hg methylators (Gustin et al. 2020). Biomagnification of mercury has been studied in the aquatic food web from plankton to fish species (Kidd et. al 2012; Hall et. al. 1997). Methyl Mercury (MeHg) is an organic form of Mercury that has harmful health effects for humans and wildlife (Chételat et al. 2020; Willacker et. al. 2020; Clarkson and Magos 2006; Scheuhammer et al. 2007). Methyl Mercury is a neurotoxin and consuming fish that has MeHg in their tissues is a main exposure for humans and wildlife (Hall et al. 1997; Cusack et al. 2017; Jackson et al. 2016; Sandheinrich et al. 2011). Federal and state agencies have advisories and guidelines for fish consumption limits for humans (EPA and FDA 2022; OHA 2022). As of February 4, 2021, the ODEQ and EPA have issued a revised 2019 Willamette Basin Mercury TMDL; the previous TMDL was issued in 2006.

##### *3.5.1.5.1 Coast Fork and Long Tom Sub-basins*

Mercury has been identified and studied within Cottage Grove and Dorena Reservoirs (Park et al. 1997; Ambers et al. 2001; Curtis 2003; Curtis et al. 2013; Hope et al. 2005; Eagles-Smith et al. 2016). Cottage Grove Reservoir has mercury contamination originating from the Black Butte Mine (Environmental Protection Agency (EPA) Superfund National Priorities List in 2010), which is approximately 15 km upstream (Eckley et al.2015). The Black Butte Mine was utilized for cinnabar mining to produce quicksilver (liquid mercury) and ceased operations in the late 1960’s. However, mercury contaminated soil from Black Butte has been transported downstream and deposited within Cottage Grove reservoir.

Anaerobic bacteria are able to convert mercury to Methylmercury, which can be released and accumulate in aquatic organisms and fish (Eckley et al. 2017). The EPA has conducted recent cleanup of the mine area in 2018 and 2020 (EPA 2020). In 2021, the EPA has planned sampling to assess conditions within Cottage Grove Reservoir and previous Black Butte cleanup actions. Signs are posted by OHA at the reservoir boat ramps to educate the public of fish consumption guidelines.

Dorena reservoir has also been found to contain mercury due to mining activities from the Bohemia Mining District, located 30 km upstream (Hygelund 2000). Although, the mining activities conducted were different from the Black Butte Mine in that quicksilver was utilized for gold and silver recovery. These mining activities resulted in lower contamination levels into Dorena Reservoir (Ambers et al. 2001). Signs are posted by the OHA at the reservoir boat ramps to educate the public of fish consumption guidelines.

#### ***3.5.1.6 Sediment Quality***

Sediment is defined as mineral and/or organic material that is eroded, transported, and deposited by wind, water, and/or glacial erosion. Sediment can be composed of clay, silt, sand, gravel, and larger rocks as well as organic matter derived from plants, animals, fungi, etc.

When wetted, sediment composed of fine-grained mineral particles (silts and clays) and organic matter are capable of adsorbing (bind/ hold) ions. They are also able to adsorb contaminants. Manmade contaminants such as pesticides and polychlorinated biphenyls (PCBs) and naturally occurring contaminants (generated from the erosion of volcanic rocks) are hydrophobic (“water-fearing”) and are adsorbed and sequestered in the sediment rather than readily dissolving in water. As such, contaminants sequestered in the sediment do not typically impact the water quality in the overlying water column unless they occur at very high concentrations.

Once adsorbed to the sediment, contaminants can persist in the sediment for years, long after they are no longer detectable in water. Although many of these manmade chemicals were banned decades ago, they are still found in lake and stream bed sediment, sometimes at concentrations high enough to be a risk to aquatic organisms. For additional information on sediment see Section 3.3.

In the Northwest Region, the *Sediment Evaluation Framework for the Pacific Northwest* (SEF) is used to evaluate sediment quality in the states of Oregon, Washington, and Idaho (NWRSET, 2018). This guidance was developed for use in these three states by federal agencies (USACE-Northwestern Division, Environmental Protection Agency – Region 10, National Marine Fisheries Service, and US Fish and Wildlife Service), the state water quality agencies (Oregon Department of Environmental Quality, Washington Department of Ecology, and Idaho Department of Environmental Quality), and the Washington Department of Natural Resources.

Per the SEF, the area of interest is identified, and sediment sampling objectives are defined. Sediment samples are collected from the area of interest and sent to laboratories for analysis. Up to nearly 60 contaminants are analyzed, and the bulk sediment concentrations measured by the laboratories are compared to freshwater thresholds ("screening levels") that are protective of benthic and epibenthic fauna.

The sediment chemical screening levels presented in the SEF are primarily used to evaluate federal and non-federal navigational dredging projects. However, the SEF thresholds may also be used to assess the quality of sediments stored behind reservoirs or in other projects in which sediments may be excavated and discharged into wetlands or waterways.

Sediment in the 11 of the 13 WVS reservoirs has been sampled and analyzed to determine the presence or absence of sediment-borne contaminants. Due to resourcing constraints Blue River and Hills Creek Reservoirs have not been sampled, no future sampling is anticipated. The EPA collected sediment samples from Cottage Grove Reservoir in 2021 relating to the Black Butte Mine clean up (Section 3.5.1.5) the results are pending.

A summary of sampling that has occurred in the reservoirs (between 2002 and 2021) appears in Table 3.5-6. Sediments in nearly all reservoirs have been analyzed for grain size distribution, total organic carbon content, heavy metals, and organochlorine pesticides. The metals analysis is performed due to the volcanic nature of the soils contributing sediment to the reservoirs and the occurrence of mines above some of the reservoirs. The pesticides analysis was typically performed due to the known history of aerial application to control forest pest species. Analysis for other contaminant groups (semivolatile organic compounds [including polynuclear aromatic hydrocarbons, phthalates, phenols, and miscellaneous extractable compounds] and polychlorinated biphenyls) was performed if there was reason to believe those chemicals might be present due to a nearby source.

To date, none of the in-water sediment samples collected have shown contaminant concentrations above the regional SEF freshwater screening levels. Pesticides were detected in forested soils adjacent to Cougar Reservoir during the 2002 sediment sampling event; however, pesticides were not detected above the regional sediment quality guidelines in the reservoir sediments.

**Table 3.5-6. Summary of Sediment Sampling and Analysis at the 13 Willamette Valley Project Reservoirs, Willamette River Basin, Oregon**

| Sub-basin | WVP Facilities | Year Sampled | Parameters analyzed (no. samples) | Above SEF FW SLs? | Notes |
|---|---|---|---|---|---|
| North Santiam | Detroit | 2010 | Metals, PAHs, SVOCs, OC pesticides, PCBs (3 samples at RO) | No | Bis(2-ethylhexyl) phthalate (common in plastics) detected above the SEF FW SL, but dismissed as a laboratory-generated contaminant |
| | | 2013 | G.S., metals, OC pesticides (5 samples in pool) | No | |
| | Big Cliff | 2013 | G.S. | No | Sediment coarse-grained, so no chemical analysis was performed |
| South Santiam | Green Peter (Middle Santiam) | 2013 | G.S., metals, OC pesticides (8 samples) | No | |
| | Foster (South Santiam) | 2013 | G.S., metals, OC pesticides (4 samples) | No | |
| McKenzie | Cougar (South Fork McKenzie) | 2002 | G.S., metals, DDX, phthalates, PAHs (28 samples: 1 downstream, 2 upland upstream, 25 in pool) | No (in pool) No (downstrm) Yes (in upland) | Most samples coarse-grained; 17 samples submitted for DDX analysis. DDE and DDT concentrations in a upland sample collected upstream of reservoir exceeded the SEF FW SLs |
| | | 2012 | G.S., metals, OC pesticides (3 composite samples in pool) | No | |
| | Blue River | NOT SAMPLED | | | |
| Middle Fork Willamette | Hills Creek | NOT SAMPLED | | | |
| | Lookout Point | 2013 | G.S., metals, OC pesticides (7 samples in pool) | No | |
| | Dexter | 2013 | G.S., metals, OC pesticides (1 composite sample in pool) | No | |

| Sub-basin | WVP Facilities | Year Sampled | Parameters analyzed (no. samples) | Above SEF FW SLs? | Notes |
|---|---|---|---|---|---|
| Fall Creek | Fall Creek | 2012 | G.S., metals, OC pesticides (3 composite samples in pool) | No | |
| Long Tom | Fern Ridge | 2005 | G.S., metals, DDX, PCBs, PAHs (9 samples) | No | 9 samples total in pool; 4 along the dam face |
| Coast Fork Willamette | Dorena | 2017 | G.S., metals, OC pesticides (2 composite samples in pool) | No | Metals below SEF FW SLs; no pesticides detected |
| Row River | Cottage Grove | 2021 | G.S., metals | Results pending | Black Butte Mine Superfund Site upstream of Cottage Grove. EPA sampled reservoir sediment to determine contamination extent. |

Abbreviations: SEF FW SL = freshwater benthic toxicity screening levels from the 2018 *Sediment Evaluation Framework for the Pacific Northwest*; G.S. = grain size; Metals = Sb, As, Cd, Cr, Cu, Pb, Hg, Ni, Ag, Zn; DDX = DDT and DDD, DDE (DDT breakdown products); OC pesticides = organochlorine pesticides (DDX, chlordane compounds, aldrin, dieldrin, lindane); PAHs = polynuclear aromatic hydrocarbons; SVOCs = semivolatile organic compounds; PCBs = polychlorinated biphenyls

### 3.5.2 Environmental Consequences

Environmental consequences in relation to water quality parameters were compared between the No Action Alternative the action alternatives. The parameters, Water Temperature and Total Dissolved Gas (TDG) were modeled and described in the Methodology section below. Parameters such as, Turbidity, Harmful Algae Blooms, and Mercury were qualitatively described by Alternative utilizing information from the River Mechanics & Geomorphology, Hydrological Processes and Climate Change sections.

#### *3.5.2.1 Methodology*

Table 3.5-7 describes how water quality effects are designated. Further screening criteria flow charts are provided for water temperature and TDG. The water quality parameters are compared to the No Action Alternative for each Alternative.

##### *3.5.2.1.1 Water Temperature*

The model CE-QUAL W2 was utilized to simulate water temperatures at all sub-basins, except for the Coast Fork and Long Tom sub-basins for the years 2011, 2015, 2016. Each year represented a different climatological condition: wet year (2011), dry year (2015), and average year (2016), and average of the three years (2011,2015,2016). CE-QUAL-W2 reservoir water temperature model output was analyzed for each of the three calendar years in each reservoir and immediately downstream (Technical Appendix D). Inflow discharge, inflow water temperature, air temperature, barometric pressure, wind speed, wind direction, and gate-specific outflow data were used as inputs for each simulation.

To assess effects in each Alternative, the hourly water temperature below each dam was used in a calculation of the 7-day Average of the Daily Max (7dADM) water temperature. The 7dADM water temperature was then compared to the temperature targets at each location to assess effects in each alternative. As stated in OAR 340-041-0028 (4) the seven-day-average maximum temperature of a stream is utilized for life stages of fish species in determining temperature thresholds, for example UWR spring Chinook salmon, UWR steelhead, and bulltrout. Please refer to the Water Quality Technical Appendix D for more detailed information.

#### *3.5.2.1.2 TDG*

Available data from Detroit/Big Cliff, Green Peter/Foster, Lookout Point/Dexter, Hills Creek, and Cougar Dams was utilized to simulate TDG with the SYSTDG model. TDG measures under the action alternatives are proposed at these dams due to data availability from gages and not discussed at Fall Creek and Blue River. This model was adapted from the Columbia River System TDG model. SYSTDG is an empirical (data-driven) model depending primarily on spill outflow (non-turbine releases) and power outflow (turbine releases) at each dam. The period of record used by the RES-SIM modeling was applied to SYSTDG at the locations listed above for each alternative. Please refer to the Water Quality Technical Appendix D for further data formulas and results, such as boxplot figures of TDG by Alternative compared to the NAA.

The SYSTDG model output includes estimated TDG based on project operations and the annual number of days above 110% (Technical Appendix D). TDG results are compared to the State of Oregon water quality standards in the Oregon Administrative Record (OAR) 340-041-0031: "Except when stream flow exceeds the ten-year, seven-day average flood, the concentration of total dissolved gas relative to atmospheric pressure at the point of sample collection may not exceed 110% of saturation". Please refer to section 3.5.3 for explanation of TDG effects.

#### *3.5.2.1.3 Turbidity*

Description is qualitatively based on information provided in the River Mechanics and Geomorphology Chapter 3.3 and Technical Appendix C which includes potential for changes in sediment supply.

The Sediment Supply analysis assumes that sediment supply from rivers upstream of WVS projects, or tributaries to WVS impacted reaches that are not downstream of a WVS reservoir, is unchanged relative to the No Action Alternative (NAA). This metric estimates the potential for changes in sediment passing WVS projects relative to NAA (see section 3.3.2.1).

#### *3.5.2.1.4 Harmful Algae Blooms (HABs)*

Description is qualitatively based on information provided in the River Mechanics and Geomorphology Chapter 3.3 and Technical Appendix C for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment or Bank Failure Potential and Climate Change Technical Appendix F.

The head-of-reservoir sediment mobilization metric is designed to indicate the potential for changes in sediment scour and deposition patterns in the most upstream portion of storage reservoirs as it may impact nutrient availability within sediments for algae. In dams that use large amounts of storage volume and operate over a wide range of elevations throughout the year, the transition from riverine to reservoir conditions can shift upstream and downstream considerable distances (see section 3.3.2.1). Head-of-reservoir sediment mobilization metric is utilized to describe potential nutrient availability within sediments entering the reservoir for algae.

Shoreline erosion of bank sediments along reservoir margins is a complex process that is influenced by the cumulative effects of: wave erosion, reservoir currents, precipitation runoff, freeze-thaw, soil properties, exposure, vegetation density and type. One commonly observed process is that during times of extended reservoir drawdown, exposed un-vegetated shoreline soils that were previously saturated are prone to erosion and slumping. The shoreline exposure metric was developed as a surrogate for shoreline erosion processes. This metric compares the number of days that the reservoir water surface spends at any elevation to identify change in shoreline exposure and indicate the potential for change in shoreline erosion in the WVS storage projects (see section 3.3.2.1). Shoreline erosion of bank sediment metric is utilized to describe potential nutrient availability within sediments for algae.

A separate potential source of sediment to the reservoir can come from bank erosion or bank failures within the reservoir itself. Drawdowns deeper than those historically experienced have the potential to re-suspend stored sediments or induce landslides (USACE, 2003) and introduce new sediment to the reservoir. The timing of these deep drawdowns is not correlated to reservoir inflow and are not fully captured in the Sediment Trap Efficiency metric. Deeper drawdowns are assumed to increase the potential for sediment re-entrainment and slope failure supplying additional suspended sediment to the reservoir. Whether this sediment would settle within the reservoir or pass downstream would depend on sediment quality and hydraulics within the reservoir (see section 3.3.2.1). Sediment Re-Entrainment or Bank Failure Potential metric is utilized to describe potential nutrient availability within sediments for algae.

#### *3.5.2.1.5 Mercury*

Description is qualitatively based on information provided in the River Mechanics and Geomorphology Chapter 3.3 and Technical Appendix C for Shoreline Exposure and Climate Change Technical Appendix F.

The shoreline erosion metric is utilized to describe the potential for the methylation process to occur due to sediments exposed during water fluctuations and rewetting of soils.

"The degree to which water level fluctuations affect Hg methylation at a particular location is expected to vary depending on a host of site-specific conditions such as: the quantity and quality of organic carbon, the microbial community structure and abundance, whether sulfate or other electron acceptors become limited during the year, and the nature of inorganic Hg speciation and associations with solid phase sediment" (Eckley et al. 2017).

It is acknowledged that anoxic conditions are also a factor in the methylation of mercury due to the role of sulfate-reducing bacteria and nutrient loading (Chen et al. 2009; Dent et al. 2014). At this time the USACE does not have the capability to simulate dissolved oxygen in the available models.

#### *3.5.2.1.6 Water Temperature Effects Criteria Methodology*

Simulated water temperatures were evaluated and compared relative to NAA using the following metrics based on the 3-year average of 2011, 2015, and 2016 (the calendar years available from CE-QUAL-W2 modeling):

- **Summer Extremes:** Number of days in which the 7dADM water temperature is below 18° C or 64.4 °F. The 18° C thresholds corresponds to the Oregon State biologically based numeric Water Quality Temperature Standard for salmon and trout rearing and migration (OAR 340-041-0028) and represents "Optimal" conditions for juveniles and adult Chinook salmon in Koch, et.al., (2020). See Appendix D **Error! Reference source not found.** for values at each location, year, and alternative in the Water Quality Technical Appendix D for model formulas and results.
- **Days Near Temperature Target:** Number of days in which the 7dADM water temperature was within 2 F of the temperature target in two-time frames: April-August and September-March (see Technical Appendix D). Temperature targets used in this analysis are those applied in the CE-QUAL-W2 model (discussed in Appendix D Section 1.2.2) except for the Cougar (CGRO) target, where the temperature target defined in the Oregon State Total Maximum Daily Load (TMDL) was used. The Oregon TMDL temperature target for Cougar is cooler than that which was used in the CE-QUAL-W2 model and allowed for a more appropriate baseline for comparing the wide range of temperatures throughout the Alternatives. This allowed a comparison of alternatives at Cougar that did not inappropriately penalize the relatively cool temperatures (downstream of the dam) that resulted during deep drafting of Cougar Reservoir in some alternatives and better aligns with the needs of ESA-listed cold water fish species being considered in this PEIS. See Figure 1-361 for annual values at each location, year, and alternative in the Water Quality Technical Appendix D for model data formulas and results.

Water temperature effects were assigned based on the metrics above at each location and alternative using criteria in Table 3.5-7. Effects Criteria Thresholds at each location are summarized in Figure 3.5-56. Please refer to Technical Appendix D for description of these metrics. Thresholds were established based on the distribution of the data and expert opinion. The results from each alternative were summarized by each metric and then categorized based on tangible timeframes that are easily relatable (ex: increments of 5, 10 days) to Effects.

**Table 3.5-7. Water Temperature Effects Criteria Definitions**

| Effects Criteria Thresholds | Days Below 18 deg C (64.4 F) | Days Within 2 Deg F of Temperature Target (April-August) | Days Within 2 Deg F of Temperature Target (September - March) |
|---|---|---|---|
| Major Benefit | 15 | 50 | 50 |

### *3.5.2.1.7 Total Dissolved Gas (TDG) Effects Criteria Methodology*

Dam releases from non-turbine outlets (defined as “spill” in this PEIS) are known to produce elevated TDG. The average number of days with spill per year are compared in each Alternative and dam (Table 3.5-8) and help to explain locations and alternatives with relatively higher TDG. Generally, TDG is generated initially at the high-head dam when spill occurs (e.g., Detroit Dam) and can increase downstream if spill occurs at the downstream re-regulating dam (e.g., Big Cliff Dam). TDG estimates from SYSTDG were then tabulated as the average number of days exceeding 110% TDG per year (Figure 3.5-57). The categorical TDG effects at each location and alternative relative to the NAA were developed based on the annual difference in number of days above 110% TDG compared to the NAA (Table 3.5-8, Figure 3.5-57). These categorical thresholds were chosen to represent the distribution of the summary data shown in Figure 3.5-57. The results from each alternative were summarized by each metric and then categorized based on tangible time frames that are easily relatable (ex: increments of 25, 50, 100 days). Effects are determined at the stream gage locations immediately downstream of the dams. Please refer to Technical Appendix D for model results.

**Figure 3.5-57. TDG Effects Criteria based on Annual Number of Days above 110% TDG levels compared to the No Action Alternative and each Alternative downstream of the dams**

<u>**Construction**</u>

The PEIS will discuss general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects during the implementation phase.

Direct effects from the construction of water temperature control towers at Detroit, Lookout Point, Green Peter, Hills Creek and long drawdown at Cougar to construct the outlet works for the routine use of the diversion tunnel may limit temperature management, increase turbidity levels and effect TDG levels. Indirect effects are uncertain at this time.

### *3.5.2.2 No Action Alternative*

Water quality effects under the No Action Alternative (NAA) would be expected to continue as described in the Section 3.5 Water Quality Affected Environment. The monthly mean water temperature at each major stream gage location immediately below the dams (excluding the

Coast Fork and Long Tom tributaries) in NAA are shown in Appendix D Figure. Table 3.5-9 summarizes the effects of the NAA.Table 3.5-10 Summarizes the effects of the No Action alternative

**Table 3.5-9. Summary of Effects of the No Action Alternative**

| Subbasin | NAA |
|---|---|
| North Santiam | Detroit interim temperature operations would continue June 1 to August 30 and through the Regulating Outlets from October 1st to November 15. Effects would remain the same as they have existed since the issuance of the 2008 BiOp and implementation of operational water temperature management. TDG average number of days above 110% TDG would continue to occur on a frequent basis with TDG exceedances downstream of Big Cliff of up to 148 days and below Detroit Dam of up to 115 days. The Average Number of Days of Spill per Year would continue to be 127 days at Detroit and 84 days at Big Cliff. |
| South Santiam | Green Peter and Foster Reservoir temperature operations would remain the same whereby the Foster fish weir and night-time spill operations of 300 cfs would remain in effect from June 16 until August 15. Green Peter water temperatures would continue to meet state monthly targets in the spring and briefly in the fall, summer temperatures would be cooler than the monthly targets. Foster reservoir historic water temperature range would continue to meet the state monthly targets in the spring and fall, summer temperatures would continue to trend slightly cooler. Although no TDG measurements exist immediately downstream of Green Peter, it is estimated that the 110% TDG level would be exceeded on average for 12 days per year based on the amount of spill occurring in NAA. Foster would be above 110% TDG for 32 days on average. The Average Number of Days of Spill per year at Green Peter would continue to be 47 days and 209 days at Foster. |
| McKenzie | The Cougar water temperature control tower would continue to be operated annually to draft water to 1541 ft elevation by November 15. Under the No Action Alternative there would be no water temperature control operations at Blue River. Cougar Reservoir typically meets the state temperature targets utilizing the water temperature control tower as compared to pre-temperature control tower results. Blue River reservoir outflow water temperatures are closest to the state temperature targets from February through May and warmer from August through November when comparing the historic temperature range. |
| Middle Fork Willamette | Fall Creek would continue with informal temperature control operations by utilizing the fish horns for temperature management from month to month to release warmer water temperatures. Hills |

| Subbasin | NAA |
|---|---|
| | Creek reservoir temperatures have not exceeded 65 °F in the summer. Temperatures at Hills Creek have met most of the temperature targets from 2016 to 2020 but were lower than the TMDL targets from 2011 to 2015. The outflow temperatures are generally close to the temperature TMDL targets for Lookout Point/Dexter, except from October through November when temperatures are higher. At Fall Creek Reservoir the outflow temperatures are generally closest to the RA Targets and Temperature TMDL targets from February through May. Hills Creek would continue above 110% TDG level for an average of 19 days per year. Lookout Point is estimated that the 110% TDG level would be exceeded on average for 0 days per year based on the amount of spill occurring in NAA. TDG immediately below Dexter would continue above 110% for an average of 20 days per year. The Average Number of Days of Spill per year would continue at Hills Creek with 120 days, Lookout Point would continue to be 31 days and Dexter would continue to be 87 days. |
| Coast Fork Willamette & Long Tom | Temperature management operations are currently not implemented in the Coast Fork & Long Tom sub-basins and Cottage Grove, Dorena and Fern Ridge dams. Within the No Action Alternative there would be no change in water temperatures. There would be no change in effects as operations would remain the same. As there are no TDG gages downstream of Cottage Grove, Dorena, or Fern Ridge dams and no proposed measures, the effects would be similar to the Water Quality Affected Environment. |
| Mainstem Willamette | There are no WVS projects located on the Mainstem Willamette River, however water temperatures downstream of the WVS projects can assist in temperature regulation on the Willamette River. Water temperature modeling of tracking heat sources in the Willamette has shown the heat content in the Willamette at Salem/Keizer during May-August in 2011, 2015, and 2016 was typically less than 20% sourced from upstream dam releases, despite the fact that roughly 50 percent streamflow during those months is attributed to upstream dam releases. The Mainstem Willamette River at Salem (SLMO) and Mainstem Willamette River at Albany (ALBO) typically observes warmest temperatures in July and August. Coolest temperatures are observed in April and October for these two locations. To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues. |

#### *3.5.2.2.1 North Santiam Dams*

**Water Temperature**

The North Santiam sub-basin represented at BCLO in Appendix D includes Detroit reservoir interim temperature operations, which assume up to 60% of total outflow released through the Spillway from June 1 to August 30 (if/when the lake is above the spillway crest) and up to 60% of total outflow released through the Regulating Outlets from October 1st to November 15. The low water year of 2015 resulted in Detroit Lake not filling to the spillway crest, which resulted in relatively warmer temperatures compared to 2011 and 2016, especially in July-October. Effects would remain the same as they have existed since the issuance of the BiOp and implementation of operational water temperature management. Please refer to section 3.5 Water Quality Affected Environment.

**TDG**

With current operations the same as stated in the Section 3.5.1 Water Quality Affected Environment, the average number of days above 110% TDG would continue to occur on a frequent basis with TDG exceedances downstream of Big Cliff of up to 148 days and below Detroit Dam of up to 115 days (Table 3.5-9). The Average Number of Days of Spill per Year would continue to be 127 days at Detroit and 84 days at Big Cliff (Table 3.5-9). TDG exceedance tend to occur when water is released through the non-turbine outlets of dams, spill and maintenance operations. Please refer to the Water Quality Technical Appendix D for further data formulas and results, such as boxplot figures of TDG by Alternative compared to the NAA.

**Turbidity**

Turbidity is typically low in the North Santiam; however recent wildfires may alter turbidity levels. Turbidity monitoring would be conducted as needed and not year-round. River Mechanics and Geomorphology Chapter 3.3 for NAA results of Potential for changes in sediment supply states “a portion of the incoming sediment load will continue to pass run-of-river reservoirs and free-flowing reaches at magnitudes and rates similar to those historically experienced”.

**HABs**

In Section 3.3 River Mechanics & Geomorphology sections for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment or Bank Failure Potential and Climate Change Technical Appendix F. Increased nutrient inputs may facilitate an increase in algae blooms. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

**Mercury**

In River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure and Climate Change Technical Appendix F. River Mechanics and Geomorphology Chapter 3.3 for

NAA results of Shoreline Exposure states “the amount of time that the storage project WSEs spend at any given elevation will not change from historical conditions. Negligible change in the amount of time that the storage project WSEs spend at any given elevation indicating that reservoir shoreline erosion processes are expected to continue at locations and rates similar to those historically experienced at each project”. This metric is utilized to describe the potential for the methylation process to occur due to water fluctuations and rewetting of soils.

##### *3.5.2.2.2 South Santiam Dams*

**Water Temperature**

South Santiam sub-basin which includes Green Peter and Foster Reservoir temperature operations would remain the same whereby the Foster fish weir and night-time spill operations of 300 cfs would remain in effect from June 16 until August 15. As Foster is a reregulating dam for Green Peter these temperature operations would remain under the No Action Alternative. As compared to the state temperature targets and historic temperature range Green Peter water temperatures would continue to meet these monthly targets in the spring and briefly in the fall, summer temperatures would be cooler than the monthly targets (Fig 3.4-3; Table 3.4-1). Foster reservoir historic water temperature range would continue to meet the state monthly targets in the spring and fall, summer temperatures would continue to trend slightly cooler (Figure 3.4-6; Table 3.4-1).

**TDG**

Under the No Action Alternative operations would remain as described in the Section 3.5 Water Quality Affected Environment. Although no TDG measurements exist immediately downstream of Green Peter, it is estimated that the 110% TDG level would be exceeded on average for12 days per year based on the amount of spill occurring in NAA. Foster would be above 110% TDG for 32 days on average (Table 3.5-9). The Average Number of Days of Spill per year at Green Peter would continue to be 47 days and 209 days at Foster (Table 3.5-9). TDG exceedance tend to occur when water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

Turbidity monitoring would be conducted as needed and not year-round. Please refer to River Mechanics and Geomorphology Chapter 3.3 for NAA results of Potential for changes in sediment supply “a portion of the incoming sediment load will continue to pass run-of-river reservoirs and free-flowing reaches at magnitudes and rates similar to those historically experienced”.

**HABs**

In Section 3.3 River Mechanics & Geomorphology sections for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment or Bank Failure Potential and Climate Change Technical

Appendix F. Increased nutrient inputs may facilitate an increase in algae blooms. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

Please refer to River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure states "the amount of time that the storage project WSEs spend at any given elevation will not change from historical conditions. Negligible change in the amount of time that the storage project WSEs spend at any given elevation indicating that reservoir shoreline erosion processes are expected to continue at locations and rates similar to those historically experienced at each project". This metric is utilized to describe the potential for the methylation process to occur due to water fluctuations and rewetting of soils.

*3.5.2.2.3 McKenzie Dams*

**Water Temperature**

McKenzie sub-basin includes Cougar and Blue River dams. The Cougar water temperature control tower would continue to be operated annually to draft water to 1541 ft elevation by November 15. Once water elevation is below 1541 ft there are no temperature control operations. Under the No Action Alternative there would be no water temperature control operations at Blue River. There would be no change in effects as operations would remain the same. As described in Section 3.5 Water Quality Affected Environment Cougar Reservoir typically meet the state temperature targets utilizing the water temperature control tower as compared to pre-temperature control tower results (Figure 3.5-3; Table 3.5-1). Blue River reservoir outflow water temperatures are closest to the state temperature targets from February through May and warmer from August through November when comparing the historic temperature range (Figure 3.5-6; Table 3.5-1).

**TDG**

Cougar reservoir would remain as described in the Section 3.5 Water Quality Affected Environment with 57 average days above 110% TDG levels (Table 3.5-9). The Average Number of Days of Spill per year at Cougar would continue to be 162 days (Table 3.5-9). In Hydrologic Processes states Cougar outflows would "meet downstream flow targets in all years" under the NAA. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

Under the NAA at Cougar reservoir, turbidity monitoring would be conducted as needed and not year-round. Please refer to River Mechanics and Geomorphology Chapter 3.3 for NAA results of Potential for changes in sediment supply “a portion of the incoming sediment load will continue to pass run-of-river reservoirs and free-flowing reaches at magnitudes and rates similar to those historically experienced”.

**HABs**

Please refer to the Section 3.5 Water Quality Affected Environment and Section 3.3 River Mechanics & Geomorphology sections for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment or Bank Failure Potential and Climate Change Technical Appendix F. Increased nutrient inputs may facilitate an increase in algae blooms. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

Please refer to the Section 3.5 Water Quality Affected Environment and River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure and Climate Change Technical Appendix F. River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure states “the amount of time that the storage project WSEs spend at any given elevation will not change from historical conditions. Negligible change in the amount of time that the storage project WSEs spend at any given elevation indicating that reservoir shoreline erosion processes are expected to continue at locations and rates similar to those historically experienced at each project”. This metric is utilized to describe the potential for the methylation process to occur due to water fluctuations and rewetting of soils.

*3.5.2.2.4 Middle Fork Willamette Dams*

**Water Temperature**

Middle Fork Willamette includes Hills Creek, Lookout Point, Dexter, and Fall Creek dams. Fall Creek would continue with informal temperature control operations by utilizing the fish horns for temperature management from month to month to release warmer water temperatures. The nine fish horns are located at varying elevations (3-720 ft, 3-765 ft, 3-800 ft) and can provide water to the Adult Fish Facility (AFF). As described in Section 3.5 Water Quality Affected Environment, Hills Creek reservoir temperatures have not exceeded 65 °F in the summer (Figure 3.5-25). Temperatures at Hills Creek met most of the temperature targets from 2016 to 2020 but were lower than the TMDL targets from 2011 to 2015 (Figure 3.5-26; Figure 3.5-27). The outflow temperatures are generally close to the temperature TMDL targets for Lookout Point/Dexter, except from October through November when temperatures are higher (Figure 3.5-29; Figure 3.5-30). At Fall Creek Reservoir the outflow temperatures are generally closest to the RA Targets and Temperature TMDL targets from February through May (Figure 3.5-30 through 33).

**TDG**

Hills Creek would continue above 110% TDG level for an average of 19 days per year. Although no TDG measurements exist immediately downstream of Lookout Point, it is estimated that the 110% TDG level would be exceeded on average for 0 days per year based on the amount of spill occurring in NAA. TDG immediately below Dexter would continue above 110% for an average of 20 days per year (Table 3.5-9). The Average Number of Days of Spill per year would continue at Hills Creek with 120 days, Lookout Point would continue to be 31 days and Dexter would continue to be 87 days (Table 3.5-9). In Table 3.2-4 Hydrologic Processes states Hills Creek outflows would “meet downstream flow targets. Minimum flow is 400 cfs. Lookout Point/Dexter would miss downstream flow target in October of driest years” under the NAA. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

Please refer to Section 3.5 Water Quality Affected Environment. Turbidity monitoring would be conducted as needed and not year-round. River Mechanics and Geomorphology Chapter 3.3 for NAA results of potential for changes in sediment supply states “a portion of the incoming sediment load will continue to pass run-of-river reservoirs and free-flowing reaches at magnitudes and rates similar to those historically experienced”.

**HABs**

Please refer to the Section 3.5 Water Quality Affected Environment and River Mechanics & Geomorphology Section 3.3 for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment or Bank Failure Potential and Climate Change Technical Appendix F. Increased nutrient inputs may facilitate an increase in algae blooms. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

Please refer to the Section 3.5 Water Quality Affected Environment and River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure and Climate Change Technical Appendix F. River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure states “the amount of time that the storage project WSEs spend at any given elevation will not change from historical conditions. Negligible change in the amount of time that the storage project WSEs spend at any given elevation indicating that reservoir shoreline erosion processes are expected to continue at locations and rates similar to those historically experienced at each project”. This metric is utilized to describe the potential for the methylation process to occur due to water fluctuations and rewetting of soils.

#### *3.5.2.2.5 Coast Fork Dams and Long Tom*

**Water Temperature**

Temperature management operations are currently not implemented in the Coast Fork & Long Tom sub-basins and Cottage Grove, Dorena and Fern Ridge dams. Within the No Action Alternative there would be no change in water temperatures. There would be no change in effects as operations would remain the same. As described in Section 3.5 Water Quality Affected Environment there are Total Maximum Daily Load (TMDL) targets but no 7dADM state temperature targets for the Coast Fork sub-basins. Historically, Cottage Grove outflow temperatures are warmest in August and begin to cool in late-September (Figure 3.7-2). Dorena Reservoir outflow temperatures are historically warmest in late- August and begin to cool by early October (Figure 3.7-5). Fern Ridge outflow temperatures are typically warmest in August and begin to cool in September (Figure 3.7-8).

**TDG**

As there are no TDG gages downstream of Cottage Grove, Dorena, or Fern Ridge dams and no proposed measures, the effects would be similar to the Water Quality Affected Environment. In Table 3.2-5 Hydrologic Processes states Dorena outflows would "maintain minimum flows except in November of driest years. Cottage Grove outflows would maintain minimum flows except in November of driest years" under the NAA. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

Please refer to Section 3.5 Water Quality Affected Environment. Turbidity monitoring would be conducted as needed and not year-round. River Mechanics and Geomorphology Chapter 3.3 for NAA results of Potential for changes in sediment supply states "a portion of the incoming sediment load will continue to pass run-of-river reservoirs and free-flowing reaches at magnitudes and rates similar to those historically experienced".

**HABs**

Please refer to the Section 3.5 Water Quality Affected Environment. River Mechanics & Geomorphology Section 3.3 sections for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment or Bank Failure Potential and Climate Change Technical Appendix F. Increased nutrient inputs may facilitate an increase in algae blooms. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

Please refer to the Section 3.5 Water Quality Affected Environment and River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure and Climate Change Technical Appendix F. River Mechanics and Geomorphology Chapter 3.3 for NAA results of Shoreline Exposure states "the amount of time that the storage project WSEs spend at any given elevation will not change from historical conditions. Negligible change in the amount of time that the storage project WSEs spend at any given elevation indicating that reservoir shoreline erosion processes are expected to continue at locations and rates similar to those historically experienced at each project". This metric is utilized to describe the potential for the methylation process to occur due to water fluctuations and rewetting of soils.

*3.5.2.2.6 Mainstem Willamette River*

**Water Temperature**

There are no WVS projects located on the Mainstem Willamette River, however water temperatures downstream of the WVS projects can assist in temperature regulation on the Willamette River. Water temperature modeling of tracking heat sources in the Willamette has shown the heat content in the Willamette at Salem/Keizer during May-August in 2011, 2015, and 2016 was typically less than 20% sourced from upstream dam releases, despite the fact that roughly 50 percent streamflow during those months is attributed to upstream dam releases (Rounds and Stratton-Garvin, In Press). The Mainstem Willamette River at Salem (SLMO) and Mainstem Willamette River at Albany (ALBO) typically observes warmest temperatures in July and August in Appendix D. Coolest temperatures are observed in April and October for these two locations.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

**Turbidity**

Turbidity monitoring would be conducted as needed and not year-round. Please refer to River Mechanics and Geomorphology Chapter 3.3 for NAA results of Potential for changes in sediment supply "a portion of the incoming sediment load will continue to pass run-of-river reservoirs and free-flowing reaches at magnitudes and rates similar to those historically experienced".

**HABs**

To the USACE knowledge, there have been no OHA advisories near Albany and Salem. Please refer to the No Action Alternative sections within River Mechanics & Geomorphology Section

3.3 sections for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment or Bank Failure Potential and Climate Change Technical Appendix F. Increased nutrient inputs may facilitate an increase in algae blooms. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

##### *3.5.2.2.7 Climate Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects. Water Quality parameters such as Water Temperature and TDG would be influenced by refill timing, storage volume, and outflow at each dam. Climate change projections for the 2030s and 2070s under RCP 8.5 show higher project inflow December-March and lower inflow April-November for the Willamette Basin. Higher winter flow may increase TDG levels if no TDG management is in place, as turbine capacity at power projects would likely be exceeded more often and result in “spill” releases through non-power outlets. Higher winter flows occurring in December-January would not be stored, as the guide curves for Willamette Projects generally begin February 1. Therefore, climate change will likely lead to a decreased release volumes in spring and summer compared to the Affected Environment. Decreased storage will likely decrease the ability to manage dam releases from different outlets for temperature management, leading to less normative release temperatures (cooler in spring-early summer; warmer in autumn).

In the No Action Alternative, Detroit dam, Green Peter dam, Foster dam, Cougar dam, Hills Creek dam, Lookout Point dam, and the Mainstem Willamette river would potentially have less flow during the summer which may cause and increase downstream water temperatures. Parameters such as Turbidity, HABs and Mercury may be influenced by reservoir storage and time of year. For example, reduced reservoir storage in the summer may facilitate an increase in algae blooms due to warm water temperatures as observed in Detroit, Green Peter, Foster, Blue River, Cougar, Hills Creek, Lookout Point, and Fall Creek reservoirs (Technical Appendix B Hydrology and Hydraulics).

#### ***3.5.2.3 Alternative 1 – Project Storage Alternative***

This section describes the Alternative 1 effects to water quality. All effects determinations are in comparison to the NAA unless stated otherwise.

##### *3.5.2.3.1 North Santiam Dams*

**<u>Water Temperature</u>**

North Santiam sub-basin would include a Water Temperature Control tower at Detroit dam for water temperature management. Big Cliff/ Detroit Dams would have a Negligible effect of days below 18C (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Major Benefit for Days Near Temperature Target from September through March

(Figure 3.5-56; Figure 3.5-14). Please refer to Technical Appendix D for all temperature model results.

Alternative 1 as compared to the NAA (Appendix D Figure 1-384) downstream of Detroit and Big Cliff dams (BCLO) would in the 2011-year scenario see water temperature increase up to 4 degrees starting in June through October. In the 2015-year scenario water temperatures would increase 2 to 3 degrees from May to August and then decrease of 4 to 7 degrees in September to October. In the 2016-year scenario water temperatures would increase 2 to 12 degrees from May to September and then decrease by 2 degrees in October. For the Average of the three years water temperatures would increase 1 to 6 degrees from May to September and then decrease by 2 degrees in October. [18]

**TDG**

Both Detroit and Big Cliff dams would have a Beneficial effect when including the structural improvements for TDG management under Alternative 1 as compared to the NAA. Detroit would have a Moderate Benefit (Figure 3.5-57; Table 3.5-12).

Under Alternative 1, the average number of days above 110% TDG levels at Big Cliff is 31 and Detroit is 39. This equates to a reduction in TDG below Big Cliff of 117 annually. Annual differences in number of days above 110% of TDG exceedances and below Detroit is reduced to 77 days as compared to the NAA. The Average Number of Days of Spill per year at Detroit is 62 days and Big Cliff is 88 days.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events relative to the NAA. Please refer to River Mechanics and Geomorphology section 3.3.2.3 there is a Moderate change downstream of Detroit Dam in relation to potential for changes in sediment supply with fine grained sediment passing into Big Cliff run-of reservoir. These additional fine-grained sediments that enter Big Cliff Reservoir from Detroit Reservoir may partially settle.

**HABs**

The River Mechanics and Geomorphology Section 3.3.2.3 concludes that Deeper drawdowns typically occur during lower flow periods, such that Alternative 1 has Negligible change as compared to the NAA in the potential for head-of-reservoir sediment mobilization at all WVS storage projects. The shoreline exposure relative to the NAA metrics relative to the NAA result in a Major change for Detroit reservoir. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

[18] For further explanation on how the 3 representative water years for temperature were selected Section 3.5.2.1 and Appendix D.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Detroit reservoir. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for this metric. Please refer River Mechanics and Geomorphology Section 3.3.2.3 for the qualitative analysis of Alternative 1 as compared to the NAA. Alternative 1 would have a Major change in shorelines exposure relative to the NAA at Detroit dam. As there is Major change in shoreline exposure at Detroit dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect. Currently the amount or levels of mercury in Detroit reservoir is unknown.

*3.5.2.3.2 South Santiam Dams*

**Water Temperature**

Alternative 1 includes a Water Temperature Control tower at Green Peter Reservoir and a modification to the existing outlets at Foster Reservoir to allow for a Facility Warm Water Supply (FWWS) pipe and modified fish weir. Green Peter/Foster Dams would see a Major Adverse effect for Days below 18 C (64.4 F) (64.4 F) (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-56; Figure 3.5-14).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Santiam River near Foster gaging site (SSFO; Appendix D Figure 1-385) in the 2011-year scenario would see an increase starting in May through October up to 10 degrees. Water temperatures are unnaturally cold during the summer below Green Peter Dam (under the NAA), so large changes in outflow temperatures is to be expected if a Water Temperature Control tower were to be constructed. In the 2015-year scenario an increase of 1 to 5 degrees from April to July and then decrease from 2 to 4 degrees from August to October. In the 2016-year scenario an increase up to 10 degrees from April to September and then decrease by 1 degree in October. For the Average of the three years (2011, 2015, 2016) an increase 1 to 6 degrees from April through September and then decrease by 2 degrees in October.

**TDG**

Under Alternative 1, structural improvement measures for TDG management would have a Negligible effect at both Green Peter and Foster (Figure 3.5-57; Table 3.5-12).

Under Alternative 1, Green Peter reservoir results in 13 average number of days above 110% TDG levels, whereas Foster would be 20 average number of days above 110%. Green Peter has a reduction of 0 days of TDG exceedances and Foster is reduced by 12 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Green Peter is 48 days and Foster is 285 days .

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. The River Mechanics and Geomorphology Section 3.3.2.3 concludes there is potential for a Moderate change in sediment supply with additional fine-grained sediments passing into Foster which may partially settle as compared to the NAA. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Green Peter Dam and partially through the Foster reservoir.

**HABs**

There are no measures for HABs within Green Peter and Foster. The River Mechanics and Geomorphology Section 3.3.2.3 concludes that deeper drawdowns typically occur during lower flow periods, such that Alternative 1 has Negligible change from the NAA in the potential for head-of-reservoir sediment mobilization at all WVS storage projects. Alternative 1 would have a Major change for shoreline exposure at Green Peter reservoir and Negligible for Foster reservoir relative to the NAA. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Green Peter and Foster. Please refer River Mechanics and Geomorphology Section 3.3.2.3 for the qualitative analysis of Alternative 1 as compared to the NAA. Alternative 1 would have a Major change in shoreline exposure relative to the NAA at Green Peter reservoir and Negligible for Foster reservoir. As there is Major change in shoreline exposure at Green Peter dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.3.3 McKenzie Dams*

**Water Temperature**

There are no Water Temperature measures for Cougar or Blue River dams under Alternative 1 as there is already a Water Temperature Control Tower at Cougar. Blue River dam is low priority as Cougar dam provides water temperature control to the McKenzie river. Cougar Dam and would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-56; Figure 3.5-14).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the South Fork McKenzie River near Rainbow site (CGRO; Appendix D Figure 1-386) in the

2011-year scenario there would be no temperature difference as compared to the NAA. In the 2015-year scenario a decrease up to 2 degrees from July to October. In the 2016-year scenario a decrease is observed up to 1 degree in July and increase of 5 degrees in September is observed. For the Average of the three years (2011, 2015, 2016) a 1-degree temperature decrease observed in July and October, an increase of 1 degree is observed in September.

**TDG**

Cougar dam results in a Minor Benefit when including the structural improvement for TDG management measure under Alternative 1 compared to the NAA (Figure 3.5-57; Table 3.5-12).

Under Alternative 1, the average number of days above 110% TDG levels would be 16 at Cougar reservoir. Cougar reservoir has a reduction of 41 days of TDG exceedances as compared to the NAA . The Average Number of Days of Spill per year at Cougar is 160 days under Alternative 1. Blue River is expected to have similar operations as stated in the Affected Environment and NAA. As the RO's are routinely utilized and not turbines TDG levels would not be expected to change.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. In River Mechanics and Geomorphology Section 3.3.2.3 there is a Minor change in sediment supply with additional fine-grained sediments passing out of Cougar downstream into the McKenzie River as compared to the NAA. Increased fine-grained sediment supply is due to deeper drafts that may pass fine-grained sediment out of Cougar Reservoir. Blue River reservoir would have a potential for a Moderate change in fine-grained sediment supply. Increased fine-grained sediment supply is due to deeper drafts in Blue River.

**HABs**

The River Mechanics and Geomorphology Section 3.3.2.3 concludes that deeper drawdowns are typically occurring during lower flow periods, such that Alternative 1 relative to the NAA has Negligible effect in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at all WVS storage projects. Alternative 1 relative to the NAA would have a Major change for the Shoreline Exposure metric at Cougar and Blue River dams. Sediment Re-Entrainment and Bank Failure Potential metric would have a Moderate change for Cougar dam and Major change for Blue River. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cougar and Blue River. Please refer River Mechanics and Geomorphology Section 3.3.2.3 for the qualitative analysis of Alternative 1 as compared to the NAA. Alternative 1 would have a Major change in shoreline exposure relative to the NAA at Cougar and Blue River dams. As there is Major change in shoreline exposure at Cougar and Blue River dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect. However, the current amount or levels of mercury in Cougar and Blue River is unknown.

#### *3.5.2.3.4 Middle Fork Willamette Dams*

**Water Temperature**

Alternative 1 includes a Water Temperature Control tower at Lookout Point to better regulate downstream temperatures to Dexter reservoir. Lookout Point/Dexter Dams would see a Moderate Adverse effect for Days below 18 C (64.4 F) (Summer), Minor Benefit for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-56; Figure 3.5-14).

Results are also compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the Middle Fork Willamette River near Dexter gaging site (DEXO; Appendix D Figure 1-388) in the 2011-year scenario would see an increase starting in May through September up to 6 degrees and decrease by 6 degrees in October. In the 2015-year scenario: increase up to 4 degrees from April to June and then decrease by 4 degrees from July to October. In the 2016-year scenario an increase up to 6 degrees from April to August and then decrease by 6 degrees in October. For the Average of the three years (2011, 2015, 2016): increase up to 3 degrees from April to August and then decrease by 5 degrees in October.

Although there are no measures for Hills Creek in Alternative 1, water temperature was modeled. Hills Creek Dam would see a Minor Adverse effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Figure 3.5-14).

As compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the Middle Fork Willamette River above Salt Creek gaging site (HCRO; Appendix D Figure 1-387) in the 2011-year scenario there would be no temperature difference from April until September and decrease by 1 degree in October as compared to the NAA. In the 2015-year scenario a decrease by 3 degrees from April to June, increase by 3 degrees in July to September, decrease by 3 degrees in October. In the 2016-year scenario there would be no temperature change observed in April and then a decrease observed up to 5 degrees from May until October. For the Average of the three years (2011, 2015, 2016) a temperature decrease up to 2 degrees is observed in May, June, and October.

There are no water temperature measures for Fall Creek, as such water temperature was not simulated. Given the low impact that was expected there were no temperature modeling.

**TDG**

Hills Creek, Lookout Point, and Dexter dams have a Negligible effect when including the structural improvement for TDG management measure included in Alternative 1 compared to the NAA (Figure 3.5-57; Table 3.5-12). Although Hills Creek was not included for a structural measure the information is provided as to what TDG effects might be observed.

Under Alternative 1, the Average number of days above 110% TDG levels at Hills Creek is 9 average days, Lookout Point is 0, and Dexter is 5 average days. Hills Creek has a reduction of 9 days of TDG exceedances, Lookout Point has 0 days reduction, and Dexter is reduced by 15 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Hills Creek is 93 days, Lookout Point is 51 days and Dexter is 89 days. Fall Creek is expected to have similar operations as stated in the Affected Environment and NAA, as such there would not be expected TDG levels to change.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. The River Mechanics and Geomorphology Section 3.3.2.3 concludes that there is a Moderate change in sediment supply with additional fine-grained sediments passing out of Hills Creek into the Middle Fork Willamette above Lookout Point as compared to the NAA. Increased fine-grained sediment supply is due to deeper drafts that may pass fine-grained sediment out of Hills Creek Reservoir and deposit within Lookout Point reservoir. Dexter reservoir would have a potential for a Minor change in fine-grained sediment supply. Downstream of Dexter Dam there would be a Negligible potential for change in sediment supply relative to the NAA.

**HABs**

There are no measures for HABs within Hills Creek, Lookout point and Fall Creek. The River Mechanics and Geomorphology Section 3.3.2.3 concludes that deeper drawdowns are typically occurring during lower flow periods, such that Alternative 1 has Negligible change in the potential for head-of-reservoir sediment mobilization at all WVS storage projects as compared to the NAA. The Shoreline Exposure metric would have a Major change for Hills Creek and Lookout Point. Fall Creek reservoir would see a Negligible change. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Hills Creek, Minor change for Lookout Point, and Negligible change for Fall Creek. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Hills Creek, Lookout Point and Fall Creek. Please refer River Mechanics and Geomorphology Section 3.3.2.3 for the qualitative analysis of Alternative 1 as compared to the NAA. The Shoreline Exposure metric within Section 3.3 would have a Major change for Hills Creek and Lookout Point as compared to the NAA. Fall Creek reservoir would see a Negligible change. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. Currently the amount or levels of mercury in Hills Creek, Lookout Point, and Fall Creek is unknown. As there would be a Major change in shoreline exposure at Hills Creek and Lookout Point dams relative to the NAA there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.3.5 Coast Fork Dams and Long Tom*

**Water Temperature**

There are no measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 1. Water temperatures would remain as described in the No Action Alternative and Affected Environment.

**TDG**

There are no TDG management measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 1. TDG would remain as described in the No Action Alternative and Affected Environment.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. The River Mechanics and Geomorphology Section 3.3.2.3 concludes that potential for changes in sediment supply would have a Moderate change as compared to the NAA in fine grained sediments into the dams due to deeper drafts from reduction of reservoir storage passing into the Coast Fork Willamette and Row River from Cottage Grove and Dorena dams. Increased fine-grained sediment supply is due deeper drafts in Cottage Grove and Dorena dams that have potential to induce bank erosion and sloughing. For Fern Ridge reservoir there is Negligible effect in sediment supply relative to the No Action Alternative in the Long Tom River free-flowing reach.

**HABs**

Please refer to the Section 3.5 Water Quality Affected Environment. The River Mechanics and Geomorphology Section 3.3.2.3 concludes that deeper drawdowns are typically occurring during lower flow periods, such that Alternative 1 has Negligible effect in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at all WVS storage projects. The Shoreline Exposure metric within Section 3.3 would have a Major change Cottage

Grove and Dorena reservoirs. Fern Ridge reservoir has a Negligible effect. Sediment Re-Entrainment and Bank Failure Potential metric would have a Moderate change for Cottage Grove and Dorena reservoirs. Fern Ridge reservoir has a Negligible effect. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cottage Grove, Dorena, and Fern Ridge dams. The River Mechanics and Geomorphology Section 3.3.2.3 concludes that Alternative 1 would have a Major change in shoreline exposure relative to the NAA for Cottage Grove and Dorena Dams. Fern Ridge reservoir has a Negligible effect. Mercury has been studied in Cottage Grove and Dorena Dams as Total Mercury (inorganic) and Methylated Mercury (organic) in sediment (Ambers et al. 2001; Eckley et al. 2015; Eckley et al. 2017). As there would be a Major change in shoreline exposure at Cottage Grove and Dorena dams there is potential for an increase for the methylation process to occur with water fluctuations and rewetting of soils.

#### *3.5.2.3.6 Mainstem Willamette River*

**Water Temperature**

Alternative 1 water temperature results for the Mainstem Willamette River at Salem (SLMO) results in a Minor Adverse effect for Days below 18 C (64.4 F) (Summer). Results are not reported for “Days Near Temperature Target from April through August” or “Days Near Temperature Target from September through March” because there are no temperature targets (Figure 3.5-56; Figure 3.5-14).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the Willamette River near Salem gaging site (SLMO; Appendix D, Figure 1-364) in the 2011-year scenario there would be no change in temperature in April and May; 1-degree temperature increase from June until September and then a 1 degree decrease in October. In the 2015-year scenario an increase up to 2-degree is observed from April until June and then decrease up to 3 degrees from July until September. In the 2016-year scenario a water temperature increase up to 2 degrees from April until August and then 1 degree decrease in October. For the Average of the three years (2011, 2015, 2016) a 2-degree temperature increase is observed in May and June and then a 1 degree decrease in October.

Alternative 1 water temperature results within the Mainstem Willamette River at Albany (ALBO) results in a Minor Adverse effect for Days below 18 C (64.4 F) (Summer). Results are not reported for “Days Near Temperature Target from April through August” or “Days Near Temperature Target from September through March” because there are no temperature targets (Figure 3.5-56; Figure 3.5-14).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the Willamette River at Albany gaging site (ALBO; Appendix D,

Figure 1-364) in the 2011-year scenario a water temperature increase up to 1 degree is observed from July until September and then a 2 degree decrease in October. In the 2015-year scenario a water temperature increases up to 2 degree is observed in April and May and then 1 degree decrease in July and August. In the 2016-year scenario a water temperature increases up to 2-degree is observed from April until June and then a 1-degree temperature decrease in September and October. For the Average of the three years (2011, 2015, 2016) a water temperature increases up to 1-degree is observed from April until June and then 1-degree decrease in October.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.3 Potential for changes in sediment supply “there is Negligible potential for changes in sediment supply relative to the No Action Alternative in the Middle Willamette free-flowing reach”.

**HABs**

To the USACE knowledge, there are no OHA HAB advisories near Albany and Salem in public records. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

*3.5.2.3.7 Climate Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects. Compared to NAA, Alternative 1 would potentially have more resiliency against climate change effects on water temperature and TDG (increased water temperature control) below Detroit and Green Peter as a result of the proposed SWS and TDG abatement measures at each location. Parameters such as Turbidity and Mercury will likely experience similar effects as those described under NAA. Increased releases from the lake surface via the proposed SWS at Detroit, Green Peter, and Lookout Point combined with reduced summer flow volumes under Alternative 1 could lead to increased phytoplankton (algae) compared to NAA (Technical Appendix B Hydrology and Hydraulics).

*3.5.2.3.8 Summary of Effects*

Below is provided a summary of Alternative 1's overall water quality effects.

**Table 3.5-10. Summary of effects to Alternative 1 as compared to the NAA.**

| Subbasin | Alternative 1 |
|---|---|
| North Santiam | Big Cliff observes a negligible to beneficial effect for water temperatures with the inclusion of a Water Temperature Control tower at Detroit dam. A beneficial effect to TDG levels is observed with structural improvement included at Detroit and Big Cliff. |
| South Santiam | Foster observes adverse to beneficial effects to downstream water temperatures with the inclusion of a water temperature control tower at Green Peter. A negligible effect to TDG levels is observed with structural improvements at Green Peter and Foster. |
| McKenzie | Cougar would have negligible effects to downstream water temperatures as there are no water temperature measures. A beneficial effect to TDG is observed when including structural improvement measure at Cougar. |
| Middle Fork Willamette | Hills Creek and Dexter downstream water temperatures would observe beneficial to adverse effects. Fall Creek temperatures would remain as described in the NAA. A negligible effect is observed when including structural improvements for TDG at Hills Creek, Lookout Point, and Dexter dams. |
| Coast Fork Willamette & Long Tom | There are no water temperature measures considered at Cottage Grove, Dorena, and Fern Ridge therefore conditions would remain similar to the NAA. Although reservoir pool elevations would stay higher throughout the summer, more water would be released September through October. There are no measures considered for TDG management therefore conditions would remain similar to the NAA. |
| Mainstem Willamette | Albany and Salem water temperatures observe an adverse effect of days below 18C (64F) during the summer as compared to the NAA. TDG gages are not located on the Willamette River as TDG concerns are typically located downstream of WVS dams. There is a negligible potential for changes in sediment supply relative to the NAA in the Middle Willamette free-flowing reach as such Turbidity is not expected to increase. HABs are not expected as there are no OHA advisories near Albany and Salem in public records. |

**<u>Water Temperature</u>**

Alternative 1 would include measures with structural improvements for water temperature include water temperature control towers (selective water withdrawal structures) at Detroit, Green Peter, and Lookout Point dams. Detroit, Green Peter and Lookout Point dams. Implementation of these measures would see a Beneficial or Negligible effect (Appendix D Figure 1-383; Table 3.5-10). Additionally, a measure to modify existing outlets, which would allow releases at varying depths for temperature control at Foster dam through a Facility Warm Water Supply (FWWS) pipe and fish weirs, is included in Alternative 1. Foster dam water temperatures would see a Beneficial or Negligible effect.

**Table 3.5-11. 3-year Average temperature difference with Effects Criteria of Alternative 1 as compared to NAA.**

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| HCRO | -6 | Minor Adverse | -6 | Negligible | 0 | Negligible |
| DEXO | -9 | Moderate Adverse | 10 | Minor Benefit | -3 | Negligible |
| CGRO | 0 | Negligible | -1 | Negligible | -1 | Negligible |
| SSFO | -35 | Major Adverse | 43 | Moderate Benefit | -9 | Negligible |
| BCLO | 0 | Negligible | 42 | Moderate Benefit | 55 | Major Benefit |
| ALBO | -5 | Minor Adverse | NA | | NA | |
| SLMO | -8 | Minor Adverse | NA | | NA | |

Please refer to Technical Appendix D for all Temperature model results by Alternative

NA is due to no temperature targets for the Willamette during this period

**TDG**

Alternative 1 includes structural improvement measures to reduce TDG at Detroit, Big Cliff, Green Peter, Foster, Lookout Point, Dexter, and Cougar dams. Detroit dam would potentially have a Moderate Benefit. Cougar dam would have a potential Minor Benefit from structural improvements for TDG. A Negligible effect would be observed at Green Peter, Foster, Hills Creek, Lookout Point, and Dexter dams (Figure 3.5-57; Table 3.5-11). Please refer to the Water Quality Technical Appendix D for further data formulas and results, such as boxplot figures of TDG by Alternative compared to the NAA.

**Table 3.5-12. Compilation of TDG model results (Appendix D Figures 2-35;2-36;2-34; Figure 3.5-57) downstream of the dams for Alternative 1.**

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| DEX | 5 | -15 | 89 | Negligible |
| LOP | 0 | 0 | 51 | Negligible |
| HCR | 9 | -9 | 93 | Negligible |
| CGR | 16 | -41 | 160 | Minor Benefit |
| FOS | 20 | -12 | 285 | Negligible |
| GPR | 13 | 0 | 48 | Negligible |
| BCL | 31 | -117 | 88 | Major Benefit |
| DET | 39 | -77 | 62 | Moderate Benefit |

**Turbidity**

There are no measures for Turbidity however sites are qualitatively described in the below sections. Potential Changes in Sediment Supply within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized.

**HABs**

There are no measures for Harmful Algae Blooms however sites are qualitatively described in the below sections. River Mechanics and Geomorphology analysis of Head-of-Reservoir, Shoreline Exposure and Sediment Re-Entrainment and Bank Failure Potential within Section 3.3 and Technical Appendix C of is utilized. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury; however, sites are qualitatively described in the below sections. Shoreline Exposure analysis within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized.

### *3.5.2.4 Alternative 2A -- Hybrid Alternative*

This section describes the Alternative 2A effects to water quality.

#### *3.5.2.4.1 North Santiam Dams*

**Water Temperature**

North Santiam sub-basin would include a Water Temperature Control tower at Detroit reservoir for water temperature management for Alternative 2A. Big Cliff/ Detroit Dams would have a Negligible effect of days below 18C (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Major Benefit for Days Near Temperature Target from September through March (Figure 3.5-56; Table 3.5-14).

Alternative 2A results as compared to the NAA the Monthly Mean of Daily Mean water temperatures at the North Santiam at Niagara gaging site (BCLO; Appendix D Figure 1-390) in the 2011-year scenario would increase in water temperatures up to 4 degrees from June to October. In the 2015-year scenario water temperatures would increase up to 3 degrees from May until August and then a 4–6-degree decrease is observed in September and October. In the 2016-year scenario water temperatures increase up to 11 degrees from May to September and then a 2-degree decrease is observed in October. For the Average of the three years a water temperature increase up to 6 degrees is observed May to September and then a 2-degree decrease is observed in October.

**TDG**

There are no TDG abatement measures under Alternative 2A for Detroit and Big Cliff dams. A Moderate Beneficial effect is observed under Alternative 2A as compared to the NAA for Detroit and Big Cliff (Figure 3.5-57; Table 3.5-15).

Under Alternative 2A, Detroit reservoir is observed to have 39 average number of days above 110% TDG levels and Big Cliff is 80 average number of days. Detroit reservoir is reduced by 77 days and Big Cliff has a reduction in 69 Annual difference in number of days above 110% of TDG exceedances as compared to the No Action Alternative. The Average Number of Days of Spill per year at Detroit is 62 days and Big Cliff is 87 days.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to Section 3.3.2.4 River Mechanics and Geomorphology Potential for changes in sediment supply for the North Santiam are described as having a Moderate change in sediment supply with additional fine-grained sediments passing into Big Cliff run-of river reservoir. Increased fine-grained sediment supply is due deeper drafts in Detroit Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Big Cliff run-of-river reservoir. There is the potential for a Minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff Dam.

**HABS**

There are no measures for HABs within Detroit. Please refer to River Mechanics and Geomorphology Section 3.3.2.4 and Technical Appendix C, Alternative 2A has Negligible effect in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Detroit reservoir. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C result in a Major change for Detroit reservoir relative to the NAA. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Detroit reservoir. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Detroit. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for this metric. Please refer River Mechanics and Geomorphology Section 3.3.2.4 for the qualitative analysis of Alternative 2A as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit dam. Currently the amount or levels of mercury in Detroit reservoir is unknown. As there is Major change in shoreline exposure at Detroit dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.4.2 South Santiam Dams*

**Water Temperature**

Alternative 2A includes the use of the RO’s to discharge colder water during fall and winter drawdown operations at Green Peter reservoir. Another measure includes the use of the spillway for surface spill in the summer at Green Peter reservoir. A measure to modify existing outlets to allow releases at varying depths for temperature control specifically at Foster reservoir through a Facility Warm Water Supply (FWWS) pipe and fish weirs. Green Peter/Foster Dams would see a Major Adverse effect for Days below 18 C (64.4 F) (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Minor Benefit for Days Near Temperature Target from September through March (Figure 3.5-56; Table 3.5-14).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Santiam River near Foster gaging site (SSFO; Appendix D Figure 1-392) in the 2011-year scenario would see an increase starting in May through October up to 10 degrees. In the 2015-year scenario an increase of 1 to 5 degrees from April to July and then decrease from 2 to 4 degrees from August to October. In the 2016-year scenario an increase up to 10 degrees from April to September and then decrease by 1 degree in October. For the Average of the three years (2011, 2015, 2016) an increase 1 to 6 degrees from April through September and then decrease by 2 degrees in October.

**TDG**

There are no TDG management measures for Green Peter and Foster dams under Alternative 2A. Green Peter would have a Major Adverse effect and Foster would result in a Moderate Adverse effect (Figure 3.5-57; Table 3.5-15).

Under Alternative 2A, the average number of days above 110% TDG levels at Green Peter is 151 days and Foster is 126 days. Green Peter has an increase of 139 days of TDG exceedances and Foster is increased by 94 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Green Peter is 190 days and Foster is 284 days. The increase in average number of days with spill per year likely contributes to the adverse effects.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to Section 3.3.2.4 River Mechanics and Geomorphology for Alternative 2A the Potential for Sediment Supply has Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that create Major potential for bank erosion and sloughing generating sediment that may pass due to concurrent reduction in reservoir storage volume. There is the potential for a Moderate change in fine-grained sediment supply to the South Fork Santiam downstream of Foster Dam with additional fine-grained sediment passing the dam.

**HABS**

Please refer to the Section 3.5 Water Quality Affected Environment. Please refer to River Mechanics and Geomorphology Section 3.3.2.4 “Alternative 2A would have a Major change at Green Peter and Minor change at Foster in the potential for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Green Peter and Foster. Please refer River Mechanics and Geomorphology Section 3.3.2.3.2 for the qualitative analysis of Alternative 2A as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. Currently the amount or levels of mercury in Green Peter and Foster reservoirs is unknown. As there is Major change in shoreline exposure at Green Peter dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.4.3 McKenzie Dams*

**Water Temperature**

There are no water temperature measures for Cougar or Blue River dams under Alternative 2A. South Fork McKenzie River near Rainbow site (CGRO) is downstream of Blue River and Cougar Dam and would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-56; Table 3.5-14).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Fork McKenzie River near Rainbow gaging site (CGRO; Appendix D Figure 1-393) in the 2011-year scenario there would be a decrease of 1-degree observed from May until August as compared to the NAA. In the 2015-year scenario a decrease up to 3-degrees is observed from June until August, as compared to the NAA. In the 2016-year scenario a decrease is observed up to 2 degrees in June and July, an increase is observed in September as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a decrease up to 2-degrees is observed from June until August as compared to the NAA.

**TDG**

There are no TDG management measures for Cougar or Blue River Reservoirs. Cougar reservoir would have a Negligible effect with Alternative 2A measures as compared to the NAA (Figure 3.5-57; Table 3.5-15).

Under Alternative 2A, the average number of days above 110% TDG levels at Cougar is 54 days (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedance Cougar is decreased by 3 days as compared to the No Action Alternative (Figure 2-36). The Average Number of Days of Spill per year at Cougar is 168 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. In section 3.3.2.4 River Mechanics and Geomorphology for Alternative 2A the Potential for changes in sediment supply describes "a Minor change in sediment supply with additional fine-grained sediments passing out of Cougar downstream into the McKenzie River. Increased fine-grained sediment supply is due to deeper drafts that may pass fine-grained sediment out of Cougar Reservoir. Blue River reservoir would have a potential for a Moderate change in fine-grained sediment supply as compared to the NAA. Increased fine-grained sediment supply is due to deeper drafts in Blue River increasing the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

**HABS**

Please refer to the Section 3.5 Water Quality Affected Environment. The River Mechanics and Geomorphology Section 3.3.2.3 concludes that Alternative 2A has Negligible effect in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Cougar reservoir. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C result in a Major change for Cougar and Blue River dams. Sediment Re-Entrainment and Bank Failure Potential metric result in a Moderate change for Cougar dam and Major change for Blue River. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cougar and Blue River. Please refer to River Mechanics and Geomorphology Section 3.3.2.4 for the qualitative analysis of Alternative 2A as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Currently the amount or levels of mercury in Cougar and Blue River is unknown. As there is Major change in shoreline exposure at Cougar and Blue River dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.4.4 Middle Fork Willamette Dams*

**Water Temperature**

Alternative 2A has no water temperature measures for the Middle Fork sub-basin. Lookout Point/Dexter Dams would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-56; Table 3.5-14).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Middle Fork Willamette River near Dexter gaging site (DEXO; Appendix D Figure 1-394) in the 2011-year scenario would see an increase starting in May through September up to 6 degrees and decrease by 6 degrees in October. In the 2015-year scenario: increase up to 4 degrees from April to June and then decrease by 4 degrees from July to October. In the 2016-year scenario an increase up to 6 degrees from April to August and then decrease by 6 degrees in October. For the Average of the three years (2011, 2015, 2016): increase up to 3 degrees from April to August and then decrease by 5 degrees in October.

Hills Creek dam would see a Moderate Adverse effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-14)).

As compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the Middle Fork Willamette River above Salt Creek gaging site (HCRO; Appendix D Figure 1-395) in the 2011-year scenario there would be no temperature difference from April until September and decrease by 1 degree in October as compared to the NAA. In the 2015-year scenario a decrease by 3 degrees from April to June, increase by 3 degrees in July to September, decrease by 3 degrees in October. In the 2016-year scenario there would be no temperature change observed in April and then a decrease observed up to 5 degrees from May until October. For the Average of the three years (2011, 2015, 2016) a temperature decrease up to 2 degrees is observed in May, June, and October.

**<u>TDG</u>**

There are no TDG measures within Alternative 2A for Hills Creek, Lookout Point, and Dexter dams although model analysis has determined Negligible effects to the sub-basin (Figure 3.5-57; Table 3.5-15). Fall Creek reservoir does not have a TDG gage and effects would be similar to the Affected Environment section 3.5.

Under Alternative 2A, Lookout Point has reduction of 0 days and on average 0 days of TDG exceedance for the year (Appendix D Figure 2-35). Dexter dam is reduced by 0 days and exceeds TDG by 20 days by average number of days (Figure 2-36). Hills Creek dam has a reduction of 1 day of Annual Difference in Number of Days above 110% and on average number of days exceeds TDG by 18 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Hills Creek is 121 days, Lookout Point is 48 days, and Dexter is 91 days (Appendix D Figure 2-34).

**<u>Turbidity</u>**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.4.2 for Alternative 2A for Potential for Sediment Supply there is a Moderate change in sediment supply with additional fine-grained sediments passing out of Hills Creek into the Middle Fork Willamette above Lookout Point. Increased fine-grained sediment supply is due deeper drafts that may pass fine-grained sediment out of Hills Creek Reservoir and deposit within Lookout Point reservoir. Dexter reservoir would have a potential for a Minor change in fine-grained sediment supply. Downstream of Dexter Dam there would be a Negligible potential for change in sediment supply.

**HABS**

Please refer to the Section 3.5 Water Quality Affected Environment. In River Mechanics and Geomorphology Section 3.3.2.4 "Alternative 2A has Negligible change in the potential for head-of-reservoir sediment mobilization at Hills Creek, Lookout Point and Fall Creek. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point. Fall Creek reservoir would see a Negligible change. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Hills Creek, Minor change for Lookout Point, Negligible change for Fall Creek reservoir. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Hills Creek, Lookout Point and Fall Creek. Please refer River Mechanics and Geomorphology Section 3.3.2.4 for the qualitative analysis of Alternative 1 as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point. Fall Creek reservoir would have a Negligible change. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. Currently it is Currently the amount or levels of mercury in Hills Creek, Lookout Point, and Fall Creek is unknown. As there would be a Major change in shoreline exposure at Hills Creek and Lookout Point dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.4.5 Coast Fork Dams and Long Tom*

**Water Temperature**

There are no measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 2A, water temperatures would remain as described in the No Action Alternative and Water Quality Affected Environment section 3.5.

**TDG**

There are no measures at Cottage Grove, Dorena dams under Alternative 2A, TDG would remain unchanged and similar to the No Action Alternative and Water Quality Affected Environment. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.4 Alternative 2A would have a Negligible potential for changes in sediment supply relative to the No Action Alternative in the Coast Fork of the Willamette River and Row River free-flowing reaches and Long Tom free-flowing reach.

**HABS**

Please refer to River Mechanics and Geomorphology Section 3.3.2.4 and Technical Appendix C Alternative 2A would have a Negligible change in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Detroit reservoir. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Negligible change for Cottage Grove, Dorena, and Fern Ridge reservoirs. Sediment Re-Entrainment and Bank Failure Potential metric would have a Negligible change for Cottage Grove, Dorena, and Fern Ridge reservoirs. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cottage Grove, Dorena, and Fern Ridge dams. However, referencing River Mechanics and Geomorphology Section 3.3.2.4 states that *"*Alternative 2A would have a Negligible change in shoreline exposure relative to the NAA for Cottage Grove, Dorena, and Fern Ridge Dams. Technical Appendix C Table 4-5 indicates a difference in shoreline exposure at Minimum Operating Pool of 0.0 ft at Cottage Grove, Dorena, and Fern Ridge Dams. Mercury has been studied in Cottage Grove and Dorena Dams as Total Mercury (inorganic) and Methylated Mercury (organic) in sediment Ambers et al. 2001; Eckley et al. 2015; Eckley et al. 2017). Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.4.6 Mainstem Willamette River*

**Water Temperature**

Alternative 2A water temperature results for the Mainstem Willamette River at Salem (SLMO) results in a Negligible effect for Days below 18 C (64.4 F) (Summer). Results are not reported for "Days Near Temperature Target from April through August" or "Days Near Temperature Target from September through March" because there are no temperature targets (Figure 3.5-56; Table 3.5-14).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River near Salem gaging site (SLMO; Appendix D Figure 1-390) in the 2011-year scenario there would be a 1-degree water temperature increase in August. In the 2015-year scenario water temperatures increase up to 2-degree in April and May and then decrease up to 2 degrees from July until September. In the 2016-year scenario a water temperature increase of 1 degree is observed in May. For the Average of the three years (2011, 2015, 2016) water temperature increases 1-degree in May and then decreases by 1 degree in July and September.

Alternative 2A water temperature results for the Mainstem Willamette River at Albany (ALBO) results in a Negligible effect for Days below 18 C (64.4 F) (Summer). Results are not reported for "Days Near Temperature Target from April through August" or "Days Near Temperature Target from September through March" because there are no temperature targets (Figure 3.5-56; Table 3.5-14).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River at Albany gaging site (ALBO; Appendix D Figure 1-390) in the 2011-year scenario a water temperature increase up to 1 degree is observed in August. In the 2015-year scenario a water temperature increase of 1 degree is observed in April and May and then 1 degree decrease in June and July. In the 2016-year scenario a water temperature increase of 1-degree is observed in May. For the Average of the three years (2011, 2015, 2016) a water temperature increase up to 1-degree is observed in May.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presumed not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.4 and Technical Appendix C for Potential for changes in sediment supply "there is Negligible potential for changes in sediment supply relative to the No Action Alternative in the Middle Willamette free-flowing reach".

**HABs**

To the USACE knowledge, there have been no OHA advisories near Albany and Salem. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

*3.5.2.4.7 Climate Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects. Compared to NAA, Alternative 2A would potentially have more resiliency against climate change effects on water temperature (increased water temperature control) below Detroit and Green Peter as a result of the proposed SWS and operational temperature control measures at those locations. TDG effects immediately below Detroit would likely be more resilient to climate change under Alternative 2A due to the proposed SWS (reducing the need for operational temperature control). Parameters such as Turbidity and Mercury will likely experience similar effects as those described under NAA. Increased releases from the lake surface via the proposed SWS at Detroit combined with reduced summer flow volumes under Alternative 2A could lead to increased phytoplankton (algae) compared to NAA (Technical Appendix B Hydrology and Hydraulics).

**Table 3.5-13. Summary of Effects of Alternative 2A as compared to the NAA**

| Subbasin | Alternative 2A |
|---|---|
| North Santiam | Big Cliff observes a negligible to beneficial effect for water temperatures with the inclusion of a Water Temperature Control tower at Detroit dam. A beneficial effect to TDG levels is observed at Detroit and Big Cliff. |
| South Santiam | Foster observes negligible to beneficial effects to downstream water temperatures. Adverse effects to TDG levels are observed at Green Peter and Foster. |
| McKenzie | Cougar would have negligible effects to downstream water temperature. A negligible effect to TDG is observed when including structural improvement at Cougar. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change. |
| Middle Fork Willamette | Hills Creek downstream water temperatures would observe an adverse to negligible effect. Dexter downstream water temperatures would observe negligible, beneficial, and adverse effects to downstream water temperatures. Fall Creek temperatures would remain as described in the NAA. A negligible effect is observed for TDG at Hills Creek, Lookout Point, and Dexter dams. |
| Coast Fork Willamette & Long Tom | There are no water temperature measures considered at Cottage Grove, Dorena, and Fern Ridge therefore conditions would remain similar to the NAA. There are no measures considered for TDG management therefore conditions would remain similar to the NAA. |
| Mainstem Willamette | Albany and Salem water temperatures observe negligible effects as compared to the NAA. Water quality parameters such as TDG, Turbidity, HABs are negligible or have not been reported as a concern. |

#### *3.5.2.4.8 Evaluation of Near-Term Operations Measures*

Please refer to Chapter 2 for descriptions of the Near-Term Operations Measures. A qualitative description of the near-term operations measure impacts to water quality parameters is provided by sub-basins. The descriptions of the Near-Term Operations can be found within Section 2.2.5, Suite of Near-term Operations. Table 3.2-13 summarizes the analysis of effects of the near-term operations on water quality by subbasins.

**North Santiam Dams**

The Near-Term Operations Measures in the North Santiam include Detroit Fall/Winter Downstream Fish Passage, Detroit Spring Downstream Fish Passage, and Big Cliff Spread Spill for TDG Abatement.

***Water Temperature***

The Near-Term Operations Measure in the fall at Detroit Dam would have no effect to downstream water temperatures.

The Near-Term Operations Measures that occur in the spring at Detroit Dam would be an improvement to downstream water temperatures as compared to the NAA (section 3.6.3.1.1). This operation does not apply a 60% spill cap (whereas the NAA does) and therefore as much water as necessary can be spilled through non turbine outlets to meet the downstream water temperature targets. Instead, downstream water temperature and TDG conditions are used to cap spill.

No effects to downstream water temperatures at Big Cliff are expected with the Near-Term Operating Measure.

***TDG***

The Near-Term Operations Measure in the Fall/Winter and Spring at Detroit may result in elevated TDG levels downstream of Detroit dam when water is discharged through the Upper Regulating Outlets (UROs) and Lower Regulating Outlets (LROs) for downstream fish passage and water temperature management. The use of RO's or non-turbine outlets may elevate TDG levels downstream of Detroit Dam and limit the ability to meet downstream water temperature targets at times. Use of the turbines during the day will help to reduce TDG levels created at night.

The Near-Term Operations Measure at Big Cliff may improve TDG levels but has limitations. When spill is necessary at Big Cliff Dam, some benefit can be realized from spreading spill across the spillway, using multiple spill bays; however, minimum gate opening constraints preclude from spreading spill under all flow regimes. Additionally, TDG is also generated by Detroit Dam operations, particularly when a non-turbine unit is used to discharge water. In this case, spreading spill at Big Cliff Dam does not prevent or abate TDG exceedances that are generated by Detroit Dam.

***Turbidity***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for Potential for changes in sediment supply effects based on integrated operations.

***HABs***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment/Bank Failure effects based on integrated operations for the Near-Term Operations Measure.

**<u>South Santiam Dams</u>**

The Near-Term Operations Measure in the South Santiam include Green Peter Outplanting Plan, Green Peter Spring Downstream Fish Passage, Green Peter Fall Downstream Fish Passage, Foster Spring Downstream Fish Passage, Foster Fall Downstream Fish Passage.

The Near-Term Operations Measure which includes the Green Peter Outplanting Plan would have no effect on water quality.

***Water Temperature***

The Near-Term Operations Measure in the spring at Green Peter may result in improved water temperatures as the spillway will release warmer water temperatures downstream of Green Peter Dam, mimicking unregulated systems more closely, as compared to the NAA. The Near-Term Operations Measure in the fall at Green Peter may result in warmer downstream water temperatures in the fall and winter from early drawdown operations of Green Peter Reservoir. These effects would be limited to the Middle Santiam. Foster Reservoir would likely help alleviate the warmer water temperature impacts.

The Near-Term Operations Measure in the spring at Foster may result in an improvement to downstream water temperatures due to delayed refill operations. The use of the Foster fish weir will also aid in improving water temperatures. The Near-Term Operations Measure in the fall at Foster may result in an improvement to downstream water temperatures due to utilizing the spillway to provide more normative water temperatures.

***TDG***

The Near-Term Operations Measure in the spring at Green Peter may result in elevated TDG levels downstream of Green Peter dam with the preferential use of non-turbine outlets. Non-turbine outlets are known to elevate TDG levels. The Near-Term Operations Measure in the fall at Green Peter may result in elevated TDG levels during drawdown and once the reservoir is held at El. 780 ft. Rain events may necessitate the need to release large amounts of water downstream in order to hold the reservoir at 780 ft elevation. These high flows may cause elevated TDG.

The Near-Term Operations Measure in the spring at Foster may result in elevated TDG levels as water releases occur through non turbine outlets. Non-turbine outlets are known to elevate TDG levels. The Near-Term Operations Measure that occur in the fall at Foster may result in elevated TDG levels when flows are high. Elevated TDG levels could occur if releases are greater than 3000 cfs.

***Turbidity***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for Potential for changes in sediment supply effects based on integrated operations.

***HABs***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment/Bank Failure effects based on integrated operations for the Near-Term Operations Measure.

**McKenzie Dams**

The Near-Term Operations Measure within the McKenzie include Cougar Fall Drawdown for Downstream Fish Passage, Cougar Spring Drawdown for Downstream Fish Passage. There are no proposed operations at Blue River in the Near-Term Operations Measure.

***Water Temperature***

The Near-Term Operations Measure at Cougar in the fall is not likely to affect downstream water temperatures as the implementation occurs during the fall and winter when water temperatures are cool. The Near-Term Operations Measure at Cougar in the spring may result in downstream water temperature management not being implemented if refill does not occur. The Water Temperature Control Tower weirs can provide temperature control at or above 1571ft elevation.

Please refer to Section 3.2.1.1.3 Hydrologic Processes for the McKenzie sub-basin based on integrated operations for the Near-Term Operations Measure.

***TDG***

The Near-Term Operations Measure at Cougar in the fall may result in elevated TDG levels while keeping the reservoir at the 1505 ft elevation. Rain events may necessitate the release of high amounts of water through the RO’s to keep the 1505 ft elevation. The Cougar RO’s are known to produce elevated TDG levels when releases are in excess of 800 cfs. The Near-Term Operations Measure at Cougar in the spring may result in elevated TDG levels due to holding Cougar Reservoir at a delayed refill state (1520-1532 ft). Rain events may necessitate the release of water to keep the 1520 – 1532 ft elevation, this water release may cause higher flow and elevate TDG levels.

Please refer to Hydrologic Processes for the McKenzie sub-basin based on integrated operations for the Near-Term Operations Measure.

***Turbidity***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for changes in sediment supply effects based on integrated operations.

***HABs***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment/Bank Failure effects based on integrated operations.

**Middle Fork Willamette Dams**

The Near-Term Operations Measure in the Middle Fork Willamette include Hills Creek Downstream Fish Passage, Lookout Point Winter Downstream Passage Operations, Lookout Point Spring and Fall Downstream Passage Operations, Fall Creek Fall/Winter Downstream Passage Operations, and Fall Creek Spring Downstream Passage Operations.

***Water Temperature***

No downstream water temperature effects are expected at Hills Creek with Near-Term Operations Measure due to timing of the operation in the winter.

The Near-Term Operations Measure at Lookout Point in the winter may result in warmer downstream water temperatures in the fall due to an earlier drawdown operation of Lookout Point Reservoir. The Near-Term Operations Measure at Lookout Point in the spring and fall may result in improved spring and early summer downstream water temperatures. The use of the RO's in the late summer and fall may also improve downstream water temperatures, however past data suggests that cold water is limited in Lookout Point Reservoir and use of the RO may not be as beneficial as the temperature management observed from operational temperature management that is implemented at Detroit Dam.

The Near-Term Operations Measure at Fall Creek would not impact downstream water temperatures in the fall and winter when water temperatures are cool. Operations in the spring may impact downstream water temperatures due to delayed refill, low reservoir elevations, and inability to use all fish horns (El. 3-720 ft, 3-765 ft, 3-800 ft). The fish horns are utilized for water temperature management.

***TDG***

No TDG effects are expected with the Near-Term Operating Measure at Hills Creek, as the regulating outlets at Hills Creek Dam are not known to produce elevated TDG.

The Near-Term Operations Measure at Lookout Point in the winter may result in elevated TDG levels during drawdown and once the reservoir is being held at El. 750 ft. Rain events may necessitate the need to release large amounts of water downstream in order to hold the reservoir at 780 ft elevation. These high flows and use of non-turbine outlets may result in elevated TDG. The Near-Term Operations Measure at Lookout Point in the spring and fall may result in elevated TDG levels with use of non-turbine outlets. Rain events may necessitate the release of large amounts of water which may cause elevated TDG levels when the water is released through non-turbine outlets.

The Near-Term Operations Measure at Fall Creek in the fall and spring may elevate TDG levels during high flow events and releasing water in order to keep the reservoir at specific elevation. Rain events may necessitate the release of water which may cause elevated TDG levels.

***Turbidity***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for changes in sediment supply effects based on integrated operations.

***HABs***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for Head-of-Reservoir, Shoreline Exposure, Sediment Re-Entrainment/Bank Failure effects based on integrated operations.

**Coast Fork Dams**

There are no proposed operations in the Coast Fork sub-basin in the Near-Term Operations Measure, therefore, there would be no effects of this measure to water quality. Please refer to Section 3.3.3.3 River Mechanics and Geomorphology and Section 3.2.1.1 Hydrologic Processes for further information.

**Mainstem Willamette**

***Water Temperature***

Please refer to Hydrologic Processes for Albany and Salem flow information.

***TDG***

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presumed not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

***Turbidity***

Please refer to River Mechanics and Geomorphology Evaluation of Near-Term Operations Measure for Potential for changes in sediment supply effects based on integrated operations.

***HABs***

To the USACE knowledge, there are no OHA HAB advisories near Albany and Salem in public records. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

3.5.2.4.9 Summary of Effects

Below is provided a summary of Alternative 2A's overall water quality effects.

**Water Temperature**

A summary of Alternative 2A measures for structural improvements of water temperature at the WVS dams includes: Water temperature control tower at Detroit reservoir; Use the RO's to discharge colder water during fall and winter drawdown operations at Green Peter reservoir; Use of the spillway for surface spill in the summer at Green Peter reservoir; Modifications to increase warm water releases through a Facility Warm Water Supply (FWWS) pipe and fish weir at Foster Dam. Detroit, Green Peter and Foster Point dams result in a Beneficial or Negligible effect (Figure 3.5-56; Table 3.5-14). Monthly Mean of Daily Mean Water Temperature difference from the NAA to Alternative 2A can be found in Appendix D Figure 1-390. Please refer to Technical Appendix D for figures of temperature model results.

**Table 3.5-14. 3-year Average temperature difference with Effects Criteria of Alternative 2A as compared to NAA.**

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| HCRO | -14 | Moderate Adverse | -6 | Negligible | 3 | Negligible |
| DEXO | 4 | Negligible | 2 | Negligible | 3 | Negligible |
| CGRO | 0 | Negligible | 3 | Negligible | -1 | Negligible |
| SSFO | 3 | Negligible | 31 | Moderate Benefit | 17 | Minor Benefit |
| BCLO | 0 | Negligible | 42 | Moderate Benefit | 57 | Major Benefit |
| ALBO | 0 | Negligible | NA | | NA | |
| SLMO | 0 | Negligible | NA | | NA | |

Please refer to Technical Appendix D for all Temperature model results by Alternative.
NA is due to no temperature targets for the Willamette during this period.

**TDG**

Under Alternative 2A, there are no measures to reduce TDG at the WVS dams. A Major Adverse effect is observed at Green Peter reservoir and a Moderate Adverse effect is observed at Foster reservoir. Detroit and Big Cliff dams would have a Moderate Benefit. A Negligible effect would be observed at Cougar, Hills Creek, Lookout Point, and Dexter dams (Figure 3.5-57; Table 3.5-15). Please refer to the Water Quality Technical Appendix D for further data formulas and results, such as boxplot figures of TDG by Alternative compared to the NAA.

**Table 3.5-15 . Compilation of TDG model results (Appendix D, Figures 2-35;2-36;2-34; Figure 3.5-57) downstream of the dams for Alternative 2A.**

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| DEX | 20 | 0 | 91 | Negligible |
| LOP | 0 | 0 | 48 | Negligible |
| HCR | 18 | -1 | 121 | Negligible |
| CGR | 54 | -3 | 168 | Negligible |
| FOS | 126 | 94 | 284 | Moderate Adverse |
| GPR | 151 | 139 | 190 | Major Adverse |
| BCL | 80 | -69 | 87 | Moderate Benefit |
| DET | 39 | -77 | 62 | Moderate Benefit |

**Turbidity**

There are no measures for Turbidity however sites are qualitatively described in the below sections. Potential Changes in Sediment Supply within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized for comparison.

**HABs**

There are no measures for Harmful Algae Blooms however sites are qualitatively described in the below sections. River Mechanics and Geomorphology analysis of Head-of-Reservoir, Shoreline Exposure and Sediment Re-Entrainment and Bank Failure Potential within Section 3.3 and Technical Appendix C of is utilized for comparison.

**Mercury**

There are no WVS EIS Alternative measures for Mercury however sites are qualitatively described in the below sections. Shoreline Exposure analysis within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized.

### *3.5.2.5 Alternative 2B -- Hybrid Alternative*

This section describes the Alternative 2B effects to water quality.

#### *3.5.2.5.1 North Santiam Dam*

**Water Temperature**

Alternative 2B includes a Water Temperature Control tower at Detroit Reservoir for water temperature management. Big Cliff/ Detroit Dams would have a Negligible effect of days below 18C (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Major Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-17).

Alternative 2B as compared to the NAA the Monthly Mean of Daily Mean water temperatures at the North Santiam at Niagara gaging site (BCLO) in the 2011-year scenario an increase up to 3-degrees is observed from June until October as compared to the NAA. In the 2015-year scenario an increase up to 3-degrees is observed from May until August and then decreases up to 6 degrees in September and October. In the 2016-year scenario an increase up to 11-degrees is observed from May until September as compared to the NAA. For the Average of the three years an increase up to 6-degrees is observed from May until September and then a decrease of 2-degrees in October as compared to the NAA.

**TDG**

There are no TDG management measures for Detroit and Big Cliff Reservoirs for Alternative 2B. Detroit and Big Cliff would have a Moderate Benefit with Alternative 2B as compared to the NAA (Figure 3.5-57; Table 3.5-18).

Under Alternative 2B, the average number of days above 110% TDG levels at Big Cliff is 80 and Detroit is 39 (Appendix D Figure 2-35). Big Cliff has a reduction in 69 Annual difference in number of days above 110% of TDG exceedances and Detroit is reduced by 77 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Detroit is 62 days and Big Cliff is 87 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to Section 3.3.2.5 River Mechanics and Geomorphology. Potential for changes in sediment supply for Alternative 2B the North Santiam are described as having a Moderate change in sediment supply with additional fine-grained sediments passing into Big Cliff run-of river reservoir. Increased fine-grained sediment supply is due deeper drafts in Detroit Reservoir that have the potential to pass sediment through Detroit Dam and partially through the Big Cliff run-of-river reservoir. There is the potential for a Minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff Dam.

**HABS**

Please refer to River Mechanics and Geomorphology Section 3.3.2.5. Alternative 2B has Negligible change in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Detroit Reservoir. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Detroit Reservoir. Big Cliff Reservoir is a run-of river project that operates in a small range of pool elevations and is not included for these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Detroit. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for this metric. Please refer River Mechanics and Geomorphology Section 3.3.2.5 for the qualitative analysis of Alternative 2B as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit dam. Currently the amount or levels of mercury in Detroit is unknown. As there is Major change in shoreline exposure at Detroit dam there is potential for an increase for the methylation process to occur with water fluctuations if. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.5.2 South Santiam Dams*

**Water Temperature**

Alternative 2B includes the use of the RO's to discharge colder water during fall and winter drawdown operations at Green Peter Reservoir. An additional measure includes the use of the spillway for surface spill in the summer at Green Peter Reservoir. Also, a measure to modify existing outlets to allow releases at varying depths for temperature control specifically at Foster Reservoir through a Facility Warm Water Supply (FWWS) pipe and fish weirs.

Green Peter/Foster Dams would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Minor Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-17)).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Santiam River near Foster gaging site (SSFO; Appendix D Figure 1-399) in the 2011-year scenario would see a water temperature increase starting in May through October up to 8 degrees, although July observed a 1-degree temperature decrease. In the 2015-year scenario an increase in water temperatures of 1 to 6 degrees from April to June, a decrease in temperatures from 1 to 13 degrees is observed from July to October. In the 2016-year scenario an increase up to 6 degrees from April to August and then decrease by 2 degrees in September and October. For the Average of the three years (2011, 2015, 2016) an increase 1 to 5 degrees from April through June and then decrease up to 3 degrees from August until October.

**TDG**

There are no TDG measures within Alternative 2B for Green Peter and Foster Reservoirs. Green Peter has a Major Adverse effect and Foster has a Moderate Adverse effect (Figure 3.5-57; Table 3.5-18).

Under Alternative 2B, the average number of days above 110% TDG levels at Green Peter is 151 days and Foster is 126 days (Appendix D Figure 2-35). Green Peter has an increase of 139 days of TDG exceedances and Foster is increased by 94 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Green Peter is 190 days and Foster is 284 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to Section 3.3.2.5 River Mechanics and Geomorphology for Potential for changes in sediment supply for Alternative 2B as compared to the NAA for the South Santiam “a Major change in sediment supply with additional fine-grained sediments passing into Foster Reservoir. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that create Major potential for bank erosion and sloughing generating sediment that may pass due to concurrent reduction in reservoir storage volume. There is the potential for a Moderate change in fine-grained sediment supply to the South Fork Santiam downstream of Foster Dam with additional fine-grained sediment passing the dam”.

Please refer to River Mechanics and Geomorphology Section 3.3.2.5. Alternative 2B would have a Major change at Green Peter and Minor change at Foster in the potential for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter Reservoir and Negligible for Foster Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Green Peter Reservoir and Negligible for Foster Reservoir. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Green Peter and Foster. Please refer River Mechanics and Geomorphology Section 3.3.2.5 for the qualitative analysis of Alternative 2B as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. Currently the amount or levels of mercury in Green Peter and Foster reservoirs is unknown. As there is Major change in shoreline exposure at Green Peter dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.5.3 McKenzie Dams*

**Water Temperature**

There are no water temperature measures for Cougar or Blue River dams under Alternative 2B. South Fork McKenzie River near Rainbow site (CGRO) is downstream of Blue River and Cougar

Dam and has a Negligible effect for Days below 18 C (64.4 F) (Summer), Minor Benefit for Days Near Temperature Target from April through August, and Minor Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-17).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Fork McKenzie River near Rainbow gaging site (CGRO; Appendix D Figure 1-400) in the 2011-year scenario there would be a water temperature decrease up to 3-degrees from April through July and a 4-degree increase in October as compared to the NAA. In the 2015-year scenario a water temperature decrease up to 7-degrees is observed from June until October, as compared to the NAA. In the 2016-year scenario a temperature decrease is observed up to 5 degrees from May until October as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a temperature decrease up to 4-degrees is observed from May until October as compared to the NAA.

**TDG**

There are no TDG management measures for Alternative 2B for Cougar Reservoir. Cougar Reservoir has a Minor Benefit effect with Alternative 2B measures (Figure 3.5-57; Table 3.5-18).

Under Alternative 2B, the average number of days above 110% TDG levels at Cougar is 27 days (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedance Cougar is decreased by 30 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Cougar is 46 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. In section 3.3.2.5 River Mechanics and Geomorphology for Alternative 2B the Potential for changes in sediment supply describes a Major change in sediment supply with additional fine-grained sediments passing out of Cougar downstream into the McKenzie River. Increased fine-grained sediment supply is due to deeper drafts that may pass fine-grained sediment out of Cougar Reservoir. Blue River Reservoir would have a potential for a Moderate change in fine-grained sediment supply. Increased fine-grained sediment supply is due to deeper drafts in Blue River increasing the potential for bank erosion and sloughing generating sediment in the reservoir that may pass the dam due to a concurrent reduction in reservoir storage volume.

**HABS**

Please refer to River Mechanics and Geomorphology Section 3.3.2.5. Alternative 2B would have a Major change at Cougar and Negligible at Blue River in the potential for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for

Cougar and Blue River dams. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cougar and Blue River. Please refer to River Mechanics and Geomorphology Section 3.3.2.5 for the qualitative analysis of Alternative 2B as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Currently the amount or levels of mercury in Cougar and Blue River is unknown. As there is Major change in shoreline exposure at Cougar and Blue River dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.5.4 Middle Fork Willamette Dams*

**Water Temperature**

Alternative 2B has no water temperature measures for the Middle Fork sub-basin. Lookout Point/Dexter Dams has a Negligible effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-17).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Middle Fork Willamette River near Dexter gaging site (DEXO; Appendix D Figure 1-401) in the 2011-year scenario there would be no temperature difference from April to October. In the 2015-year scenario observes a 1-degree increase in May, a water temperature decrease up to 3-degrees is observed from June until September. In the 2016-year scenario most months see no change in water temperatures except for August which decreases by 1 degree as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a water temperature decrease by 1 degrees is observed from July through September.

Hills Creek dam would see a Major Adverse effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-17).

As compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the Middle Fork Willamette River above Salt Creek gaging site (HCRO; Appendix D Figure 1-402) in the 2011-year scenario there would be no temperature difference from April to October as compared to the NAA. In the 2015-year scenario a decrease up to 2 degrees are observed in May and October, water temperature increases up to 9 degrees in June through September as compared to the NAA. In the 2016-year scenario water temperature decrease is observed up to 4 degrees from May until October, although September would increase by 1 degree. For the Average of the three years (2011, 2015, 2016) a water temperature decrease up to 1 degree is observed in May and October, a temperature increase up to 2-degrees occurs in July through September.

**TDG**

There are no TDG measures for Hills Creek, Lookout Point and Dexter dams although model analysis has determined effects to the sub-basin. Hills Creek, Lookout Point and Dexter dams would have a Negligible effect with Alternative 2B measures (Figure 3.5-57; Table 3.5-18).

Under Alternative 2B, Lookout Point has reduction of 0 days and on average 0 days of TDG exceedance for the year (Appendix D Figure 2-35). Dexter dam TDG is reduced by 0 days and exceeds TDG by 20 days as compared to the average number of days (Appendix D Figure 2-36). Hills Creek dam has a reduction of 0 days of Annual Difference in Number of Days above 110% and on average number of days exceeds TDG by 18 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Hills Creek is 129 days, Lookout Point is 50 days, and Dexter is 88 days (Appendix D Figure 2-34).

TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.5 for Alternative 2B. There is a Moderate change in sediment supply with additional fine-grained sediments passing out of Hills Creek into the Middle Fork Willamette above Lookout Point. Increased fine-grained sediment supply is due deeper drafts that may pass fine-grained sediment out of Hills Creek Reservoir and deposit within Lookout Point Reservoir. Dexter Reservoir would have a potential for a Minor change in fine-grained sediment supply. Downstream of Dexter Dam there would be a Negligible potential for change in sediment supply”.

**HABS**

Please refer to River Mechanics and Geomorphology Section 3.3.2.5. Alternative 2B has Negligible change in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Hills Creek, Lookout Point and Fall Creek dams. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point. Fall Creek Reservoir would see a Negligible change. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Hills Creek, Minor change for Lookout Point, Negligible change for Fall Creek Reservoir. Dexter Reservoir is a run-of river project that operates in a small range of pool elevations and is not included in these metrics.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Hills Creek, Lookout Point and Fall Creek. Please refer River Mechanics and Geomorphology Section 3.3.2.5 for the qualitative analysis of Alternative 2B as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point. Fall Creek reservoir would see a Negligible change. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. Currently the amount or levels of mercury in Hills Creek, Lookout Point, and Fall Creek is unknown. As there would be a Major change in shoreline exposure at Hills Creek and Lookout Point dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.5.5 Coast Fork Dams and Long Tom*

**Water Temperature**

There are no measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 2B, water temperatures would remain as described in the No Action Alternative and Affected Environment.

**TDG**

There are no measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 2B, TDG would remain unchanged and similar to the No Action Alternative and Water Quality Affected Environment. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.5 Potential for changes in sediment supply section there is Negligible potential for changes in sediment supply relative to the No Action Alternative in the Coast Fork of the Willamette River and Row River free-flowing reaches and Long Tom free-flowing reach.

**HABS**

Please refer to River Mechanics and Geomorphology Section 3.3.2.5 and Technical Appendix C. Alternative 2B has Negligible change in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Detroit Reservoir. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Negligible change for Cottage Grove, Dorena, and Fern Ridge Reservoirs. Sediment Re-Entrainment and Bank Failure Potential metric would have a Negligible change for Cottage Grove, Dorena, and

Fern Ridge reservoirs. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cottage Grove, Dorena, and Fern Ridge dams. However, referencing River Mechanics and Geomorphology Section 3.3.2.5, Alternative 2B has a Negligible change in shoreline exposure relative to the NAA for Cottage Grove, Dorena, and Fern Ridge Dams. Mercury has been studied in Cottage Grove and Dorena dams as Total Mercury (inorganic) and Methylated Mercury (organic) in sediment Ambers et al. 2001; Eckley et al. 2015; Eckley et al. 2017).

*3.5.2.5.6 Mainstem Willamette River*

**Water Temperature**

Alternative 2B water temperature results for the Mainstem Willamette River at Salem (SLMO;) results in a Negligible effect for Days below 18 C (64.4 F) (Summer). Results are not reported for "Days Near Temperature Target from April through August" or "Days Near Temperature Target from September through March" because there are no temperature targets (Figure 3.5-57; Table 3.5-17)).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River near Salem gaging site (SLMO; Appendix D Figure 1-390) in the 2011-year scenario there would be a 1-degree water temperature increase in August. In the 2015-year scenario water temperatures decrease by 2-degree from July through September. In the 2016-year scenario a water temperature increase of 1 degree is observed in May. For the Average of the three years (2011, 2015, 2016) water temperature increases 1-degree in May and then decreases by 1 degree in July.

Alternative 2B water temperature results for the Mainstem Willamette River at Albany (ALBO) results in a Negligible effect for Days below 18 C (64.4 F) (Summer). Results are not reported for "Days Near Temperature Target from April through August" or "Days Near Temperature Target from September through March" because there are no temperature targets (Figure 3.5-57; Table 3.5-17).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River at Albany gaging site (ALBO; Appendix D Figure 1-390) in the 2011-year scenario a water temperature increase up to 1 degree is observed in August. In the 2015-year scenario a water temperature decreases by 2-degrees from June through August. In the 2016-year scenario a water temperature increase of 1-degree is observed in May. For the Average of the three years (2011, 2015, 2016) no temperature change is observed.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to the River Mechanics and Geomorphology Section 3.3.2.5.2 and Technical Appendix C (Table 4-14) which states there is Negligible potential for changes in sediment supply relative to the No Action Alternative in the Middle Willamette free-flowing reach.

**HABs**

To the USACE knowledge, there are no OHA HAB advisories near Albany and Salem in public records. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

*3.5.2.5.7 Climate Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects. Compared to NAA, Alternative 2B would potentially have more resiliency against climate change effects on water temperature and TDG (increased water temperature control) below Detroit as a result of the proposed SWS and TDG abatement measures at each location. Parameters such as Turbidity and Mercury will likely experience similar effects as those described under NAA. Increased releases from the lake surface via the proposed SWS at Detroit combined with reduced late summer flow volumes under Alternative 2B could lead to increased phytoplankton (algae) compared to NAA (Technical Appendix B Hydrology and Hydraulics).

*3.5.2.5.8 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.5.2.4, for description of effects due to the Near-Term Operations Measure.

**Table 3.5-16. Summary of Effects of Alternative 2B as compared to the NAA**

| Subbasin | Alternative 2B |
|---|---|
| North Santiam | Big Cliff observes a negligible to beneficial effect for water temperatures with the inclusion of a Water Temperature Control tower at Detroit dam. A beneficial effect to TDG levels is observed at Detroit and Big Cliff. |

| Subbasin | Alternative 2B |
|---|---|
| South Santiam | Foster observes negligible to beneficial effects to downstream water temperatures. Adverse effects to TDG levels are observed at Green Peter and Foster. |
| McKenzie | Cougar would have negligible to beneficial effects to water temperature as Cougar has a Water Temperature Control Tower and provides water temperature control to the McKenzie. Blue River is low priority for water temperature control. A beneficial effect to TDG is observed at Cougar. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change. |
| Middle Fork Willamette | Hills Creek downstream water temperatures would observe an adverse to negligible effect. Dexter downstream water temperatures would observe negligible effects to downstream water temperatures. Fall Creek temperatures would remain as described in the NAA. A negligible effect is observed when including structural improvements for TDG at Hills Creek, Lookout Point, and Dexter dams. |
| Coast Fork Willamette & Long Tom | There are no water temperature measures considered at Cottage Grove, Dorena, and Fern Ridge therefore conditions would remain similar to the NAA. There are no measures considered for TDG management therefore conditions would remain similar to the NAA. |
| Mainstem Willamette | Albany and Salem water temperatures observe negligible effects as compared to the NAA. TDG gages are not located on the Willamette River as TDG concerns are typically located downstream of WVS dams. |

*3.5.2.5.9 Summary of Effects*

Below is provided a summary of Alternative 2B's overall water quality effects.

**Water Temperature**

Alternative 2B structural improvements for water temperature measures include: Water temperature control tower at Detroit Reservoir; Use the RO's to discharge colder water during fall and winter drawdown operations at Green Peter Reservoir; Use of the spillway for surface spill in the summer at Green Peter Reservoir. Modifying existing outlets to allow releases at varying depths for temperature control specifically at Foster Reservoir through a Facility Warm Water Supply (FWWS) pipe and fish weirs. Monthly Mean of Daily Mean Water Temperature difference from the NAA to Alternative 2B can be found in Appendix D Figure 1-396.

**Table 3.5-17. 3-year Average temperature difference with Effects Criteria of Alternative 2B as compared to NAA.**

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| HCRO | -21 | Major Adverse | -6 | Negligible | 1 | Negligible |
| DEXO | 4 | Negligible | 6 | Negligible | 4 | Negligible |
| CGRO | 0 | Negligible | 10 | Minor Benefit | 16 | Minor Benefit |
| SSFO | 3 | Negligible | 31 | Moderate Benefit | 18 | Minor Benefit |
| BCLO | 0 | Negligible | 42 | Moderate Benefit | 57 | Major Benefit |
| ALBO | 0 | Negligible | NA | | NA | |
| SLMO | -2 | Negligible | NA | | NA | |

Please refer to Technical Appendix D for all Temperature model results by Alternative

NA is due to no temperature targets for the Willamette during this period

<u>**TDG**</u>

Under Alternative 2B there are no measures to reduce TDG. A Major Adverse effect is observed at Green Peter Reservoir and a Moderate Adverse effect is observed at Foster Reservoir. Detroit and Big Cliff dams would potentially have a Moderate Benefit. A Minor Beneficial effect would be observed at Cougar Reservoir. A Negligible effect would be observed at Hills Creek, Lookout Point, and Dexter dams (Figure 3.5-57; Table 3.5-18)).

**Table 3.5-18. Compilation of TDG model results (Appendix D, Figures 2-35;2-36;2-34; Figure 3.5-57) downstream of the dams for Alternative 2B.**

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| DEX | 20 | 0 | 88 | Negligible |
| LOP | 0 | 0 | 50 | Negligible |
| HCR | 18 | 0 | 129 | Negligible |

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| CGR | 27 | -30 | 46 | Minor Benefit |
| FOS | 126 | 94 | 284 | Moderate Adverse |
| GPR | 151 | 139 | 190 | Major Adverse |
| BCL | 80 | -69 | 87 | Moderate Benefit |
| DET | 39 | -77 | 62 | Moderate Benefit |

**Turbidity**

There are no measures for Turbidity however sites are qualitatively described in the below sections. Potential Changes in Sediment Supply within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized for comparison.

**HABs**

There are no measures for Harmful Algae Blooms however sites are qualitatively described in the below sections. River Mechanics and Geomorphology analysis of Head-of-Reservoir, Shoreline Exposure and Sediment Re-Entrainment and Bank Failure Potential within Section 3.3 and Technical Appendix C of is utilized for comparison.

**Mercury**

There are no WVS EIS Alternative measures for Mercury however sites are qualitatively described in the below sections. Shoreline Exposure analysis within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized.

### *3.5.2.6 Alternative 3A – Operations-Focused Fish Passage Alternative*

This section describes the Alternative 3A effects to water quality.

#### *3.5.2.6.1 North Santiam Dam*

**Water Temperature**

Water temperature measures under Alternative 3A include Detroit Reservoir utilizing the RO's to discharge colder water during drawdown operations in the fall and winter to reduce downstream water temperatures. The Detroit spillway would be utilized for surface spill in the summer which would assist in blending water temperatures below in Big Cliff. The lower RO's would be lined to limit cavitation effects and assist in releasing cooler water in the late fall at Detroit Reservoir.

Big Cliff/ Detroit Dams would have a Major Adverse effect of days below 18C (Summer), Moderate Adverse effect for Days Near Temperature Target from April through August, and Minor Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-20).

Alternative 3A as compared to the NAA the Monthly Mean of Daily Mean water temperatures at the North Santiam at Niagara gaging site (BCLO; Appendix D Figure 1-405) the 2011-year scenario indicates an increase in water temperatures up to 7-degrees from August through October. Monthly Mean of Daily Max, Water Temperature difference from NAA (Alt3A-NAA). In the 2015-year scenario water temperatures increase up to 10 degrees from April until September, a 1-degree temperature decrease occurs in October. In the 2016-year scenario a water temperature increase up to 15-degrees is observed from May until October as compared to the NAA. For the average of the three years water temperatures increase up to 9-degrees from May until October.

**TDG**

Under Alternative 3A, both Detroit and Big Cliff have a Major Adverse effect as there are no TDG management measures (Figure 3.5-57; Table 3.5-21).

Under Alternative 3A, the average number of days above 110% TDG levels at Big Cliff is 312 and Detroit is 307. Observing the Annual difference in number of days above 110% of TDG exceedances Big Cliff has an increase of 164 days and Detroit is increased by 192 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Big Cliff is 147 days and Detroit is 249. The adverse effects are likely due to an increase of average number of days with spill per year.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.6, Alternative 3A which states the potential for changes in sediment supply for the North Santiam are described as having a Major change in sediment supply with additional fine-grained sediments passing into Big Cliff run-of-river reservoir. Increased fine-grained sediment supply is due deeper drafts in Detroit reservoir. There is potential for a Moderate change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff dam.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.6. Alternative 3A would have Major change in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Detroit Reservoir. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Detroit

Reservoir. Big Cliff Reservoir is a run-of river project that operates in a small range of pool elevations and is not included for these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Detroit. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for this metric. Please refer River Mechanics and Geomorphology Section 3.3.2.6 for the qualitative analysis of Alternative 3A as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit dam. Currently the amount or levels of mercury in Detroit is unknown. As there is Major change in shoreline exposure at Detroit dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.6.2 South Santiam Dams*

**Water Temperature**

Water temperature measures under Alternative 3A include Green Peter utilizing the RO's to discharge colder water during drawdown operations in the fall and winter to reduce downstream water temperatures and volitional downstream fish passage. The Green Peter and Foster dam spillways would be utilized in the summer for surface spill.

Green Peter/Foster Dams would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Minor Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-20).

Alternative 3A results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Santiam River near Foster gaging site (SSFO; Appendix D Figure 1-406) the 2011-year scenario would see a water temperature increase starting in May through October up to 8 degrees, although July has no temperature change as compared to the NAA. In the 2015-year scenario water temperatures increase from 1 to 4 degrees in April through June, a decrease in temperatures from 4 to 13 degrees is observed from July to September. In the 2016-year scenario water temperatures increase up to 7 degrees from May to August and then decrease by 1 degree in September and October. For the Average of the three years (2011, 2015, 2016) an increase 1 to 4 degrees from May through June and then decrease up to 2 degrees from August and September.

**TDG**

Under Alternative 3A, both Green Peter and Foster Reservoir would have an Adverse effect as there are no TDG management measures. Green Peter would have a Major Adverse effect and Foster would have a Moderate Adverse effect (Figure 3.5-57; Table 3.5-21).

Under Alternative 3A, the average number of days above 110% TDG levels at Green Peter is 151 days and Foster is 127 days. Observing the Annual difference in number of days above 110% of TDG exceedances Green Peter has an increase of 139 days and Foster is 95 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Green Peter is 189 days and Foster is 220 days. The adverse effects are likely due to an increase of average number of days with spill per year.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.6. Potential for changes in sediment supply for the South Santiam there is a Major change in sediment supply with additional fine-grained sediments passing into Foster Reservoir as compared to the NAA. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Green Peter Dam and partially through the Foster Reservoir. There is potential for a Moderate change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster dam. Increased suspended sediments may cause an elevation in turbidity levels during drawdown operations or precipitation events.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.6. Alternative 3A has Major change at Green Peter and Minor change at Foster in the potential for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter Reservoir and Negligible for Foster Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Green Peter Reservoir and Negligible for Foster Reservoir. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Green Peter and Foster. Please refer River Mechanics and Geomorphology Section 3.3.2.6 for the qualitative analysis of Alternative 3A as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. Currently the amount or levels of mercury in Green Peter and Foster reservoirs is unknown. As there is Major change in shoreline exposure at Green Peter dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

#### *3.5.2.6.3 McKenzie Dams*

**Water Temperature**

Water temperature measures under Alternative 3A include a modification to the spillway at Blue River Reservoir to provide better water temperature management. The spillway would be used in the summer for surface spill. Not a direct water temperature measure but equally as important is Cougar Reservoir implementing spring and fall drawdown operations for volitional downstream fish passage. And Blue River implementing a fall drawdown 15 ft below minimum conservation (1180 ft).

South Fork McKenzie River near Rainbow site (CGRO) is downstream of Blue River and Cougar Dam and would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Minor Adverse for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-20).

Temperature results for Alternative 3A effects are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Fork McKenzie River near Rainbow gaging site (CGRO; Appendix D Figure 1-407) in the 2011-year scenario there would be a water temperature decrease from 1 to 5-degrees from April through August, a 6-degree water temperature increase would occur in October as compared to the NAA. In the 2015-year scenario a water temperature increase of 1 to 2 degrees is observed in May, August, and September. A temperature decrease of 1-2 degrees is observed in June and July for the 2015-year scenario. In the 2016-year scenario a temperature increase is observed up to 6 degrees from April until July, a temperature decrease of up to 6 degrees occurs from August until October as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a temperature increase up to 7-degrees is observed from April until August, a temperature decrease of 3-4 degrees occurs in September and October as compared to the NAA.

**TDG**

There are no TDG measures under Alternative 3A for Cougar Reservoir. Cougar Reservoir would have a Negligible with Alternative 3A measures (Figure 3.5-57; Table 3.5-21).

Under Alternative 3A, the average number of days above 110% TDG levels at Cougar is 77 days. Observing the Annual difference in number of days above 110% of TDG exceedance Cougar is 20 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Cougar is 240 days.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to Section 3.3.2.6 River Mechanics and Geomorphology Potential Changes in Sediment Supply for Alternative 3A there is a Moderate change in sediment supply with additional fine-grained sediments passing out of

Cougar downstream into the McKenzie River. Increased fine-grained sediment supply is due to deeper drafts that may pass fine-grained sediment out of Cougar Reservoir. Blue River Reservoir would have a potential for a Moderate change in fine-grained sediment supply as compared to the NAA. Increased fine-grained sediment supply is due to deeper drafts in Blue River Cougar Reservoir would implement a spring and fall drawdown, while Blue River would implement a fall drawdown.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.6. Alternative 3A has Major change at Cougar and Minor change at Blue River in the potential for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Sediment Re-Entrainment and Bank Failure Potential metric would have a Moderate change for Cougar and Blue River dams. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cougar and Blue River. Please refer River Mechanics and Geomorphology Section 3.3.2.6 for the qualitative analysis of Alternative 3A as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. The Shoreline Exposure metric was developed as a surrogate for shoreline erosion processes and is a result of operational change. Currently the amount or levels of mercury in Cougar and Blue River is unknown. As there is Major change in shoreline exposure at Cougar and Blue River dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.6.4 Middle Fork Willamette Dams*

**Water Temperature**

Water temperature measures under Alternative 3A include Hills Creek Reservoir modification to the spillway and use the spillway for surface spill in the summer. Lookout point Reservoir would utilize the RO’s to discharge colder water during drawdown operations in fall and winter to reduce downstream water temperatures. The Lookout Point spillway would be utilized in the summer for surface spill. Dexter spillway would be utilized in order to spread surface spill.

Lookout Point/Dexter Dams would see a Major Adverse effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-20)).

Water temperature results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Middle Fork Willamette River near Dexter gaging site (DEXO; Appendix D Figure 1-408) in the 2011-year scenario water temperature increase from 1 to 6 degrees is observed from April to September. In the 2015-year scenario observes a 1-3 degree increase from April through July, then decrease of 1 degree in September. In the 2016-year scenario a 2 to 6-degree water temperature increase is observed from April through August and decrease by 1 degree in October as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a water temperature increases from 1-4 degrees in April through September and decreases by one degree in October.

Hills Creek dam would see a Major Adverse for Days below 18 C (64.4 F) (Summer), Major Benefit for Days Near Temperature Target from April through August, and Minor Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-20).

As compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Middle Fork Willamette River above Salt Creek gaging site (HCRO; Appendix D Figure 1-409) in the 2011-year scenario water temperature increase from 2 to 11 degrees is observed from April to August, a decrease from 4 to 6 degrees occurs in September and October. In the 2015-year scenario observes a 1-6 degree increase from April through July, then decrease of 1 degree in October as compared to the NAA. In the 2016-year scenario water temperature increase 3-6 degrees from April through July and decrease up to 6 degrees from August to October as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a water temperature increase 2 to 7 degrees from April through August and then decrease up to 4 degrees in September and October.

**TDG**

Under Alternative 3A, there are no TDG measures at Lookout Point and Dexter dams. Lookout Point and Hills Creek would have a Negligible effect and Dexter Reservoir would have a Minor Adverse effect with Alternative 3A measures (Figure 3.5-57; Table 3.5-21).

Under Alternative 3A, the average number of days above 110% TDG levels at Hills Creek is 13 days, Lookout Point is 0 days, and Dexter is 53 days (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedances Hills Creek is decreased by 6 days, Lookout Point is 0 days, and Dexter is increased to 33 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Hills Creek is 82 days, Lookout Point is 225 days, and Dexter is 146 days (Appendix D Figure 2-34). The adverse effects are likely due to an increase of average number of days with spill per year.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. In River Mechanics and Geomorphology Section 3.3.2.6 for Alternative 3A the potential for changes in sediment supply for the Middle Fork Willamette is stated as having a Major change in sediment supply into Dexter Reservoir with additional fine-grained sediments passing out of Lookout Point run-of-river reservoir. Increased fine-grained sediment supply is due deeper drafts that may pass fine-grained sediment out of Lookout Point Reservoir decreasing trap efficiency and increasing the potential for bank erosion and sloughing. There is a potential for a Moderate change in sediment supply with additional fine-grained sediment passing into the Middle Fork of the Willamette below Dexter dam.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.6. Alternative 3A has potential for Minor changes at Hills Creek, Major changes at Lookout Point, Negligible changes at Fall Creek dams for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Minor change for Hills Creek, Major change for Lookout Point, and Negligible change for Fall Creek Reservoirs. Sediment Re-Entrainment and Bank Failure Potential metric would have a Negligible change for Hills Creek, Major change for Lookout Point, and Negligible change for Fall Creek Reservoirs. Dexter Reservoir is a run-of river project that operates in a small range of pool elevations and is not included in these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Hills Creek, Lookout Point and Fall Creek. Please refer River Mechanics and Geomorphology Section 3.3.2.6 for the qualitative analysis of Alternative 3A as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Minor change for Hills Creek, Major change for Lookout Point. Fall Creek reservoir would see a Negligible change. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. Currently the amount or levels of mercury in Hills Creek, Lookout Point, and Fall Creek is unknown. As there would be changes in shoreline exposure at Hills Creek and Lookout Point dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.6.5 Coast Fork Dams and Long Tom*

**Water Temperature**

There are no measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 3a, water temperatures would remain as described in the No Action Alternative and Water Quality Affected Environment.

**TDG**

There are no TDG measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 3A, TDG would remain unchanged and similar to the No Action Alternative and Water Quality Affected Environment. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to Section 3.3.2.6 River Mechanics and Geomorphology, Potential for changes in sediment supply section, which states there is a Moderate change in sediment supply with additional fine-grained sediments passing into the Coast Fork Willamette and Row River from Cottage Grove and Dorena dams. Increased fine-grained sediment supply is due deeper drafts in Cottage Grove and Dorena dams that have potential to induce bank erosion and sloughing generating sediment that may pass the dam to a concurrent reduction in reservoir storage volume. There is Negligible change in sediment supply relative to the NAA in the Long Tom River.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.6. Alternative 3A has Negligible change in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Cottage Grove, Dorena, and Fern Ridge dams. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cottage Grove and Dorena Reservoirs. Fern Ridge Reservoir results in a Negligible change. Sediment Re-Entrainment and Bank Failure Potential metric would have a Moderate change for Cottage Grove and Dorena Reservoirs. Fern Ridge Reservoir results in a Negligible change. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cottage Grove, Dorena, and Fern Ridge dams. However, referencing River Mechanics and Geomorphology Section 3.3.2.6 Alternative 3A would have a Major change in shoreline exposure relative to the NAA for Cottage Grove and Dorena Dams. Fern Ridge Reservoir would have a Negligible change. Mercury has been studied in Cottage Grove and Dorena Dams as Total Mercury (inorganic) and Methylated Mercury (organic) in sediment Ambers et al. 2001; Eckley et al. 2015; Eckley et al. 2017).

#### *3.5.2.6.6 Mainstem Willamette River*

**Water Temperature**

Alternative 3A water temperature results for the Mainstem Willamette River at Salem (SLMO) results in a Minor Adverse effect for Days below 18 C (64.4 F) (Summer). Results are not reported for “Days Near Temperature Target from April through August” or “Days Near Temperature Target from September through March” because there are no temperature targets (Figure 3.5-57; Table 3.5-20).

Mainstem Willamette River Alternative 3A results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River near Salem gaging site (SLMO; Figure 1-384) 2011-year scenario water temperature increases by 1 degree from June through September as compared to the NAA. In the 2015-year scenario temperature increases 1 to 2 degrees in April through June and then decreases by 1 degree in July and August as compared to the NAA. In the 2016-year scenario water temperatures increase up to 2-degrees from May until August as compared to the NAA. For the average of the three years (2011,2015, 2016) water temperature increases up to 2 degrees from May until July as compared to the NAA.

Alternative 3A water temperature results for the Mainstem Willamette River at Albany (ALBO) results in a Minor Adverse effect for Days below 18 C (64.4 F) (Summer). Results are not reported for “Days Near Temperature Target from April through August” or “Days Near Temperature Target from September through March” because there are no temperature targets (Figure 3.5-57; Table 3.5-20).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River at Albany gaging site (ALBO; Figure 1-384) in the 2011-year scenario water temperatures increase up to 2 degrees from June through September as compared to the NAA. In the 2015-year scenario water temperatures increase up to 2-degrees in May and June as compared to the NAA. In the 2016-year scenario water temperatures increase up to 2-degrees from May until August as compared to the NAA. For the average of the three years (2011,2015, 2016) water temperatures increase up to 2-degrees from May until August as compared to the NAA.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and

Geomorphology Section 3.3.2.6 and Technical Appendix C Potential for changes in sediment supply "there is Negligible potential for changes in sediment supply relative to the No Action Alternative in the Middle Willamette free-flowing reach".

**<u>HABs</u>**

To the USACE knowledge, there have been no OHA advisories near Albany and Salem. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

*3.5.2.6.7 Climate Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects. Compared to NAA, Alternative 3B would potentially have less resiliency against climate change effects on water temperature (decreased water temperature control) below Detroit, Hills Creek, and Lookout Point, and lower on the mainstem Willamette at Salem as a result of the lower storage and outflows at each location. However, Alternative 3B would potentially have more resiliency against climate change effects on water temperature (more normative water temperature) below Green Peter-Foster due to the elevation of the summer lake levels at that project. TDG will likely have more resiliency against climate change effects below Lookout Point-Dexter due to the reduced reservoir storage and expected hydrologic effects shown in Technical Appendix B (Hydrology and Hydraulics). Parameters such as Turbidity, HABs, and Mercury will likely experience similar effects as those described under NAA.

*3.5.2.6.8 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.5.2.4, for description of effects due to the Near-Term Operations Measure.

**Table 3.5-19. Summary of Effects of Alternative 3A as compared to the NAA**

| Subbasin | Alternative 3A |
|---|---|
| North Santiam | Big Cliff has adverse effects for days near 18C (64.4F) summer. Beneficial effects are observed for days near temperature targets from April through August and September through March. Adverse effects to TDG levels are observed at Detroit and Big Cliff. |
| South Santiam | Foster observes negligible to beneficial effects to downstream water temperatures. Adverse effects to TDG levels are observed at Green Peter and Foster. |
| McKenzie | Cougar would have negligible to adverse effects to water temperature as Cougar has a Water Temperature Control Tower and provides water temperature control to the McKenzie. A negligible effect to TDG is observed at Cougar. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change. |

| Subbasin | Alternative 3A |
|---|---|
| Middle Fork Willamette | Hills Creek downstream water temperatures would observe an adverse to negligible effect. Dexter downstream water temperatures would observe beneficial to adverse effects to downstream water temperatures. Fall Creek temperatures would remain as described in the NAA. A negligible effect is observed at Hills Creek and Lookout Point. Dexter dam observes adverse effects to TDG. |
| Coast Fork Willamette & Long Tom | There are no water temperature measures considered at Cottage Grove, Dorena, and Fern Ridge therefore conditions would remain similar to the NAA. There are no measures considered for TDG management therefore conditions would remain similar to the NAA. |
| Mainstem Willamette | Albany and Salem water temperatures observe adverse effects as compared to the NAA. TDG gages are not located on the Willamette River as TDG concerns are typically located downstream of WVS dams. |

*Summary of effects*

Below is provided a summary of Alternative 3A's overall water quality effects.

**Water Temperature**

Alternative 3A would utilize operation-based measures for fish passage survivability within the WVS dams and compared to the NAA. Operational improvements for water temperature measures include: Utilizing the RO's to discharge cold water during drawdown operations in the fall and winter to reduce water temperatures below Detroit, Green Peter, and Lookout Point dams; Utilizing the spillway for surface spill in the summer at Detroit, Green Peter, Foster, Blue River, Hills Creek, and Lookout point dams. Spreading spill would be conducted at Dexter and Lookout Point. Modify existing outlets to allow releases at varying depths for temperature control by modifying the spillway to allow releases at varying depths for temperature control at Blue River and Hills Creek dams; Lining of the lower RO tunnels to limit cavitation effects and to assist in temperature control at Detroit dam. Monthly Mean of Daily Mean Water Temperature difference from NAA to Alternative 3A can be found in Appendix D Figure 1-404.

**Table 3.5-20. 3-year Average temperature difference with Effects Criteria of Alternative 3a as compared to NAA.**

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| HCRO | -16 | Major Adverse | 56 | Major Benefit | 16 | Minor Benefit |
| DEXO | -30 | Major Adverse | 2 | Negligible | 4 | Negligible |
| CGRO | 0 | Negligible | -1 | Negligible | -12 | Minor Adverse |
| SSFO | 3 | Negligible | 40 | Moderate Benefit | 18 | Minor Benefit |
| BCLO | -43 | Major Adverse | -24 | Moderate Adverse | 10 | Minor Benefit |
| ALBO | -9 | Minor Adverse | NA | | NA | |
| SLMO | -7 | Minor Adverse | NA | | NA | |

Please refer to Technical Appendix D for all Temperature model results by Alternative.
NA is due to no temperature targets for the Willamette during this period

**TDG**

A summary of Alternative 3A includes no measures for TDG abatement at the WVS dams. A potential Major Adverse effect would be observed at Detroit, Big Cliff, and Green Peter dams. A Moderate Adverse effect would be observed at Foster Reservoir. A potential Minor Adverse effect would be observed at Dexter Reservoir. A potential Negligible effect would be observed at Cougar, Hills Creek, and Lookout Point dams (Figure 3.5-57; Table 3.5-21).

**Table 3.5-21. Compilation of TDG model results (Appendix D Figures 2-35;2-36;2-34; Figure 3.5-57) downstream of the dams for Alternative 3A.**

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| DEX | 53 | 33 | 146 | Minor Adverse |

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| LOP | 0 | 0 | 225 | Negligible |
| HCR | 13 | -6 | 82 | Negligible |
| CGR | 77 | 20 | 240 | Negligible |
| FOS | 127 | 95 | 220 | Moderate Adverse |
| GPR | 151 | 139 | 189 | Major Adverse |
| BCL | 312 | 164 | 147 | Major Adverse |
| DET | 307 | 192 | 249 | Major Adverse |

**Turbidity**

There are no measures for Turbidity however sites are qualitatively described in the below sections. Potential Changes in Sediment Supply within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized for comparison.

**HABs**

There are no measures for Harmful Algae Blooms however sites are qualitatively described in the below sections. River Mechanics and Geomorphology analysis of Head-of-Reservoir, Shoreline Exposure and Sediment Re-Entrainment and Bank Failure Potential within Section 3.3 and Technical Appendix C is utilized for comparison.

**Mercury**

There are no WVS EIS Alternative measures for Mercury however sites are qualitatively described in the below sections. Shoreline Exposure analysis within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized.

### *3.5.2.7 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at Cougar*

This section describes the Alternative 3B effects to water quality.

#### *3.5.2.7.1 North Santiam Dam*

**Water Temperature**

Water temperature measures under Alternative 3B include Detroit Reservoir utilizing the RO’s to discharge colder water during drawdown operations in the fall and winter to reduce downstream water temperatures. The Detroit spillway would be utilized for surface spill in the summer which would assist in blending water temperatures below in Big Cliff. The lower RO's would be lined to limit cavitation effects and assist in releasing cooler water in the late fall at Detroit Reservoir.

Big Cliff/ Detroit Dams would have a Negligible effect of days below 18C (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 23).

Alternative 3B as compared to the NAA the Monthly Mean of Daily Mean water temperatures at the North Santiam at Niagara gaging site (BCLO; Appendix D Figure 1-412) the 2011-year scenario indicates an increase in water temperatures up to 4-degrees from May through July, an 8 degree temperature decrease is observed in September as compared to the NAA. Monthly Mean of Daily Max, Water Temperature difference from NAA (Alt3B-NAA). In the 2015-year scenario water temperatures decrease up to 5 degrees from May until October, although a 1-degree temperature increase is observed in August. In the 2016-year scenario a water temperature increase up to 2-degrees is observed in May and June, a temperature decrease of 1 to 2 degrees occurs in July and September. For the average of the three years water temperatures increase by 1-degrees in July, and then decrease up to 5 degrees in September and October as compared to the NAA.

**TDG**

Both Detroit and Big Cliff have a Moderate Adverse effect when including Alternative 3B as there are no TDG abatement measures (Figure 3.5-57; Table 3.5-24).

Under Alternative 3B, the average number of days above 110% TDG levels at Big Cliff is 226 and Detroit is 203 (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedances Big Cliff has an increase of 78 days and Detroit is increased by 87 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Big Cliff is 125 days and Detroit is 197 (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.7 for Potential for changes in sediment supply for the North Santiam section which states "there is a Moderate change in sediment supply with additional fine-grained sediments passing into Big Cliff run-of-river reservoir. Increased fine-grained sediment supply is due deeper drafts in Detroit Reservoir. There is potential for a Minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff dam".

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.7, which states Alternative 3B has Major changes in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Detroit Reservoir. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Detroit Reservoir. Big Cliff Reservoir is a run-of-river project that operates in a small range of pool elevations and is not included for these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Detroit. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for this metric. Please refer River Mechanics and Geomorphology Section 3.3.2.7 for the qualitative analysis of Alternative 3B as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit dam. Currently the amount or levels of mercury in Detroit is unknown. As there is Major change in shoreline exposure at Detroit dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.7.2 South Santiam Dams*

**Water Temperature**

Water temperature measures under Alternative 3B include Green Peter utilizing the RO’s to discharge colder water during drawdown operations in the fall and winter to reduce downstream water temperatures and volitional downstream fish passage. The Green Peter and Foster dam spillways would be utilized in the summer for surface spill.

Green Peter/Foster Dams would see a Major Adverse effect for Days below 18 C (64.4 F) (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 23).

Alternative 3B results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Santiam River near Foster gaging site (SSFO; Appendix D Figure 1-413) the 2011-year scenario would see a water temperature increase starting in June through October up to 12 degrees, although July would have a 2-degree temperature decrease as compared to the NAA. In the 2015-year scenario water temperatures increase from 1 to 10 degrees in April through September as compared to the NAA. In the 2016-year scenario water temperatures increase up to 14 degrees from April through September as compared to the NAA. For the Average of the three years (2011, 2015, 2016) an increase 1 to 8 degrees from April through October as compared to the NAA.

**TDG**

There are no TDG abatement measures at Green Peter and Foster. Both Green Peter and Foster dams would have a Minor Adverse effect under Alternative 3B as compared to the NAA (Figure 3.5-57; Table 3.5-24).

Under Alternative 3B, the average number of days above 110% TDG levels at Green Peter is 62 days and Foster is 69 days (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedances Green Peter has an increase of 50 days and Foster is 37 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Green Peter is 235 days and Foster is 211 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.7 Potential for changes in sediment supply for the South Santiam "there is Major change in sediment supply with additional fine-grained sediments passing into Foster Reservoir. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have the potential to pass sediment through Green Peter Dam and partially through the Foster Reservoir. There is potential for a Moderate change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster dam."

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.7, which states Alternative 3B would have Major change at Green Peter and Minor change at Foster in the potential for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter Reservoir and Negligible for Foster Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Green Peter Reservoir and Negligible for Foster Reservoir. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Green Peter and Foster. Please refer River Mechanics and Geomorphology Section 3.3.2.7 for the qualitative analysis of Alternative 3B as compared to the NAA. "The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. Currently the amount or levels of mercury in Green Peter and Foster reservoirs is unknown. As there is Major change in shoreline exposure at Green Peter dam there is potential for an increase for the methylation process to occur with water. Changes in shoreline exposure is a long-term, direct effect.

#### *3.5.2.7.3 McKenzie Dams*

**Water Temperature**

Water temperature measures under Alternative 3B include modifying the diversion tunnel at Cougar Reservoir to provide better temperature control. Measures for Blue River include a modification to the spillway to provide better water temperature management. The Blue River spillway would be used in the summer for surface spill

South Fork McKenzie River near Rainbow site (CGRO) is downstream of Blue River and Cougar Dam and would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Minor Benefit for Days Near Temperature Target from April through August, and Minor Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 23)).

Temperature results for Alt 3B effects are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Fork McKenzie River near Rainbow gaging site (CGRO; Appendix D Figure 1-414) in the 2011-year scenario there would be a water temperature decrease from 1 to 3-degrees from April through July, a 4-degree water temperature increase would occur in October as compared to the NAA. In the 2015-year scenario a water temperature decrease of 1 to 7 degrees is observed in May through October as compared to the NAA. In the 2016-year scenario a temperature decrease is observed up to 5 degrees from June through October as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a temperature decrease up to 5-degrees is observed from May through October as compared to the NAA.

**TDG**

There are no TDG management measures for Cougar Reservoir although a Minor Beneficial effect is observed with Alternative 3B measures (Figure 3.5-57; Table 3.5-24).

Under Alternative 3B, the average number of days above 110% TDG levels at Cougar is 26 days (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedance Cougar is decreased to 31 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Cougar is 46 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.7 Potential Changes in Sediment Supply there is a potential for a Major change in sediment supply with additional fine-grained sediments passing out of Cougar downstream into the McKenzie River. Increased fine-grained sediment supply is due to deeper drafts that may pass fine-grained sediment out of Cougar Reservoir. Blue River Reservoir would have a potential for a Moderate change in fine-grained sediment supply downstream of Blue River dam. Increased fine-grained sediment supply is due to deeper drafts in Blue River".

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.7, which states Alternative 3B has Major change at Cougar and Minor change at Blue River in the potential for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Cougar and Moderate change for Blue River dams. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cougar and Blue River. Please refer River Mechanics and Geomorphology Section 3.3.2.7 for the qualitative analysis of Alternative 3B as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Currently the amount or levels of mercury in Cougar and Blue River is unknown. As there is Major change in shoreline exposure at Cougar and Blue River dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

#### *3.5.2.7.4 Middle Fork Willamette Dams*

**Water Temperature**

Water temperature measures under Alternative 3B include Hills Creek Reservoir modification to the spillway and use the spillway for surface spill in the summer. Lookout point Reservoir would utilize the RO's to discharge colder water during drawdown operations in fall and winter to reduce downstream water temperatures. The Lookout Point spillway would be utilized in the summer for surface spill. Dexter spillway would be utilized in order to spread surface spill.

Lookout Point/Dexter Dams would see a Minor Adverse effect for Days below 18 C (64.4 F) (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5-23).

Water temperature results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Middle Fork Willamette River near Dexter gaging site (DEXO; Appendix D Figure 1-415) in the 2011-year scenario water temperature increase from 1 to 8 degrees is observed from April to August. In the 2015-year scenario observes a 1 degree decrease from June through September as compared to the NAA. In the 2016-year scenario a 2 to 6-degree water temperature increase is observed from April through July and decrease up to 7-degrees from August until October as compared to the NAA. For the Average of the three years (2011, 2015, 2016) a water temperature increases from 1-4 degrees in April through August and decreases up to 3-degrees in September and October.

Hills Creek dam would see a Major Adverse for Days below 18 C (64.4 F) (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 23).

As compared to the NAA the Monthly Mean of Daily Mean water temperatures (deg F) at the Middle Fork Willamette River above Salt Creek gaging site (HCRO; Appendix D Figure 1-416) in the 2011-year scenario water temperature increase from 1 to 5 degrees is observed from April to October. In the 2015-year scenario observes a 2-9 degree increase from April through September as compared to the NAA. In the 2016-year scenario water temperature increase 3-8 degrees from April through September as compared to the NAA. For the Average of the three years (2011, 2015, 2016) water temperatures increase 2 to 7 degrees from April through September as compared to the NAA.

**TDG**

There are no TDG abatement measures at Lookout Point, Hills Creek and Dexter dams. Lookout Point and Hills Creek would have a Negligible effect and Dexter Reservoir have a Minor Adverse effect with Alternative 3B as compared to the NAA (Figure 3.5-57; Table 3.5-24).

Under Alternative 3B, the average number of days above 110% TDG levels at Hills Creek is 19 days, Lookout Point is 0 days, and Dexter is 62 days (Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedances Hills Creek is 0 days, Lookout Point is 0 days, and Dexter is increased to 42 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Hills Creek is 89 days, Lookout Point is 196 days, and Dexter is 126 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.7 Potential for changes in sediment supply for the Middle Fork Willamette "there is a Major change in sediment supply into Dexter Reservoir with additional fine-grained sediments passing out of Lookout Point run-of-river reservoir. Increased fine-grained sediment supply is due deeper drafts that may pass fine-grained sediment out of Lookout Point Reservoir decreasing trap efficiency and increasing the potential for bank erosion and sloughing. There is a potential for a Moderate change in sediment supply with additional fine-grained sediment passing into the Middle Fork of the Willamette below Dexter dam".

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.7, which states Alternative 3B has a Major change at Hills Creek, Major change at Lookout Point, Negligible changes at Fall Creek dams for head-of-reservoir sediment mobilization relative to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point Reservoirs. Fall Creek reservoir would result in a Negligible change. Sediment Re-Entrainment and Bank Failure Potential metric would have a Negligible change for Hills Creek, Major change for Lookout Point, and Negligible change for Fall Creek Reservoirs. Dexter Reservoir is a run-of river project that operates in a small range of pool elevations and is not included in these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Hills Creek, Lookout Point and Fall Creek. Please refer to River Mechanics and Geomorphology Section 3.3.2.7 for the qualitative analysis of Alternative 3B as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point Reservoirs. Fall Creek reservoir would result in a Negligible change. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. Currently the amount or levels of mercury in Hills Creek, Lookout Point, and Fall Creek is unknown. As there would be changes in shoreline exposure at Hills Creek and Lookout Point dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.7.5 Coast Fork Dams And Long Tom*

**Water Temperature**

There are no temperature measures for Cottage Grove, Dorena, Fern Ridge dams under Alternative 3B. Conditions would remain as described in the No Action Alternative and Water Quality Affected Environment.

**TDG**

There are no measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 3B. TDG would remain unchanged and similar to the No Action Alternative and Water Quality Affected Environment. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.7 potential for changes in sediment supply section would have a

Moderate change in sediment supply with additional fine-grained sediments passing into the Coast Fork Willamette and Row River from Cottage Grove and Dorena dams. Increased fine-grained sediment supply is due deeper drafts in Cottage Grove and Dorena dams that have potential to induce bank erosion and sloughing generating sediment with the reduction of reservoir storage volume. There is Negligible change in sediment supply relative to the NAA in the Long Tom River.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.7, which states Alternative 3B has Negligible change in the potential for head-of-reservoir sediment mobilization relative to the NAA due to changes in operations at Cottage Grove, Dorena, and Fern Ridge dams. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cottage Grove and Dorena Reservoirs. Fern Ridge Reservoir would have a Negligible change. Sediment Re-Entrainment and Bank Failure Potential metric would have a Moderate change for Cottage Grove and Dorena Reservoirs. Fern Ridge Reservoir results in a Negligible change. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cottage Grove, Dorena, and Fern Ridge dams. However, referencing River Mechanics and Geomorphology Section 3.3.2.7 “Alternative 3B has a Major change in shoreline exposure relative to the NAA for Cottage Grove and Dorena Dams. Fern Ridge Reservoir results in a Negligible change. Mercury has been studied in Cottage Grove and Dorena Dams as Total Mercury (inorganic) and Methylated Mercury (organic) in sediment Ambers et al. 2001; Eckley et al. 2015; Eckley et al. 2017).

*3.5.2.7.6 Mainstem Willamette River*

**Water Temperature**

Alternative 3B water temperature results for the Mainstem Willamette River at Salem (SLMO) results in a Negligible effect for Days below 18 C (64.4 F) (Summer). Results are not reported for “Days Near Temperature Target from April through August” or “Days Near Temperature Target from September through March” because there are no temperature targets (Figure 3.5-57; Table 3.5 23)).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River near Salem gaging site (SLMO; Appendix D Figure 1-411) 2011-year scenario water temperature increases by 1 degree from May through August and decreases by 1 degree in September and October as compared to the NAA. In the 2015-year scenario temperature increases by 1 degree in May and October and decreases by 1 degree in July and September as compared to the NAA. In the 2016-year scenario water temperatures increase up to 2-degrees from May until July and then decreases by 1 degree in

September as compared to the NAA. For the average of the three years (2011,2015, 2016) water temperature increases by 1 degree in May and June and then decreases by 1 degree in September as compared to the NAA.

Alternative 3B water temperature results for the Mainstem Willamette River at Albany (ALBO) results in a Negligible effect for Days below 18 C (64.4 F) (Summer). Results are not reported for "Days Near Temperature Target from April through August" or "Days Near Temperature Target from September through March" because there are no temperature targets (Figure 3.5-57; Table 3.5 23).

Mainstem Willamette River results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River at Albany gaging site (ALBO; Appendix D Figure 1-411) in the 2011-year scenario water temperatures increase up to 2 degrees from June through August and then decreases by 1 degree in October as compared to the NAA. In the 2015-year scenario water temperatures increase by 1-degrees in May and October as compared to the NAA. In the 2016-year scenario water temperatures increase up to 2-degrees from April through July and then decreases up to 2 degrees from August until October as compared to the NAA. For the average of the three years (2011,2015, 2016) water temperatures increase by 1-degrees from May until July and then decrease by 1-degree in September as compared to the NAA.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.7 and Technical Appendix C Potential for changes in sediment supply "there is Negligible potential for changes in sediment supply relative to the No Action Alternative in the Middle Willamette free-flowing reach".

**HABs**

To the USACE knowledge, there are no OHA HAB advisories near Albany and Salem in public records. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

*Climate 3.5.2.7.7 Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects. Compared to NAA, Alternative 3B would potentially have less resiliency against climate change effects on water temperature (decreased water temperature control) below Detroit, Hills Creek, and Lookout Point, and lower on the mainstem Willamette at Salem as a result of the lower storage and outflows at each location. However, Alternative 3B would potentially have more resiliency against climate change effects on water temperature (more normative temperatures) below Lookout Point-Dexter due to operational lake elevations. TDG levels will likely have more resiliency against climate change effects below Lookout Point-Dexter due to the reduced reservoir storage and expected hydrologic effects shown in Technical Appendix B (Hydrology and Hydraulics). Parameters such as Turbidity, HABs, and Mercury will likely experience similar effects as those described under NAA.

*3.5.2.7.8 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.5.2.4, for description of effects due to the Near-Term Operations Measure.

**Table 3.5-22. Summary of Effects of Alternative 3B as compared to the NAA**

| Subbasin | Alternative 3B |
|---|---|
| North Santiam | Big Cliff has negligible effects for days near temperature targets ranges as compared to the NAA. Adverse effects to TDG levels are observed at Detroit and Big Cliff. |
| South Santiam | Foster observes negligible, beneficial, and adverse effects to measures for downstream water temperatures. Adverse effects to TDG levels are observed at Green Peter and Foster. |
| McKenzie | Cougar would have negligible to beneficial effects to water temperature measures. A beneficial effect to TDG is observed at Cougar. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change. |
| Middle Fork Willamette | Hills Creek would observe negligible, beneficial, and adverse effects to measures for downstream water temperatures. Dexter would observe negligible, beneficial, and adverse effects to measures for downstream water temperatures. Fall Creek temperatures would remain as described in the NAA. A negligible effect is observed for TDG at Hills Creek and Lookout Point. Dexter dam observe an adverse effects. |
| Coast Fork Willamette & Long Tom | There are no water temperature measures considered at Cottage Grove, Dorena, and Fern Ridge therefore conditions would remain similar to the NAA. There are no measures considered for TDG management therefore conditions would remain similar to the NAA. |

| Subbasin | Alternative 3B |
|---|---|
| Mainstem Willamette | Albany and Salem water temperatures observe negligible effects as compared to the NAA. TDG gages are not located on the Willamette River as TDG concerns are typically located downstream of WVS dams. |

### *3.5.2.7.9 Summary of Effects*

Below is provided a summary of Alternative 3B's overall water quality effects.

**Water Temperature**

Alternative 3B measures include operational improvements for water temperature: Utilizing the RO's to discharge cold water during drawdown operations in the fall and winter to reduce water temperatures below Detroit, Green Peter, and Lookout Point dams; Utilizing the spillway for surface spill in the summer at Detroit, Green Peter, Foster, Blue River, Hills Creek, and Lookout point dams. Modify existing outlets to allow releases at varying depths for temperature control: Modifying the spillway to allow releases at varying depths for temperature control at Blue River and Hills Creek dams; Lining of the lower RO tunnels to limit cavitation effects and to assist in temperature control at Detroit dam; Modifying the Cougar dam diversion tunnel for water temperature control and complying with dam safety. Monthly Mean of Daily Mean Water Temperature difference from NAA to Alternative 3B can be found in Appendix D Figure 1-411.

**Table 3.5-23. 3-year Average temperature difference with Effects Criteria of Alternative 3B as compared to NAA.**

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| HCRO | -45 | Major Adverse | 31 | Moderate Benefit | 3 | Negligible |
| DEXO | -6 | Minor Adverse | 24 | Moderate Benefit | 7 | Negligible |
| CGRO | 0 | Negligible | 13 | Minor Benefit | 16 | Minor Benefit |
| SSFO | -45 | Major Adverse | 28 | Moderate Benefit | 0 | Negligible |
| BCLO | 0 | Negligible | -2 | Negligible | 3 | Negligible |
| ALBO | -2 | Negligible | NA | | NA | |

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| SLMO | -2 | Negligible | NA | | NA | |

Please refer to Technical Appendix D for all Temperature model results by Alternative.
NA is due to no temperature targets for the Willamette during this period

**TDG**

There are no TDG abatement measures for Alternative 3B. A potential Moderate Adverse effect would be observed at Detroit and Big Cliff dams. A potential Minor Adverse effect would be observed at Green Peter, Foster, and Dexter dams. A potential Minor Benefit would be observed at Cougar Reservoir. A potential Negligible effect would be observed at, Hills Creek and Lookout Point dams (Figure 3.5-57; Table 3.5-24).

**Table 3.5-24. Compilation of TDG model results (Appendix D Figures 2-35;2-36;2-34; Figure 3.5-57) downstream of the dams for Alternative 3B.**

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| DEX | 62 | 42 | 126 | Minor Adverse |
| LOP | 0 | 0 | 196 | Negligible |
| HCR | 19 | 0 | 89 | Negligible |
| CGR | 26 | -31 | 46 | Minor Benefit |
| FOS | 69 | 37 | 211 | Minor Adverse |
| GPR | 62 | 50 | 235 | Minor Adverse |
| BCL | 226 | 78 | 125 | Moderate Adverse |
| DET | 203 | 87 | 197 | Moderate Adverse |

**Turbidity**

There are no measures for Turbidity however sites are qualitatively described in the below sections. Potential Changes in Sediment Supply within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized for comparison.

**HABs**

There are no measures for Harmful Algae Blooms however sites are qualitatively described in the below sections. River Mechanics and Geomorphology analysis of Head-of-Reservoir, Shoreline Exposure and Sediment Re-Entrainment and Bank Failure Potential within Section 3.3 and Technical Appendix C is utilized for comparison.

**Mercury**

There are no WVS EIS Alternative measures for Mercury however sites are qualitatively described in the below sections. Shoreline Exposure analysis within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized.

### *3.5.2.8 Alternative 4 – Structures-Based Fish Passage Alternative*

This section describes the Alternative 4 effects to water quality.

#### *3.5.2.8.1 North Santiam Dam*

**Water Temperature**

Alternative 4 measure at Detroit Reservoir includes a water temperature control tower.

Big Cliff/ Detroit Dams would have a Negligible effect of days below 18C (Summer), Moderate Benefit for Days Near Temperature Target from April through August, and Major Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 26).

Alternative 4 results as compared to the NAA the Monthly Mean of Daily Mean water temperatures at the North Santiam at Niagara gaging site (BCLO; Appendix D Figure 1-419) in the 2011-year scenario see water temperature increase up to 3 degrees starting in June through October. In the 2015-year scenario water temperatures would increase 2 to 3 degrees from May to August and then decrease up to 6 degrees in September and October. In the 2016-year scenario water temperatures would increase up to 11 degrees from May to September and then decrease by 2 degrees in October. For the average of the three years (2011,2015,2016) water temperatures would increase up to 6 degrees from May until September and then decrease by 2 degrees in October.

**TDG**

Structural improvement measures to improve TDG at Detroit Reservoir is included in the design of the proposed water temperature control tower under Alternative 4. Detroit Reservoir has a Moderate Beneficial effect and Big Cliff Reservoir has a Major Beneficial effect with Alternative 4 measures (Figure 3.5-57; Table 3.5 27).

Under Alternative 4, the average number of days above 110% TDG levels at Big Cliff is 37 and Detroit is 39 (Figure 2-35). Observing the Annual difference in number of days above 110% of

TDG exceedances Big Cliff has a reduction of 111 days and Detroit has a reduction of 77 days as compared to the No Action Alternative (Figure 2-36). The Average Number of Days of Spill per year at Big Cliff is 86 days and Detroit is 62 (Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 Potential for changes in sediment supply section, which states "there is Moderate change in sediment supply with additional fine-grained sediments passing into the Big Cliff run-of-reservoir. Increased fine-grained sediment supply is due deeper drafts in Detroit dams that have potential to induce bank erosion and sloughing. A Minor change in fine-grained sediment supply to the North Fork Santiam River downstream of Big Cliff dam".

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.8, which states Deeper drawdowns are typically occurring during lower flow periods, such that Alternative 4 has Negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at all WVS storage projects. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Detroit Reservoir. Big Cliff Reservoir is a run-of river project that operates in a small range of pool elevations and is not included for these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Detroit. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for this metric. Please refer River Mechanics and Geomorphology Section 3.3.2.8 for qualitative analysis of Alternative 4 as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Detroit dam. Currently the amount or levels of mercury in Detroit is unknown. As there is Major change in shoreline exposure at Detroit dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.8.2 South Santiam Dams*

**Water Temperature**

Alternative 4 measures at Green Peter Reservoir include utilizing the RO's to discharge colder water during drawdown operation in the fall and winter to reduce downstream water temperatures. The Green Peter spillway is used for surface spill in the summer. At Foster

Reservoir the existing outlets would be modified to allow releases at varying depths for temperature control through a Forebay Warm Water Supply (FWWS) pipe and fish weirs.

Green Peter/Foster Dams has a Major Benefit effect for Days below 18 C (64.4 F) (Summer), Minor Benefit for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 26*0*).

Alternative 4 results as compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Santiam River near Foster gaging site (SSFO; Appendix D Figure 1-420) in the 2011-year scenario water temperatures would increase up to 5 degrees from May until September, although a 2-degree decrease occurs in July. In the 2015-year scenario water temperatures would increase up to 5 degrees from April to June and then decrease up to 13 degrees from July through October. In the 2016-year scenario water temperatures would increase up to 5 degrees from April to August and then decrease by 2 degrees in October. For the average of the three years water temperatures would increase up to 4 degrees from April until June and decrease up to 2 degrees from July through October.

**TDG**

Structural improvement measures to improve TDG at Foster Reservoir are included at the Foster adult fish collection facility. Foster Reservoir would have a Negligible effect and Green Peter Reservoir would have a Major Adverse effect for Alternative 4 measures (Figure 3.5-57; Table 3.5 27).

Under Alternative 4, the average number of days above 110% TDG levels at Green Peter is 135 days and Foster is 19 days (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedances Green Peter has an increase of 123 days and Foster is decreased to 13 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Green Peter is 185 days and Foster is 211 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 Potential for changes in sediment supply section "there is the potential for Moderate change in sediment supply with additional fine-grained sediments passing into Foster Reservoir. Increased fine-grained sediment supply is due deeper drafts in Green Peter Reservoir that have potential to induce bank erosion and sloughing. There is potential for a Minor change in fine-grained sediment supply to the South Fork Santiam River downstream of Foster Dam. Increased fine-grained sediment supply is due to deeper drafts in Green Peter Reservoir that may pass sediment through Green Peter dam and partially through Foster Reservoir".

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.8, which states "Deeper drawdowns are typically occurring during lower flow periods, such that Alternative 4 has Negligible change in the potential for head-of-reservoir sediment mobilization and sediment trap efficiency at all WVS storage projects. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter Reservoir and Negligible for Foster Reservoir. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Green Peter reservoir and Negligible for Foster Reservoir. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Green Peter and Foster. Please refer River Mechanics and Geomorphology Section 3.3.2.8 for the qualitative analysis of Alternative 4 as compared to the NAA. "The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Green Peter reservoir and Negligible for Foster reservoir. Currently the amount or levels of mercury in Green Peter and Foster reservoirs is unknown. As there is Major change in shoreline exposure at Green Peter dam there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.8.3 McKenzie Dams*

**Water Temperature**

There are no temperature measures in Alternative 4 for Cougar or Blue River dams. South Fork McKenzie River near Rainbow site (CGRO) is downstream of Blue River and Cougar Dam and would see a Negligible effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 26).

Results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the South Fork McKenzie River near Rainbow gaging site (CGRO; Appendix D Figure 1-421) in the 2011-year scenario water temperature would decrease by 1 degree from May until August. In the 2015-year scenario a decrease up to 3 degrees from July to October. In the 2016-year scenario a decrease is observed up to 2 degrees in July and increase of 4 degrees in August and September. For the Average of the three years (2011, 2015, 2016) water temperature decreases up to 2 degrees from June until August and then increase by 1 degree in September.

**TDG**

Cougar dams has a Minor Benefit when including the structural improvement for TDG management measure in Alternative 4 as compared to the NAA (Figure 3.5-57; Table 3.5 27).

Under Alternative 4, the average number of days above 110% TDG levels at Cougar is 17 days. Observing the Annual difference in number of days above 110% of TDG exceedance Cougar is decreased to 41 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Cougar is 168 days.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 Potential for changes in sediment supply section "there is Minor change in sediment supply with additional fine-grained sediments passing out of Cougar downstream into the McKenzie River. Increased fine-grained sediment supply is due to deeper drafts that may pass fine-grained sediment out of Cougar Reservoir. Blue River Reservoir would have a potential for a Moderate change in fine-grained sediment supply. Increased fine-grained sediment supply is due to deeper drafts in Blue River

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.8, which states Deeper drawdowns are typically occurring during lower flow periods, such that Alternative 4 has Negligible change in the potential for head-of-reservoir sediment at all WVS storage projects. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Sediment Re-Entrainment and Bank Failure Potential metric would have a Moderate change for Cougar and Major change for Blue River dams. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cougar and Blue River. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 for the qualitative analysis of Alternative 4 as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cougar and Blue River dams. Currently the amount or levels of mercury in Cougar and Blue River is unknown. As there is Major change in shoreline exposure at Cougar and Blue River dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

#### *3.5.2.8.4 Middle Fork Willamette Dams*

**Water Temperature**

Alternative 4 measures at Hills Creek and Lookout Point dams include water temperature control towers to better regulate downstream water temperatures. There are no Alternative 4 temperature measures for Dexter or Fall Creek Reservoirs.

Lookout Point/Dexter Dams would see a Major Adverse effect for Days below 18 C (64.4 F) (Summer), Negligible effect for Days Near Temperature Target from April through August, and Negligible effect for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 26).

As compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Middle Fork Willamette River near Dexter gaging site (DEXO; Appendix D Figure 1-422) in the 2011-year scenario water temperature would increase starting in April through September up to 8 degrees and decrease by 6 degrees in October. In the 2015-year scenario water temperature would increase up to 3 degrees in April and May and then decrease up to 3 degrees from August to October. In the 2016-year scenario water temperatures would increase up to 5 degrees from April to August and then decrease up to 6 degrees in September and October. For the average of the three years water temperatures would increase up to 4 degrees from April through August and then decrease up to 5 degrees in September and October.

Hills Creek dam has a Major Adverse for Days below 18 C (64.4 F) (Summer), Major Benefit for Days Near Temperature Target from April through August, and Moderate Benefit for Days Near Temperature Target from September through March (Figure 3.5-57; Table 3.5 26)

As compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Middle Fork Willamette River above Salt Creek gaging site (HCRO; Appendix D Figure 1-423) in the 2011-year scenario water temperatures would increase up to 12 degrees from April through September and then decrease by 5 degrees in October. In the 2015-year scenario water temperatures would increase up to 6 degrees from April through August and then decrease by 3 degrees in October. In the 2016-year scenario water temperatures would increase up to 9 degrees from April through August and then decrease by 7 degrees in September and October. For the average of the three years (2011,2015,2016) water temperatures would increase up to 8 degrees from April through August and then decrease up to 5 degrees in September and October.

**TDG**

Alternative 4 measures include structural improvements for TDG at Lookout Point Reservoir within the water temperature control tower. Dexter Reservoir includes structural improvements to reduce TDG and mechanical degassing methods in the fish collection/hatchery areas downstream of the dam. Lookout Point, Dexter, and Hills Creek dams would have a Negligible effect with Alternative 4 TDG measures as compared to the NAA (Figure 3.5-57; Table 3.5 27).

Under Alternative 4, the average number of days above 110% TDG levels at Hills Creek is 9 days, Lookout Point is 0 days, and Dexter is 5 days (Appendix D Figure 2-35). Observing the Annual difference in number of days above 110% of TDG exceedances Hills Creek is reduced by 9 days, Lookout Point is 0 days, and Dexter is reduced by 15 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Hills Creek is 123 days, Lookout Point is 49 days, and Dexter is 91 days (Appendix D Figure 2-34).

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 Potential for changes in sediment supply section there is Moderate change in sediment supply with additional fine-grained sediments passing into Hills Creek Reservoir. Increased fine-grained sediment supply is due deeper drafts in Hills Creek Reservoir that have potential to induce bank erosion and sloughing. There is potential for a Minor change in fine-grained sediment supply to the Dexter run-of-river reservoir. Increased fine-grained sediment supply is due to deeper drafts in Lookout Point Reservoir that may pass sediment due to reduction in reservoir storage volume.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.8, which states Deeper drawdowns are typically occurring during lower flow periods, such that Alternative 4 has Negligible change in the potential for head-of-reservoir sediment mobilization at all WVS storage projects. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point Reservoirs. Fall Creek Reservoir would result in a Negligible change. Sediment Re-Entrainment and Bank Failure Potential metric would have a Major change for Hills Creek, Minor change for Lookout Point, and Negligible change for Fall Creek Reservoirs. Dexter Reservoir is a run-of river project that operates in a small range of pool elevations and is not included in these metrics. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Hills Creek, Lookout Point and Fall Creek. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 for the qualitative analysis of Alternative 4 as compared to the NAA. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Hills Creek and Lookout Point Reservoirs. Fall Creek reservoir would result in a Negligible change”. Dexter reservoir is a run-of river project that operates in a small range of pool elevations and is not included in this metric. Currently the amount or levels of mercury in Hills Creek, Lookout Point, and Fall Creek is unknown. As there would be changes in shoreline exposure at Hills Creek and Lookout Point dams there is potential for an increase for the methylation process to occur with water fluctuations. Changes in shoreline exposure is a long-term, direct effect.

*3.5.2.8.5 Coast Fork Dams and Long Tom*

**Water Temperature**

There are no temperature measures for Cottage Grove, Dorena, Fern Ridge dams under Alternative 4. Conditions would remain as described in the No Action Alternative and Water Quality Affected Environment.

**TDG**

There are no TDG measures at Cottage Grove, Dorena and Fern Ridge dams under Alternative 4, conditions would remain as described in the No Action Alternative and Water Quality Affected Environment. TDG exceedance may occur if water is released through the non-turbine outlets of dams, spill and maintenance operations.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 Potential for changes in sediment supply section there is the potential for Moderate change in sediment supply with additional fine-grained sediments passing into the Coast Fork Willamette and Row River free-flowing reaches from Cottage Grove and Dorena River. Increased fine-grained sediment supply is due deeper drafts in Cottage Grove and Dorena dams that have potential to induce bank erosion and sloughing. There is Negligible result in sediment supply relative to the NAA in the Long Tom river free-flowing reach". Increased suspended sediments may cause an elevation in turbidity levels during drawdown operations or precipitation events.

**HABs**

Please refer to River Mechanics and Geomorphology Section 3.3.2.8, which states Deeper drawdowns are typically occurring during lower flow periods, such that Alternative 4 has Negligible change in the potential for head-of-reservoir sediment mobilization at all WVS storage projects. The Shoreline Exposure metric within Section 3.3 and Technical Appendix C would have a Major change for Cottage Grove and Dorena Reservoirs. Fern Ridge Reservoir results in a Negligible change. Sediment Re-Entrainment and Bank Failure Potential metric would have a Moderate change for Cottage Grove and Dorena Reservoirs. Fern Ridge Reservoir results in a Negligible change. These metrics provide a qualitative analysis to describe potential nutrient availability within sediments for algae.

**Mercury**

There are no WVS EIS Alternative measures for Mercury within Cottage Grove, Dorena, and Fern Ridge dams. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 Shoreline Exposure has a Major change in bank exposure relative to the NAA for Cottage Grove and Dorena Dams. Fern Ridge Reservoir results in a Negligible change. Mercury has been studied in Cottage Grove and Dorena Dams as Total Mercury (inorganic) and Methylated Mercury (organic) in sediment (Ambers et al. 2001; Eckley et al. 2015; Eckley et al. 2017).

#### *3.5.2.8.6 Mainstem Willamette River*

**Water Temperature**

Alternative 4 water temperature within the Mainstem Willamette River at Salem (SLMO) results in a Minor Adverse effect for Days below 18 C (64.4 F) (Summer). Results are not reported for "Days Near Temperature Target from April through August" or "Days Near Temperature Target from September through March" because there are no temperature targets (Figure 3.5-57; Table 3.5-26).

Mainstem Willamette River Alternative 4 results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River near Salem gaging site (SLMO; Appendix D Figure 1-418) 2011-year scenario water temperature increases by 1 degree in June and August to September and decreases by 1 degree in October as compared to the NAA. In the 2015-year scenario temperature increases up to 2 degrees from April to May and decreases up to 2 degrees in July and September as compared to the NAA. In the 2016-year scenario water temperatures increase by 1-degrees from May until July and then decreases by 1 degree in October as compared to the NAA. For the average of the three years (2011,2015, 2016) water temperature increases by 1 degree in May as compared to the NAA.

Alternative 4 water temperature within the Mainstem Willamette River at Albany (ALBO) results in a Negligible effect for Days below 18 C (64.4 F) (Summer). Results are not reported for "Days Near Temperature Target from April through August" or "Days Near Temperature Target from September through March" because there are no temperature targets (Figure 3.5-57; Table 3.5-26).

Mainstem Willamette River Alternative 4 results are compared to the NAA the Monthly Mean of Daily Mean water temperatures at the Willamette River at Albany gaging site (ALBO; Appendix D Figure 1-418) in the 2011-year scenario water temperatures increase up to 2 degrees from July through September and then decreases by 2 degrees in October as compared to the NAA. In the 2015-year scenario water temperatures increase by 1-degrees in April and May and then decreases by 1 degree in July and August as compared to the NAA. In the 2016-year scenario water temperatures increase up to 2-degrees from April through August and then decreases by 1 degree from September through October as compared to the NAA. For the average of the three years (2011,2015, 2016) water temperatures increase by 1-degrees in April through May and August and then decrease by 1-degree in October as compared to the NAA.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

**Turbidity**

An increase in suspended sediments may cause an elevation in turbidity levels during drawdown operations, low flow or precipitation events. Please refer to River Mechanics and Geomorphology Section 3.3.2.8 and Technical Appendix C Potential for changes in sediment supply “there is Negligible potential for changes in sediment supply relative to the No Action Alternative in the Middle Willamette free-flowing reach”.

**HABs**

To the USACE knowledge, there are no OHA HAB advisories near Albany and Salem in public records. At this time the USACE cannot control cyanobacteria bloom formation and growth. Further research is needed to determine factors that assist in toxin production and toxin suppression.

*3.5.2.8.7 Climate Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects. Compared to NAA, Alternative 4 would potentially have more resiliency against climate change effects on water temperature and TDG (increased water temperature control) below Detroit, Lookout Point, and Hills Creek as a result of the proposed SWS and TDG abatement measures at each location. Parameters such as Turbidity and Mercury will likely experience similar effects as those described under NAA. Increased releases from the lake surface via the proposed SWS at Detroit, Lookout Point, and Hills Creek combined with reduced summer flow volumes under Alternative 1 could lead to increased phytoplankton (algae) compared to NAA (Technical Appendix B Hydrology and Hydraulics).

*3.5.2.8.8 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.5.2.4, for description of effects due to the Near-Term Operations Measure.

**Table 3.5-25. Summary of Effects of Alternative 4 as compared to the NAA**

| Subbasin | Alternative 4 |
|---|---|
| North Santiam | Big Cliff has negligible to beneficial effects for downstream water temperatures. Beneficial effects to TDG levels are observed at Detroit and Big Cliff. |
| South Santiam | Foster observes negligible to beneficial effects to downstream water temperatures. Negligible to adverse effects to TDG levels is observed at Green Peter and Foster. |
| McKenzie | Cougar observes negligible l effects to water temperature measures. A beneficial effect to TDG is observed at Cougar. Blue River is not expected to change as the RO’s are utilized and TDG levels would not be expected to change. |

| Subbasin | Alternative 4 |
|---|---|
| Middle Fork Willamette | Hills Creek would observe beneficial and adverse effects to measures for downstream water temperatures. Dexter would observe negligible and adverse effects to measures for downstream water temperatures. Fall Creek temperatures would remain as described in the NAA. A negligible effect is observed for TDG at Hills Creek, Lookout Point and Dexter. |
| Coast Fork Willamette & Long Tom | There are no water temperature measures considered at Cottage Grove, Dorena, and Fern Ridge therefore conditions would remain similar to the NAA. There are no measures considered for TDG management therefore conditions would remain similar to the NAA. |
| Mainstem Willamette | Albany and Salem water temperatures observe negligible to adverse effects as compared to the NAA. TDG gages are not located on the Willamette River as TDG concerns are typically located downstream of WVS dams. |

#### *3.5.2.8.9 Summary of effects*

Below is provided a summary of Alternative 4's overall water quality effects.

**Water Temperature**

Alternative 4 structural improvements for water temperature measures include: Water temperature control towers at Detroit, Hills Creek, and Lookout Point dams; Modify existing outlets to allow releases at varying depths for temperature control at Foster Reservoir through a Facility Warm Water Supply (FWWS) pipe and fish weirs. Utilizing the RO's to discharge cold water during drawdown operations in the fall and winter to reduce water temperatures below Green Peter dam. Utilizing the spillway for surface spill in the summer at Green Peter dam. Monthly Mean of Daily Mean Water Temperature differences from the NAA to Alternative 4 can be found in Appendix D Figure 1-418.

**Table 3.5-26. 3-year Average temperature difference with Effects Criteria of Alternative 4 as compared to NAA**

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| HCRO | -27 | Major Adverse | 64 | Major Benefit | 24 | Moderate Benefit |

| Location | Difference from NAA in Days Below 18C each year | Days Below 18C Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Apr-Aug) | Days Near Target (Apr-Aug) Effects Criteria | Annual Average Number of Days within 2 degrees F of Temperature Target (Sep-Mar) | Days Near Target (Sep-Mar) Effects Criteria |
|---|---|---|---|---|---|---|
| DEXO | -15 | Major Adverse | 4 | Negligible | -2 | Negligible |
| CGRO | 0 | Negligible | 2 | Negligible | -1 | Negligible |
| SSFO | 19 | Major Benefit | 15 | Minor Benefit | 6 | Negligible |
| BCLO | 0 | Negligible | 42 | Moderate Benefit | 58 | Major Benefit |
| ALBO | -4 | Negligible | NA | | NA | |
| SLMO | -5 | Minor Adverse | NA | | NA | |

Please refer to Technical Appendix D for all Temperature model results by Alternative.
NA is due to no temperature targets for the Willamette during this period

**TDG**

Alternative 4 includes structural improvement measures to reduce TDG at Detroit, Green Peter, Foster, Lookout Point, Dexter, and Cougar dams. Detroit and Lookout Point dams TDG measure would be incorporated into the water temperature control tower design. A mechanical degassing method is included at the AFF for TDG reduction at Big Cliff and Dexter dams.

Green Peter Reservoir has a potential Major Adverse effect. Detroit Reservoir would potentially have a Moderate Benefit. Cougar Reservoir would have a potential Minor Benefit from structural improvements for TDG. A Negligible effect would be observed at Foster, Hills Creek, Lookout Point, and Dexter dams (Figure 3.5-57; Table 3.5-27).

**Table 3.5-27. Compilation of TDG model results (Appendix D Figures 2-35;2-36;2-34; Figure 3.5-57) downstream of the dams for Alternative 4.**

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| DEX | 5 | -15 | 91 | Negligible |
| LOP | 0 | 0 | 49 | Negligible |
| HCR | 9 | -9 | 123 | Negligible |
| CGR | 17 | -41 | 168 | Minor Benefit |

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| FOS | 19 | -13 | 285 | Negligible |
| GPR | 135 | 123 | 165 | Major Adverse |
| BCL | 37 | -111 | 86 | Major Benefit |
| DET | 39 | -77 | 62 | Moderate Benefit |

**Turbidity**

There are no measures for Turbidity however sites are qualitatively described in the below sections. Potential Changes in Sediment Supply within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized for comparison.

**HABs**

There are no measures for Harmful Algae Blooms however sites are qualitatively described in the below sections. River Mechanics and Geomorphology analysis of Head-of-Reservoir, Shoreline Exposure and Sediment Re-Entrainment and Bank Failure Potential within Section 3.3 and Technical Appendix C of is utilized for comparison.

**Mercury**

There are no WVS EIS Alternative measures for Mercury however sites are qualitatively described in the below sections. Shoreline Exposure analysis within the River Mechanics and Geomorphology Section 3.3 and Technical Appendix C is utilized.

#### *3.5.2.9 Alternative 5. Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 impacts are similar to Alternative 2B except the integrated temperature and habitat flow regime (Measure #30a as described in Section 2.2.1.1) has been replaced by the refined integrated temperature and habitat flow regime (Measure #30b as described in Section 2.2.1.2 and Appendix A). Refer to impact descriptions in Alternative 2B, Section 3.5.2.5 for all Alternative 5 regions and effects. Please see Technical Appendix D for metric calculations and supporting figures for Water Temperature and TDG.

*3.5.2.9.1 North Santiam Dams*

**Water Temperature**

Alternative 5 includes a Water Temperature Control tower at Detroit reservoir for water temperature management. Because of the similarities in operations and structural assumptions for Alternative 5 and Alternative 2B in the North Santiam, refer to Appendix D Section 1.6.4.1 for a comparison of Alternative 2B and NAA water temperature effects at Detroit and Big Cliff Dams.

Lake level and storage at Detroit Lake in Alternative 5 was identical to Alternative 2B in 2011, 2015, and 2016. Compared to NAA, Alternative 5 lake levels were generally higher in 2015 and 2016 aside from September-November in 2015 where the power pool was utilized for downstream flow augmentation (Appendix D). The increased storage compared to NAA coincided with reduced outflows during spring and increased outflows in summer during 2015 and 2016 under Alternative 5. Total outflow in 2011 was generally similar in Alternative 5 and NAA at Detroit Lake. The proposed SWS and FSS in Alternative 5 allowed all outflow within powerhouse capacity (assumed at 4600 cfs) to be routed from a floating outlet through the Power outlets for temperature management, rather than the Spillway or URO flow for temperature management that was used in NAA (Appendix D Figure 1-359).

**TDG**

Under Alternative 5 there are no measures for TDG abatement at Detroit and Big Cliff. Detroit Reservoir has a Moderate Beneficial effect and Big Cliff Reservoir has a Major Beneficial effect with Alternative 5 measures (Figure 3.5-57; Table 3.5-29).

Under Alternative 5, the average number of days above 110% TDG levels at Big Cliff is 79 and Detroit is 39 (Appendix D Figure 2-35; Table 3.5-29). North Santiam Alternative 5 TDG effects essentially match those in Alternative 2B with Big Cliff resulting in a reduction of 69 number of days in annual difference the above 110% TDG and Detroit reduced by 77 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Detroit is 62 days and Big Cliff is 86 days (Appendix D Figure 2-34).

*3.5.2.9.2 South Santiam Dams*

**Water Temperature**

Alternative 5 includes the use of the RO’s to discharge colder water during fall and winter drawdown operations at Green Peter reservoir. Additional measures include use of the spillway for surface spill in the summer at Green Peter reservoir and a measure to modify existing outlets to allow releases at varying depths for temperature control specifically at Foster reservoir with a modification to the Facility Warm Water Supply (FWWS) pipe and fish weirs. Because of the similarities in operations and structural assumptions for Alternative 5 and

Alternative 2B in the South Santiam, refer to Appendix D for a comparison of Alternative 2B and NAA water temperature effects at Green Peter and Foster Dams.

Lake level and storage at Green Peter in Alternative 5 was nearly identical to Alternative 2B in 2011, 2015, and 2016. Compared to NAA, Alternative 5 lake levels were generally higher in 2011, 2015, and 2016 aside from October-November during RO drawdown for fish passage (Appendix D Figure 1-361, Figure 1-362, and Figure 1-363). Some increased storage in 2015 coincided with reduced outflows during spring and increased outflows in July-October comparing Alternative 5 to NAA. 2011 and 2016 operations were generally similar in Alternative 5 and NAA at Green Peter Lake January-June but followed increased outflows in July-October to draft the lake for fish passage operations through the ROs in autumn. The proposed operational temperature management through the spillway (during spring/summer) and RO (during autumn) in Alternative 5 led to increased outflow from these outlets and decreased power outflow compared to NAA (Appendix D Figure 1-362).

Lake level and storage at Foster in Alternative 5 was nearly identical to Alternative 2B in 2011, 2015, and 2016. Compared to NAA, Alternative 5 lake levels were generally similar in 2011 and 2016 but increased in 2015 under Alternative 5 compared to NAA (Appendix D Figure 1-364, Figure 1-365, and Figure 1-366). Total outflow from Foster Dam was affected by upstream operations at Green Peter Dam. The proposed modifications to the fish weir and FWWS in Alternative 5 resulted in lower outflow routed through the Power outlets for temperature management, especially during spring and summer, compared to NAA (Appendix D Figure 1-362).

**TDG**

There are no TDG measures within Alternative 5 for Green Peter and Foster reservoirs. Foster Reservoir would have a Negligible effect and Green Peter Reservoir would have a Moderate Adverse effect for Alternative 5 measures (Figure 3.5-57; Table 3.5-29).

South Santiam Alternative 5 TDG effects match those in Alternative 2B, with the average number of days above 110% TDG levels at Green Peter 151 days and Foster at 126 days (Appendix D Figure 2-35; Table 3.5-29). Green Peter results in an increase of 139 days of TDG exceedances and Foster is increased by 94 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Green Peter is 190 days and Foster is 284 days (Appendix D Figure 2-34).

#### *3.5.2.9.3 McKenzie Dams*

**Water Temperature**

There are no water temperature measures for Cougar or Blue River dams under Alternative 2B. Because of the similarities in operations and structural assumptions for Alternative 5 and Alternative 2B in the McKenzie River, refer to Appendix D Section 1.6.4.3 for a comparison of Alternative 2B and NAA water temperature effects at Cougar Dam.

Lake level and storage at Cougar in Alternative 5 was nearly identical to Alternative 2B in 2011, 2015, and 2016. Compared to NAA, Alternative 5 lake levels were lower in 2011, 2015, and 2016 to allow for proposed fish passage operations through the diversion tunnel (Appendix D Figure 1-367, Figure 1-368, and Figure 1-369). The decreased storage coincided with reduced outflows during spring and summer (Appendix D Figure 1-367). Outflows were primarily routed through the diversion tunnel in Alternative 5, except when the lake refilled to about 30 feet above the RO intake (e.g., 2011).

**TDG**

There are no TDG management measures for Alternative 5 for Cougar Reservoir. Cougar dams has a Minor Benefit under Alternative 5 as compared to the NAA (Figure 3.5-57; Table 3.5-29).

Under Alternative 5, the average number of days above 110% TDG levels at Cougar is 13 days (Appendix D Figure 2-35; Table 3.5-29). The minimal change from Alternative 5 to Alternative 2B is likely due to differences in the draft rate during the spring drawdown at Cougar (for more information, see Appendix D Section 1.5.8.3.1 and Section 3.2 Hydrologic Processes and Technical Appendix B Hydrology and Hydraulics). Observing the Annual difference in number of days above 110% of TDG exceedance Cougar is decreased by 49 days as compared to the No Action Alternative (Appendix D Figure 2-36). The Average Number of Days of Spill per year at Cougar is 29 days (Appendix D Figure 2-34).

#### *3.5.2.9.4 Middle Fork Willamette Dams*

**Water Temperature**

Alternative 5 has no water temperature measures for Hills Creek Dam. The primary differences related to the expected water temperature below Hills Creek Dam in Alternative 5 and Alternative 2B are related to the timing and extent of the lake drafting in 2015 and 2016. The differences compared to Alternative 2B in the drawdown are limited to about 2 weeks in 2015 and 2-4 weeks in 2016 (Appendix D Figure 1-370). The downstream temperature associated with these differences would likely be Minor and represented by a Minor to Negligible temporal shift (backward in time) of the temperature signal (Appendix D Figure 1-188) during June-July of 2015 and July-September of 2016. The deeper draft and use of the RO at Hills Creek in Alternative 5 during September of 2016 compared to Alternative 2B may result in warmer surface water releases during September followed by cooler releases in October as the lake is allowed to equilibrate with the ambient air sooner in the autumn. Given the brief and variable (relatively warmer and cooler) periods in which these differences from Alternative 2B occur, it is expected that Alternative 5 water temperature impacts would be likely be negligibly different than the metrics shown in Appendix D Figure 1-379, Figure 1-380, and Figure 1-381.

Lake level and storage at Hills Creek in Alternative 5 were nearly identical to Alternative 2B in 2011 and 2015. Operational differences between Alternative 5 and Alternative 2B in 2016 are likely a result of RES-SIM using Hills Creek to meet mainstem flow targets at Salem during

September. Compared to NAA, Alternative 5 lake levels were generally increased in the refill periods of 2015 and 2016 (early summer) before the lake was drafted and the power pool was utilized for downstream flow augmentation (Appendix D Figure 1-370, Figure 1-371, and Figure 1-372). The increased storage coincided with reduced outflows during spring and increased outflows in May-June during 2015 and August-October in 2016 (Appendix D Figure 1-371). 2011 operations were generally similar in Alternative 5, Alternative 2B, and NAA at Hills Creek Lake.

Alternative 5 has no water temperature measures for Lookout Point Dam and operations in Alternative 5 closely resemble those in Alternative 2B (Appendix D). It is likely that the Negligible temperature effects from Hills Creek operations would be Negligible, relatively short-lived (days to weeks) when incorporated into the proposed Alternative 5 operations at Lookout Point and Dexter Dams. Because of the similarities in operations and structural assumptions for Alternative 5 and Alternative 2B at Lookout Point, refer to Appendix D Section 1.6.4.4 for a comparison of Alternative 2B and NAA water temperature effects.

Lake level and storage at Lookout Point in Alternative 5 were similar to Alternative 2B and NAA in 2011, 2015, and 2016 (Appendix D Figure 1-373, Figure 1-374, and Figure 1-375) aside from minor differences in timing of refill and release rates that were associated with upstream Hills Creek Dam operations.

**TDG**

Under Alternative 5 there are no TDG measures for Hills Creek, Lookout Point and Dexter dams although model analysis has determined effects to the sub-basin. Lookout Point, Dexter, and Hills Creek dams would have a Negligible effect with Alternative 5 TDG measures as compared to the NAA (Figure 3.5-57; Table 3.5-29).

Middle Fork Willamette Alternative 5 TDG effects essentially match those in Alternative 2B, with Lookout Point resulting in a reduction of 0 days and on average 0 days of TDG exceedance for the year (Appendix D Figure 2-35; Table 3.5-29) compared to NAA. Dexter dam has reduction of 16 days and on average 5 days of TDG exceedance for the year (Appendix D Figure 2-35) compared to NAA. Hills Creek dam has a reduction of 3 days of Annual Difference in Number of Days above 110% and on average number of days exceeds TDG by 18 days as compared to the No Action Alternative. The Average Number of Days of Spill per year at Hills Creek is 138 days, Lookout Point is 52 days, and Dexter is 87 days (Appendix D Figure 2-34).

#### *3.5.2.9.5 Coast Fork Dams And Long Tom*

Under Alternative 5 there are no Water Temperature or TDG measures at Cottage Grove, Dorena and Fern Ridge dams, conditions would remain as described in the No Action Alternative and Water Quality Affected Environment.

#### *3.5.2.9.6 Mainstem Willamette River*

**Water Temperature**

Streamflow in Alternative 5 was nearly identical to Alternative 2B and NAA in 2011 and 2016. In 2015, alternative 5 streamflow was generally lower from April to mid-June and higher from mid-June to mid-September compared with NAA (Appendix D Figure 1-376). Streamflow at Salem was generally similar May-September in Alternative 5 compared to Alternative 2B aside from a two-week period in August of 2015, where Alternative 5 resulted in lower streamflow than Alternative 2B. Similar to Alternative 2B, flow differences between Alternative 5 and NAA were primarily in 2015 and responsive to the Measure 30 dam outflow increases in advance of heat wave events (Appendix D Figure 1-376). While temperature simulations are not available for Alternative 5, results would likely be similar to those in Alternative 2B, aside from differences provided in this section (Middle Fork Willamette operation changes in 2015 and 2016) and the two-week period in August of 2015. It is flow changes resulted in warmer water temperatures April to mid-June and cooler water temperatures from mid-June to mid-September compared with NAA in 2015 (Appendix D Figure 1-200, Figure 1-201). Water temperatures at Salem were also affected by upstream dam operations and the proposed SWS-FSS structure at Detroit Dam, which likely contributed to warmer temperatures seen in 2011 and 2015 comparing Alternative 2B to NAA. Overall water temperature differences between Alternative 2B and NAA were less than 2 degrees Celsius.

**TDG**

To the USACE knowledge, there are no TDG gages located on the Willamette River and TDG is presume not to be an issue, as this is a water quality parameter most affected by dam operations. Therefore, TDG gages are typically located downstream of WVS projects where there are known issues.

#### *3.5.2.9.7 Climate Change*

Please reference Technical Appendices B and F for Climate Change qualitative effects closely matched to Alternative 2B. Compared to the No Action Alternative, Alternative 5 would potentially increase resiliency against climate change impacts on water temperature and TDG (increased water temperature control) below Detroit as a result of the proposed SWS and TDG abatement measures at each location.

**Table 3.5-28. Summary of Effects of Alternative 5 as compared to the NAA**

| Subbasin | Alternative 5 |
|---|---|
| North Santiam | Water temperature at Detroit and Big Cliff may have similar effects as Alternative 2B compared to the NAA. A beneficial effect to TDG levels is observed at Detroit and Big Cliff. |

| Subbasin | Alternative 5 |
|---|---|
| South Santiam | Water temperature at Green Peter and Foster may have similar effects as Alternative 2B compared to the NAA. Adverse effects to TDG levels are observed at Green Peter and negligible at Foster. |
| McKenzie | Water temperature at Cougar may have similar effects to as Alternative 2B compared to the NAA. A minor benefit to TDG is observed when at Cougar. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change. |
| Middle Fork Willamette | Water temperature at Lookout Point and Dexter may have similar effects as Alternative 2B compared to the NAA. Minor differences in lake level at Hills Creek may lead to negligible differences in downstream water temperature. Fall Creek temperatures would remain as described in the NAA. A negligible effect is observed for TDG at Hills Creek, Lookout Point, and Dexter dams. |
| Coast Fork Willamette & Long Tom | There are no water temperature measures considered at Cottage Grove, Dorena, and Fern Ridge therefore conditions would remain similar to the NAA. There are no measures considered for TDG management therefore conditions would remain similar to the NAA. |
| Mainstem Willamette | Water temperature at Albany and Salem may have similar effects as Alternative 2B compared to the NAA. Water quality parameters such as TDG, Turbidity, HABs are negligible or have not been reported as a concern. |

*3.5.2.9.8 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.5.2.4, for description of effects due to the Near-Term Operations Measure.

*3.5.2.9.9 Summary of Effects*

Below is provided a summary of Alternative 5's overall water quality effects.

**Water Temperature**

Alternative 5 is based on Alternative 2B, which had the following measures that affected operations, lake storage, and water temperature: Changes to tributary targets below Foster, Detroit, Lookout Point, and Cougar that are higher than the NAA BiOp targets when those reservoirs are more than 90% full and less than the NAA BiOp when those reservoirs are less than 90% full; Changes to baseline mainstem targets at Salem and Albany while adding a Salem flow target tied to forecasted air temperature; Construct temperature control structure at Detroit; Deep fall drawdown to 35' over the regulating outlet at Green Peter, use of RO in fall, use spillway for surface spill in spring and summer; Deep spring and fall drawdown to 30 feet over the diversion tunnel at Cougar, with a limited refill window between June 15$^{th}$ and November 15$^{th}$ (essentially a delayed refill); Modifications to existing outlets at Foster Dam that would allow releases at varying depths for temperature control by modifying the Facility Warm Water Supply (FWWS) pipe and fish weirs.

RES-SIM simulations of lake levels and dam outflows were used as a basis for assessing the water temperature effects of Alternative 5 in 2011, 2015, and 2016 and are discussed in this section. The underlying assumptions in Alternative 5 were similar to Alternative 2B aside from changes to the spring flow targets at Salem that are lower than BiOp dry year targets in years when water supply forecasted flows at Salem are projected to be less than 25% of normal. This provides additional spring storage in dry years allowing for targets that closely resemble BiOp flow targets to be met in dry summers.

Given the similarities between Alternative 5 and Alternative 2B in the measures, operations, and structural assumptions for Detroit, Green Peter, Foster, and Cougar Dams, it is reasonable to assume any water temperature differences between Alternative 5 and Alternative 2B would be due to model instabilities or processing errors in RES-SIM or CE-QUAL-W2 at those locations. Refer to section Appendix D Section 1.6.4 for details regarding the differences between Alternative 2B and NAA for a description of Alternative 5 water temperature effects. Therefore, this section will focus on the differences in the Middle Fork Willamette, where Minor differences in lake level at Hills Creek may lead to Negligible differences in downstream water temperature.

A full explanation of the RES-SIM analysis and findings can be found in Section 3.2 Hydrologic Processes and Technical Appendix B Hydrology and Hydraulics. Unlike the other alternatives, water temperature simulations were not available in Alternative 5, so a qualitative assessment of potential water temperature downstream of WVS dams is provided in Appendix D Section 1.6.8. Effects are qualitatively described below.

**TDG**

Alternative 5 has no specific measures to reduce TDG. Alternative 5 is based on Alternative 2B, which had the following measures that affected operations total outflow and spill rates that contributes to TDG: Changes to tributary targets below Foster, Detroit, Lookout Point, and Cougar that are higher than the NAA BiOp targets when those reservoirs are more than 90% full and less than the NAA BiOp when those reservoirs are less than 90% full; Changes to baseline mainstem targets at Salem and Albany while adding a Salem flow target tied to forecasted air temperature; Construct temperature control structure at Detroit; Deep fall drawdown to 35' over the regulating outlet at Green Peter, use of RO in fall, use spillway for surface spill in spring and summer; Deep spring and fall drawdown to 30 feet over the diversion tunnel at Cougar, with a limited refill window between June 15$^{th}$ and November 15$^{th}$ (essentially a delayed refill); Modifications to existing outlets at Foster Dam that would allow releases at varying depths for temperature control by modifying the Facility Warm Water Supply (FWWS) pipe and fish weirs.

**Table 3.5-29. Compilation of TDG model results (Appendix D Figures 2-35;2-36;2-34; Figure 3.5-57) downstream of the dams for Alternative 5**

| Location | Average Number of Days Above 110% TDG | Annual Difference in Number of Days Above 110 % TDG compared to the No Action Alternative | Average Number of Days with Spill Per Year | Magnitude of Effects |
|---|---|---|---|---|
| DEX | 20 | 0 | 87 | Negligible |
| LOP | 0 | 0 | 52 | Negligible |
| HCR | 18 | -1 | 138 | Negligible |
| CGR | 13 | -45 | 29 | Minor Benefit |
| FOS | 126 | 94 | 284 | Negligible |
| GPR | 151 | 139 | 190 | Moderate Adverse |
| BCL | 79 | -69 | 86 | Major Benefit |
| DET | 39 | -77 | 62 | Moderate Benefit |

**Turbidity, HABs and Mercury**

Alternative 5 impacts are similar to Alternative 2B for these parameters. Refer to Alternative 2B, Section 3.5.25 for effects as these will not be described further.

## 3.6 VEGETATION

Vegetation is an important element of ecosystems providing environmental functions that are valuable to nearby human communities (e.g., improving water quality, providing shade, and controlling erosion of soils) and providing valuable habitat functions for amphibians, reptiles, birds, invertebrates, fish, and mammals. Plants are considered primary producers in the food web, providing the foundation for other organisms, including humans, and fish and wildlife species, to survive.

### 3.6.1 Affected Environment

Vegetation in the WRB is diverse and vegetative communities are associated with certain habitat types, ranging from alpine meadows and montane forest in the mountains to prairies, oak savannas, and riparian forest on the valley floor.

The area of analysis for vegetation consists of all reservoirs up to the maximum pool elevation and associated aquatic, wetland, riparian, and upland vegetative communities. In addition, the analysis area also includes project stream reaches and associated riparian vegetative communities as listed in Section 3.6.2.

All federal and state listed (listed under the endangered species act) plant species occurring in Oregon are administratively protected by the Oregon Department of Agriculture (ODA). See Section 3.6.1.2 for further detail. Table 3.6-1 shows listing status of special status plants and fungi within the Willamette basin.

#### *3.6.1.1 Existing Vegetation*

Existing vegetation in the analysis area is described here by Environmental Protection Agency (EPA) ecoregions (Thorson et al., 2003). Over the course of several iterations, the EPA worked to divide up the North American continent by different geographic areas and associated ecological communities. Each iteration split these geographic areas and ecological communities up more specifically. EPA Level III ecoregions (a level less specific than Level IV ecoregions) in the Willamette basin include 1, Coast Range; 3, Willamette Valley; and 4, Cascades (Thorson et al., 2003). However, the analysis area does not include the High Cascades or the Coast Range. EPA Level IV ecoregions, which are the most specific ecoregions, include 3b, 3c, 3d, 4a, and 4b within the analysis area. These are described below.

##### *3.6.1.1.1 Ecoregion 3: Willamette Valley*

The Willamette Valley is a wide floodplain valley at about 200 to 500 feet in elevation with fertile soils. These soils derive from deposits from the Missoula floods that took place between 20,000 and 15,000 years ago, when the ice dam that formed glacial Lake Missoula at the end of the last ice age burst repeatedly, resulting in flooding that backed up the Willamette River to present day Eugene, Oregon (Wallick et al., 2013). Historic vegetation in the valley (i.e., pre-European settlement) was a mosaic of gallery forest lining the braided and meandering

Willamette River, wet and upland prairie along the floodplains and terraces, and oak savanna in the foothills. Prairies and oak woodlands likely established during a warm climatic period after the ice age and were maintained by indigenous peoples through prescribed fire until the mid-1800s. The Willamette Valley is densely populated, containing most of Oregon's larger towns and cities surrounded by prime farmland. Consequently, only a remnant of natural vegetation exists today, with less than 2 percent of prairie and less than 1 percent of oak savanna remaining (Christy and Alverson, 2011). Those patches that remain are isolated, threatened by invasive species, and harbor numerous rare and endemic species.

##### *3.6.1.1.2 Ecoregion 3b: Willamette River and Tributaries Gallery Forest*

The Willamette River and Tributaries Gallery Forest hugs the mainstem and tributaries below about 600 feet in elevation. Most of the vegetation analysis area is in this ecoregion. Black cottonwood (*Populus balsamifera*), Oregon ash (*Fraxinus latifolia*), red alder (*Alnus rubra*), bigleaf maple (*Acer macrophyllum*), and Douglas-fir (*Pseudotsuga menziesii*) dominate what remains of the forest, with agricultural fields currently the main vegetation type. The main crops along the Willamette mainstem includes grass for seed as well as fruit and nut trees.

The majority of this ecoregion lies within the historic floodplain of the Willamette River, but revetments and reduced flooding following dam construction have reduced the effective floodplain, isolating oxbow lakes and increasing the land area available for farming and towns (Krass et al., 2021). Aquatic vegetation occurs in the Willamette River and tributaries as well as in sloughs and oxbows. Wapato (*Sagittaria latifolia*) is a culturally important species with edible tubers harvested by the Kalapuya peoples and others. Wapato is an aquatic emergent plant found in side channels and slower waters of the Willamette River. Several high priority aquatic invasive species threaten water quality and wapato. These include water primrose (*Ludwigia* spp.) and yellow floating heart (*Nymphoides peltata*) (Krass et al., 2021). Important riparian vegetative communities that include native willows (*Salix* spp.) and black cottonwood are readily established on gravel bars. Changes to these gravel bars associated with channel migration provide the conditions needed for seedling establishment depending on whether there are channel-forming flows (Wallick et al., 2013). Gravel bars also provide ideal conditions for invasion by noxious weeds including butterfly bush (*Buddleia davidii)* and purple loosestrife *(Lythrum salicariae)*.

##### *3.6.1.1.3 Ecoregion 3c: Prairie Terraces*

The Prairie Terraces ecoregion occurs on both sides of the Willamette River and once extended from Eugene to Portland, Oregon as a mosaic of wet and upland prairie supporting a diverse community of plants, animals, and insects. Nearly all of this land now consists of farms or cities, including hundreds of crop species and livestock thriving on the rich soil. Remnant prairie patches harbor numerous ESA-listed plant and animal species (USFWS, 2010). Wet prairies are dominated by tufted hairgrass (*Deschampsia cespitosa*) and support hundreds of other plant species. Sheet flow of water during winter rains occurs at these sites due to an impermeable clay layer formed by ash from the eruption of Mount Mazama, which is now Crater Lake. The recently delisted (86 FR 13200) Bradshaw's desert parsley (*Lomatium bradshawii*) occurs in

Willamette Valley and Southwest Washington wet prairies. Upland prairies were once dominated by short stature native bunch grasses such as California oatgrass (*Danthonia californica*) and Roemer's fescue (*Festuca roemeri*), but these have mostly been replaced with agricultural species including tall fescue (*Schedonorus arundinaceus*), tall oatgrass (*Arrhenatherum elatius*), and creeping bentgrass (*Agrostis stolonifera*). Upland prairies support several ESA-listed plant species, including: the threatened Kincaid's lupine (*Lupinus oreganus*), a host plant for the larva of the endangered Fender's blue butterfly (*Icaricia icarioides fenderi*); the endangered Willamette daisy (*Erigeron decumbens*), which occurs in both wet and upland prairies; and the threatened Nelson's checkermallow (*Sidalcea nelsoniana*) (USFWS, 2010).

##### *3.6.1.1.4 Ecoregion 3d: Valley Foothills*

The Valley Foothills ecoregion occurs around the valley margins and were once dominated by Oregon white oak (*Quercus garryana*) savanna mixed with California black oak (*Quercus kelloggii*) in the south valley and areas including ponderosa pine (*Pinus ponderosa*). Much of this region is now farmed for Christmas trees and wine grapes, and fire suppression has caused the oak savanna to transition to Douglas-fir forest.

##### *3.6.1.1.5 Ecoregion 4a: Western Cascades Lowlands and Valleys*

The Western Cascades Lowlands and Valleys ecoregion occurs in the lower elevations of the western slope of the Cascade Mountains from Eugene to Portland, Oregon below about 3,000 feet in elevation. This region is characterized by heavy rainfall and warm soils and supports a lush mixed conifer forest of western hemlock (*Tsuga heterophylla*) and Douglas-fir, with bigleaf maple and alder in riparian areas. Forest land in this region is a mix of private timber and Bureau of Land Management (BLM) and U.S. Forest Service (USFS) managed lands, with rural communities and farms in the valleys. Special habitats within this region support rare plant species. Some of these include seepy cliffs with Thompson's mistmaiden (*Romanzoffia thompsonii*), riparian forest with tall bugbane (*Cimicifuga elata* var. *elata*), and old growth forest with associated rare lichen and fungi species.

##### *3.6.1.1.6 Ecoregion 4b: Western Cascades Montane Highlands*

The Western Cascades Montane Highlands ecoregion occurs on the western slope of the Cascades above about 3,000 feet in elevation. This region is characterized by a wet climate with heavy winter snowfall. Forests are primarily managed by the USFS and support a mixed conifer forest of Douglas-fir, western hemlock, noble fir (*Abies procera*), and Pacific silver fir (*Abies amabilis*). Cougar, Blue River, and Hills Creek reservoirs occur at the lower elevation range of this region, but the majority of the analysis area here is below 3,000 feet.

##### *3.6.1.1.7 Vegetation in Reservoirs*

Reservoir drawdown zones, areas around the perimeter of the reservoirs where soil saturation is affected by water level fluctuations, create unique ephemeral habitat for plants and animals as well as opportunities for invasive species to rapidly spread and colonize new locations.

USACE manages the water levels in the reservoirs by typically maintaining low water in the winter and re-filling reservoirs in spring, holding water over the summer at full pool. This "backwards" hydrologic regime allows for emergent marsh to form around many reservoirs despite winter drawdowns. In recent years, drought, early draw downs (required by the 2008 Biological Opinion), and summer low water have resulted in reservoirs not filling. This has allowed for establishment of novel communities of drought-tolerant plants. Reed canary grass (*Phalaris arundinacea*) forms extensive monoculture stands covering hundreds of acres, most notably forming a ring around Fern Ridge, but also in shallower upstream portions of most reservoir pools. This species appears to expand occupied areas during low water years.

Common species in reservoir waters include reed canary grass, hardstem bulrush (*Schoenoplectus acutus*), broadleaf cattail (*Typha latifolia*), both native and introduced milfoils (*Myriophyllum* spp.), both native and introduced pondweeds (*Potamogeton* spp.), American waterweed (*Elodia canadensis*), Brazilian waterweed (*Egeria densa*), marsh seedbox (*Ludwigia palustris*), and common bladderwort (*Utricularia vulgaris).* Ephemeral drawdown zone and low water year communities often include beggar-ticks (*Bidens* spp.), cudweeds (*Gnaphalium* spp.), smartweeds (*Persicaria* spp.), spikerushes (*Eleocharis* spp.), and flatsedges (*Cyperus* spp.). Dense beds of aquatic moss (*Fontinalis* sp.) persist. Reservoir margins often support dense thickets of willows, red-osier dogwood (*Cornus stolonifera*), Douglas spirea (*Spirea douglasii*), and black cottonwood. In steeper areas, these species transition immediately to upland vegetation.

Reservoirs host several special status plant species which are listed in Table 3.6-1. Special Status Plant and Fungi Species Occurring in the Analysis Area and described by subbasin in Section 3.6.1.4. Invasive species of concern are listed in Table 3.6-22, and notable species are discussed by subbasin in Section 3.6.1.4.

##### *3.6.1.1.8 2020 Wildfires*

In September of 2020, large catastrophic wildfires altered vegetation and devastated communities in the North Santiam (Beachy Creek Fire) and McKenzie (Holiday Farm Fire) watersheds. These fires burned hot, killing most trees and altering the landscape and vegetation for years to come. Most burned areas were within Ecoregion 4a and included mainly private timber lands and federally managed forests. Salvage logging and hazard tree removal operations are currently in process.

##### *3.6.1.1.9 Historic Vegetation in the Willamette Valley*

Vegetation of Oregon's Willamette Valley has been dramatically altered since the time of pre-Euro-American settlement, approximately 150 years ago. The native plant communities in the valley likely developed at the end of the last ice age and Missoula floods as the climate warmed and prairie plant communities were established. The Willamette Valley is within the traditional territory of the Kalapuya people (Berreman, 1937), and indigenous people managed and maintained the landscape using frequent fires to keep prairies and woodlands open from about 9,300 to 200 B.P. (Walsh et al., 2010). This was most likely done to maintain populations of plants such as camas (*Camassia* spp.), an important starchy tuber and food source, and to open the landscape for hunting. Wapato tubers, which grow in shallow water and thrive in sloughs and oxbows along the Willamette River, were another important food source (Krass et al., 2021).

Beginning in 1850, the General Land Office (GLO) of the U.S. government surveyed land in the west, resulting in the township and range system. These surveys often included information on vegetation, and Christy and Alverson (2011) used these to reconstruct the vegetation of the Willamette Valley at that time. By 1850, only about 4 percent of the valley had been converted to farms, and 1 percent was affected by logging, so this represents a snapshot of the major vegetation types prior to land conversion. This work resulted in a map of the valley showing a riparian corridor (7 percent of analysis area) along the Willamette River, flanked by extensive prairies (31 percent) and savanna (18 percent), with woodlands (13 percent) and upland forest (26 percent) in the foothills (Figure 3.6-1. ).

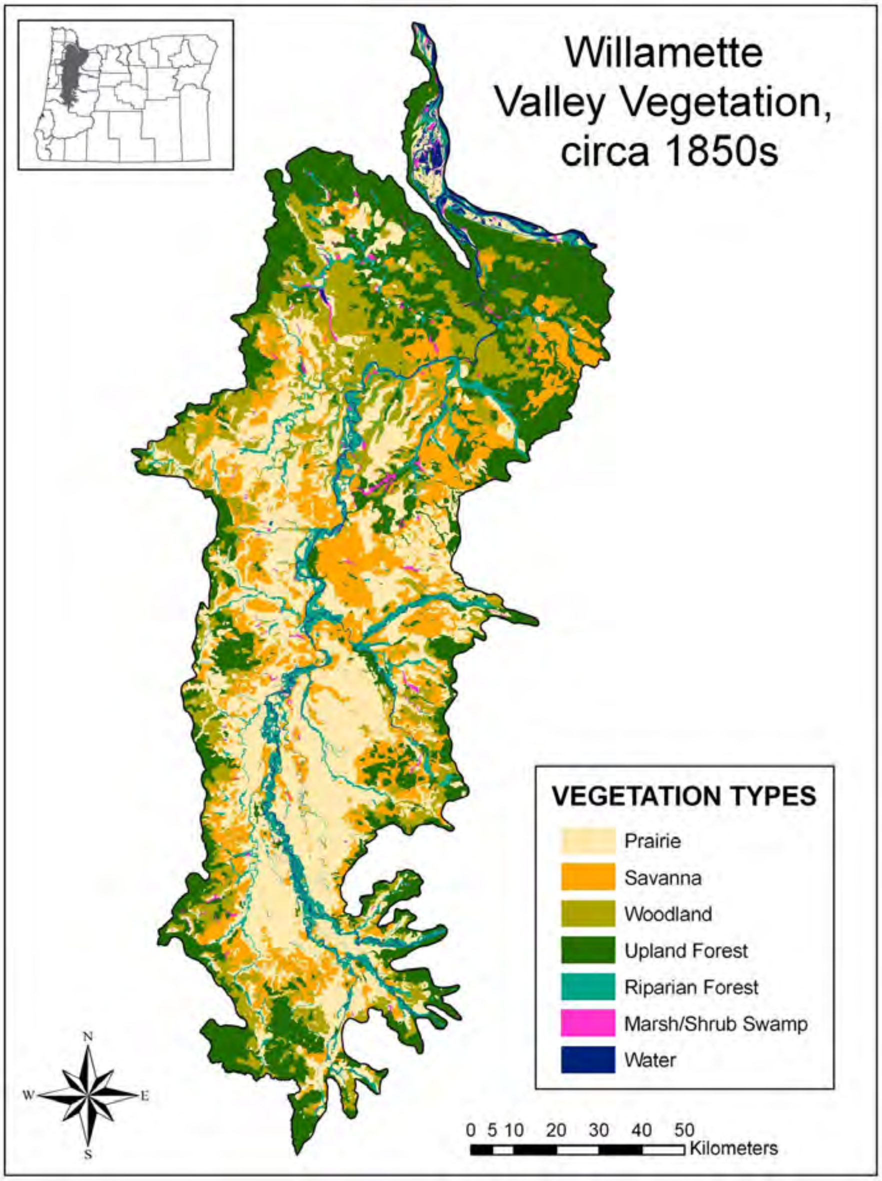

**Figure 3.6-1. Willamette Valley vegetation, circa 1850s.**

Source: ORBIC, 2019

1.ESA = Endangered Species Act, SOC = Species of Concern, LT = Listed as Threatened, LE = Listed as Endangered, C = Candidate

2. ORBIC = Oregon Biodiversity Information Center (ratings explained in Section 3.6.1.2.)

3. OCS = Oregon Conservation Strategy Species

4. NS = North Santiam, SS = South Santiam, MK = McKenzie, MF = Middle Fork, CF = Coast Fork, LT = Long Tom, MW = Mainstem Willamette; numbers shown for each subbasin represent number of observed occurrences of each species.

Note: This table excludes historic and suspected extirpated occurrences. Locations may have been counted in more than one subbasin if near a confluence.

#### *3.6.1.2 **Special Status Plant and Fungi Species***

The U.S. Army Corps of Engineers (USACE) identifies special status species within Operating Projects such as those within the Willamette Valley System (WVS) under Engineering Regulation (ER) 1130-2-540. Special status plant species include those listed by USFWS under the ESA as Threatened, Endangered, Candidate, or Species of Concern (Federally listed); the State of Oregon as Endangered, Threatened, or Candidate (State listed); the Oregon Biodiversity Information Center (ORBIC) as 1 or 2; or Oregon Conservation Strategy (OCS) species. ESA is the regulation that requires Federal and State to protect species and associated habitats. Therefore, the Federal and State governments maintain lists of species that receive protection under the ESA. ORBIC helps protect species and habitats in Oregon by mapping rare species locations and ranking species by their rarity and risk of extirpation. An ORBIC rank of "1" means that the species is considered to be threatened or endangered throughout its range; and an ORBIC rank of "2" means that the species is considered to be threatened, endangered, or extirpated from Oregon, but secure or abundant elsewhere (ORBIC, 2019). OCS species are those that ODFW has determined are of the greatest conservation need in Oregon (ODFW, 2021).

**Error! Reference source not found.**1 lists the sensitive plant and fungi species found in the study area. ORBIC maintains Oregon's geo-database of sensitive species and was used to generate the plant and fungi sensitive species occurrences in **Error! Reference source not found.**1. A selection of all species of plants and fungi occurring within one mile of the project area was created using the following data sources with the ArcGIS select-by-location tool: the WVS project boundaries, the Slices Framework two-year floodplain dataset (Hulse et al., 2002), and Willamette River tributary stream reaches between the 13 dams of the WVS and the mainstem Willamette River (these lines were selected from the National Hydrography Dataset: USGS, 2021). The Slices Framework is a spatially explicit system for tracking changes in the Willamette River and its floodplain used for conservation and restoration planning, accessed through the Oregon Explorer Natural Resources Digital Library. Additional occurrences identified on USACE lands were added by USACE project botanists.

##### *3.6.1.2.1 Focus Special Status Plant Species*

While the survival of most of the species in **Error! Reference source not found.**1 does not rely on the altered hydrologic regime around the dams and reservoirs due to their location in upland habitats, some do. These include aquatic, wetland, and wet prairie species. These are discussed in greater detail by subbasin in Section 3.6.1.4. The following are species that may rely on the current hydrologic regime.

Water howellia (*Howellia aquatilis*) is an aquatic plant that was listed as threatened under the ESA in 1994 and by the State of Oregon. It is also an OCS species. One current occurrence is within the analysis area in a fen along the mainstem Willamette River near Canby, Oregon. Several historic collections were also located along the Willamette River. Habitat for water howellia is restricted to small vernal pools, freshwater wetlands, and old river oxbows with an annual cycle of drying in summer and filling with water in winter. Much of the habitat in Oregon was lost due to land conversion, hydrologic changes after dam construction, and river channelization. Since stable populations exist outside of Oregon, water howellia has been Federally delisted as of July 16, 2021 (86 FR 31955).

Other aquatic species that rely on the current hydrologic regime include three-colored monkeyflower (*Diplacus tricolor*)*,* dotted smartweed *(Persicaria punctata),* toothcup (*Rotala ramosior),* pale bullrush (*Scirpus pallidus),* drooping bullrush (*Scirpus pendulus),* humped bladderwort (*Utricularia gibba),* dotted watermeal (*Wolffia borealis),* Columbia watermeal (*Wolffia columbiana),* wheel fruited water-starwort (*Callitriche trochlearis),* and waterthread pondweed *(Potamogeton diversifolius).* These species are not State or Federally listed, but all are on ORBIC list 2.

Wet prairie habitat is less reliant on the current hydrologic regime, as precipitation is the primary hydrologic driver in these sites. Keeping the water levels low within the reservoirs may alter local hydrology, which may change the wet prairie plant community over time. This scenario most likely is currently occurring at Fern Ridge, where wet prairie (protected as a Research Natural Area) is only a few inches above the elevation of the reservoir when it is full. USACE biologists have observed extremely dry conditions at these sites following two years of low water during the summer as well as a spring drought in 2021. Wet prairie species are noted in **Error! Reference source not found.**1 and include several Federal and State listed species.

Reservoir drawdown zones support a unique ephemeral flora around lake margins. USACE biologists and others (biologists not affiliated with the USACE) have located several sensitive plant species in these areas including Howell's montia (*Montia howellii)*, a State candidate, and several ORBIC list 2 bryophytes including bending Bruch's moss (*Bruchia flexuosa)* and serrated earth moss (*Ephemerum serratum)*.

A few water-loving sensitive plants occur in seeps and wet cliffs along the Willamette River and tributaries. Species include Oregon sullivantia (*Sullivantia oregana),* a Federal and State species of concern, and Thompson's mistmaiden (*Romanzoffia thompsonii)* and Alaskan singlespike sedge (*Carex scirpoidea* ssp. *stenochlaena,* ORBIC list 2).

#### *3.6.1.3 Invasive Plant Species*

Invasive plant species are a major threat to agriculture, native ecosystems, and rare species worldwide. As humans travel and engage in commerce, novel species arrive in new locations. Many of these species are not suited to the new locations, but a few are able to flourish and may outcompete native plant species. The Willamette Valley is hospitable to a wide range of invasive plant species due to a mild climate and a number of introductions that have happened over time. The Oregon Department of Agriculture (ODA) maintains the State noxious weed list and has rated weeds accordingly:

- A-Listed Weed: A weed of known economic importance which occurs in the state in small enough infestations to make eradication or containment possible; or is not known to occur, but its presence in neighboring states make future occurrence in Oregon seem imminent.
- B-Listed Weed: A weed of economic importance which is regionally abundant, but which may have limited distribution in some counties.
- T-Designated Weed: A designated group of weed species that are selected and will be the focus for prevention and control by the Noxious Weed Control Program. Action against these weeds will receive priority. T-designated noxious weeds are determined by the Oregon State Weed Board and directs ODA to develop and implement a statewide management plan. T-designated noxious weeds are species selected from either the A or B list.
- Weed Biological Control (bio): Oregon implements biological control, or "biocontrol" as part of its integrated pest management approach to managing noxious weeds. This is the practice of using host-specific natural enemies such as insects or pathogens to control noxious weeds (ODA, 2020).

The WVS manages weeds using Integrated Pest Management (IPM) as outlined in the ER 1130-2-540, the 2009 USACE Invasive Species Policy (USACE, 2009), and a local Draft IPM plan. Invasive species management with pesticides (including herbicides) also requires compliance with the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA) and the Clean Water Act National Pollutant Discharge Elimination System (NPDES) Permit for aquatic applications.

#### *3.6.1.3.1 Willamette Invasive Plants*

Invasive plant species listed by ODA and known to occur within one mile of the analysis area are listed in Table 3.6-22 as well as their ODA noxious weed rating and presence regionally and across the WVS. Locations were discovered using a combination of online tools including the ODA Weed Mapper (ODA, 2021) and the OregonFlora Project Mapper (OregonFlora, 2021). Some species may no longer occur in the analysis area due to successful eradication. Invasive plant species of particular concern are discussed by subbasin in the next section.

**Table 3.6-2. Noxious Weeds Occurring in the Vegetation Analysis Area**

| Scientific Name | Common Name | Is it aquatic? | ODA Noxious[1] | Project or Regional Presence |
|---|---|---|---|---|
| *Abutilon theophrasti* | velvetleaf | No | B | Long Tom and Mainstem |
| *Acroptilon repens* | Russian knapweed | No | B, bio | Salem near Santiam, 1 record |
| *Adonis aestivalis* | pheasant's eye | No | B | Eugene and Corvallis - Historic |
| *Ailanthus altissima* | tree of heaven | No | B | Hills Creek fire camp, Mainstem Willamette in Eugene and Portland |
| *Alliaria petiolata* | garlic mustard | No | B, T | Benton County and Portland |
| *Ambrosia artemisiifolia* | ragweed | No | B | Eugene to Columbia River |
| *Amorpha fruticosa* | indigo bush | No | B | Portland |

| Scientific Name | Common Name | Is it aquatic? | ODA Noxious[1] | Project or Regional Presence |
|---|---|---|---|---|
| *Brachypodium sylvaticum* | false-brome | No | B | Ubiquitous |
| *Buddleia davidii* | butterfly bush | No | B | Ubiquitous |
| *Butomus umbellatus* | flowering rush | Aquatic | A | Arlington |
| *Carduus nutans* | musk thistle | No | B, bio | Oakridge, Molalla River |
| *Carduus pycnocephalus* | Italian thistle | No | B | Coast Fork Willamette, Willamette Mainstem |
| *Centaurea calcitrapa* | purple star-thistle | No | A, T | Portland |
| *Centaurea diffusa* | diffuse knapweed | No | B, bio | Lane County |
| *Centaurea jacea notho* subsp. *pratensis* | meadow knapweed | No | B, bio | Ubiquitous |
| *Centaurea stoebe* ssp. *micranthos* | spotted knapweed | No | B, T, bio | Cougar, Hills Creek, Forest Service managed |
| *Centaurea solstitialis* | yellow starthistle | No | B, bio | Lane, once plus 2011 LOP |
| *Chondrilla juncea* | rush skeletonweed | No | B, T, bio | I-5, near LOP |
| *Cirsium arvense* | Canada thistle | No | B, bio | Ubiquitous |
| *Cirsium vulgare* | bull thistle | No | B, bio | Ubiquitous |
| *Clematis vit-alba* | old man's beard | No | B | Coast, Valley |
| *Conium maculatum* | poison hemlock | No | B, bio | Ubiquitous |
| *Convolvulus arvense* | field bindweed | No | B, bio | Ubiquitous |
| *Cynoglossum officinale* | houndstounge | No | B | Near BCL and HCR |
| *Cyperus esculentus* | Yellow nutsedge | No | B | Albany to Confluence |
| *Cytisus scoparius* | Scotch broom | No | B, bio | Ubiquitous |
| *Cytisus striatus* | Portuguese broom | No | B, T | West Eugene and East of Salem |
| *Daphne laureola* | spurge laurel | No | B | CTG, FOS - Menear's Bend |
| *Echium plantagineum* | Paterson's curse | No | A, T | Linn County |
| *Egeria densa* | South American waterweed | Aquatic | B | FRN, mainstem |
| *Euphorbia oblongata* | oblong spurge | No | A, T | FOS - Road Shoulder between Sunnyside and Lewis Parks, Along WR north of Albany |
| *Galega officinalis* | goatsrue | No | A, T | Portland, OR |
| *Genista monspessulana* | French broom | No | B, bio | Lane County |
| *Geranium lucidum* | shining geranium | No | B | Fern Ridge, Dorena, Cottage Grove |
| *Geranium robertianum* | herb robert | No | B | FOS, GPR, Portland |
| *Glyceria declinata* | low mannagrass | Aquatic | - | FRN, Polk County |
| *Hedera helix* | English Ivy | No | B | Ubiquitous |

| Scientific Name | Common Name | Is it aquatic? | ODA Noxious[1] | Project or Regional Presence |
|---|---|---|---|---|
| *Hedera hibernica* | Irish ivy | No | B | ubiquitous: the common ivy in PNW |
| *Heracleum mantegazzianum* | giant hogweed | No | A, T | Oakridge, Eugene, and Portland |
| *Hieracium aurantiacum* | orange hawkweed | No | A, T | 2 Portland records, otherwise not in project area |
| *Hypericum perforatum* | St. John's wort | No | B, bio | Ubiquitous |
| *Impatiens glandulifera* | policeman's helmet | No | B | Portland, OR |
| *Iris pseudacorus* | yellow flag iris | Aquatic | B | Ubiquitous |
| *Lamiastrum galeobdelon* | yellow archangels | No | B | Coast Fork Willamette, Middle Fork Willamette, McKenzie River, FRN, Portland |
| *Lathyrus latifolius* | everlasting peavine | No | B | Ubiquitous |
| *Lepidium chalepense* | lens-podded whitetop | No | B | Corvallis, OR |
| *Lepidium latifolium* | perennial pepperweed | No | B, T | Portland, OR |
| *Linaria dalmatica* | dalmatian toadflax | No | B, T, bio | Portland |
| *Linaria vulgaris* | yellow toadflax | No | B, bio | Mainstem Willamette Eugene to Portland |
| *Ludwigia* spp. | primrose willow | Aquatic | B, T | FRN, Long Tom, Mainstem Willamette to Portland |
| *Lysimachia vulgaris* | garden yellow loosestrife | No | A, T | Willamette River North of Salem |
| *Lythrum salicariae* | purple loosestrife | No | B, bio | FRN, Long Tom, Mainstem Willamette, and North and South Santiam. |
| *Myriophyllum aquaticum* | parrot feather | Aquatic | B | FRN, DOR, Mainstem Willamette |
| *Myriophyllum spicatum* | Eurasian watermilfoil | Aquatic | B | FRN and Mainstem Willamette |
| *Nymphoides peltata* | yellow floatingheart | Aquatic | A | Springfield millrace |
| *Onopordum acanthium* | Scotch thistle | No | B | Ubiquitous |
| *Orobanche minor* | Small broomrape | No | B | Portland |
| *Phragmites australis* ssp. *australis* | common reed | Aquatic | B | Portland |
| *Pilosella cespitosum* | meadow hawkweed | No | B, T | South Santiam and Portland |
| *Fallopia cuspidatum* | giant knotweed | No | B | establishing |
| *Fallopia japonicum* | Japanese knotweed | No | B | establishing |
| *Fallopia sachalinense* | giant knotweed | No | B | establishing |

| Scientific Name | Common Name | Is it aquatic? | ODA Noxious[1] | Project or Regional Presence |
|---|---|---|---|---|
| *Fallopia* X *'bohemicum'* | giant knotweed | No | B | Fern Ridge, Cottage Grove office, Dorena roadsides |
| *Potentilla recta* | sulphur cinquefoil | No | B | Middle Fork Willamette and around Portland |
| *Pueraria lobata* | kudzu | No | A, T | Canby and Portland along Willamette |
| *Ranunculus ficaria* | lesser celandine | No | B | DOR, Middle Fork Willamette, Mainstem, Portland |
| *Rorippa sylvestris* | creeping yellow cress | No | B | Canby and near FRN |
| *Rubus* spp. | introduced blackberries | No | B | Ubiquitous |
| *Sagittaria platyphyla* | delta arrowhead | Aquatic | A, T | Portland |
| *Salvia aethiopsis* | Mediterranean sage | No | B, bio | Near GPR and BCL |
| *Senecio jacobaea* | tansy ragwort | No | B, T, bio | Ubiquitous |
| *Silybum marianum* | milkthistle | No | B, bio | Jasper-Lowell Road and Mainstem Willamette |
| *Solanum rostratum* | bufflaobur | No | B | Portland |
| *Spartium junceum* | Spanish broom | No | B | Near DOR |
| *Taeniatherum caput-medusae* | medusa-head rye | No | B | Ubiquitous |
| *Tribulus terrestris* | puncturevine | No | B, bio | Eugene |
| *Tripidium ravennae* | ravennagrass | No | A, T | Corvallis |
| *Ulex europaeus* | gorse | No | B, T, bio | Powerline near Pleasant Hill |
| *Ventanata dubia* | ventanata grass | No | B | Fern Ridge, DOR, widespread in Willamette Valley |
| *Xanthium spinosum* | spiny cocklebur | No | B | Eugene to Portland |

1. For an explanation of the ODA weed ratings see Section 3.6.1.3.

### 3.6.1.4 Subbasin Plant community Descriptions

The WVS consists of seven subbasins: North Santiam, South Santiam, McKenzie, Middle Fork Willamette, Coast Fork Willamette, Long Tom, and Mainstem Willamette. The vegetative communities for each of these subbasins is described in more detail below.

#### *3.6.1.4.1 North Santiam Subbasin*

The North Santiam Subbasin, east of Salem, Oregon is dominated by coniferous forest on steep terrain around Detroit and Big Cliff reservoirs, and grades to flatter farmland and valley floor downstream. The forested lands are in the 4a ecoregion and managed mostly for private timber lands and federally managed forest. Downstream lands grade into ecoregions 3b, 3c, and 3d.

Much of the watershed was burned in the 193,573-acre Beachy Creek Fire and western portion of the Lionshead Fire (204,469 acres) in September 2020. Nearly all of the land surrounding Big

Cliff was burned to the water, and the north side of Detroit and the town of Detroit were also burned. The Beachy Creek Fire burned downstream of Big Cliff to the town of Lyons. Details and maps are available on InciWeb (NWCC, 2021).

No current locations of special status plant or fungi species have been found within a mile of the Detroit or Big Cliff Reservoirs either by USACE biologists or in the 2019 ORBIC database (ORBIC, 2019). Downstream along the North Santiam River, several wet and upland prairie species occur within one mile of the river (see **Error! Reference source not found.**1). A forest with large trees and old growth structure occurs on USFS managed lands along the south side of Detroit Reservoir. Seepy cliffs occurring at both Big Cliff and Detroit reservoirs and likely have not been surveyed for plants.

No noxious weeds of particular concern were identified in the North Santiam subbasin apart from the usual ubiquitous species (see Table 3.6-22).

#### *3.6.1.4.2 South Santiam Subbasin*

The South Santiam Subbasin, east of Albany, Oregon is dominated by coniferous forest on steep terrain around Foster and Green Peter reservoirs, and grades to flatter farmland and valley floor downstream. The forested lands are in the 4a ecoregion and managed mostly for private timber lands and Federally managed forest. Downstream lands grade into ecoregions 3b, 3c, and 3d.

Several special status species occur on USACE lands around Foster and Green Peter reservoirs and downstream. These include tall bugbane, Howell's montia (a State candidate species), and several ORBIC list 2 species (see **Error! Reference source not found.**1). A small pond between Foster Reservoir and N River Road near Lewis Creek Park was found to contain three rare aquatic species, humped bladderwort, dotted watermeal, and Columbia watermeal. The pond is separated from Foster Reservoir. Green Peter Reservoir is mostly surrounded by forest dominated by Douglas-fir. USACE managed lands support stands of big trees with old growth structure and other special habitats.

Invasive plant species Mediterranean sage (*Salvia aethiopsis*), meadow hawkweed (*Pilosella cespitosum*, both are B list weeds), and oblong spurge (*Euphorbia oblongata*, an A list weed) have been found in the South Santiam subbasin but not elsewhere in the Willamette Valley. Equipment cleaning and monitoring could help prevent spread of these and other invasive species.

#### *3.6.1.4.3 McKenzie Subbasin*

Blue River and Cougar reservoirs occur in ecoregions 4a and 4b in the western Cascades. The McKenzie River flows west through forest and small communities, then into the Willamette Valley and the Willamette River near Coburg, Oregon. In September 2020, much of the McKenzie watershed was burned in the 173,393-acre Holiday Farm Fire. Forested areas and vegetation burned to the river in most places from just downstream of the town of McKenzie

Bridge to downstream of Vida, Oregon. Nearly all the land around Blue River Reservoir was burned. Details and maps are available on InciWeb (NWCC, 2021).

Several special status species occur around the reservoirs but are not aquatic species. These are all State candidate and ORBIC list 2 species (see **Error! Reference source not found.**1). Shaddy horkelia *(Horkelia congesta ssp. congesta)*, an SOC and State candidate, and wayside aster (*Eucephalus vialis)*, a Federal SOC and State threatened species, occurring near the confluence with the Willamette River.

No noxious weeds of particular concern were identified in the North Santiam subbasin except the usual ubiquitous species (see Table 3.6-22).

### *3.6.1.4.4 Middle Fork Willamette River Subbasin*

The middle fork of the Willamette River drains a large watershed, and the analysis area includes all previously described ecoregions (3b, 3c, 3d, and 4a). Much of the land around Lookout Point and Hills Creek reservoirs is managed by the USFS, with USACE land and private timber near Fall Creek and Dexter. The towns of Lowell and Dexter are adjacent to Dexter Reservoir, and small farms, prairies, and woodlands occurring downstream. The confluence with the Coast Fork occurs near Mt. Pisgah and is in conservation management by local non-profit groups working to restore flows and native vegetation to old gravel mine sites along with restoration in upland areas.

In terms of special status species, Howell's montia (state candidate) is known to occur in multiple locations around the reservoirs, including a large population found growing on the exposed lakebed at the Hardesty Mountain trailhead during a site visit. This tiny early spring annual plant is likely found in ideal conditions on the exposed mud, but only a few plants were located on a later visit to the same location by USACE biologists. Dotted smartweed occurs in a pond downstream of Hills Creek. Several upland ORBIC list 2 species and tall bugbane occuring around these reservoirs. Special status species habitats in this watershed include oak balds, sunlit canopy openings in mature and old forests, seepy cliffs, and old growth forest in the 4a ecoregion as well as prairies and woodlands downstream.

Invasive species of concern include Sulphur cinquefoil (*Potentilla recta*) and tree of heaven (*Ailanthus altissima*) at Hills Creek, and a report of gorse (*Ulex europaeus*) near Pleasant Hill. Suphur cinquefoil has been found at Lookout Point and Fall Creek as well.

### *3.6.1.4.5 Coast Fork Subbasin*

Cottage Grove and Dorena reservoirs are located at the transition from ecoregion 3 to 4 at the south end of the Willamette Valley within the Coast Fork Subbasin. These reservoirs are surrounded by a combination of upland prairie, woodland, and conifer forest, and USACE lands are surrounded mostly by private farms and timber lands. Downstream the rivers are bordered by forests, farms, and the town of Cottage Grove.

Wayside aster, a Federal SOC and State Threatened species, occurs in several locations near both reservoirs in upland areas. Shaggy horkelia, a Federal SOC and State candidate, occurs near Dorena, above the maximum water surface elevation of the reservoir. Shaggy horkelia also occurs near the confluence of the Row River and Coast Fork Willamette River. Bradshaw's desert parsley (*Lomatium bradshawii,* ESA-delisted in 2019 and State Endangered) occurs nearly a mile from the Coast Fork Willamette in proximity to the confluence of the Coast Fork with the Middle Fork. Thin-leaved peavine (*Lathyrus holochlorus)*, a Federal SOC, occurs in four locations in this watershed mostly near water in forested areas. Several other State candidate and ORBIC list 1 species occuring in this subbasin as well (see **Error! Reference source not found.**1).

No noxious weeds of particular concern were identified in the Coast Fork Subbasin apart from the usual ubiquitous species (see Table 3.6-22).

### *3.6.1.4.6 Long Tom Subbasin*

Fern Ridge Reservoir, the only reservoir located west of the Willamette River, is a wide shallow reservoir on the Long Tom River. Prior to dam construction in 1942, the land consisted mostly of farms, prairies, and gallery forest (i.e., formed as a corridor along a river). Current vegetation surrounding Fern Ridge Reservoir is a mix of ecoregions 3b, 3c, and 3d, with some conifer forest of Douglas-fir and ponderosa pine. The Long Tom River below Fern Ridge dam was channelized by the USACE and is lined by a narrow strip of forest or is immediately adjacent to farmland in places.

Wet and upland prairies in this subbasin support numerous Federally listed and ORBIC listed species, much of which are protected as a Research Natural Area and/or designated critical habitat for Fender's blue butterfly (USFWS, 2010). These sites are located above the maximum water level of the reservoir and are managed in accordance with a Biological Opinion from USFWS (USFWS, 2011). Several ORBIC list 2 aquatic species occuring in these wet and upland prairies (see **Error! Reference source not found.**1).

Invasive primrose willow (*Ludwigia spp.*) has been found in the Long Tom River and has mostly been removed. One small patch was discovered and eradicated in Fern Ridge Reservoir, and surveys have not identified any more. Preventing this species from establishing in Fern Ridge Reservoir is a high priority. Parrot feather (*Myriophyllum aquaticum*), yellow flag iris (*Iris pseudacorus*), South American waterweed (*Egeria densa*), and Eurasian watermilfoil (*Myriophyllum spicatum*) are all common in and around Fern Ridge Reservoir.

### *3.6.1.4.7 Mainstem Willamette River Subbasin*

From the confluence of the Coast and Middle Forks, the Willamette River flows northward through the wide, relatively flat Willamette Valley through major towns and farms to Portland. In many places, narrow strips of gallery forest line the river, while in other locations farms and towns are immediately adjacent to the riverbanks. Parks and conservation areas provide larger forested stretches along with other types of habitats. Numerous old oxbows and sloughs have been isolated from the river but may connect during high flows. These may be sources of invasive species spread but many also contain sensitive species. Wet and upland prairie occuring near the river as well.

Water howellia (a Federally delisted and State threatened species) occurs in a fen near Canby, Oregon just west of the mainstem Willamette River. Other ESA-listed species occurring near the Mainstem Willamette River and within the two-year floodplain, especially in prairies, but with habitat occurring outside of the river channel. Numerous ORBIC list 1 and 2 species occurring along the Willamette River, including many aquatic species (see **Error! Reference source not found.**1).

In terms of invasive plant species occurring within this subbasin, there are many including but not limited to: primrose willow, yellow floating heart, milfoils, and loosestrife occurring in this subbasin (Krass, 2021).

### 3.6.2 Environmental Consequences

This section discusses the potential effects of the alternatives on vegetation. The area of analysis for vegetation consists of all reservoirs up to the maximum pool elevation and associated aquatic, wetland, riparian, and upland vegetative communities. The analysis area also includes the following stream reaches and associated riparian zones:

- Middle Fork Willamette River downstream of Hills Creek Dam to the confluence with the Coast Fork Willamette River;
- Coast Fork Willamette River downstream of Cottage Grove Dam to the confluence with the Middle Fork Willamette River;
- Row River from downstream of Dorena Dam to the confluence with the Coast Fork Willamette River;
- South Fork McKenzie River downstream of Cougar Dam to the confluence with the McKenzie River;
- McKenzie River from the South Fork McKenzie River confluence to the confluence with the Willamette River;
- Blue River downstream of Blue River Dam to the confluence with the McKenzie River;
- Long Tom River downstream of Fern Ridge Dam to the confluence with the Willamette River (includes Coyote Creek from Fern Ridge Dam to the confluence with the Willamette River);
- South Santiam River downstream of Foster Dam to the confluence with the North Santiam River;
- North Santiam River downstream to the confluence with the South Santiam River;
- Santiam River to the confluence with the Willamette River; and
- Willamette River mainstem to Willamette Falls.

For the purpose of more accurately characterizing of the potential occurrence of special status and invasive plant species, a 1-mile buffer surrounding the analysis area was used. The discussion below includes the qualitative methods to evaluate effects to vegetation for each alternative.

### 3.6.3 Methodology

The method used to assess the existing conditions and the alternatives' effects to vegetation was a qualitative analysis based on species presence or absence or suitable habitat present as shown in ORBIC data and direct coordination with USACE biologists in the Willamette Valley who have expertise in both common and rare plant species and conduct routine monitoring of vegetative communities throughout the WVS analysis area. It should be noted that federally ESA-listed plant species would not be affected by any of the alternatives presented in this document because these plants are only located near the analysis area in the vicinity of Fern Ridge. Operations at Fern Ridge would not be modified in any way that would affect these plants for any alternative.

Potential effects to vegetative communities within the WVS analysis area entail indirect effects related to hydrology, sediment transport, erosion, invasive species, and slope failure. Climate change is also anticipated to affect vegetative communities within the WVS over time and is analyzed for each alternative though it is not a result of any of the USACE-proposed alternatives.

Direct effects to vegetation may be included as part of specific construction activities during implementation; however, this PEIS will discuss general qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects during the implementation phase and any applicable permits would be obtained at that time. Direct adverse effects to vegetation associated with construction would include clearing and grubbing for the construction areas or access roads. Following the completion of construction actions that disturb vegetation, areas would be restored with native plants and seed to the extent possible, which would potentially benefit vegetative communities.

The following measures have an effect on vegetation within the WVS analysis area:

- Gravel augmentation below dams (#384);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b);
- Augment instream flows by using the inactive pool (#718);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);

- Augment instream flows by using the power pool (#304);
- Deeper fall reservoir drawdowns to fish passage (#40); and
- Spring reservoir drawdown for downstream fish passage (#720).

Measures that would not likely affect vegetation as part of the WVS O&M program include the following: Adapt Hatchery Program (#719), Maintenance of existing and new fish release sites above dams (#726), Construct adult fish facility (#722), Construct water temperature control tower (#105), Use ROs to discharge colder water (#166), Structural improvements to reduce TDG (#174), Foster Fish Ladder Temperature Improvement (#479), Use spillway for surface spill in summer (#721), Construct structural downstream fish passage (#392), Pass water over spillway in spring for fish passage (#714), Provide Pacific lamprey passage and infrastructure (#52), and Restore upstream and downstream passage at drop structures (#639). These measures are not discussed further in regard to effects to vegetation.

**All comparisons of magnitude or duration in the effects analysis for each action alternative are in comparison to the NAA unless stated otherwise.**

**Error! Reference source not found.**3 describes the evaluation criteria for the effect factors (magnitude and duration) and provides a definition for the scale of each effect factor.

**Table 3.6-3. Evaluation Criteria for Potential Effects to Vegetation**

| Effect Scale | Definition |
|---|---|
| **Magnitude** | |
| None/Negligible | Vegetative communities would remain unchanged and no effects would be observable. |
| Minor | Effects to vegetation would be observable (e.g., signs of erosion, changes in vegetation types, sediment deposits over previously vegetated areas) though the effects would be small and localized. |
| Moderate | Effects to vegetative communities would be observable at a regional scale but not be easily measured (e.g., changes to species composition). |
| Major | Effects to vegetation would be readily observable and measurable (e.g., obvious changes in vegetated area and species composition) and would have substantial ecological consequences (e.g., dominance of invasive plant species) at a regional level. Mitigation measures to reduce the adverse effects would be required, though long-term adverse effects to vegetative communities would be expected. |
| **Duration** | |
| Short-term | Disturbance to vegetation would be short in duration, lasting only as long as a discreet construction project or single event in an area. |
| Long-term | Disturbance to vegetation would be ongoing or last beyond operation changes or the completion of a discreet construction project. |

### *3.6.3.1 No Action Alternative*

Vegetation effects associated with the No Action Alternative are related to the current hydrologic regime of the WVS. The current hydrologic regime is the opposite of the natural hydrologic regime. The WSE is the highest within the reservoirs from May through September when the maximum conservation pool is being maintained, whereas naturally this would be the driest time of year within the reservoir area. Summertime reservoir storage has both an adverse and a beneficial effect on vegetation. These effects are minor and long-term. Maximum reservoir storage covers more physical area with water, which means only plant species tolerant of inundation (aquatic plants) can grow in these large areas. The beneficial effect to vegetation associated with maximum summertime reservoir storage is that there is more water available in the soil to support a plant community around the reservoir, which would not be there otherwise because summer precipitation is low throughout the WVS.

Within the WVS, downstream flows are managed so that wintertime flooding, which would naturally occurring without the dams, is mitigated. In addition, revetments within the WVS help ensure that banks are not overtopped in any sort of high flow event. These flood mitigation actions limit the hydrologic connectivity across the floodplains of WVS streams. Therefore, riverine wetlands, off-channel areas, backwater sloughs, and oxbows, that support a diverse plant community, experience drier conditions than they would outside of a managed system and rely more on precipitation than they would otherwise.

#### *3.6.3.1.1 Climate Change*

Climate change is anticipated to lead to wetter winters (increased precipitation) and drier summers (increased temperature and evapotranspiration) which would adversely affect vegetation in the Willamette Valley independent of the WVS operation and maintenance actions over the course of the next 30 years. Effects include increased frequency of wildfires and lower plant survival rates due to drought. A plant community will persist within the WVS analysis area but would likely change in composition with more drought tolerant species becoming increasingly predominant throughout the region. As the plant community changes, invasive plants species are anticipated to move into areas where the native vegetative communities have shrunk. Additionally, climate change is anticipated to continue to increase water temperature over time as air temperatures increase and snowmelt contributes less runoff within the basin. In terms of vegetation, increased water temperatures means a greater frequency of algal blooms, which can adversely affect phytoplankton through shade since phytoplankton are dependent on sunlight for growth. This has ramifications for wildlife species as well which is evaluated in Section 3.9. These vegetation-related climate change effects would be true for the NAA as well as all other alternatives.

### *3.6.3.2 Measures Common to All Action Alternatives*

Measures that are common to all action alternatives that would provide minor long-term benefits to vegetation within the WVS include gravel augmentation below dams (#384) and maintaining or altering revetments (#9).

Gravel augmentation within the Middle Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins is intended to improve instream habitat for ESA-listed UWR Chinook and steelhead as well as other native fish; however, there would be secondary benefits to vegetation. By adding gravel to these streams, there is more potential for sediment transport and accumulation along the stream margins, re-engaging floodplain habitat such as adjacent wetlands, backwater sloughs, and oxbows. In these areas, wetland and riparian vegetation would benefit through improved hydrologic conditions. It should also be noted that engaging more floodplain areas could also have minor long-term effects to riparian vegetation through erosion along the stream banks. However, increasing the hydrologic connectivity across the floodplain and the benefits that has to the vegetative communities outweighs concerns related to potential erosion.

In the same way, maintaining or altering revetments using nature-based engineered techniques is anticipated to improve connections between vegetative communities along the stream margins with the wetland and riparian areas further landward. Currently some of the revetments consist of rock, devoid of vegetation. Converting these to vegetated embankments would allow for better hydrologic connectivity and ecological function along the edges of WVS stream reaches. Using native plant species (e.g., various willows, red osier dogwood, black cottonwood, etc.) as part of the revetment updates and maintenance would increase the seedbank of native plants that can move within the subbasin riparian corridors. Making these improvements would provide moderate long-term benefits for hydrologic connectivity and the native wetland plant community, improving overall wetland condition and ecological function.

#### *3.6.3.3 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

One measure associated with Alternative 1 that would affect vegetation over the NAA, is reducing minimum flows to the Congressionally authorized minimum flow requirements (#723) to benefit reservoir refill objectives within the entire WVS. Therefore, there would be an overall decrease in flows at the North Santiam and South Santiam rivers as well as Fall Creek, which flows into the Middle Fork Willamette. However, the decrease in flow is minor and therefore, long-term hydrologic effects to the vegetative communities along the banks of these streams are anticipated to be negligible. There would also be an increase of downstream flows from the Dexter and Lookout Point dams, which are along the Middle Fork Willamette, which would slightly improve hydrologic conditions for the plant community along the riverbanks. These long-term beneficial effects are also anticipated to be negligible over existing conditions.

In terms of effects to vegetative communities at reservoirs, Alternative 1 also includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows using the inactive pool (#718) is proposed for Fall Creek, Blue River, Cottage Grove, and Dorena. This measure allows the projects to drawdown the pools during the fall.

There is also the potential for minor adverse local effects to wetlands from slope failures along the upstream reservoir rims due to either of these measures as compared to the NAA. If slope failures did occur, there is potential that the landslide debris could bury existing vegetative communities, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, a plant community would re-establish over time but there is potential for this area to re-establish with invasive plant species, which typically proliferate faster than native species.

#### *3.6.3.3.1 Climate Change*

See the NAA for a description of effects due to Climate Change that applies to each action alternative for vegetation. In the case of Alternative 1, augmenting instream flows by using the power pool and the inactive pool would be implemented. However, these do not entail deep drawdowns so these are anticipated to have only minor long-term effects to vegetative communities at the reservoirs (Lookout Point, Hills Creek, Cougar, Green Peter, Detroit, Cottage Grove, Dorena, Fall Creek, and Blue River) that would be compounded by climate change effects. Specifically, a plant community would persist at these reservoirs but would slightly change in composition with more drought tolerant species becoming increasingly predominant throughout the region. Altered hydrology would allow a shift toward more invasive plant assemblages, as non-native species are often more adaptive and resilient and would likely colonize exposed reservoirs more quickly, outcompeting native plants. Ultimately these Alternative 1 effects combined with climate change effects would be anticipated to cause moderate long-term effects to vegetative communities across the WRB.

#### *3.6.3.3.2 Alternative 1 Vegetation Effects Summary Table*

Table 3.6-4 below presents a summary of the effects to vegetation within the WVS as a result of implementation of Alternative 1.

**Table 3.6-4. Summary of effects for vegetation under Alternative 1 as compared to the Alternative 1 – Improve Fish Passage Through Storage-Focused Measures**

| Subbasin | Alternative 1 |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with benefits to riverine vegetative communities<br>North and South Santiam rivers - minor decreases to downstream flows with negligible hydrological effects to riverine vegetation<br>Green Peter and Detroit - drawdowns with minor hydrological effects to vegetative communities around the reservoirs<br>Green Peter and Detroit - slope failures with minor adverse localized effects to vegetation |
| Long Tom Subbasin | Negligible change |

| Subbasin | Alternative 1 |
|---|---|
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to riverine vegetative communities<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible hydrological effects to riverine vegetation<br>Cougar - drawdowns with minor hydrological effects to vegetative communities around the reservoirs<br>Cougar - slope failures with minor adverse localized effects to vegetation |
| Middle Fork of the Willamette Subbasin | Middle Fork Willamette - gravel augmentation downstream of WVS dams with benefits to riverine vegetative communities<br>Middle Fork Willamette - minor decreases to downstream flows with negligible hydrological effects to riverine vegetation<br>Lookout Point, Hills Creek, and Fall Creek - drawdowns with minor hydrological effects to vegetative communities around the reservoirs<br>Lookout Point, Hills Creek, and Fall Creek - slope failures with minor adverse localized effects to vegetation |
| Coast Fork of the Willamette Subbasin | Cottage Grove and Dorena – drawdowns with minor hydrological effects to vegetative communities around the reservoirs<br>Cottage Grove and Dorena - slope failures with minor adverse localized effects to vegetation |
| Mainstem Willamette River | Negligible change |

#### *3.6.3.4 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (includes structural downstream passage at Cougar Dam)*

In terms of effects to vegetation, as a hybrid of the rest of the alternatives, Alternative 2A includes negligible to minor hydrologic impacts to vegetation in the long-term relative to the NAA. Stream flows would be adapted by the integrated temperature and habitat flow regime measure (#30a) which would have negligible effects to streamside wetland and aquatic vegetation within the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins because the hydrological effects that might affect vegetation would be negligible as compared to the NAA.

In terms of effects to vegetative communities at the reservoirs, Alternative 2A also includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit (as in Alternative 1) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River and this measure allows the projects to drawdown the pools during the fall. There is also the potential for minor adverse local effects to vegetative communities from slope failures along the upstream reservoir rims due to either of these measures. If slope failures did occur, there is potential that the landslide debris could bury vegetative communities, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

In addition, measures that would affect vegetation within the WVS as part of Alternative 2A include a deeper fall reservoir drawdown for fish passage (#40) at Green Peter reservoir (October 15 to December 15). As the reservoir drawdown occurs, the water tables would lower within the wetlands occurring around the reservoir edges and within the reservoir itself. The lowering of the water tables would have hydrological effects to vegetation. As the soils dry up, wetland and aquatic plants that depend on a high water table for survival, would die. In the long term, these areas would not be able to sustain these vegetative communities except the most resilient plants, including invasive plant species as discussed below. The drawdowns would have long-term moderate effects to vegetation surrounding Green Peter reservoir as well as negligible effects to the downstream vegetative communities within the South Santiam subbasin.

In addition, aquatic invasive plant species are known to establish in drawdown zones. The Willamette Aquatic Invasives Network (WAIN) recently published an extensive report on aquatic invasive species in the Willamette River (Krass et al., 2021). This document details processes and types of flows that may cause aquatic invasive plants to thrive or spread. "Scour events during high water can dislodge fragments for further downstream dispersal, flush the area of organic matter, and alter sediment conditions. Conversely, low scour results in increased opportunity for denser plant growth and deeper root establishment that could withstand future high water events." The report focuses primarily on a few high priority invasive plants and details impacts caused by them. High priority aquatic invasive species include *Ludwigia* species, yellow floating heart (currently in the Willamette River), and flowering rush (not found in the Willamette River Basin yet). Medium priority aquatics invasive species include yellow flag iris, narrowleaf cattail, purple loosestrife, tree of heaven, knotweeds, and parrots feather. Ubiquitous aquatic invasive species include reed canary grass, curly leaf pond weed, and Eurasian watermilfoil.

The fall drawdown is likely to allow invasive and versatile species such as but not limited to reed canary grass, yellow flag iris, purple loosestrife, and knotweeds to expand existing populations long-term around Green Peter reservoir as well as downstream through seed or fragment dispersal. These are species that thrive along intermittently inundated areas (e.g., reservoirs). Because of the drawdowns, the time period that portions of the reservoir bed would be exposed and susceptible to invasive species propagation would increase, likely increasing the prevalence of these invasive species around the reservoir (to be transported downstream) long-term. Vegetation monitoring, management, and restoration would need to be incorporated into regular drawdown actions to mitigate moderate effects that could lead to invasive plant population expansion both around the reservoirs and downstream. As the invasive plant population expands, areas that were occupied by native vegetative communities would shrink.

During the first couple years of the fall drawdown, sediment releases are anticipated that could accumulate along downstream stream margins within the South Santiam subbasin, which could temporarily cover vegetative communities in these areas. In addition, it is possible that sediment could be deposited along the downstream channel in such a way that causes erosion in another area adversely affecting nearby vegetative communities primarily along streambanks. When the channel changes shape in an area due to sedimentation, another portion of the channel would potentially be eroded due to stream hydraulics. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and vegetative communities would likely re-establish in these areas. Therefore, only minor short-term effects to vegetation within the South Santiam subbasin are anticipated as a result of sedimentation.

##### *3.6.3.4.1 Near-term Operations Measure*

The overall description of the near-term operations measure can be found within Chapter 2, Section 2.2.5. The analysis of the near-term operations measure effects on vegetation is broken down into subbasins below. This analysis applies to Alternatives 2A, 2B, 3A, 3B, 4, and 5 and this section is referred back to for each Alternative since the near-term operations would be the same for each.

**<u>Santiam Subbasin</u>**

The near-term operations measure within the Santiam subbasin that would affect vegetation indirectly by affecting hydrology and ultimately soil saturation include the following:

- Change in outlet operations at Detroit based on reservoir water surface elevation;
- Fall drawdown at Green Peter and increase in the use of the spillway during the spring; and
- Delayed spring refill and earlier reduction in pool elevation at Foster.

These operational measures would have minor long-term effects to vegetation surrounding Detroit Reservoir because water levels in the reservoir would be lower and would expose more of the reservoir bed. This would affect hydrology and soil saturation that some aquatic and wetland plants around the reservoir depend on for survival. In addition, versatile plants like invasive non-native plants would be more likely to become established and shrink areas occupied by native vegetative communities. The drawdowns are likely to facilitate encroachment of species such as reed canary grass within the reservoir and would increase seed dispersal to downstream areas. To better understand the vegetative response to a change in reservoir elevation, additional monitoring would be needed.

The fish passage operations at Green Peter and Foster would result in lower reservoir levels. These operational measures would have moderate long-term adverse effects to vegetation within aquatic and wetland areas surrounding Green Peter and minor long-term adverse effects to vegetation at Foster reservoir. Aquatic invasive plant species are known to establish in drawdown zones. The drawdowns are likely to facilitate encroachment of invasive plant species such as reed canary grass within the reservoir and would increase seed dispersal to downstream areas. To better understand the vegetative response to a change in reservoir elevation, additional monitoring would be needed.

**Long Tom Subbasin**

There are no local operations proposed under the near-term operations measure within the Long Tom subbasin; therefore, there would be no effects to vegetation as a result of this measure in this subbasin.

**McKenzie Subbasin**

The near-term operations within the McKenzie subbasin that would affect vegetation include the following:

- Delayed spring refill and fall drawdown at Cougar with a downstream flow restriction during some drawdown periods.

These operations have a target elevation of ~1,500 feet and would result in lower reservoir levels throughout the growing season. This operational measure would result in moderate long-term adverse effects to vegetation surrounding the Cougar Reservoir. Like other instances of drawdowns, the effects would entail less hydrology and soil saturation as well as proliferation of invasive non-native plant species within the exposed reservoir bed and within wetland areas around the reservoir. Due to the timing of the drawdowns, exposure of the reservoir bed to invasive plant species would increase. To better understand the vegetative response to a change in reservoir elevation, additional monitoring would be needed.

**Middle Fork Willamette River Subbasin**

The near-term operations within the Middle Fork Willamette subbasin that would affect vegetation include the following:

- Change in outlet operations at Hills Creek based on reservoir water surface elevation;
- Lower spring and summer maximum reservoir elevation at Lookout Point and a fall drawdown, increased use of the spillway based on reservoir water surface elevation; and
- Delayed spring refill from the longer fall drawdown at Fall Creek with step increases in reservoir water surface elevation through the winter.

Similar to other near-term operations measure, the lower reservoir elevations at Lookout Point, Fall Creek, and Hills Creek would result in moderate long-term adverse effects to vegetation surrounding Lookout Point, Fall Creek, and Hills Creek reservoirs. Like other instances of drawdowns, the effects would entail less hydrology and soil saturation as well as proliferation of invasive non-native plant species within the exposed reservoir bed and within wetland areas around the reservoir. Due to the timing of the drawdowns, exposure of the reservoir bed to invasive plant species would increase. To better understand the vegetative response to a change in reservoir elevation, additional monitoring would be needed.

**Coast Fork Subbasin**

There are no local operations proposed under the near-term operations measure within the Coast Fork subbasin, therefore, there would be no effects of this measure to vegetation in this subbasin.

**Mainstem Willamette River**

There are no operations proposed under the near-term operations measure along the Mainstem Willamette River, therefore, no effects of this measure to vegetation are anticipated. There is a slight potential for seed dispersal of invasive plant species occurring downstream of the project subbasins; however, the effects of this along the mainstem would be negligible.

*3.6.3.4.2 Climate Change*

See No Action Alternative, Section 3.6.3.41, for a description of effects due to Climate Change that applies to each action alternative for vegetation. In the case of Alternative 2A, the drawdown at Green Peter reservoir would have moderate long-term effects to vegetative communities at the reservoir and would be compounded by climate change effects. Specifically, a plant community would persist at the reservoir but would likely change in composition with more drought tolerant species becoming increasingly predominant throughout the region. Altered hydrology would allow a shift toward more invasive plant assemblages, as non-native species are often more adaptive and resilient and would likely colonize exposed reservoirs more quickly, outcompeting native plants.

*3.6.3.4.3 Alternative 2A Vegetation Effects Summary Table*

Table 3.6-5 below presents a summary of the effects to vegetation within the WVS as a result of implementation of Alternative 2A.

**Table 3.6-5. Summary of effects for Vegetation under Alternative 2A as compared to the Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (includes structural downstream passage at Cougar Dam)**

| Subbasin | Alternative 2A |

| Coast Fork of the Willamette Subbasin | Negligible change |
| Mainstem Willamette River | Negligible change |

#### *3.6.3.5 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Similar to Alternative 2A, Alternative 2B stream flows would be adapted to fish survival and passage needs which is not anticipated to have a measurable effect to the frequency of inundation and therefore, would have negligible effects to vegetative communities within the downstream aquatic and riparian areas of North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins. In terms of effects to vegetative communities at reservoirs, Alternative 2B (similar to Alternative 1 and 2A) includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit (as in Alternatives 1 and 2A) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River and this measure allows the projects to drawdown the pools during the fall. There is also the potential for minor adverse local effects to vegetative communities from slope failures along the upstream reservoir rims due to either of these measures. If localized erosion did occur, there is potential that the landslide debris could bury vegetative communities, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

The primary difference between Alternatives 2A and 2B is that at the Cougar dam, the diversion tunnel would be used for fish passage for Alternative 2B whereas for Alternative 2A, an FSS would be used. Therefore, the primary difference in effects to wetlands for Alternative 2B as opposed to those stated for Alternative 2A, is effects to vegetation as a result of a spring reservoir drawdown (#720) and a deeper fall reservoir drawdown (#40) at Cougar reservoir (in order to get to the right water surface elevation for the diversion tunnel) in addition to the fall drawdown at Green Peter. The deep spring season drawdown at Cougar would occur May 1 to July 1 and the deep fall season drawdown at Cougar and Green Peter would occur October 15 to December 15. As the reservoir drawdowns occur, the water tables would lower within the wetland and aquatic areas that occur around the reservoir edges. These wetland and aquatic areas would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that the vegetative communities in these areas need; however, it is not clear to what extent. The drawdowns would have long-term moderate effects to vegetation surrounding Cougar and Green Peter reservoirs as well as negligible effects to the downstream vegetative communities within the McKenzie and South Santiam subbasins.

The drawdowns are also likely to allow invasive and versatile species such as but not limited to reed canary grass, yellow flag iris, purple loosestrife, and knotweeds to expand existing populations long-term around Cougar and Green Peter reservoir as well as downstream through seed or fragment dispersal, as previously discussed for Alternative 2A in Section 3.6.3.4. These are species that thrive along intermittently inundated areas (e.g., reservoirs). Because of the drawdowns, the time period that portions of the reservoir bed would be exposed and susceptible to invasive species propagation would increase, likely increasing the prevalence of these invasive species around the reservoir (to be transported downstream) long-term. Vegetation monitoring, management, and restoration would need to be incorporated into regular drawdown actions to mitigate moderate effects that could lead to invasive plant population expansion both around the reservoirs and downstream.

In addition to effects to vegetative communities around Cougar and Green Peter reservoirs as a result of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to vegetative communities as a result of slope failure. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a slope failure risk. If slope failure did occur, there is potential that the landslide debris could bury existing vegetation, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

During the first couple years of the spring reservoir drawdowns (#720) and deeper fall reservoir drawdowns (#40) at Cougar and Green Peter, sediment releases are anticipated that could accumulate along downstream stream margins within the South Santiam and McKenzie subbasins, which could temporarily cover vegetative communities in these areas. In addition, it is possible that sediment could be deposited along the downstream channel in such a way that causes erosion in another area adversely affecting nearby vegetative communities primarily along streambanks. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and vegetative communities would likely re-establish in these areas. Therefore, only minor short-term effects to vegetation within the McKenzie and South Santiam subbasins are anticipated as a result of sedimentation.

###### *3.6.3.5.1 Near-term Operations Measure*

See Alternative 2A, Section 3.6.3.4, for a description of effects due to the Near-Term Operations Measure.

###### *3.6.3.5.2 Climate Change*

See No Action Alternative, Section 3.6.3.41, for a description of effects due to Climate Change that applies to each action alternative for vegetation. In the case of Alternative 2B, the drawdowns at Cougar and Green Peter reservoirs would have moderate long-term effects to vegetative communities at the reservoirs and would be compounded by climate change effects. Specifically, a plant community would persist at these reservoirs but would likely change in composition with more drought tolerant species becoming increasingly predominant throughout the region. Altered hydrology would allow a shift toward more invasive plant assemblages, as non-native species are often more adaptive and resilient and would likely colonize exposed reservoirs more quickly, outcompeting native plants.

### 3.6.3.6 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures

Measures that would potentially affect the plant community within the WVS as part of Alternative 3A include integrated temperature and habitat flow regime (#30a), which is not anticipated to have a measurable effect to the frequency of inundation wetland and aquatic areas and therefore would have negligible effects to vegetative communities within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to vegetative communities at reservoirs, Alternative 3A (similar to Alternatives 1, 2A, and 2B) includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit (as in Alternatives 1, 2A, and 2B) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Cottage Grove, Dorena, Fall Creek, and Blue River, and this measure allows the projects to drawdown the pools during the fall. There is also the potential for minor adverse local effects to vegetative communities from slope failures along the upstream reservoir rims due to either of these measures. If slope failures did occur, there is potential that the landslide debris could bury vegetative communities, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

In addition, a spring reservoir drawdown (#720) at Cougar, Detroit, and Lookout Point reservoirs (May 1 to July 1) and deeper fall reservoir drawdowns (#40) at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs (October 15 to December 15) would occur for fish passage. As the reservoir drawdowns occur, the water tables would lower within the wetland and aquatic areas that occur around the reservoir edges. These wetland and aquatic areas would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that the vegetative communities in these areas need; however, it is not clear to what extent. These actions would have long-term moderate effects to vegetation surrounding these reservoirs as well as minor effects to the downstream vegetative communities within the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins and potentially the Willamette River Mainstem.

The spring and fall drawdowns are likely to allow invasive and versatile species such as but not limited to reed canary grass, yellow flag iris, purple loosestrife, and knotweeds to expand existing populations around the reservoirs as well as downstream through seed or fragment dispersal, as previously discussed for Alternative 2A in Section 3.6.3.4. These are species that thrive along intermittently inundated areas (e.g., reservoirs). At Lookout Point, sulfur cinquefoil has been found and may be capable of colonizing the reservoir bed. Because of the drawdowns, the time period that portions of the reservoir bed would be exposed and susceptible to invasive species propagation would increase, likely increasing the prevalence of these invasive species around the reservoir (to be transported downstream). Vegetation monitoring, management, and restoration would need to be incorporated into regular drawdown actions to mitigate moderate effects that could lead to invasive plant population expansion both around the reservoirs and downstream.

In addition to effects to vegetative communities around the reservoirs listed above as a result of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to vegetative communities as a result of slope failure. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a slope failure risk. If slope failure did occur, there is potential that the landslide debris could bury existing vegetation, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

During the first couple years of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), sediment releases are anticipated that could accumulate along downstream stream margins within the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins, which could temporarily cover vegetative communities in these areas. In addition, it is possible that sediment could be deposited along the downstream channel in such a way that causes erosion in another area adversely affecting nearby vegetative communities primarily along streambanks. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and vegetative communities would likely re-establish in these areas. Therefore, only minor short-term effects to vegetation within the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins are anticipated as a result of sedimentation.

###### *3.6.3.6.1 Near-term Operations Measure*

See Alternative 2A, Section 3.6.3.4, for description of effects due to the Near-Term Operations Measure.

#### *3.6.3.6.2 Climate Change*

See No Action Alternative, Section 3.6.3.41, for a description of effects due to Climate Change that applies to each action alternative for vegetation. In the case of Alternative 3A, the drawdowns at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs would have moderate long-term effects to vegetative communities at the reservoirs and would be compounded by climate change effects. Specifically, a plant community would persist at these reservoirs but would likely change in composition with more drought tolerant species becoming increasingly predominant throughout the region. Altered hydrology would allow a shift toward more invasive plant assemblages, as non-native species are often more adaptive and resilient and would likely colonize exposed reservoirs more quickly, outcompeting native plants.

#### *3.6.3.7 Alternative 3B – Improve Fish Passage Through Operations-Focused Measures using Diversion Tunnel at COU*

In terms of measures that affect vegetation, Alternative 3B is very similar to Alternative 3A. One of the differences is that under Alternative 3B, the spring reservoir drawdown (#720) would occur at Cougar, Green Peter, and Hills Creek reservoirs instead of Cougar, Detroit, and Lookout Point reservoirs. In addition, at Cougar the spring and fall drawdowns would be down to the diversion tunnel to allow for downstream fish passage. Another difference is that augmenting instream flows by using the power pool (#304) would not be implemented at Cougar for Alternative 3B as it had in Alternative 3A. Overall effects for Alterative 3B are characterized in more detail below.

A measure that would potentially affect the plant community within the WVS as part of Alternative 3B include adaptive fish flows (#30a), which is not anticipated to have a measurable effect to the frequency of inundation wetland and aquatic areas and therefore would have negligible effects to vegetative communities within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to vegetative communities at reservoirs, Alternative 3B includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Green Peter, and Detroit (as in Alternatives 1, 2A, and 2B) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Cottage Grove, Dorena, Fall Creek, and Blue River, and this measure allows the projects to drawdown the pools during the fall. There is also the potential for minor adverse local effects to vegetative communities from slope failures along the upstream reservoir rims due to either of these measures. If slope failures did occur, there is potential that the landslide debris could bury vegetative communities, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

In addition, a spring reservoir drawdown (#720) at Cougar, Green Peter, and Hills Creek Point reservoirs (May 1 to July 1) and deeper fall reservoir drawdowns (#40) at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs (October 15 to December 15) would occur for fish passage. As the reservoir drawdowns occur, the water tables would lower within the wetland and aquatic areas that occur around the reservoir edges. These wetland and aquatic areas would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that the vegetative communities in these areas need; however, it is not clear to what extent. These actions would have long-term moderate effects to vegetation surrounding these reservoirs as well as minor effects to the downstream vegetative communities within the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins and potentially the Willamette River Mainstem.

The spring and fall drawdowns are likely to allow invasive and versatile species such as but not limited to reed canary grass, yellow flag iris, purple loosestrife, and knotweeds to expand existing populations around the reservoirs as well as downstream through seed or fragment dispersal, as previously discussed for Alternative 2A in Section 3.6.3.4. These are species that thrive along intermittently inundated areas (e.g., reservoirs). At Lookout Point, sulfur cinquefoil has been found and may be capable of colonizing the reservoir bed. Because of the drawdowns, the time period that portions of the reservoir bed would be exposed and susceptible to invasive species propagation would increase, likely increasing the prevalence of these invasive species around the reservoir (to be transported downstream). Vegetation monitoring, management, and restoration would need to be incorporated into regular drawdown actions to mitigate moderate effects that could lead to invasive plant population expansion both around the reservoirs and downstream.

In addition to effects to vegetative communities around the reservoirs listed above as a result of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to vegetative communities as a result of slope failure. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a slope failure risk. If slope failure did occur, there is potential that the landslide debris could bury existing vegetation, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

During the first couple years of the spring reservoir drawdown (#720) and deeper fall reservoir drawdown (#40), sediment releases are anticipated that could accumulate along downstream stream margins within the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins, which could temporarily cover vegetative communities in these areas. In addition, it is possible that sediment could be deposited along the downstream channel in such a way that causes erosion in another area adversely affecting nearby vegetative communities primarily along streambanks. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and vegetative communities would likely re-establish in these areas. Therefore, only minor short-term effects to vegetation within the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins are anticipated as a result of sedimentation.

##### *3.6.3.7.1 Near-term Operations Measure*

See Alternative 2A, Section 3.6.3.4, for description of effects due to the Near-Term Operations Measure.

##### *3.6.3.7.2 Climate Change*

See No Action Alternative, Section 3.6.3.41, for a description of effects due to Climate Change that applies to each action alternative for vegetation. In the case of Alternative 3B, the drawdowns at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs would have moderate long-term effects to vegetative communities at the reservoirs and would be compounded by climate change effects. Specifically, a plant community would persist at these reservoirs but would likely change in composition with more drought tolerant species becoming increasingly predominant throughout the region. Altered hydrology would allow a shift toward more invasive plant assemblages, as non-native species are often more adaptive and resilient and would likely colonize exposed reservoirs more quickly, outcompeting native plants.

#### *3.6.3.8 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

Effects to vegetation for Alternative 4 would be similar to that of Alternative 1 since these both of these alternatives avoid spring and fall drawdowns and instead utilize structures for water quality and fish passage objectives. This alternative would include: Construct water temperature control towers (#105) at Detroit, Hills Creek, and Lookout Point; Provide Pacific lamprey passage and infrastructure (#52) at Cougar, Dexter, and Hills Creek; restore upstream and downstream passage at drop structures (#639) within the Long Tom River downstream of

Fern Ridge; and construct structural downstream fish passage (#392) at Cougar, Detroit, Foster, Hills Creek, and Lookout Point. Measures included are focused on improving water quality and fish passage.

A measure that would potentially affect the plant community within the WVS as part of Alternative 4 include integrated temperature and habitat flow regime (#30a), which is not anticipated to have a measurable effect to the frequency of inundation wetland and aquatic areas and therefore would have negligible effects to vegetative communities within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to vegetative communities at reservoirs, Alternative 4 includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Cottage Grove, Dorena, Fall Creek, and Blue River and this measure allows the projects to drawdown the pools during the fall. There is also the potential for minor adverse local effects to vegetative communities from slope failures along the upstream reservoir rims due to either of these measures. If slope failures did occur, there is potential that the landslide debris could bury vegetative communities, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

#### *3.6.3.8.1 Near-term Operations Measure*

See Alternative 2A, Section 3.6.3.4, for description of effects due to the Near-Term Operations Measure.

#### *3.6.3.8.2 Climate Change*

See No Action Alternative, Section 3.6.3.41, for a description of effects due to Climate Change that applies to each action alternative for vegetation. In the case of Alternative 4, augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718) would be implemented. However, these do not entail deep drawdowns so these are anticipated to have minor long-term effects to vegetative communities at the reservoirs (Lookout Point, Hills Creek, Cougar, Green Peter, Detroit, Cottage Grove, Dorena, Fall Creek, and Blue River) that would be compounded by climate change effects. Specifically, a plant community would persist at these reservoirs but would slightly change in composition with more drought tolerant species becoming increasingly predominant throughout the region. Altered hydrology would allow a shift toward more invasive plant assemblages, as non-native species are often more adaptive and resilient and would likely colonize exposed reservoirs more quickly, outcompeting native plants. Ultimately these Alternative 4 effects combined with climate change effects would be anticipated to cause moderate long-term effects to vegetative communities across the WRB.

#### *3.6.3.8.3 Alternative 4 Vegetation Effects Summary Table*

Table 3.6-9 below presents a summary of the effects to vegetation within the WVS as a result of implementation of Alternative 4.

#### *3.6.3.9 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 is nearly identical to Alternative 2B. However, similar to Alternative 2B, Alternative 5 stream flows would be adapted to fish survival and passage needs except that the integrated temperature and habitat flow regime (#30a, as described in Section 2.3.1.1) has been replaced by the refined integrated temperature and habitat flow regime (#30b as described in Section 2.3.1.2 and Appendix A). Neither of these measures would have a measurable effect to the frequency of inundation and therefore, would have negligible effects to vegetative communities within the downstream aquatic and riparian areas of North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to vegetative communities at reservoirs, Alternative 5 (similar to Alternative 1, 2A, and 2B) includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River and this measure allows the projects to drawdown the pools during the fall. There is also the potential for minor adverse local effects to vegetative communities from slope failures along the upstream reservoir rims due to either of these measures. If slope failures did occur, there is potential that the landslide debris could bury vegetative communities, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

As with Alternative 2B, at the Cougar dam, the diversion tunnel would be used for fish passage for Alternative 5. Therefore, the spring reservoir drawdown (#720) at Cougar would occur May 1 to July 1 and the deeper fall reservoir drawdown (#40) at Cougar and Green Peter would occur October 15 to December 15. As the reservoir drawdowns to the diversion tunnel occur, the water tables would lower within the wetland and aquatic areas that occur around the reservoir edges. These wetland and aquatic areas would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that the vegetative communities in these areas need; however, it is not clear to what extent. The drawdowns would have moderate long-term adverse effects to vegetation surrounding Cougar and Green Peter reservoirs as well as negligible effects to the downstream vegetative communities within the McKenzie and South Santiam subbasins.

The drawdowns are also likely to allow invasive and versatile species such as but not limited to reed canary grass, yellow flag iris, purple loosestrife, and knotweeds to expand existing populations long-term around Cougar and Green Peter reservoir as well as downstream through seed or fragment dispersal, as previously discussed for Alternative 2A in Section 3.6.3.4. These are species that thrive along intermittently inundated areas (e.g., reservoirs). Because of the drawdowns, the time period that portions of the reservoir bed would be exposed and susceptible to invasive species propagation would increase, likely increasing the prevalence of these invasive species around the reservoir (to be transported downstream) long-term. Vegetation monitoring, management, and restoration would need to be incorporated into regular drawdown actions to mitigate moderate effects that could lead to invasive plant population expansion both around the reservoirs and downstream.

In addition to effects to vegetative communities around Cougar and Green Peter reservoirs as a result of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to vegetative communities as a result of localized erosion. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a risk for localized erosion. If localized erosion did occur, there is potential that the debris could bury existing vegetation, ultimately causing a short-term loss of vegetated area, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Furthermore, the plant community that is re-established may include invasive plant species, which typically proliferate faster than native species.

During the first couple years of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) at Cougar and Green Peter, sediment releases are anticipated that could accumulate along downstream stream margins within the South Santiam and McKenzie subbasins, which could temporarily cover vegetative communities in these areas. In addition, it is possible that sediment could be deposited along the downstream channel in such a way that causes erosion in another area adversely affecting nearby vegetative communities primarily along streambanks. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and vegetative communities would likely re-establish in these areas. Therefore, only minor short-term adverse effects to vegetation within the McKenzie and South Santiam subbasins are anticipated as a result of sedimentation.

#### *3.6.3.9.1 Near-term Operations Measure*

See Alternative 2A, Section 3.6.3.4, for a description of effects due to the Near-Term Operations Measure.

#### *3.6.3.9.2 Climate Change*

See No Action Alternative, Section 3.6.3.41, for a description of effects due to Climate Change that applies to each action alternative for vegetation. In the case of Alternative 5, the drawdowns at Cougar and Green Peter reservoirs would have long-term moderate adverse effects to vegetative communities at the reservoirs and would be compounded by climate change effects. Specifically, a plant community would persist at these reservoirs but would likely change in composition with more drought tolerant species becoming increasingly predominant throughout the region. Altered hydrology would allow a shift toward more invasive plant assemblages, as non-native species are often more adaptive and resilient and would likely colonize exposed reservoirs more quickly, outcompeting native plants.

#### *3.6.3.9.3 Alternative 5 Vegetation Effects Summary Table*

Table 3.6-10 below presents a summary of the effects to vegetation within the WVS as a result of implementation of Alternative 5.

**Table 3.6-10. Summary of effects for Vegetation under Alternative 5 as compared to the Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)**

## 3.7 WETLANDS

Wetlands are important ecosystems providing environmental functions that are valuable to nearby human communities (e.g., improving water quality and flood protection) and providing valuable habitat functions for amphibians, reptiles, birds, invertebrates, fish, and mammals. Wetlands are identified by vegetation type (i.e., hydrophytic vegetation), soil type (i.e., hydric soils), and wetland hydrology (e.g., high water table, soil saturation, etc.). Wetlands are typically found in transitional areas between upland areas (e.g., hillsides) and aquatic areas (e.g., reservoirs).

Within this section, wetlands will be within the context of general habitat classification at the landscape scale. For the affected environment and environmental consequences analysis for specific plant species or assemblages, see Chapter 3.6 Vegetation.

### 3.7.1 Affected Environment

The federal Clean Water Act (CWA) gives the Corps the authority to regulate discharges of pollutants into "Waters of the U.S.," which includes wetlands see Chapter 7 for further information. In Oregon, CWA regulatory authority has also been given to the Oregon Department of Environmental Quality (ODEQ) under Section 401 of the CWA. Within Oregon, the Oregon Department of State Lands has regulatory authority over removal and placement of fill within waters of the State. Wetlands and waterways protected by the CWA are called jurisdictional waters and wetlands. Placing or removing material in wetlands or within waterways may require federal and state permitting.

The WVS area of analysis for wetlands consists of all reservoirs up to the maximum pool elevation (a.k.a., "full pool"), riparian corridors associated with the project stream reaches including around the reservoirs, and the Ordinary High Water Mark (OHWM) along the project stream reaches (listed in 3.7.2). The area of analysis for wetlands was determined because of the following: the maximum pool elevation is the jurisdictional boundary when assessing in-water impacts to reservoirs in Oregon; wetlands within the riparian corridors of the WVS may be hydrologically connected to stream flows within WVS stream reaches as well as reservoirs; and the OHWM is the jurisdictional boundary for streams and rivers.

#### *3.7.1.1 Willamette Valley Wetlands*

Historically, seasonal wetlands were common throughout the Willamette Basin. Roughly 90% of the historic wetlands have been converted to agriculture or other means of development (Oregon Conservation Strategy, 2016). Within the Willamette Basin, wetlands can take many forms including but not limited to backwater sloughs (riverine), oxbow lakes (riverine and palustrine), emergent wetlands (palustrine and riverine), seasonal ponds (palustrine), forested wetlands (palustrine), and wet prairies (palustrine).

For this analysis, the focus are wetlands that may be affected by the WVS. These wetlands include those located along the channels of slow-moving low-gradient stream reaches downstream of the dams, where the floodplain and the channel migration zone broaden. Backwater sloughs and oxbow lakes are formed when a stream channel migrates across the floodplain over time. This process shifts primary stream flows from previously used channels, now backwater sloughs, and completely isolates other portions, which become oxbow lakes. These wetlands are part of the riverine and palustrine systems within the analysis area. In these areas, large floodplain wetland complexes sometimes form over a period of time particularly in lower gradient areas. Vegetation within a backwater slough includes emergent species as well as woody species such as willows (*Salix* spp.), alder (*Alnus rubra*), Oregon ash (*Fraxinus latifolia*), and black cottonwood (*Populus balsamifera*). Backwater sloughs and oxbow lakes provide habitat for various fish, reptiles, amphibians, mammals, and birds. Due to the slower movement of water through backwater sloughs, juvenile salmonids use these areas for rearing and refugia during high water events.

In addition to wetlands located along stream reaches downstream of the dams, wetlands located around or hydrologically connected to the WVS reservoirs, many of which are within the Cascade foothills, are also being considered in this analysis. The reservoirs of the Willamette Basin, operated and maintained by USACE, provide a hydrological regime which results in wetland formation along the edges of the reservoirs despite the lower pool elevations during the winter (see Section 3.6.1.1.7). This hydrologic regime is opposite what would be observed at wetlands around a natural lake. Due to the steep topography of the reservoirs found within the Cascade foothills (see Section 3.6.1.1.5 and 3.6.1.1.6), the formation of these wetlands is generally limited to lower gradient areas near the upstream end of the reservoirs. "Vegetation In Reservoirs" (Section 3.6.1.1.7) provides a list of plants that are associated with these wetlands. The wetlands around the reservoirs provide foraging, breeding, and rearing habitat for numerous species of birds, mammals, reptiles, and amphibians.

All wetland types described in this section are more abundant within the lower elevation reservoirs (Cottage Grove, Dorena, and Fern Ridge) and within the Willamette Valley in areas adjacent to the Mainstem Willamette River and the lower sections of tributaries to the Willamette River.

#### *3.7.1.1.1 National Wetland Inventory (NWI)*

The U.S. Fish and Wildlife Service (USFWS) National Wetlands Inventory (NWI) is a publicly available resource that provides data and mapping on the classification and distribution of wetlands within the U.S. NWI data serves as a planning resource to promote the understanding, conservation, and restoration of wetlands (USFWS, 2021). It is important to note that NWI data is determined through a desktop analysis and therefore this data cannot be used to determine accurate acreage of wetlands within the analysis area.

Within the NWI data, wetlands are classified according to the Cowardin system (1979) into different types based on soil types, hydrologic regime, and vegetation type. The systems of wetland types found within the area of analysis include lacustrine, palustrine, and riverine. Lacustrine wetlands are lakes, reservoirs, or other waterbodies that are situated in a topographic depression or a dammed river channel and are more than 20 acres. Palustrine wetlands include all non-tidal wetlands dominated by trees, shrubs, and persistent emergent vegetation (i.e., plants with their roots underwater but leaves and stems above). Within the area of analysis, palustrine wetlands are located along stream channels. Riverine wetlands are located within the channels of the rivers and streams found throughout the area of analysis. Table 3.7-1 provides summaries of each wetland type included in the subbasin discussion below.

**Table 3.7-1. NWI Wetland Types in the WVS**

| NWI Code | Cowardin Classification | Description |
|---|---|---|
| PEM | Palustrine emergent | Non-tidal wetland dominated by emergent, herbaceous vegetation |
| PSS | Palustrine scrub-shrub | Non-tidal wetland dominated by woody vegetation less than 20 feet tall |
| PFO | Palustrine forested | Non-tidal wetland dominated by woody vegetation 20 feet tall or taller |
| PUB | Palustrine unconsolidated bottom | Non-tidal wetland with 25% or more cover by particles smaller than stones and with less than 30% vegetative cover |
| PAB | Palustrine aquatic bed | Non-tidal wetland dominated by vegetation that grows on or below the surface of the water |
| LUB | Lacustrine unconsolidated bottom | Water body in topographic depression or a dammed river channel, 25% or more cover by particles smaller than stones, with less than 30% vegetative cover |
| RUB | Riverine unconsolidated bottom | A wetland contained within a channel, 25% or more cover by particles smaller than stones, and less than 30% vegetative cover |
| RUS | Riverine unconsolidated shore | A wetland contained within a channel, unconsolidated substrates with less than 75% cover of stones, boulders, or bedrock and less than 30% vegetative cover. |

#### *3.7.1.1.2 North Santiam Subbasin*

According to the NWI data, Big Cliff and Detroit Lake reservoirs are classified as lacustrine unconsolidated bottom (LUB) and include adjacent PEM, PSS, PFO wetlands. Within the analysis area, along the North Santiam River to its confluence with the South Santiam River, riverine unconsolidated bottom (RUB), riverine unconsolidated shore (RUS), palustrine emergent (PEM), palustrine scrub-shrub (PSS), and palustrine forested (PFO) wetlands are located within and alongside the stream channel. This includes some side channels, backwater sloughs, and irrigation ditches. In the vicinity of Stayton Island there is a complex of wetlands within the North Santiam River floodplain that are connected to Wilderness Park and Riverfront Park in Stayton, Oregon. Near the confluence of the North Santiam River with the South Santiam River, there is a large floodplain wetland in the vicinity of Wiseman Island.

#### *3.7.1.1.3 South Santiam Subbasin*

Green Peter Lake and Foster Lake reservoirs are classified as LUB and no adjacent wetlands are shown in the NWI data. South Santiam River downstream of Foster Dam to its confluence with the North Santiam River is classified as RUB and RUS, has PEM, PSS, and PFO wetlands along its edge, and includes side channels, backwater sloughs, and irrigation ditches. There also appears to be a number of nearby ponds, which appear to be gravel pits, classified as palustrine unconsolidated bottom (PUB) along the South Santiam River. Closer to the confluence of the North and South Santiam rivers, there are a number of floodplain wetland complexes according to the NWI data.

#### *3.7.1.1.4 McKenzie Subbasin*

Blue River Lake and Cougar Lake reservoirs are both classified as LUB and do not show adjacent wetlands in the NWI data. The Blue River, South Fork McKenzie River, and McKenzie River are all classified as RUB and RUS and have PEM, PSS, and PFO wetlands along their edges including side channels, oxbows, backwater sloughs, and irrigation canals. Within the mainstem fo the McKenzie River Leaburg Dam and Leaburg Canal provide addition wetland areas along the banks. In the vicinity of Walterville and Springfield, Oregon there are a number of floodplain wetland complexes bisected by the McKenzie River according to the NWI data.

#### *3.7.1.1.5 Middle Fork Willamette River*

Hills Creek Lake, Lookout Point Lake, Dexter Lake, and Fall Creek Lake reservoirs are all classified as LUB and include a couple of adjacent PEM and PSS wetlands according to the NWI data. Downstream of Hills Creek Dam, the Middle Fork Willamette River to its confluence with the Coast Fork Willamette River is RUB and RSC and includes PEM, PSS, and PFO wetlands along it and nearby PUB and palustrine aquatic bed (PAB) wetlands within the floodplain and channel migration zone. There is a smaller floodplain wetland complex just downstream of Dexter Dam as well as a larger floodplain wetland complex with side channels and islands and PEM, PSS, PFO, PUB, PAB, and LUB wetlands located just upstream and at the confluence of the Middle Fork with the Coast Fork south of Springfield, Oregon.

#### *3.7.1.1.6 Coast Fork Willamette River*

According to the NWI data, both Dorena Lake and Cottage Grove Lake reservoirs are LUB and have large PEM wetlands located at their upstream ends. The Row River downstream of Dorena Dam to its confluence with the Coast Fork Willamette River includes many PEM, PSS, PFO wetlands, particularly closer to the confluence. The Coast Fork Willamette River appears to lack wetlands in areas where it is highly channelized with a disconnected floodplain through Cottage Grove, Oregon. But just downstream of its confluence with Row River there are several floodplain wetland complexes and many small PEM, PSS, and PFO wetlands in the surrounding area. In addition, there is large floodplain wetland complex just downstream of Creswell, Oregon with oxbows, backwater sloughs, and side channels.

#### *3.7.1.1.7 Long Tom Subbasin*

The Fern Ridge Lake reservoir is classified as a LUB wetland and is surrounded by a large PEM, PSS, and PFO wetland complex, primarily on the south side. The adjacent PEM wetlands are considered wet prairies and include vegetation specific to Willamette Valley wet prairies described in Section 3.6.4.6. Fern Ridge Lake reservoir has multiple tributaries that feed into it including the Long Tom River, Amazon Canal, and East and West Coyote Creeks. These tributaries are similar in size and wetland complexes associated with them. Directly downstream of Fern Ridge Dam, Kirk Pond, Coyote Creek, and the Long Tom River include both backwater sloughs and oxbow lakes. Many of these habitat types were formed by the Corps of Engineers when the Long Tom River channel was modified in the 1940s. This large wetland complex maintains connections with the Long Tom River via culverts and forms a large wetland complex classified as PFO around the historic channel. Beyond the wetland complex, the Long Tom River (classified as RUB) is highly channelized and there are very few adjacent wetlands shown in the NWI data, though there are some nearby PUB/PEM oxbows and irrigation ditches that flow into the Long Tom. Closer to the Long Tom River's confluence with the Willamette there are a few PEM, PSS, and PFO wetlands.

#### *3.7.1.1.8 Mainstem Willamette River*

Along the Willamette River mainstem downstream to Willamette Falls, there are many types and sizes of wetlands within or along the floodplain. As within other basins, there are a number of off-channel floodplain features such as oxbows, side channels, irrigation ditches, and backwater sloughs. Many of these are associated with river meanders and form large floodplain wetland complexes. There are a number of natural areas that are also associated with these wetland floodplain complexes: Blue Ruin Island, Sam Daw's Landing, Bowers Rock State Park, Luckiamute State Natural Area, Minto-Brown Island Park, Beardsley Bar Landing, Willamette Mission State Park, Grand Island, and Molalla River State Park.

### 3.7.2 Environmental Consequences

This section discusses the potential effects of the alternatives on wetlands. As previously stated, the WVS area of analysis for wetlands consists of all reservoirs up to the maximum pool elevation (a.k.a., "full pool"), riparian corridors associated with the project stream reaches including around the reservoirs, and the Ordinary High Water Mark (OHWM) along the project stream reaches listed below.

- Middle Fork Willamette River downstream of Hills Creek Dam to the confluence with the Coast Fork Willamette River;
- Coast Fork Willamette River downstream of Cottage Grove Dam to the confluence with the Middle Fork Willamette River;
- Row River from downstream of Dorena Dam to the confluence with the Coast Fork Willamette River;

- South Fork McKenzie River downstream of Cougar Dam to the confluence with the McKenzie River;
- McKenzie River from the South Fork McKenzie River confluence to the confluence with the Willamette River;
- Blue River downstream of Blue River Dam to the confluence with the McKenzie River;
- Long Tom River downstream of Fern Ridge Dam to the confluence with the Willamette River (includes Coyote Creek from Fern Ridge Dam to the confluence with the Willamette River);
- South Santiam River downstream of Foster Dam to the confluence with the North Santiam River;
- North Santiam River downstream to the confluence with the South Santiam River;
- Santiam River to the confluence with the Willamette River; and
- Willamette River mainstem to Willamette Falls.

The discussion below includes the qualitative methods used to evaluate wetland effects.

#### *3.7.2.1 Methodology*

The method used to analyze effects to wetlands was qualitative based on potential wetland presence within the WVS analysis area per NWI data and relating that to effects associated with each alternative. Potential effects to wetlands within the WVS analysis area as a result of the alternatives entail indirect effects related to hydrology, sediment transport, erosion, and invasive species. Climate change is also anticipated to affect wetlands within the WVS over time and is analyzed for each alternative though it is not a result of any of the Corps-proposed alternatives.

Direct effects to wetlands may be included as part of specific construction activities during implementation; however, this PEIS will discuss general qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects during the implementation phase. During the planning process for any site-specific project, the Corps would determine whether wetlands are present onsite and, if so, conduct wetland delineations and functional assessments of areas that would be directly affected by construction. The delineations and functional assessments would be used to determine wetland boundaries and the ecological function and value of each wetland affected. Such direct effects could include excavation in wetlands, placing fill in wetlands, impacting wetland vegetation, or altering wetland hydrology. Applicable permits and approvals would be obtained prior to action implementation. In cases of unavoidable impacts to wetlands, the Corps may be required to mitigate for the impacts.

**All comparisons of magnitude or duration in the effects analysis for each action alternative are in comparison to the NAA unless stated otherwise.**

The following measures (described in Chapter 2) have effects on wetlands that will be evaluated in this PEIS:

- Gravel augmentation below dams (#384);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9);
- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b);
- Augment instream flows by using the inactive pool (#718);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Augment instream flows by using the power pool (#304);
- Deeper fall reservoir drawdowns for fish passage (#40); and
- Spring reservoir drawdown for downstream fish passage (#720).

Measures unlikely to affect wetlands as part of the WVS O&M program or those that would require site-specific considerations beyond the scope of this programmatic document are not discussed further, include the following:

- Adapt hatchery program (#719)
- Maintenance of existing and new fish release sites above dams (#726)
- Construct adult fish facility (#722)
- Construct water temperature control tower (#105)
- Use ROs to discharge colder water (#166)
- Structural improvements for TDG (#174)
- Foster fish ladder temperature improvement (#479)
- Use spillway for summer surface spill (#721)
- Construct structural downstream fish passage (#392)
- Spring spillway fish passage (#714)
- Provide Pacific lamprey passage and infrastructure (#52)
- Restore upstream and downstream passage at drop structures (#639)

Table 3.7-2 describes the evaluation criteria used to determine the magnitude and duration of effects.

**Table 3.7-2. Evaluation Criteria for Potential Effects to Wetlands**

| Effect Scale | Definition |
|---|---|
| **Magnitude** | |
| None/negligible | Wetlands would not be affected and no effects would be observable. |
| Minor | Effects to wetlands would be observable (e.g., signs of erosion, changes in vegetation types, sediment deposits) though the effects would be small and localized. |
| Moderate | Effects to wetlands would be observable at a regional scale but not be easily measured (e.g., changes to wetland acreage). |
| Major | Effects to wetlands would be readily observable and measurable (e.g., obvious changes in wetland acreage) and would have substantial ecological consequences (e.g., loss of wetland habitat for special status species) at a regional level. Mitigation measures to reduce the adverse effects would be required, though long-term adverse effects to wetlands would be expected. |
| **Duration** | |
| Short-term | Disturbance to wetlands would be short in duration, lasting only as long as a discreet construction project or single event in an area (e.g., construction access over a wetland using minimization measures). |
| Long-term | Disturbance to wetlands would ongoing or last beyond operation changes or the completion of construction projects. |

#### *3.7.2.2 No Action Alternative*

Wetland effects associated with the No Action Alternative are related to the current hydrologic regime of the WVS. The current hydrologic regime is the opposite of the natural hydrologic regime. The WSE is the highest within the reservoirs from May through September when the maximum conservation pool is being maintained, whereas naturally this would be the driest time of year within the reservoir area. This condition creates and maintains wetlands along the edge of full-pool elevation within the reservoirs even when precipitation is at its lowest annual levels. The No Action Alternative would continue to support these wetlands, resulting in no or negligible effect.

Within the WVS, downstream flows are managed so that wintertime flooding, which would naturally occur without the dams, is mitigated. In addition, revetments within the WVS help ensure that banks are not undercut or overtopped in any sort of high flow event. These flood mitigation actions limit the hydrologic connectivity across the floodplains of WVS streams. Therefore, riverine wetlands experience drier conditions than they would outside of a managed system and rely more on precipitation than they would otherwise. Under the No Action Alternative, flow management would not change and these conditions would remain the same. Thus, the effect would be none/negligible.

Climate change is anticipated to lead to wetter winters (increased temperature and precipitation) and longer drier summers (increased temperature and evapotranspiration) which would adversely affect wetlands in the Willamette Valley independent of the WVS operation and maintenance actions over the course of the next 30 years. Having drier summers is anticipated have moderate long-term adverse effects to wetlands within the WVS analysis area. Wetland soils and wetland vegetative communities are largely dependent on wetland hydrology as a result of a high water table, precipitation, and overland flows primarily. With longer drier summers, wetland hydroperiods (how long wetlands are inundated or wetland soils are saturated) would change for some wetlands which would change the wetland plant community. In addition, wetland area within the WVS analysis area may shrink which would adversely affect a number of other resources such as water quality, fish and wildlife, and vegetation. As native wetland vegetative communities shrink, invasive plant species would thrive, which would ultimately have adverse effects to the ecological functions of the wetlands that do remain. These wetland-related climate change effects are anticipated for the NAA as well as all other alternatives.

#### *3.7.2.3 Measures Common to All Action Alternatives*

Measures that are common to all action alternatives that would provide minor benefits to wetlands within the WVS include gravel augmentation below dams (#384) and maintaining or altering revetments (#9).

Gravel augmentation below dams within the Middle Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins is intended to improve instream habitat for ESA-listed UWR Chinook and steelhead as well as other native fish; however, there would be secondary benefits to wetlands. By adding gravel to these streams, there is more potential for sediment transport and accumulation along the stream margins, re-engaging floodplain areas. These areas often contain wetlands and with better hydrologic connectivity within the floodplain, wetland hydrology would be better supported (i.e., more regular inundation and soil saturation). Therefore, adding gravel and re-engaging floodplain areas is anticipated to provide long-term benefits to wetlands along the WVS stream reaches downstream of the dams. It should also be noted that engaging more floodplain areas could also have minor long-term effects to wetlands through erosion. However, increasing the hydrologic connectivity across the floodplain and the benefits that has to wetlands outweighs concerns related to potential erosion.

In the same way, maintaining revetments using bio-engineered techniques is anticipated to improve vegetative communities along the stream margins within the wetland and riparian areas further landward. Currently some of the revetments consist of rock, devoid of vegetation. Converting these to vegetated embankments would allow for better hydrologic connectivity and ecological function along the edges of WVS stream reaches. Using native plant species (e.g., various willows, red osier dogwood, black cottonwood, etc.) as part of the revetment updates and maintenance would increase the seedbank of native wet-tolerant plants that can move within the subbasin and propagate within streamside wetlands. Making these improvements would provide moderate long-term benefits for wetland hydrologic connectivity and the native wetland plant community, improving overall wetland condition and ecological function.

#### *3.7.2.4 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

One measure associated with Alternative 1 that would affect wetlands compared to the NAA, is reducing minimum flows to the Congressionally authorized minimum flow requirements (#723) to benefit reservoir refill objectives within the entire WVS. In Alternative 1, there would be an overall decrease in flows at the North Santiam and South Santiam rivers as well as Fall Creek, which flows into the Middle Fork Willamette. However, these decreases in flow are minor and therefore, hydrologic effects to the PEM/PSS/PFO wetlands along these streams are anticipated to be negligible. There would also be an increase of downstream flows from the Dexter and Lookout Point dams, which are along the Middle Fork Willamette, which would slightly improve hydrologic conditions for the streamside PEM/PSS/PFO wetlands. Generally, more flow in stream channels benefits wetlands within or next to the channels by increasing the water table within these areas. However, these flow increases are so slight, that these beneficial effects are anticipated to be negligible over existing conditions.

In terms of effects to wetlands around reservoirs, Alternative 1 also includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek, Blue River, Cottage Grove, and Dorena. This measure allows the projects to drawdown the pools during the fall. There is also the potential for minor, adverse, local effects to wetlands from localized erosion along the upstream reservoir rims due to either of these measures. If localized erosion did occur, there is potential that the debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

##### *3.7.2.4.1 Climate Change*

See the NAA for a description of effects due to Climate Change that applies to each action alternative for wetlands. Alternative 1 maximizes storage within the reservoirs and effects of downstream flows would be anticipated to be negligible. Climate change is anticipated to cause moderate long-term effects to wetlands within the WRB, which would not be affected by Alternative 1 measures.

#### *3.7.2.4.2 Alternative 1 Wetlands Effects Summary Table*

Table 3.7-3 below presents a summary of the effects to wetlands within the WVS as a result of implementation of Alternative 1.

**Table 3.7-3. Summary of Effects for Wetlands Under Alternative 1 as Compared to the Alternative 1 – Improve Fish Passage Through Storage-Focused Measures**

| Subbasin | Alternative 1 |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with long-term benefits to streamside wetlands<br>North and South Santiam rivers - minor decreases to downstream flows with negligible long-term effects to streamside wetlands<br>Green Peter and Detroit - drawdowns with minor long-term effects to wetlands around the reservoirs<br>Green Peter and Detroit – localized erosion with minor short-term adverse effects to wetlands |
| Long Tom Subbasin | Negligible change |

| Coast Fork of the Willamette Subbasin | Cottage Grove and Dorena – drawdowns with minor long-term effects to wetlands around the reservoirs<br>Cottage Grove and Dorena - localized erosion with minor short-term adverse effects to wetlands |
| Mainstem Willamette River | Negligible change |

### 3.7.2.5 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (includes structural downstream passage at Cougar Dam)

For Alternative 2A stream flows will be the integrated temperature and habitat flow regime (#30a), which is not anticipated to have a measurable effect to the frequency of inundation and therefore would have negligible effects to PEM/PSS/PFO wetlands within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to wetlands around reservoirs, Alternative 2A also includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit (as in Alternative 1) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River and this measure allows the projects to drawdown the pools during the fall. As these drawdowns occur, the water table that provides hydrology to the wetlands around the reservoirs would drop. As the water table drops, wetlands would change in character (e.g, loss of wetland plants and soil moisture) and be less likely to provide ecological functions (e.g., water quality, wildlife habitat, biodiversity) over time. There is also the potential for minor, adverse, local effects to wetlands localized erosion along the upstream reservoir rims due to either of these measures. If erosion did occur, there is potential that the sediment could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

In addition, measures that would affect wetlands within the WVS as part of Alternative 2A include deeper fall season drawdowns (#40) at Green Peter reservoir (October 15 to December 15) for fish passage. As the reservoir drawdown occurs, the water tables would lower within the wetlands that occur around the reservoir edges. These wetlands would become reliant on precipitation as the primary source of hydrology during this period. During the fall, precipitation is capable of supplementing the water that these wetlands need; however, it is not clear to what extent. The fall drawdown at Green Peter is anticipated to cause moderate observable effects (e.g., dead or dying wetland plants) to wetlands around the reservoir.

In addition to changes to the water tables in wetlands around Green Peter reservoir as a result of the deeper fall reservoir drawdowns (Measures #40), there could be effects to wetlands as a result of localized erosion. Green Peter reservoir has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a risk of localized erosion. If localized erosion did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

During the first couple years of the fall drawdown, sediment releases are anticipated that could accumulate along downstream stream margins within the South Santiam subbasin, affecting the hydrologic connectivity between the active channels and streamside PEM/PSS/PFO wetlands. The sediment transported downstream could be deposited so that a wetland is further removed from the stream channel and is therefore less likely to be influenced by the flow within the active channel. Another possibility is that sediment could be deposited along the downstream channel in such a way that causes erosion of a nearby wetland as the streamflow adjusts around the deposited material. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and therefore, only a negligible short-term effect is anticipated.

##### *3.7.2.5.1 Near-term Operations Measure*

The description of the near-term operations measure can be found within Chapter 2, Section 2.2.5. The analysis of the near-term operations measure effects on wetlands is broken down into subbasins below. This analysis applies to Alternatives 2A, 2B, 3A, 3B, 4, and 5 and this section is referred back to for each Alternative since the near-term operations would be the same for each.

**Santiam Subbasin**

The near-term operations measure within the Santiam subbasin that would affect wetlands indirectly by affecting hydrology and ultimately soil saturation and wetland plant survival include the following:

- Change in outlet operations at Detroit based on reservoir water surface elevation;
- Fall drawdown at Green Peter and increase in the use of the spillway during the spring; and
- Delayed spring refill and earlier reduction in pool elevation at Foster.

These operational measures would have minor long-term effects to vegetation surrounding Detroit Reservoir because water levels in the reservoir would be lower and would expose more of the reservoir bed. This would affect hydrology and soil saturation that support wetland soils and wetland plants around the reservoir.

The fish passage operations at Green Peter and Foster would result in lower reservoir levels. As the reservoir levels lower, the water tables would lower within the wetlands that occur around the reservoir edges. These wetlands would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing wetland hydrology within these wetlands; however, it is not clear to what extent. These operational measures would have moderate long-term adverse effects to wetlands surrounding

Green Peter within aquatic and wetland areas and minor long-term adverse effects to wetlands at Foster reservoirs.

**Long Tom Subbasin**

There are no local operations proposed under the near-term operations measure within the Long Tom subbasin, therefore, there would be no effects of this measure to wetlands in this subbasin.

**McKenzie Subbasin**

The near-term operations within the McKenzie subbasin that would affect wetlands include the following:

- Delayed spring refill and fall drawdown at Cougar with a downstream flow restriction during some drawdown periods.

These operations have a target elevation of ~1,500 feet and would result in lower reservoir levels throughout the growing season. This operational measure would result in moderate, long-term, adverse effects to wetlands surrounding the Cougar Reservoir. As the reservoir levels lower, the water tables would lower within the wetlands that occur around the reservoir edges. These wetlands would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing wetland hydrology within these wetlands; however, it is not clear to what extent.

**Middle Fork Willamette River Subbasin**

The near-term operations within the Middle Fork Willamette subbasin that would affect wetlands include the following:

- Change in outlet operations at Hills Creek based on reservoir water surface elevation;
- Lower spring and summer maximum reservoir elevation at Lookout Point and a fall drawdown, increased use of the spillway based on reservoir water surface elevation; and
- Delayed spring refill from the longer fall drawdown at Fall Creek with step increases in reservoir water surface elevation through the winter.

Similar to other near-term operations, the lower reservoir levels at Lookout Point, Fall Creek, and Hills Creek would result in moderate long-term adverse effects to wetlands around the reservoirs. As the reservoir levels lower, the water tables would lower within the wetlands that occur around the reservoir edges. These wetlands would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing wetland hydrology within these wetlands; however, it is not clear to what extent.

**Coast Fork Subbasin**

There are no local operations proposed under the near-term operations measure within the Coast Fork subbasin, therefore, there would be no effects of this measure to wetlands in this subbasin.

**Mainstem Willamette River**

No effects to wetlands along the Mainstem Willamette River are anticipated as a result of the near-term operations measure.

*3.7.2.5.2 Climate Change*

See No Action Alternative, Section 3.7.2.2., for a description of effects due to Climate Change that applies to each action alternative for wetlands. In the case of Alternative 2A, the fall drawdown at Green Peter is anticipated to cause minor observable effects to wetlands around the reservoir, but this would be compounded by climate change effects which are anticipated to cause long-term, moderate, and observable (at the regional scale) effects to wetlands throughout the WVS. Therefore, it is possible that the effects of the deep drawdown combined with the effects of climate change could cause major effects to wetlands at Green Peter reservoir, including loss of wetland acreage and ecological functions specific to wetlands. It is worth noting that because on-the-ground wetland surveys have not been conducted, it is unclear how many wetlands and how large an area would be affected.

*3.7.2.5.3 Alternative 2A Wetlands Effects Summary Table*

Table 3.7-4 below presents a summary of the effects to wetlands within the WVS as a result of implementation of Alternative 2A.

**Table 3.7-4. Summary of Effects for Wetlands under Alternative 2A as Compared to the Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (includes structural downstream passage at Cougar Dam)**

| Subbasin | Alternative 2A |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with long-term benefits to streamside wetlands<br>North and South Santiam rivers - minor decreases to downstream flows with negligible long-term effects to streamside wetlands<br>Green Peter and Detroit - drawdowns with minor long-term effects to wetlands around the reservoirs<br>Green Peter – deep fall season drawdown with long-term moderate effects to wetlands around reservoir and negligible short-term effects (sediment) to downstream South Santiam reaches |

| Subbasin | Alternative 2A |

| Coast Fork of the Willamette Subbasin | Negligible change |
| Mainstem Willamette River | Negligible change |

#### *3.7.2.6 Alternative 2B -- Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Similar to Alternative 2A, Alternative 2B stream flows will be adapted to fish survival and passage needs which is not anticipated to have a measurable effect to the frequency of inundation and therefore, would have negligible effects to PEM/PSS/PFO wetlands within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins. In terms of effects to wetlands around reservoirs, Alternative 2B (similar to Alternative 1 and 2A) includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit (as in Alternatives 1 and 2A) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River and this measure allows the projects to drawdown the pools during the fall. As these drawdowns occur, the water table that provides hydrology to the wetlands around the reservoirs would drop. As the water table drops, wetlands would change in character (e.g, loss of wetland plants and soil moisture) and be less likely to provide ecological functions (e.g., water quality, wildlife habitat, biodiversity) over time. There is also the potential for minor adverse local effects to wetlands from localized erosion along the upstream reservoir rims due to either of these measures. If localized erosion did occur, there is potential that the debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

The primary difference between Alternatives 2A and 2B is that at the Cougar dam, the diversion tunnel will be used for fish passage for Alternative 2B whereas for Alternative 2A, an FSS will be used. Therefore, the primary difference between Alternative 2B and Alternative 2A is effects to wetlands as a result of spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) in order to get the right water surface elevation for the diversion tunnel at Cougar reservoir, in addition to the deeper fall reservoir drawdown at Green Peter. . The spring reservoir drawdown at Cougar would occur May 1 to July 1 and the deeper fall reservoir drawdown at Cougar and Green Peter would occur October 15 to December 15. As the reservoir drawdowns occur, the water tables would lower within the wetlands that occur around the reservoir edges. These wetlands would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that these wetlands need; however, it is not clear to what extent. The spring and fall drawdowns at Cougar and the fall drawdown at Green Peter are anticipated to cause moderate observable effects (e.g., dead or dying wetland vegetation) to wetlands around the reservoirs.

In addition to changes to the water tables in wetlands around Cougar and Green Peter reservoirs as a result of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to wetlands as a result of localized erosion. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a risk of localized erosion. If localized erosion did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

During the first couple years of the spring reservoir drawdowns (#720) and deeper fall reservoir drawdowns (#40) at Cougar and Green Peter, sediment releases are anticipated that could accumulate along downstream stream margins within the South Santiam and McKenzie subbasins, affecting the hydrologic connectivity between the active channels and streamside PEM/PSS/PFO wetlands. The sediment transported downstream could be deposited so that a wetland is further removed from the stream channel and is therefore less likely to be influenced by the flow within the active channel. Another possibility is that sediment could be deposited along the downstream channel in such a way that causes erosion of a nearby wetland as the streamflow adjusts around the deposited material. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and therefore, only a negligible short-term effect is anticipated.

##### *3.7.2.6.1 Near-term Operations Measure*

See Alternative 2A, Section 3.7.2.5.1, for description of effects due to the Near-Term Operations Measure.

##### *3.7.2.6.2 Climate Change*

See No Action Alternative, Section 3.7.2.2., for a description of effects due to Climate Change that applies to each action alternative for wetlands. In the case of Alternative 2B, the spring drawdown at Cougar and fall drawdown at both Cougar and Green Peter is anticipated to cause minor observable effects to wetlands around the reservoirs, but this would be compounded by climate change effects which are anticipated to cause long-term, moderate, and observable (at the regional scale) effects to wetlands throughout the WVS. Therefore, it is possible that the effects of the deep drawdowns combined with the effects of climate change could cause major effects to wetlands at Cougar and Green Peter reservoirs, including loss of wetland acreage and ecological functions specific to wetlands. It is worth noting that because on-the-ground wetland surveys have not been conducted, it is unclear how many wetlands and how large an area would be affected.

##### *3.7.2.6.3 Alternative 2B Wetlands Effects Summary Table*

Table 3.7-5 below presents a summary of the effects to wetlands within the WVS as a result of implementation of Alternative 2B.

**Table 3.7-5. Summary of Effects for Wetlands under Alternative 2B as Compared to the Alternative 2B -- Integrated Water Management Flexibility and ESA-Listed Fish Alternative**

| Subbasin | Alternative 2B |

| Coast Fork of the Willamette Subbasin | Negligible change |
| Mainstem Willamette River | Negligible change |

#### *3.7.2.7 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures*

Measures that would potentially affect the wetlands within the WVS as part of Alternative 3A include integrated temperature and habitat flow regime (#30a), which is not anticipated to have a measurable effect to the frequency of inundation and therefore would have negligible effects to PEM/PSS/PFO wetlands within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to wetlands around reservoirs, Alternative 3A (similar to Alternatives 1, 2A, and 2B) includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit (as in Alternatives 1, 2A, and 2B) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Cottage Grove, Dorena, Fall Creek, and Blue River and this measure allows the projects to drawdown the pools during the fall. As these drawdowns occur, the water table that provides hydrology to the wetlands around the reservoirs would drop. As the water table drops, wetlands would change in character (e.g, loss of wetland plants and soil moisture) and be less likely to provide ecological functions (e.g., water quality, wildlife habitat, biodiversity) over time. There is also the potential for minor, adverse, local effects to wetlands from localized erosion along the upstream reservoir rims due to either of these measures. If localized erosion did occur, there is potential that the debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

In addition, a spring reservoir drawdown (#720) at Cougar, Detroit, and Lookout Point reservoirs (May 1 to July 1) and deeper fall reservoir drawdowns (#40) at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs (October 15 to December 15) for fish passage are part of Alternative 3A. These spring and fall drawdowns would also affect hydrologic conditions that support PEM/PSS/PFO wetlands that are along the reservoirs. As the reservoir drawdowns occur, the water tables would lower, making the wetlands reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that these wetlands need; however, it is not clear to what extent. The spring and fall drawdowns are anticipated to cause moderate observable effects (e.g., dead or dying wetland vegetation) to wetlands around the reservoirs.

In addition to changes to the water tables in wetlands around Cougar and Green Peter reservoirs as a result of a spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to wetlands as a result of localized erosion. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a risk of localized erosion. If localized erosion did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

During the first couple years of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), sediment releases are anticipated that could accumulate along downstream stream margins within the Middle Fork Willamette, North Santiam, South Santiam, and McKenzie subbasins, affecting the hydrologic connectivity between the active channels and streamside PEM/PSS/PFO wetlands. The sediment transported downstream could be deposited so that a wetland is further removed from the stream channel and is therefore less likely to be influenced by the flow within the active channel. Another possibility is that sediment could be deposited along the downstream channel in such a way that causes erosion of a nearby wetland as the streamflow adjusts around the deposited material. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and therefore, only a negligible short-term effect is anticipated.

##### *3.7.2.7.1 Near-term Operations Measure*

See Alternative 2A, Section 3.7.2.5.1, for description of effects due to the Near-Term Operations Measure.

##### *3.7.2.7.2 Climate Change*

See No Action Alternative, Section 3.7.2.2., for a description of effects due to Climate Change that applies to each action alternative for wetlands. In the case of Alternative 3A, spring drawdowns at Cougar, Detroit, and Lookout Point and deep fall drawdowns at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs are anticipated to cause minor observable effects to wetlands around the reservoirs, but this would be compounded by climate change effects which are anticipated to cause long-term, moderate, and observable (at the regional scale) effects to wetlands throughout the WVS. Therefore, it is possible that the effects of the deep drawdowns combined with the effects of climate change could cause major effects to wetlands at these reservoirs, including loss of wetland acreage and ecological functions specific to wetlands. It is worth noting that because on-the-ground wetland surveys have not been conducted, it is unclear how many wetlands and how large an area would be affected but because the deep drawdowns would be extensive for Alternatives 3A and 3B, major effects would be anticipated.

##### *3.7.2.7.3 Alternative 3A Wetlands Effects Summary Table*

Table 3.7-6 below presents a summary of the effects to wetlands within the WVS as a result of implementation of Alternative 3A.

**Table 3.7-6. Summary of Effects for Wetlands under Alternative 3A as compared to the Alternative 3A – Improve Fish Passage Through Operations-Focused Measures**

#### *3.7.2.8 Alternative 3B – Improve Fish Passage Through Operations-Focused Measures using Diversion Tunnel at COU*

In terms of measures that affect wetlands, Alternative 3B is very similar to Alternative 3A. One of the differences is that under Alternative 3B the spring reservoir drawdown (#720) would occur at Cougar, Green Peter, and Hills Creek reservoirs instead of Cougar, Detroit, and Lookout Point reservoirs. In addition, at Cougar the spring and fall drawdowns will be down to the diversion tunnel to allow for downstream fish passage. Another difference is that augmenting instream flows by using the power pool (#304) will not be implemented at Cougar for Alternative 3B as it had in Alternative 3A. Overall effects for Alterative 3B are characterized in more detail below.

A measure that could potentially affect the wetlands within the WVS as part of Alternative 3B include integrated temperature and habitat flow regime (#30a, which is not anticipated to have a measurable effect to the frequency of inundation and therefore would have negligible effects to PEM/PSS/PFO wetlands within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

The spring reservoir drawdown (#720) at Cougar, Green Peter, and Hills Creek reservoirs (May 1 to July 1) and deeper fall reservoir drawdowns (#40) at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs (October 15 to December 15) for fish passage would affect hydrologic conditions that support PEM/PSS/PFO wetlands along the reservoirs. As the reservoir drawdowns occur, the water tables would lower, making the wetlands reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that these wetlands need; however, it is not clear to what extent. Nor is it clear as to how seasons might shift within the next 30 years as a result of climate change. These effects, which would likely include a loss of wetland acreage, would be moderate. The spring and fall drawdowns are anticipated to cause moderate observable effects (e.g., dead or dying wetland vegetation) to wetlands around the reservoirs, while the long-term effects of climate change are anticipated to cause moderate, observable at the regional scale, effects to wetlands throughout the WVS.

In addition to changes to the water tables in wetlands around Cougar and Green Peter reservoirs as a result of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to wetlands as a result of localized erosion. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a risk of localized erosion. If localized erosion did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

During the first couple years of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), sediment releases are anticipated that could accumulate along downstream stream margins within the Middle Fork Willamette, North Santiam, South Santiam, and McKenzie subbasins, affecting the hydrologic connectivity between the active channels and streamside PEM/PSS/PFO wetlands. The sediment transported downstream could be deposited so that a wetland is further removed from the stream channel and is therefore less likely to be influenced by the flow within the active channel. Another possibility is that sediment could be deposited along the downstream channel in such a way that causes erosion of a nearby wetland as the streamflow adjusts around the deposited material. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and therefore, only a negligible short-term effect is anticipated.

Alternative 3B includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Cottage Grove, Dorena, Fall Creek, and Blue River and this measure allows the projects to drawdown the pools during the fall. There is also the potential for minor, adverse, local effects to wetlands from localized erosion along the upstream reservoir rims due to either of these measures. If localized erosion did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

*3.7.2.8.1 Near-term Operations Measure*

See Alternative 2A, Section 3.7.2.5.1, for description of effects due to the Near-Term Operations Measure.

*3.7.2.8.2 Climate Change*

See No Action Alternative, Section 3.7.2.2., for a description of effects due to Climate Change that applies to each action alternative for wetlands. In the case of Alternative 3B, spring drawdowns at Cougar, Green Peter, and Hills Creek reservoirs and deep fall drawdowns at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs are anticipated to cause minor observable effects to wetlands around the reservoirs, but this would be compounded by climate change effects which are anticipated to cause long-term, moderate, and observable (at the regional scale) effects to wetlands throughout the WVS. Therefore, it is possible that the effects of the deep drawdowns combined with the effects of climate change could cause major effects to wetlands at these reservoirs, including loss of wetland acreage and ecological functions specific to wetlands. It is worth noting that because on-the-ground wetland surveys have not been conducted, it is unclear how many wetlands and how large an area would be affected but because the deep drawdowns would be extensive for Alternatives 3A and 3B, major effects would be anticipated.

*3.7.2.8.3 Alternative 3B Wetlands Effects Summary Table*

Table 3.7-7 below presents a summary of the effects to wetlands within the WVS as a result of implementation of Alternative 3B.

**Table 3.7-7. Summary of Effects for Wetlands under Alternative 3B as Compared to the Alternative 3B – Improve Fish Passage Through Operations-Focused Measures using Diversion Tunnel at COU**

### *3.7.2.9 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

Effects to wetlands from Alternative 4 would be similar to those of Alternative 1 since these both of these alternatives avoid spring and fall drawdowns and instead utilize structures for water quality and fish passage objectives. This alternative would include constructing water temperature control towers (#105) at Detroit, Hills Creek, and Lookout Point; Providing Pacific lamprey passage and infrastructure (#52) at Cougar, Dexter, and Hills Creek; restore upstream and downstream passage at drop structures (#639) on the Long Tom River downstream of Fern Ridge; and constructing structural downstream fish passage (#392) at Cougar, Detroit, Foster, Hills Creek, and Lookout Point. Measures included are focused on improving water quality and fish passage.

Measures that would potentially affect the wetlands within the WVS as part of Alternative 4 include integrated temperature and habitat flow regime (#30a), which is not anticipated to have a measurable effect to the frequency of inundation and therefore would have negligible effects to PEM/PSS/PFO wetlands within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to wetlands around reservoirs, Alternative 4 includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit (as in Alternatives 1, 2A, 2B, and 3A) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Cottage Grove, Dorena, Fall Creek, and Blue River and this measure allows the projects to drawdown the pools during the fall. As these drawdowns occur, the water table that provides hydrology to the wetlands around the reservoirs would drop. As the water table drops, wetlands would change in character (e.g, loss of wetland plants and soil moisture) and be less likely to provide ecological functions (e.g., water quality, wildlife habitat, biodiversity) over time. There is also the potential for minor, adverse, local effects to wetlands from localized erosion along the upstream reservoir rims due to either of these measures. If localized erosion did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

#### *3.7.2.9.1 Near-term Operations Measure*

See Alternative 2A, Section 3.7.2.5.1, for description of effects due to the Near-Term Operations Measure.

#### *3.7.2.9.2 Climate Change*

See No Action Alternative, Section 3.7.2.2., for a description of effects due to Climate Change that applies to each action alternative for wetlands. Alternative 4 entails minor hydrologic effects to wetlands around the reservoirs and negligible hydrologic effects to riverine wetlands within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins. Climate change is anticipated to cause moderate long-term effects to wetlands within the WRB, which would not be anticipated to be further exacerbated by Alternative 4 measures.

#### *3.7.2.9.3 Alternative 4 Wetlands Effects Summary Table*

Table 3.7-8 below presents a summary of the effects to wetlands within the WVS as a result of implementation of Alternative 4.

**Table 3.7-8. Summary of Effects for Wetlands under Alternative 4 as Compared to the Alternative 4 – Improve Fish Passage with Structures-Based Approach**

| Subbasin | Alternative 4 |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with long-term benefits to streamside wetlands<br>North and South Santiam rivers - minor decreases to downstream flows with negligible long-term effects to streamside wetlands<br>Green Peter and Detroit - drawdowns with minor long-term effects to wetlands around the reservoirs<br>Green Peter and Detroit - localized erosion with short-term minor adverse effects to wetlands |
| Long Tom Subbasin | Negligible change |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with long-term benefits to streamside wetlands<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible long-term effects to streamside wetlands |

#### *3.7.2.10 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 is nearly identical to Alternative 2B. However, similar to Alternative 2B, Alternative 5 stream flows will be adapted to fish survival and passage needs except that the integrated temperature and habitat flow regime (#30a) has been replaced by the refined integrated temperature and habitat flow regime (#30b). Neither of these measures would have a measurable effect to the frequency of inundation and therefore, would have negligible effects to wetlands within the downstream aquatic and riparian areas of North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of effects to wetlands around reservoirs, Alternative 5 (similar to Alternatives 1, 2A, and 2B) includes augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718), which both result in reservoir drawdowns below the normal rule curve elevations. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Green Peter, and Detroit (as in Alternatives 1 and 2A) and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River and this measure allows the projects to drawdown the pools during the fall. As these drawdowns occur, the water table that provides hydrology to the wetlands around the reservoirs would drop. As the water table drops, wetlands would change in character (e.g, loss of wetland plants and soil moisture) and be less likely to provide ecological functions (e.g., water quality, wildlife habitat, biodiversity) over time.

There is also the potential for minor adverse local effects to wetlands from localized erosion along the upstream reservoir rims due to either of these measures. If slope failures did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

As with Alternative 2B, the diversion tunnel will be used for fish passage at the Cougar dam for Alternative 5. Therefore, the spring reservoir drawdown (#720) at Cougar would occur May 1 to July 1 and the deeper fall reservoir drawdowns (#40) at Cougar and Green Peter would occur October 15 to December 15. As the reservoir drawdowns occur, the water tables would lower within the wetlands that occur around the reservoir edges. These wetlands would become reliant on precipitation as the primary source of hydrology. During the spring and fall, precipitation is capable of supplementing the water that these wetlands need; however, it is not clear to what extent. The spring and fall drawdowns at Cougar and the fall drawdown at Green Peter are anticipated to cause moderate observable effects (e.g. dead or dying wetland plants) to wetlands around the reservoirs.

In addition to changes to the water tables in wetlands around Cougar and Green Peter reservoirs as a result of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40), there could be effects to wetlands as a result of localized erosion. Cougar reservoir has a mapped ancient landslide along the reservoir rim about 1.3 miles upstream of the dam and Green Peter has a large ancient landslide directly upstream of the dam, although it is difficult to tell from available information whether the landslide is in contact with the reservoir and drawdowns would therefore pose a localized erosion risk. If localized erosion did occur, there is potential that the landslide debris could bury existing wetlands, ultimately causing a long-term loss of wetland function and acreage, which would be considered a minor effect since effects are anticipated to be relatively small and limited to a certain area. Because wetland surveys specific to these areas have not been conducted to date, it is impossible to quantify the wetland acreage that could be affected.

During the first couple years of the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) at Cougar and Green Peter, sediment releases are anticipated that could accumulate along downstream stream margins within the South Santiam and McKenzie subbasins, affecting the hydrologic connectivity between the active channels and streamside PEM/PSS/PFO wetlands. The sediment transported downstream could be deposited so that a wetland is further removed from the stream channel and is therefore less likely to be influenced by the flow within the active channel. Another possibility is that sediment could be deposited along the downstream channel in such a way that causes erosion of a nearby wetland as the streamflow adjusts around the deposited material. It should be noted that this sediment is anticipated to be flushed downstream after a couple of years of high flow events that typically occur in the winter and therefore, only a negligible short-term effect is anticipated.

#### *3.7.2.10.1 Near-term Operations Measure*

See Alternative 2A, Section 3.7.2.5.1, for description of effects due to the Near-Term Operations Measure.

#### *3.7.2.10.2 Climate Change*

See No Action Alternative, Section 3.7.2.2., for a description of effects due to Climate Change that applies to each action alternative for wetlands. In the case of Alternative 5, the spring drawdown at Cougar and fall drawdown at both Cougar and Green Peter is anticipated to cause minor observable effects to wetlands around the reservoirs, but this would be compounded by climate change effects which are anticipated to cause long-term, moderate, and observable (at the regional scale) effects to wetlands throughout the WVS. Therefore, it is possible that the effects of the deep drawdowns combined with the effects of climate change could cause major effects to wetlands at Cougar and Green Peter reservoirs, including loss of wetland acreage and ecological functions specific to wetlands. It is worth noting that because on-the-ground wetland surveys have not been conducted, it is unclear how many wetlands and how large an area would be affected.

#### *3.7.2.10.3 Alternative 5 Wetlands Effects Summary Table*

Table 3.7-9 below presents a summary of the effects to wetlands within the WVS as a result of implementation of Alternative 5.

**Table 3.7-9. Summary of Effects for Wetlands under Alternative 5 as Compared to the Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)**

## 3.8 FISH AND AQUATIC HABITAT

This section covers fish and aquatic habitat found in the Willamette River and its tributaries. Management and conservation of these aquatic resources is a high priority for the U.S. Army Corps of Engineers (USACE) and one of the authorizing purposes of the WVS.

### 3.8.1 Affected Environment

The Affected Environment describes the anadromous and non-anadromous fish, and aquatic habitat affected by the WVS.

#### *3.8.1.1 Anadromous and Migratory Fish*

Operation and maintenance of the WVS affects aquatic wildlife and ESA-listed species in the WBR. Federally threatened anadromous and migratory fish species include:

- UWR spring Chinook salmon (*Oncorhynchus tshawytscha*),
- UWR winter steelhead (*Oncorhynchus mykiss*), and
- Bull trout (*Salvelinus confluentus*).

Although not federally listed under the ESA, Pacific lamprey (*Entosphenus tridentatus*) is another sensitive and culturally important anadromous fish also affected by the WVS. Pacific Lamprey are found in the Willamette Falls adult fishway (Hess et al. 2020), the mainstem of the Willamette (Clemens & Schrek, 2021), and there is some evidence of a landlocked population in the Middle Fork Willamette (Larson et al., 2020). About 3% of Snake River returns stray to the Willamette River (Hess et al., 2022). The Willamette River and its tributaries constitute one management unit, but it is generally recognized that distinct populations exist within this unit (ODFW, 2019). USACE currently incorporates lamprey features into new and existing adult salmonid facilities to pass lamprey upstream of the traps. Aside from routes in operation at each dam (e.g., spillways, turbine penstocks, regulating outlets), there are currently no specific facilities in place for passage of juvenile stages of lamprey downstream of dams.

In 1999, NMFS listed the Upper Willamette River Chinook evolutionarily significant unit (ESU) (*O. tshawytscha*) (UWR Chinook salmon) as a threatened species under the ESA. This ESU includes all naturally spawned populations of spring-run Chinook salmon in the Clackamas River and in the Willamette River, and its tributaries upstream of the Willamette Falls near Oregon City, OR. The Willamette/Lower Columbia Technical Recovery Team (WLCTRT) identifies seven independent, historical populations within this ESU:

- Clackamas River
- Molalla River
- North Santiam River
- South Santiam River

- Calapooia River
- McKenzie River
- Middle Fork Willamette River

Anadromous species rear (grow) in freshwater and migrate to the ocean. Chinook salmon emerge from gravel "redds" (i.e., nests), rear in freshwater, then migrate to the ocean a few months to one year after emergence. For this reason, medium-size cobble are preferred spawning characteristics because it allows for adequate flow and aeration. Adult Chinook salmon spend one to five years at sea before returning to freshwater to spawn. Chinook salmon are semelparous, that is – like coho, sockeye, pink, and chum salmon – they perish after spawning.

Table 3.8-1 is adapted from Table 3-4 from the NMFS 2008 Willamette Project Biological Opinion. The top row indicates the month of the calendar year. The rows indicate the life history stage. Darker shades indicate peak activity for the life stage, lighter shades indicate less pronounced life history stage activity. White cells indicate little or no life stage activity within the Willamette River system.

**Table 3.8-1. Life history timing for UWR spring Chinook salmon**

| Month | J | F | M | A | M | J | J | A | S | O | N | D |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Upstream Migration | | | | | | | | | | | | |
| SpawnCing in Tributaries | | | | | | | | | | | | |
| Intragravel Development | | | | | | | | | | | | |
| Juvenile Rearing | | | | | | | | | | | | |
| Juvenile Out-migration | | | | | | | | | | | | |

UWR spring Chinook salmon are one of the most genetically distinct groups of Chinook salmon (Figure 3.8-1) in the Columbia River basin. Historically, before the placement of a fish ladder at Willamette Falls, passage by returning adult salmonids over Willamette Falls was possible only during the winter and spring high-flow periods. The early run timing of UWR Chinook salmon relative to other lower Columbia River spring-run populations is viewed as an adaptation to flow conditions at Willamette Falls. Since the Willamette Valley was not glaciated during the last epoch, the reproductive isolation provided by Willamette Falls was probably uninterrupted for a considerable time and provided the potential for significant local adaptation relative to other Columbia River populations.

The largest spring Chinook populations in the ESU were found historically in the North Santiam and the Middle Fork Willamette subbasins. The Coast Fork, Long Tom, and Blue River historically produced very small numbers, if any, spring Chinook.

Prior to the start of WVS dam construction in sub-basins where spring Chinook salmon populations occurred, the count of wild spring Chinook salmon returning to Willamette Falls was about 55,000 in 1946 and 47,000 in 1947. Although runs were already in decline due to fishing and land use practices, runs continued to diminish as WVS dams were constructed in the Santiam, McKenzie, and Middle Fork sub-basins. After 1960, less than 20,000 wild Chinook were counted at Willamette Falls. WVS dams and revetments were constructed mostly in eastside tributaries of the Willamette Basin during the 1950s and 1960s. WVS projects block access to critical habitat for Chinook and other ESA-listed species and more recently, the number of wild returns has been just over 10,000. While fish passage at high head dams continues to be evaluated, Congress approved authority for the Willamette Hatchery Mitigation Program (USACE, 1948).

**Figure 3.8-1. Adult Chinook Salmon – largest species of the Pacific salmonids**

Limiting factors identified in the UWR Recovery Plan (ODFW and NMFS 2011) for UWR Chinook and steelhead are listed below. All except the last two items, in part or in whole, can be related to effects of operation and maintenance of the WVS.

- Habitat access (impaired downstream passage of juveniles and steelhead kelts at water control facilities, leading to direct and delayed mortality) due to dams
- Habitat access (impaired adult access to holding and spawning habitat due to migration barriers) due to dams
- Habitat access (lack of spawning opportunity due to pre-spawning mortality impacts associated with handling stresses at sorting facilities and altered hydrology/WQ below dams)
- Population traits (impaired productivity and diversity) due to hatchery fish interbreeding with wild fish on the spawning grounds

- Competition (due to hatchery programs)
- Food web (impaired growth and survival from changes to estuarine food web)
- Predation by naturally produced native and non-native species, hatchery summer steelhead, hatchery rainbow trout, birds in the estuary
- Physical habitat quality due to excessive fine sediments due to land use practices
- Physical habitat quality due to flood control/hydropower sources
- Impaired habitat complexity and diversity
- Impaired water temperature
- Impaired water quality from input of toxins
- Altered hydrology below dams
- Insufficient stream flows and floodplain storage from land use practices
- Mortality from targeted fisheries and from bycatch

A recent summary of population viability was completed by NOAA NWFSC (NWFSC, 2022). Although NOAA has not completed a new status review since 2016, the information in the NWFSC report indicates the status of the UWR Chinook populations is likely unchanged from the previous status review completed (NOAA 2016). Figure 3.8-2 shows UWR Chinook spring salmon adult counts at Willamette Falls and population spawning abundance in key WRB sub-basins and Table 3.8-2 shows estimated risk of extinction for the various UWR populations.

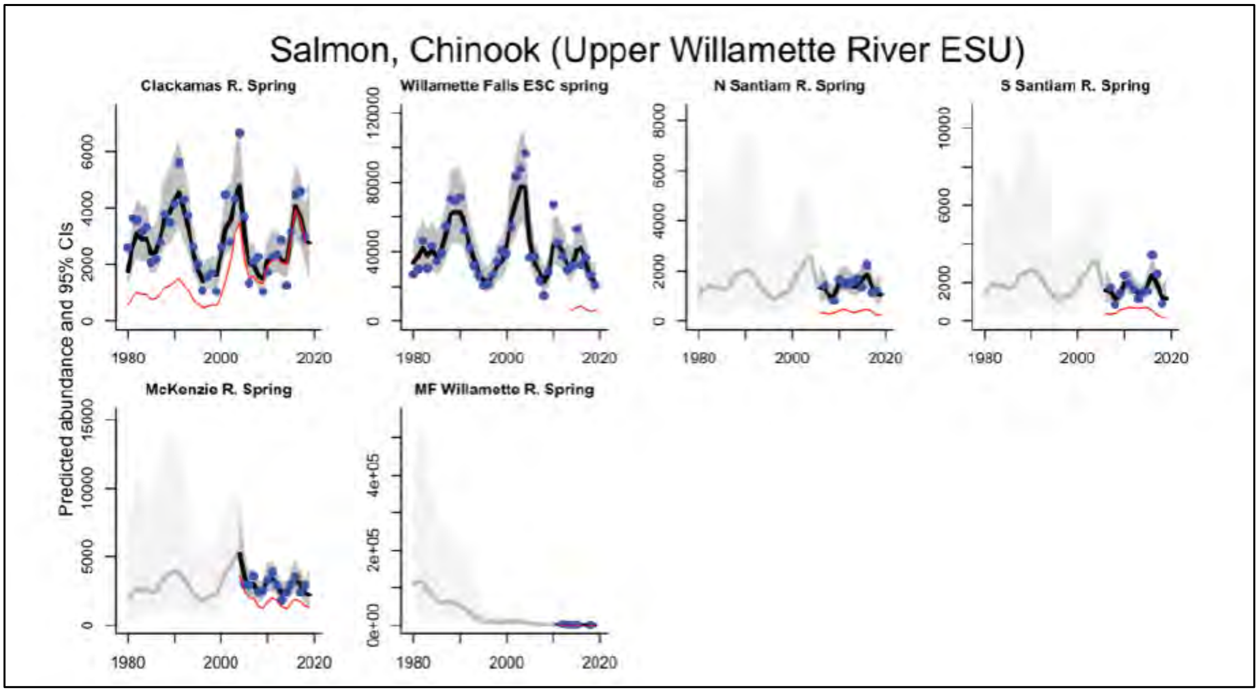

**Figure 3.8-2. Smoothed trend in estimated total (thick black line) and natural (thin red line) Willamette Falls counts and population spawning abundance. Points show the annual raw spawning abundance estimates. Chart from NWFSC (2022; Figure 79).**

**Table 3.8-2. Risk of extinction for UWR Chinook salmon (adapted from UWR Recovery Plan, ODFW & NMFS 2011, Table 3-3)**

| Stratum | Population | Extinction Risk Category |
|---|---|---|
| Upper Willamette | Clackamas | Low |
| | Molalla | Very High |
| | North Santiam | Very High |
| | South Santiam | Very High |
| | Calapooia | Very High |
| | McKenzie | Moderate |
| | Middle Fork Willamette | Very High |

The UWR steelhead (Figure 3.8-3) was listed as a threatened species under the ESA in 1999. This DPS includes all naturally spawned populations of winter-run steelhead in the Willamette River and its tributaries upstream of Willamette Falls to the Calapooia River. This distinct population segment (DPS) does not include any artificially propagated steelhead stocks that reside within the historical geographic range of the DPS. Hatchery summer-run steelhead occur in the Willamette River basin but are an out-of-basin stock that are not included as part of the DPS (71 FR 834). There are four independent populations recognized within the UWR winter-run steelhead DPS:

- Molalla River,
- North Santiam River,
- South Santiam River, and
- Calapooia River.

**Figure 3.8-3. Spawning Steelhead Trout**

Steelhead life history is slightly different than Chinook: juveniles rear in freshwater for one to three years, and can remain in the ocean up to six years. Furthermore, steelhead may be iteroparous, that is, they may return to the ocean after spawning. Spawners returning to the ocean are known as “kelts.” This fish species also express a completely freshwater life history type. Steelhead that remain in freshwater are said to “residualize” as rainbow trout. This flexibility allows the species to optimize resources in both the freshwater and ocean environments.

All runs of Chinook and steelhead are designated by the time of year which they return to freshwater as adults. In the Willamette, adult Chinook salmon enter the freshwater environment mainly in spring. These are known as spring Chinook salmon. Adult steelhead in the Willamette begin entering freshwater in the winter, with peak upstream migration rates in early spring, to take advantage of higher river flows which support upstream migration. These are referred to as winter steelhead.

Table 3.8-3 is adapted from Table 3-8 from the NMFS 2008 Willamette Project Biological Opinion. The top row indicates the month of the calendar year. The rows indicate the life history stage. Darker shades indicate peak activity for the life stage, lighter shades indicate less pronounced life history stage activity. White cells indicate little or no life stage activity within the Willamette River system.

Viability was determined by NMFS for all UWR steelhead populations at a moderate risk of extinction (Table 3.8-4) in their most recent status review (NMFS 2016). A recent summary of population viability was completed by NOAA NWFSC (NWFSC 2022). The information suggests the status of the populations likely remains the same as found in the most recent status review (NOAA 2016), however the NWFSC (2022) notes that the DPS has experienced a declining abundance trend.

**Table 3.8-3. Life history timing for UWR winter steelhead**

| Month | J | F | M | A | M | J | J | A | S | O | N | D |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Upstream Migration | | | | | | | | | | | | |
| Spawning in Tributaries | | | | | | | | | | | | |
| Intragravel Development | | | | | | | | | | | | |
| Juvenile Rearing | | | | | | | | | | | | |
| Juvenile Out-migration | | | | | | | | | | | | |

**Table 3.8-4. Risk of Extinction Categories for UWR Steelhead Populations. Adapted from Table 3.4 in NOAA & ODFW 2011**

| Stratum | Population | Extinction Risk Category |
|---|---|---|
| Upper Willamette | Molalla | Moderate |
| | North Santiam | Moderate |
| | South Santiam | Moderate |
| | Calapooia | Moderate |

Data source: UWR Recovery Plan (ODFW and NMFS 2011).

Figure 3.8-4 shows the trend in population spawning abundance of the UWR steelhead from 1980 to 2019.

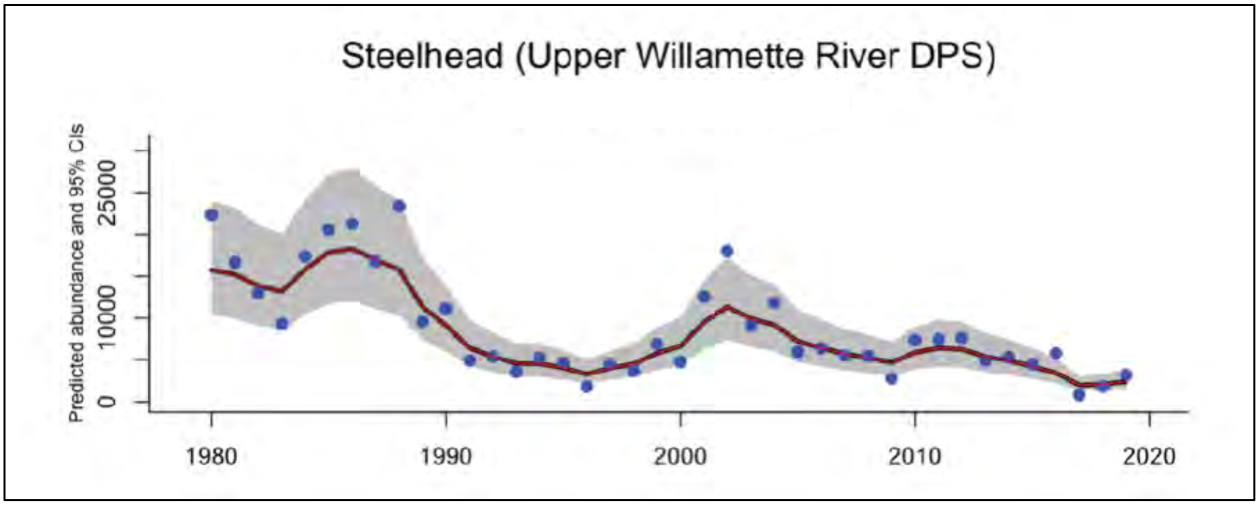

**Figure 3.8-4. Smoothed trend in estimated natural population spawning abundance.**

Note: Points show the annual raw spawning abundance estimates. Abundance estimates include both early (non-native) and late-winter (native) steelhead. Abundance estimates for Willamette Falls likely includes a much larger proportion of non-native fish than for the East Side tributary estimates. Points show the annual raw spawning abundance estimates. Chart from NWFSC (2022; Figure 87)

### *3.8.1.2 Non-Anadromous Fish*

The Willamette River Basin supports diverse populations of anadromous and resident fish species and aquatic organisms. These fish species are a mix of native and non-native (i.e., introduced) species. Table 3.8-5 lists the species found in the basin and their protected status.

**Table 3.8-5. Fish species found in the Willamette River Basin**

| Common name | Scientific name | Federal status | State status | Native or Introduced |
|---|---|---|---|---|
| Steelhead Trout | *Oncorhynchus mykiss* | Threatened | Sensitive-Critical | Native |
| Chinook Salmon | *Oncorhynchus tshawytscha* | Threatened | Sensitive-Critical | Native |
| Chiselmouth | *Acrocheilus alutaceus* | | | Native |
| Bull Trout | *Salvelinus confluentus* | Threatened | Sensitive | Native |
| Largescale Sucker | *Catostomus macrocheilus* | | | Native |
| Mountain Sucker | *Catostomus platyrhynchus* | | | Native |
| Prickly Sculpin | *Cottus asper* | | | Native |
| Mottled Sculpin | *Cottus bairdii* | | | Native |
| Paiute Sculpin | *Cottus beldingii* | | | Native |

| Common name | Scientific name | Federal status | State status | Native or Introduced |
|---|---|---|---|---|
| Shorthead Sculpin | *Cottus confuses* | | | Native |
| Riffle Sculpin | *Cottus gulosus* | | | Native |
| Reticulate Sculpin | *Cottus perplexus* | | | Native |
| Torrent Sculpin | *Cottus rhotheus* | | | Native |
| Pacific Lamprey | *Entosphenus tridentatus* | | Sensitive | Native |
| Threespine Stickleback | *Gasterosteus aculeatus* | | | Native |
| Western Brook Lamprey | *Lampetra richardsoni* | | Sensitive | Native |
| Peamouth | *Mylocheilus caurinus* | | | Native |
| Coastal Cutthroat Trout | *Oncorhynchus clarkii* | | | Native |
| Rainbow Trout | *Oncorhynchus mykiss* | | | Native |
| Oregon Chub | *Oregonichthys crameri* | | | Native |
| Sand Roller | *Percopsis transmontane* | | | Native |
| Mountain Whitefish | *Prosopium williamsoni* | | | Native |
| Northern Pikeminnow | *Ptychocheilus oregonensis* | | | Native |
| Longnose Dace | *Rhinichthys cataractae* | | | Native |
| Leopard Dace | *Rhinichthys falcatus* | | | Native |
| Speckled Dace | *Rhinichthys osculus* | | | Native |
| Redside Shiner | *Richardsonius balteatus* | | | Native |
| Brown Bullhead | *Ameiurus nebulosus* | | | Introduced |
| Western Mosquitofish | *Gambusia affinis* | | | Introduced |
| Pumpkinseed | *Lepomis gibbosus* | | | Introduced |

| Common name | Scientific name | Federal status | State status | Native or Introduced |
|---|---|---|---|---|
| Warmouth | *Lepomis gulosus* | | | Introduced |
| Bluegill | *Lepomis macrochirus* | | | Introduced |
| Smallmouth Bass | *Micropterus dolomieu* | | | Introduced |
| Largemouth Bass | *Micropterus salmoides* | | | Introduced |
| Coho Salmon | *Oncorhynchus kisutch* | | | Introduced |
| Kokanee | *Oncorhynchus nerka* | | | Introduced |
| White Crappie | *Pomoxis annularis* | | | Introduced |
| Black Crappie | *Pomoxis nigromaculatus* | | | Introduced |

**Bull Trout**

Bull trout (Figure 3.8-5) are native to the Willamette River basin. The USFWS listed all populations of bull trout (*Salvelinus confluentus*) within the coterminous United States as a threatened species in 1999 (64 FR 58910). USFWS combines bull trout core habitat (i.e., habitat that could supply all elements for the long-term security of bull trout) with core populations (i.e., a group of one or more local bull trout populations that exist within core habitat) to create a "core area," which is the basic unit on which to gauge recovery within a unit. There are six bull trout recovery units which are used in the USFWS' Recovery Plan for the Coterminous United States Population of Bull Trout (2015). The Willamette River Basin – including the Upper Willamette River, Clackamas River, North Santiam River, and South Santiam River – is within the Coastal Recovery Unit (USFWS, 2015). Populations in the Willamette Basin currently exist in the Clackamas, McKenzie River and Middle Fork Willamette River basins. Bull trout populations also occupied portions of the North Santiam River historically, and were last observed there in 1945. USFWS is exploring the feasibility of expanding bull trout distribution into the North Santiam River (Hudson, 2017).

Of all the native salmonids in the Pacific Northwest of the United States, bull trout have the most specific habitat requirements, which are often referred to as "the four Cs": cold, clean, complex, and connected habitat. These requirements include cold water temperatures compared to other salmonids (often less than 54 degrees Fahrenheit); the cleanest stream substrates; complex stream habitat including deep pools, overhanging banks and large woody debris; and connectivity between spawning and rearing areas and downstream foraging, migration, and overwintering habitats. Bull trout populations are therefore dependent on cold-water fluvial habitat with limited human disturbance. In the Pacific Northwest, these habitats are largely located at high elevation, and suitable areas for spawning rearing, and foraging are patchily distributed. Habitat components that influence bull trout distribution and abundance include water temperature, cover, channel form and stability, valley form, spawning and rearing substrate, and migratory corridors (USFWS, 2015). In the Willamette Basin bull trout populations are located in the Cascade Mountains in areas that are the least impacted by human disturbances and maintain the coolest natural water temperatures in the basin. The WVS effects existing bull trout populations in the McKenzie and Middle Fork, which reside above Cougar Dam and Hills Creek Dam.

Connectivity to other habitat downstream of Cougar and Hills Creek dams could be important for several reasons, including: 1) population growth (especially for smaller populations) and life history diversity, 2) genetic exchange, 3) and, following catastrophic events, access to suitable habitat or recolonization sources. Climate adaptation is yet another reason habitat connectivity can be important. Major losses of suitable bull trout habitat throughout their range are expected from climate change projections (e.g., Isaak et al. 2012; Wenger et al. 2013). Reductions in downstream population boundaries for bull trout driven by climate change have already been observed (e.g. LeMoine et al., 2020).

Where risks are higher than the potential benefits, connectivity could be a detriment for bull trout. Downstream of Cougar and Hills Creek dams there is limited suitable spawning habitat for bull trout (Zymonas et al. 2021), and both human disturbances and water temperatures increase, thereby constraining the habitat value and risks for bull trout that move downstream. Individuals dispersing downstream therefore must “recruit” back to the spawning population above the dam. If the rate of spawner recruitment is lower than the rate of dispersal downstream, then downstream dispersal will result in population decline. If recruitment to the spawning population is not maintained by individuals remaining above the dam, then local extinction could occur (e.g. Al-Chokhachy et al., 2015). The likelihood of genetic exchange among populations above Cougar and Hills Creek dams appears low given the number of dams fish need to pass, effects of poor habitat conditions in lower watershed areas on bull trout survival rates and migration patterns, and lack of genetic exchanged documented (see Zymonas et al. 2021). In the face of climate change with the potential for increasing water temperatures, the negative consequences of connectivity become ever more important for managers to consider. Dispersal by bull trout downstream of WVS dams may be maladaptive for bull trout in today’s degraded environment below WVS dams, lack of spawning habitat, and expected further degradation with climate change.

Under existing conditions, bull trout populations above Cougar dam are stable (Figure 3.8.6) and the bull trout population above Hills Creek Dam has been steadily increasing in abundance for nearly a decade (Figure 3.8.7), based on redd counts reported by Zymonas et al. (2021). Depending on the type of action taken, changing fish passage conditions could increase emigration rates of bull trout downstream of these dams. It is uncertain if this will lead to net-negative effects for the currently stable/growing populations above WVS dams and result in a decline in recruitment and spawner abundance, or provide a net positive effect by expanding rearing and forage opportunities. Managing or minimizing changes in habitat conditions, especially below dams where human impacts are higher, will be difficult to achieve due to the pervasive nature of climate change and the limited extent of restoration actions (e.g. Isaak et al. 2022).

**Figure 3.8-5. Bull Trout (*Salvelinus confluentus*)**

Figure 3.8-6 shows the generally upward trend in **annual redd counts from 2005 to 2019 for bull trout in the Roaring River, a tributary of the South Fork McKenzie above Cougar Dam**.

Figure 3.8-7 shows a steeper upward trend since 2013 in annual redd counts for bull trout above Hills Creek Dam in the Middle Fork Willamette Basin.

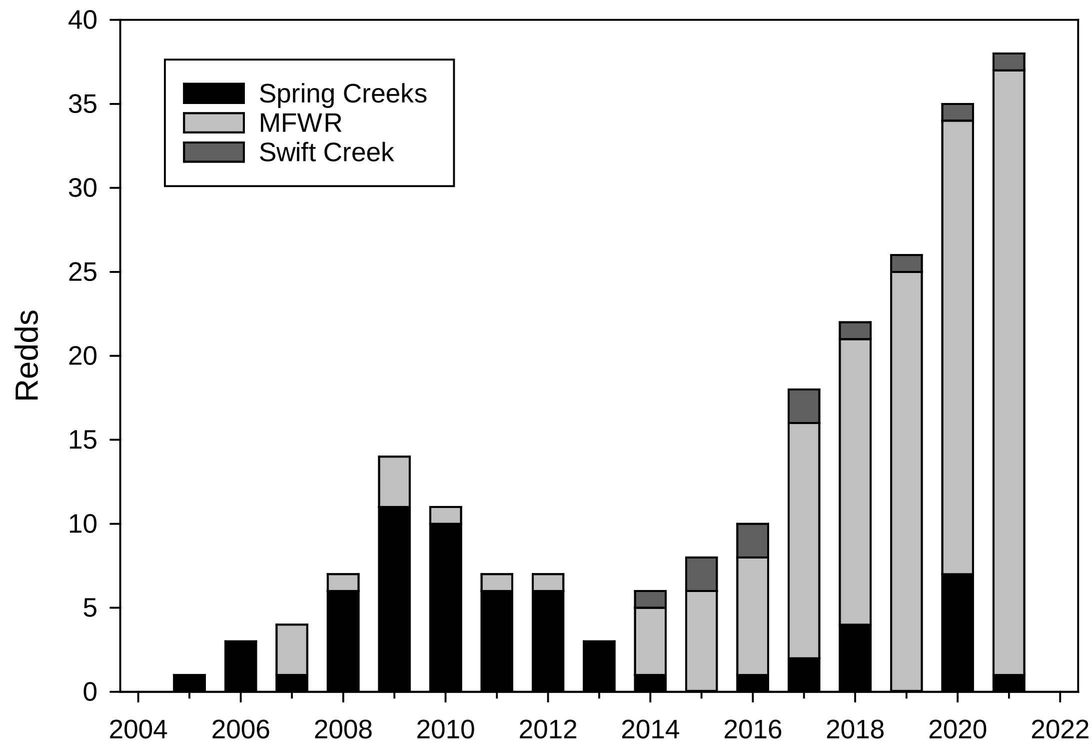

**Figure 3.8-7. Annual redd counts for bull trout in the Middle Fork Willamette Basin, above Hills Creek Dam. Figure reproduced from Zymonas et al. 2022.**

## Oregon Chub

Oregon chub (*Oregonichthys crameri*) is a native *cyprinid* that is found in the Willamette River basin primarily in off-channel or floodplain habitats with little to no water velocity. USFWS listed Oregon chub as endangered in 1993 and reclassified as threatened in 2010. When listed in 1993 there were only 1,000 known individuals. However, thanks to conservation efforts, the population grew to over 140,000 fish in at least 80 habitats by the time of delisting in 2015 (Figure 3.8-8). USFWS officially de-listed Oregon Chub on February 17, 2015 (USFWS, 2015).

ODFW has been implementing the Post-Delisting Monitoring Plan for the Oregon Chub (USFWS, 2014). The purpose is to track changes in distribution, abundance, habitat conditions, and threats after delisting. Relevant information for the North Santiam sub-basin is included below and is from the 2017 Oregon Chub Investigations Report (Bangs and Meeuwig, 2018).

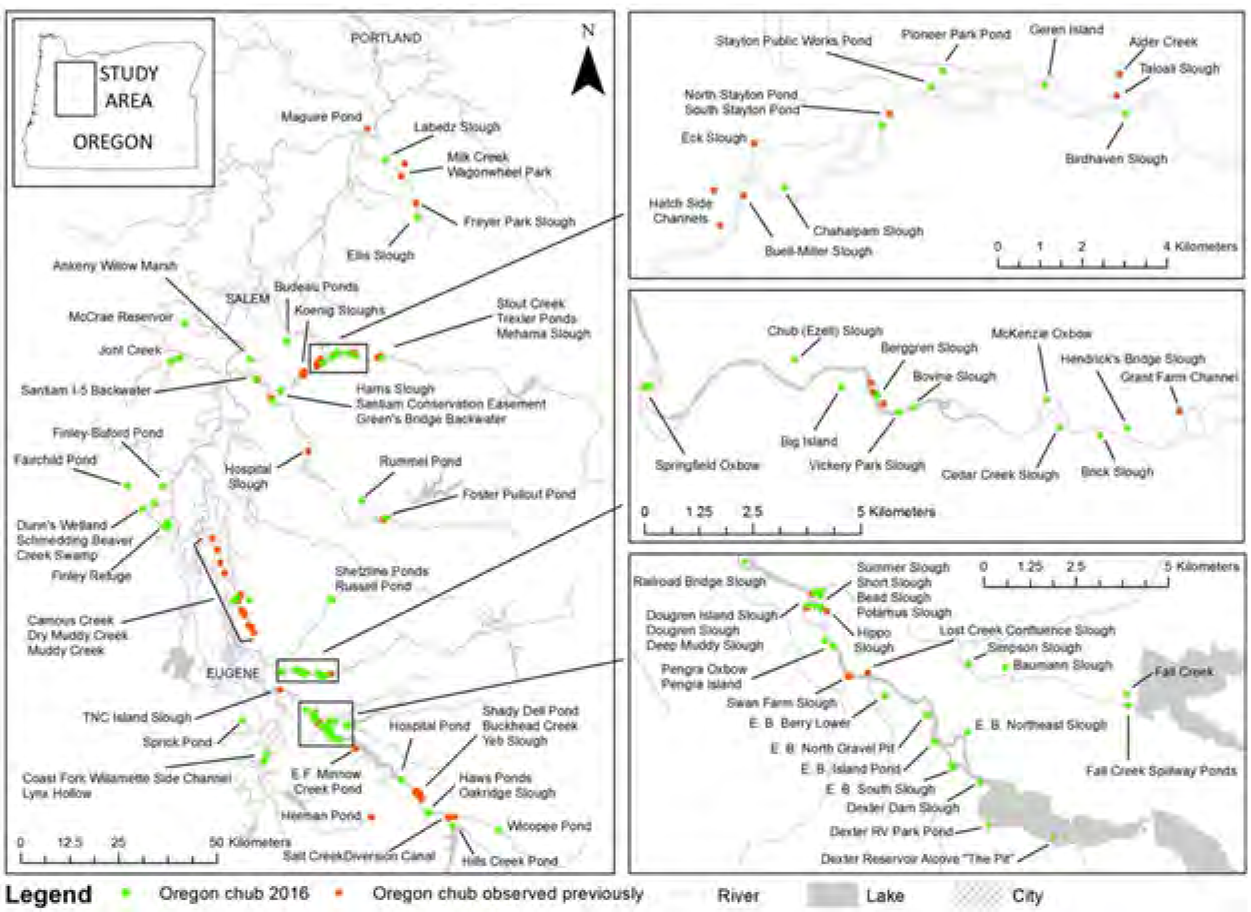

**Figure 3.8-8. All known Oregon Chub population in the Willamette River basin in 2017**

Note: Green circles indicate locations where Oregon Chub were detected during sampling. Red circles indicate locations where Oregon Chub were not detected during sampling but were observed previously. Overlapping symbols represent multiple locations occurring at or near the same survey location. Figure is from ODFW 2017 Oregon Chub Investigations (2018).

**Coastal Cutthroat Trout**

Coastal Cutthroat trout (*Oncorhynchus clarkii clarkii*) can be found in the Willamette River drainage into the headwaters of most tributaries (such as Stout, Ayers, and Shellburg Creeks) as well as a fluvial population (BLM, 2006). Anadromous coastal cutthroat trout have not be documented above Willamette Falls. The species management unit above Willamette Falls is considered 'not at risk' due to its wide distribution, relatively high abundance, and resilience to events that reduce abundance (ODFW, 2005).

**Rainbow Trout**

Native rainbow trout (*Oncorhynchus mykiss*) are river and lake dwelling in the Willamette River Basin, which provides habitat for all life stages. In addition to the native population, triploid (sterile) hatchery rainbow trout are released at various locations to provide for sport fishing opportunities. These hatchery fish come from various facilities (Leaburg, Willamette, Roaring River, Wizard Falls, Marion Forks, and Desert Springs). Although management operations proposed in this draft PEIS are not expected to impact native rainbow trout, there is evidence that stocked rainbow trout may affect native spring Chinook salmon and winter steelhead through competition and possibly predation (ref).

**Kokanee**

Kokanee (*Oncorhynchus nerka*) are a non-migratory sockeye salmon and are currently stocked to support a popular sport fishery. Kokanee are not native to the Willamette River Basin and were first stocked by the Oregon Fish Commission in 1959 (Wetherbee et al. 1965). Effects of non-native kokanee on native species have not been documented. Kokanee have become a major fishery for many anglers that contribute to the recreation attraction, local businesses, and livability of the area.

There are two types of kokanee salmon: stream spawners and lake shoreline spawners. During rearing and foraging, they inhabit the lake. Sexual maturity usually occurs at age three. For example, Kokanee in Detroit Reservoir naturally reproduce in the North Santiam River and tributaries, such as the Breitenbush, Tumble, French and Blowout Creeks, in the fall (Wetherbee, 1965).

Kokanee compete for zooplankton with other species in the lake whether stocked or naturally spawned. Monthly zooplankton data collected by Kokanee Power of Oregon (KPO) volunteers in recent years at Detroit Reservoir indicate there is sufficient zooplankton to support a healthy kokanee population. Low food supply reduces the kokanee growth rate. Large rainbow trout have been known to feed on kokanee.

Kokanee are most often found in deeper colder water and during the summer months are 80-100 feet below the surface in the reservoir but will change their depth depending on water temperature.

**Western Brook Lamprey**

The western brook lamprey is found in the Willamette River basin and is likely the second most common and widely distributed lamprey in Oregon after the Pacific lamprey (Kostow 2002 as cited in ODFW 2005). Western brook lampreys have no special state or federal status but are considered by the state as “at risk” (ODFW, 2005). Overall, little is known about western brook lamprey abundance and productivity in the Willamette River Basin.

### *3.8.1.3 Willamette System Features*

The lower Willamette consists mostly of sandy shores, rocky outcrops, and vegetated riprap that is seasonally available for use by aquatic fish and invertebrates (Friesen et al. 2005). Overall, water quality is good in upstream river sections closer to the foothills of the Cascades and declines with respect to temperature, oxygen demands, and agricultural nutrification downstream (Krass et al. 2021).

The Willamette River has undergone substantial man-made alterations and simplification since the 1850’s (Krass et al. 2021) including WVS project operations beginning in the early to mid-1900’s. The Willamette Falls Adult Fishway was constructed in the late 1880’s despite the fact that the falls presented a natural barrier to passage (Bennett 1986). Operation of the WVS may affect aquatic species by altering river flow and water temperatures, foremost in tributaries where WVS dams exist, and by impeded or blocking migration to and from habitat. Flood flows downstream of the WVS system have been reduced, and summer low flows have been increased. Water temperatures are generally cooler in summer below dams within tributaries. In fall, when water is discharged from reservoirs to support flood risk management, water temperatures below dams can be warmer than pre-dam conditions. These changes in river flow and water temperatures as discharged from WVS dams has altered the availability of aquatic habitat and biological responses of aquatic organisms (Figure 3.8-9).

In addition to dams, the WVS included construction of revetments to reduce bank erosion along the mainstem Willamette River and lower reaches of its major tributaries. The upper Willamette River upstream of Salem has been transformed from a braided to a channelized system along the valley floor to accommodate urbanization and agricultural expansion (Wallick et al. 2007). In reaches now seasonally or continuously impounded by dam operations, aquatic habitat has substantially changed, supporting animals and plants capable of using more lentic-type habitat conditions.

**Figure 3.8-9. Adult Mayfly**

Several actions have been completed over the last 10-15 years to restore access of Chinook and steelhead to habitat upstream of WVS dams, including construction of four new adult fish facilities (Minto, Foster, Cougar and Fall Creek) for collection and transport of adult Chinook and steelhead to spawning habitat upstream of WVS dams in the North Santiam River, South Santiam River, South Fork McKenzie and Fall Creek. Downstream fish passage actions have also been taken at Foster Dam with use of a fish spill weir, and an annual reservoir drawdown to riverbed elevation at Fall Creek Dam. Ongoing efforts include operations for downstream fish passage and temperature improvement implemented at several dams, improvements to road access to adult fish release sites at spawning grounds above the dams, and ongoing research to fill data gaps supporting alternative selection and design. While it is generally accepted that upstream passage can be accomplished through appropriate infrastructure and best management practices using traps and trucks, downstream passage effectiveness is less certain and potential solutions are complicated by large water level elevation fluctuations in reservoirs for flood control. Therefore, the WVS project effects are less certain with respect to the feasibility of juvenile downstream survival.

#### *3.8.1.4 Hatcheries, wild salmon, and steelhead*

When the WVS was authorized, the dams were anticipated to have a negative impact on wild salmon and steelhead runs. Hatchery production of Chinook salmon, steelhead, and game fish already established by the state of Oregon was increased to mitigate for lost habitat above WVS dams. These hatchery programs originally included winter steelhead, however at the request of the state of Oregon, the Corps-funded winter steelhead hatchery was discontinued in the 1980’s in favor of summer steelhead. Over time, the resident fish hatchery program was also simplified from a program of several species to solely rainbow trout production with a Corps funded annual basin-wide release of 277,000 pounds (ODFW and USACE, 2016). In recent years, the total abundance of wild spring Chinook upstream migration at Willamette Falls was just over 10,000 annually, while total abundance of hatchery spring Chinook upstream migration at Willamette Falls is around 20,000.

**Table 3.8-6. Hatchery production goals (number of smolts) for UWR spring Chinook salmon in each sub-basin according to the Hatchery Genetics Management Plans**

| Sub-basin | ESA Conservation Purpose (per HGMP) | Remaining Discretionary Corps Release (per HGMP) | ODFW-funded Release per HGMP | Total Hatchery Release |
|---|---|---|---|---|
| North Santiam | 630,000 | 74,000 | 0 | 704,000 |
| South Santiam | 350,000 | 289,000 | 382,000 | 1,021,000 |
| McKenzie | 604,750 | 0 | 0 | 604,750 |
| Middle Fork Willamette | NA | 2,039,000 | 0 | 2,039,000 |

**Table 3.8-7. Hatchery production goals (number of smolts) for summer steelhead in each sub-basin according to the Hatchery Genetics Management Plan**

| Sub-basin | Discretionary Corps Release (per HGMP) | ODFW-funded Release per HGMP | Total Hatchery Release |
|---|---|---|---|
| North Santiam | 0 | 121,000 | 121,000 |
| South Santiam | 0 | 121,000 | 121,000 |
| McKenzie | 0 | 108,000 | 108,000 |
| Middle Fork Willamette/Mainstem | 157,000 | 0 | 157,000 |

USACE's hatchery programs – UWR spring Chinook salmon, summer steelhead, and rainbow trout – can impact ESA-listed fish through fish attenuation to a captive rearing environment, a reduction in the frequency of wild type genes (i.e., domestication effects), increased risk of pre-spawn mortality, competition, introgression, predation, and recreational fishery impacts. Much research is available regarding these potential impacts (Christie et al. 2016, Araki et al. 2009, Araki et al. 2008, Weber and Fausch 2003, Wang et al. 2002, Fleming and Petersson 2001, Berejikian 1995, Waples 1991, Reisenbichler and McIntyre 1977). Genetic effects of hatchery fish have been observed over as few as one salmon generation, when offspring had one hatchery parent (Araki et al. 2008). Several studies in salmonids have shown that wild-born fish achieve greater fitness in the wild than hatchery fish (Araki et al. 2008, Anderson et al. 2013, Milot et al. 2013) including studies in the Willamette (O'Malley et al. 2014).

The proportion of hatchery origin spawners below dams is currently very high, and would not be expected to change in the future even when fish passage at dams is improved unless decisions are made to reduce hatchery releases. Offspring of hatchery spawners below dams are not marked when they return, and some will be inadvertently outplanted above dams. For example, in the South Santiam, where only unclipped (or non-adipose fin clipped) fish are to be outplanted above Foster Dam, otolith data reported by ODFW indicate that non-clipped hatchery origin fish represent about 12% of “NOR” salmon released above Foster Dam (ODFW 2014).

Due to low abundance of naturally produced spring Chinook, hatchery spring Chinook are being used to supplement the natural origin population to promote reintroduction efforts above WVS dams. The ODFW and NMFS Upper Willamette River Conservation and Recovery Plan (2011) describes an approach to isolate natural from hatchery origin spawners using a “split-basin” approach, whereby wild fish refuges are designated above dams. Below dams, hatchery fish would continue to spawn with wild fish, or would be collected at trapping facilities for brood, outplanting above dams to support reintroduction, or food. The effectiveness of a split-basin approach to adequately control effects of hatchery fish on wild Chinook and steelhead population has not been demonstrated. Wild fish production below dams is already impacted by degraded habitat conditions, and is expected to continue to have very high levels of hatchery origin spawners, among other factors. Releases of juvenile hatchery Chinook and steelhead below dams may result in competition when juvenile hatchery Chinook are released below dams and negative fitness effects when hatchery adults return and spawn in the wild.

Since both wild and hatchery fish must utilize below dam habitat during their juvenile and adult phases, effects may remain for both the below and above dam wild population components. Therefore, hatchery practices can be expected to constrain wild salmon and steelhead population performance once fish passage is provided through a variety of ways and to varying degees including competition, genetic introgression (breeding between hatchery and wild fish), increased pre-spawn mortality, and decreased fecundity. Some recent scientific studies indicate that the hatcheries themselves may have detrimental impacts to wild ESA-listed species without directed management and careful consideration of production levels given available habitat (Paquet et al. 2011). Stocking of rainbow trout may also lead to competition with rearing juvenile salmon and steelhead (NMFS 2008).

The Upper Willamette Hatchery Programs final EIS evaluated the Hatchery Genetic Management Plans to determine the risk of jeopardy to ESA-listed (NMFS 2019). NMFS determined that an integrated hatchery for Chinook salmon (i.e., a hatchery where a small proportion of natural origin fish are taken for the production of hatchery fish in the following year) in the Willamette posed some risks but did not result in jeopardy to either UWR spring Chinook or winter steelhead (NMFS 2019). Increasing the proportion of naturally-produced fish into the hatchery broodstock was also identified by the Hatchery Science Review Group (HSRG) in 2009 as an important way to improve the status of UWR Chinook salmon. Currently the spring Chinook hatchery programs integrate natural origin brood on the schedule and terms developed in the 2019 Hatchery BiOp (NMFS, 2019). Integration rates for 2019 to 2021 are provided in Table 3.8-8. Integration of natural origin brood into Chinook hatchery broodstock has occurred on a limited basis in recent years (pNOB range 0.0 to 0.15), and therefore the high levels of hatchery origin spawners both above and below the dams in the WVS are potentially reducing the fitness in naturally spawning populations. Natural origin brood summer steelhead are a strictly introduced species in the Willamette Basin, and so there is no ability to incorporate natural origin brood. Therefore, summer steelhead spawning in the wild with native winter steelhead will continue to result in negative genetic effects for UWR steelhead.

**Table 3.8-8. The proportion of natural origin brood used in spring Chinook spawning hatcheries in recent years (2019-2021). Data provided by K. Reis, personal communication to R. Piaskowski, April 2022.**

| Collection Facility | Return Year | Total Number of Natural-origin salmon (NOR) collected | Number of NOR used in Broodstock | Total Number of Broodstock Spawned | Proportion of Natural Origin Brood (pNOB)[1] |
|---|---|---|---|---|---|
| Minto | 2019 | 827 | 0 | 476 | 0.00 |
| | 2020 | 1,626 | 46 | 446 | 0.10 |
| | 2021 | 482 | 0 | 404 | 0.00 |
| Foster | 2019 | 133 | 0 | 314 | 0.00 |
| | 2020 | 354 | 0 | 283 | 0.00 |
| | 2021 | 173 | 0 | 352 | 0.00 |
| McKenzie[2] | 2019 | 138 | 100 | 654 | 0.15 |
| | 2020 | 34 | 34 | 471 | 0.07 |
| | 2021 | 15 | 5 | 555 | 0.01 |
| Dexter[3] | 2019 | 190 | 87 | 1,502 | 0.06 |
| | 2020 | 196 | 74 | 1,545 | 0.05 |
| | 2021 | 58 | 5 | 870 | 0.01 |

[1] pNOB is calculated as the number of unmarked (NOR) broodstock divided by the total number of broodstock. As limiting factors such as downstream passage and habitat (including flow and water quality) are addressed, the number of NORs should increase over time. With higher NORs, increased NOR integration rates may occur within the terms of the HGMPs, resulting in a higher future pNOB.

2 Total includes Chinook collected at McKenzie and Leaburg Hatchery traps. Total does not include fish handled at the Leaburg Sorter.

[3] Total includes broodstock collected for Middle Fork and Coast Fork Willamette basin releases. Offspring of NOR brood are only released into the Middle Fork Willamette basin.

Note: Information provided by K. Reis with ODFW by email to R. Piaskowski on April 27, 2022.

In addition to the potential for reducing fitness in naturally spawned populations, hatchery rearing practices can impact smolt success by increasing competition with wild fish. Hatchery fish tend to be naïve to predators which can increase wild fish vulnerability to predation when hatchery releases are high. These processes operate through density dependence, i.e., at high densities, there may be too many individuals for the habitat to support which may increase competition and predation vulnerability. Although the magnitude of density dependence is uncertain in the Willamette, there is some evidence of habitat saturation within the broader Columbia Plateau. Density-dependent effects due to high hatchery production levels and hatchery adult returns are described for the Columbia River (ISAB, 2015), and in integrated model exercises for the Willamette River Basin (Scheuerell, 2019). Density dependence among

UWR spring Chinook is possible with greater hatchery production (Particularly under currently implemented production schedules to meet the need for hatchery production in the next year), conservation, and harvest goals.

USACE's hatchery mitigation obligations may, at times, be in conflict with other agency missions. ODFW continues to operate a summer steelhead program exclusively for harvest within winter steelhead DPS habitat (e.g., North and South Santiam) while the Corps has discontinued its program in these sub-basins. Hatchery summer steelhead generally demonstrate lower overall ability to survive and reproduce than winter steelhead. Weigel et al. (2018) found evidence of summer-winter steelhead hybridization, and genetic information indicated consistently lower summer steelhead productivity when compared to winter steelhead. Competition between the two juvenile run types has been described for the Clackamas (Kostow et al., 2003) and may occur in the Willamette where the two forms overlap in space and time. Recent work has demonstrated a minimum residualization rate (i.e., the rate at which non-native summer steelhead remain in the North Santiam basin after release) of at least 12% (Harnish et al. 2014). Declines in winter steelhead productivity, increased competition with non-native summer steelhead, and potential summer steelhead predation on juvenile spring Chinook may have negative impacts for ESA listed species in the WBR.

Hatchery produced rainbow trout potentially pose some risks to spring Chinook and winter steelhead. Both State and Corps rainbow trout hatchery programs result in spatial overlap with ESA-listed juvenile winter steelhead and spring Chinook within standing water bodies (i.e., WVS project reservoirs). There are concerns with respect to competition with winter steelhead and predation on Chinook and steelhead fry (ODFW & USACE 2018). Promoting local fisheries with trout stocking also results in take of juvenile Chinook and steelhead.

Given the potential for significant effects that can occur, the maintenance of harvest hatchery programs has the potential to constrain the ability to re-establish sustainable wild fish populations of Chinook and steelhead above WVS dams, even with improved fish passage. The hatchery BiOp (2019) endorsed management actions to reduce summer steelhead production levels in the South Santiam and update acclimatization practices in the North Santiam to discourage spatial overlap between summer steelhead and winter steelhead. The effects of juvenile releases and adult returns of hatchery fish will need to be carefully monitored in order for a split-basin approach to ensure there is not a substantial impact wild fish populations.

#### *3.8.1.5 Hatchery risk metrics and performance*

Several metrics assist hatchery managers to determine the level of genetic hatchery influence on ESA-listed species. Johnson and Friesen (2014) demonstrated that UWR hatchery origin spring Chinook salmon are genetically similar to the wild type; however genetic introgression (i.e., when genes from hatchery fish show up in wild fish) and spawner densities are consistently monitored to assess population risks and performance. The proportion of hatchery origin spawners present on the spawning ground (pHOS), allows managers to assess potential introgression with wild origin spawners within the DPS and wild spawner contribution to reintroduction above projects. pHOS targets are set for each basin and generally range from 10 to 20% above project with exceptions where native fish populations have not yet been re-established (ODFW & USACE 2016a, ODFW & USACE 2016b, ODFW & USACE 2016c, ODFW & USACE 2016d). Results from baseline monitoring show that pHOS is higher below dams, often near 100% in some cases (Sharpe 2018). Above dams, pHOS can vary from 1 to 99% (Sharpe 2018) depending on the adult release strategy (outplanting) and level of passage at dams. pHOS above dams is expected to potentially decrease as passage is implemented if outplanting protocols are changed to be generally more consistent with the state recovery plan (ODFW 2011).

Managers measure population sustainability using Cohort Replacement Rate (CRR), or the ability of one generation to produce enough successful mature progeny to replace them. The CRR allows managers to gauge the productivity of each generation to determine if spawner cohorts are at least replacing themselves (value of 1), or declining (value less than 1). On average, values greater than 1 indicate a growing population and values less than 1 indicate population decrease or population capacity (i.e., maximum number of adults have been produced given the available habitat). Hatchery production levels in the HGMP's have been determined based on the number of smolts and expected survival that will result in a CRR value of at least 1. Replacement is observed below projects but pHOS and the potential for introgression remains high (Sharpe et al. 2018).

Rates of mortality of adults prior to spawning (pre-spawn mortality) are believed to likely increase with increased hatchery production (Bowerman et al. 2018, Benda et al. 2015, Keefer et al. 2017), which likely reflects negative effects of high densities of adults during migration, holding or spawning, particularly below dams. Pre-spawn mortality varies throughout the system and is associated with warmer stream temperatures (Benda et al. 2015), body condition (Keefer et al. 2017), travel time (Caudill et al. 2017), elevation, and pathogenicity (Bowerman et al. 2018). Spawners entering the dam tailrace or traps may be more vulnerable to pre-spawn mortality due to lengthened travel times, higher fish densities, and increased handling/holding associated with sorting fish for reintroduction versus other program purposes (e.g., fishing opportunity). These factors appear to have greater effects at lower elevations and basin-wide pre-spawn mortality is variable depending on these physical parameters. Hatchery managers at traps and facilities can mitigate for some project effects through best management practices, which include reducing fish densities through frequent transport, decreased holding and handling, and monitoring for disease.

#### *3.8.1.6 North Santiam Sub-Basin*

USACE operates a system of two dams in the North Santiam. Operation of these structures have resulted in a decrease in the frequency and magnitude of floods, an increase in low flows (Riseley 2012), blockage of access for upstream migrating fish, and reduction in the survival and passage rates of downstream migrating fish (ODFW and NMFS 2011). Downstream, three diversion dams also exist affecting fish passage and stream flows to a lesser extent. The mean annual precipitation for the entire Santiam River basin is 78.2 in. (1971–2000) (U.S. Geological Survey 2012). River channels of the middle and upper reaches of the sub-basin are constrained.

The lower reach of the river, near the Willamette River confluence is mainly comprised of a wide, unconstrained flood plain. The economy of the Santiam River basin is supported by agriculture, timber harvesting, recreation, and manufacturing.

Approximately 70 percent of the basin is forested. Timber is harvested on both private, state and Federal lands. Higher elevation areas in the basin are managed by the Willamette National Forest. Forests have been altered by land use and historical logging (Dykaar and Wigington 2000), affecting the hydrology, reducing large wood within streams and rivers, and increasing sun exposure in some locations. Wildfires in recent years have significantly affected riparian forest areas above and below Detroit and Big Cliff dams. Despite these changes, the Santiam River variably provides adequate streamflow for fish and aquatic invertebrates (Wevers et al. 1992).

The North Santiam River supports diverse populations of anadromous and resident fish species and aquatic organisms. These fish species are a mix of native and non-native (i.e., introduced) species. There are many native resident fish species as well as several introduced species found in the North Santiam sub-basin. As discussed, large numbers of hatchery salmon and trout are released annually in the sub-basin. Only managed species or those with special status are discussed below due to the lack of data available on other native and non-native species in the sub-basin. Oregon Chub, recently delisted, is present in the Santiam sub-basin. Bull trout have been extirpated since the mid-1940's.

###### *3.8.1.6.1 Passage for ESA-listed salmonids and steelhead at Detroit Dam/Big Cliff Dam Complex*

Only adult hatchery origin UWR Chinook salmon are outplanted above Detroit Dam. These fish are collected at the Minto adult fish facility downstream of Big Cliff dam and transported by truck to spawn naturally in streams above Detroit Reservoir. To complete their migration to the ocean, juvenile progeny must pass downstream of Detroit Dam using the available spillway, the powerhouse or through regulating outlets. Survival through these passage routes is not considered adequately safe or effective under existing operations. More specific information on route specific survival and passage rates is included in appendix X (Fish Benefit Workbook inputs). Hatchery origin adult returns to Minto have met both broodstock and conservation needs in 60% of return years (ODFW & USACE 2016a). The hatchery affects to natural origin fish in the North Santiam vary with respect to disease transmission, introgression, and density-dependent predation and competition (NMFS & ODFW 2011). Pre-spawn mortality of adult Chinook salmon in the North Santiam is relatively low compared to other sub-basins, with the exception of 2015, a particularly dry year. Active building of Chinook redds occurs both upstream and downstream of Corps dams (Sharpe et al. 2018, Mapes et al. 2017). Passage and survival rates of juvenile Chinook through these routes under existing operations have not resulted in re-establishment of a sustainable population above the Detroit Dam, although female cohort replacement has been documented to exceed 1.0 for at least one brood year since 2008 (O'Malley et al. 2015).

Downstream passage at Detroit dam is not considered safe and effective. Therefore, currently unmarked (presumptive wild origin) UWR Chinook salmon and winter steelhead collected at the Minto Adult Collection Facility are outplanted below Detroit Dam by ODFW into a four-mile reach between Minto and Big Cliff dams. Emergency and contingency operations are in place particularly for dry years, and wild origin fish were outplanted above Detroit in 2015. Total dissolved gas between Minto and Big Cliff do exceed environmental thresholds (>110%) during flood control operations and there is concern that spawning fish and incubating eggs are negatively impacted during these periods of supersaturation. USACE manages TDG by releasing water from multiple outlets whenever possible (i.e., RO's, powerhouse, and spillway) and by spreading spill over multiple spill bays when possible.

In addition to operating the projects to achieve environmental flows (e-flows), the Corps uses controlled water releases to manipulate temperature for ESA-listed species downstream of Detroit Dam when reservoir elevation is above spillway crest. Willamette river basin temperatures tend to be too cool in the summer and too warm in the fall. This interim action dampens the downstream effects of non-normative temperatures on spawning fish and incubating eggs. These releases are effective during most of the year except during fall drafting, when only warmer surface waters are available for release. This results in winter water temperatures that are warmer than usual which may disrupt UWR Chinook salmon and winter steelhead spawning and migration and accelerate egg incubation and emergence timing.

###### *3.8.1.6.2 Hatcheries, wild salmon and steelhead in the North Santiam*

USACE's hatchery program in the North Santiam affects to natural origin UWR spring Chinook and winter steelhead vary but occur primarily through increased pHOS and increased risk of pre-spawn mortality. Currently pHOS below Minto ranges from ~60-70%. PHOS, and spawning distribution is not expected to change until actions are taken to increase abundances of wild spring Chinook salmon and winter steelhead or a reduction in abundance of hatchery spring Chinook spawners. USACE plans to continue annual monitoring to assess spring Chinook pHOS. Above Detroit Dam, only hatchery spring Chinook salmon are currently outplanted, so pHOS will be near 100% until passage is implemented. Implementation of the approved HGMP for the North Santiam allows integration of natural origin brood in order to reduce domestication effects associated with exclusive hatchery production upstream of Detroit Dam.

There are three areas where adult spring Chinook and winter steelhead spawn in the North Santiam sub-basin. Under existing fish passage conditions, there are limitations within each one.

Below Minto Trap (winter steelhead and spring Chinook salmon): NWFSC estimates this area contains just over 54% of the current usable spawning area for spring Chinook salmon in the sub-basin (Bond et al. 2017). Spawning success of natural-origin (NOR) fish is limited by a high proportion of hatchery-origin Chinook spawners (pHOS), effects of dam operations on flow, temperature and TDG. Just below Upper and Lower Bennett dams is the downstream extent of spring Chinook spawning due to high water temperatures in this lower elevation part of the watershed. Recent wildfires have severely impacted riparian and adjacent forest conditions in recent years, which may affect the quality of this habitat by increasing input of fine sediments to the stream and increasing water temperatures.

Big Cliff Dam to Minto Trap (winter steelhead and spring Chinook salmon): The NWFSC estimated this reach contains about 5% of the usable spawning habitat for Chinook in the sub-basin (Bond et al. 2018; see Table 1.5). This high gradient reach consists of falls, cascades, riffles and deep pools. Spawning success is assumed to be limited by the effects of dam operations on flow, temperature and TDG. Only natural origin spring Chinook and winter steelhead are outplanted between Minto and Big Cliff. Recent wildfires have severely impacted riparian and adjacent forest conditions in recent years, which may affect the quality of this habitat by increasing input of fine sediments to the stream and increasing water temperatures.

Above Detroit Reservoir in the Breitenbush and North Santiam rivers: Only hatchery spring Chinook are currently transported above Detroit Reservoir. NWFSC estimates these reaches contain 46% of the usable spawning habitat for spring Chinook. About half the spawning habitat for winter steelhead in the sub-basin is located above Big Cliff Dam (ODFW and NMFS 2011; see Table 6-6). Recent wildfires have severely impacted riparian and adjacent forest conditions in recent years, which may affect the quality of this habitat by increasing input of fine sediments to the stream and increasing water temperatures. Surface spill operations at Detroit Dam can increase passage and survival of downstream migrants, however the ability to provide spill in the spring and summer is unpredictable since it depends on winter and spring hydrology. Therefore, only hatchery origin spawners are outplanted to spawning habitat above Detroit dam except under contingency or emergency operations.

#### *3.8.1.7 South Santiam Sub-Basin*

Much like the North Santiam, the South Santiam is characterized by historically depleted riparian habitat. USACE operates a system of two dams in the South Santiam. Operation of these structures have included a decrease in the frequency and magnitude of floods (USGS 2012), impeded or blocked access for upstream migrating fish, and reduced survival and passage rates of downstream migrating fish (ODFW and NMFS 2011). Located downstream of WVS dams, Lebannon Water Diversion Dam affects stream flows to a lesser extent. The mean annual precipitation for the entire Santiam River basin is 78.2 in. (1971–2000) (U.S. Geological Survey 2012). River channels upstream of Corps dams are constrained, while the lower reach of the river is mainly comprised of a wide, unconstrained flood plain. Northern Pikeminnow, *Ptychocheilus oregonensis*) (Figure 3.8-10) are a primary predator but there is evidence that juvenile salmonids represent a smaller proportion of the diet. Phytoplankton abundance generally increases further downstream, primarily blue algae and diatoms (Altman et al. 1997).

In the South Santiam Subbasin, NWFSC estimated that about 59% of the usable spawning habitat for spring Chinook is located below Foster Dam, 30% above Foster Dam, and 10% above Green Peter Dam (Bond et al. 2018). The pHOS below Foster Dam for spring Chinook is very high, has a high potential to continue unless hatchery releases are reduced, in an effort to potentially positively affect the fitness and productivity of the naturally spawning population. For winter steelhead, research indicates substantial overlap in space in time of naturally produced winter steelhead juveniles and residual summer steelhead (Harnish et al. 2015). Introgression with hatchery summer steelhead is an ongoing impact for native winter steelhead in the sub-basin and Willamette Basin (Weigel et al. 2019a). Introgression associated with non-native steelhead above Foster Dam may also be introduced through the trap-and-transport program (Weigel et al. 2019b). The UWR Recovery Plan (ODFW and NMFS 2011) references 18% of the available spawning habitat for steelhead lies above Foster Dam.

**Figure 3.8-10. Northern Pikeminnow**

A passage program for spring Chinook and winter steelhead exists at Foster Dam. Downstream fish passage occurs using a combination of a weir and special spillway operations to support downstream passage of smolts and kelts. Due to concerns about collection efficiency of the original spillway weir, the Corps redesigned the structure to improve collection rates; however, the new weir saw higher injury rates, particularly for winter steelhead kelts. Upstream passage occurs using a trap and haul approach. Since cold water releases from Foster discouraged returning adults migrating upstream from entering the ladder at the Foster Adult Fish Facility, the Corps has reduced the effects of temperatures on adult collection rates using temporary actions for spill which also support juvenile passage downstream of Foster dam. USACE uses the weir to skim warm surface waters to encourage adults to enter the ladder. These solutions have been demonstrated to perform reasonably well. The wild population of spring Chinook salmon above Foster is considered self-sustaining. However, bull trout have been extirpated from the South Santiam. Currently, neither Chinook nor winter steelhead are transported above Green Peter Dam.

##### *3.8.1.7.1 Green Peter/Foster Dam Complex*

Historically, spring Chinook and winter steelhead were outplanted above Green Peter dam. A fish ladder and lift were used to transport adults, and a high head bypass system was used to pass juveniles downstream (USACE 1995). These passage systems were abandoned for several reasons. The fish ladder used deeper and cooler water from Green Peter, resulting in a temperature differential that discouraged adults migrating upstream from entering the fish ladder. Similarly, juveniles migrating downstream were not attracted to the entrance possibly due to poor flow cues near the entrance or conditions upstream in the reservoir. Last, predation rates from northern pikeminnow (*Ptychocheilus oregonensis*) were believed to be high in Green Peter Reservoir at the time (USACE 1995). Given the complications for up and downstream passage, both of these systems were ultimately abandoned. The NMFS 2008 Biological Opinion did not include passage at Green Peter in the RPA and recommended that jeopardy could be avoided by implementing passage at other projects, while research at Green Peter may be deemed necessary by NMFS at their discretion. A relict population of adfluvial (i.e., landlocked) UWR spring Chinook has been documented to successfully reproduce above Green Peter (Romer & Monzyk 2014). As progeny of hatchery origin outplants that were landlocked and successfully reproduced, this population is considered to be natural origin (see "Responses to Comments on the Draft EIS" in NMFS 2019).

Downstream of Green Peter and Foster, the Corps operates a trap and haul program to transport UWR spring Chinook and winter steelhead above Foster dam. Natural origin adults that enter the fish ladder at the Foster Fish Facility are outplanted near the head of Foster Reservoir or into upstream reaches. Hatchery origin fish that enter the ladder are not outplanted above the dam. Cold water from power peaking operations at Green Peter decreases ladder temperatures below Foster and can discourage adults from entering the ladder when temperature differences between the ladder and the incoming stream below the dam are too great. USACE is currently designing improvements to the fish ladder to increase temperatures and collection efficiency and uses temporary measures to ensure optimal ladder temperatures. In the past, juveniles migrating downstream do so through a removable spill weir. However, juveniles are now passed downstream using a special spill operation. USACE is currently investigating improvements to the weir design to decrease injury rates, particularly for winter steelhead; it also conducts a spill operation for downstream passage of juvenile Chinook, steelhead, and kelts at night whenever possible, in the meantime.

###### *3.8.1.7.2 Hatcheries, wild salmon and steelhead in the South Santiam*

The existing South Santiam Hatchery impacts natural origin spring Chinook and winter steelhead to varying degrees in the South Santiam with respect to disease transmission, introgression, and density-dependent predation and competition (NMFS & ODFW 2011). In recent years, pre-spawn mortality below Foster Dam has been lower than pre-spawn mortality above. The number of spring Chinook redds below Foster also exceeds the number of redds above (Sharpe et al. 2018); however, most production downstream of Foster is hatchery origin whereas only unclipped (and presumably natural origin) are outplanted above Foster. However, up to a third of presumably natural origin spring Chinook outplanted above Foster are of hatchery origin (Sharpe et al. 2018). Keefer et al. (2017) compared fish released in the reservoir to those released directly into the upper tributaries and found that reservoir-released fish experienced cooler temperatures. This may translate to lower pre-spawn mortality for these fish. However, the reservoir-released fish were also more likely to fall back over Foster Dam

(11% fallback rate). They hypothesized that these fallbacks may be volitional, as genetic analysis has found that up to 35% of transported fish do not originate from above Foster (Evans et al. 2016).

The NMFS 2008 Biop and the Upper Willamette River Conservation and Recovery Plan (ODFW and NOAA 2011) identify a goal of <30% pHOS for the entire South Santiam spring Chinook population and <5% pHOS for the entire South Santiam winter steelhead population. Below Foster Dam pHOS for spring Chinook ranges from ~60-90% (Sharpe 2015, 2016) due to the presence of the South Santiam Hatchery in the Foster tailrace and the transport of collected NOR fish above the dam. Above Foster pHOS for spring Chinook is low due to the transport of NOR fish above the dam. Routine monitoring is conducted to assess spring Chinook spawner abundance, distribution, pre-spawn mortality and pHOS.

#### *3.8.1.8 McKenzie Sub-Basin*

There are two dams operated by the Corps in the McKenzie Sub-Basin – Cougar Dam on the South Fork and Blue River Dam on the Blue River. Other dams in the sub-basin are operated by the Eugene Water and Electric Board, located along the mainstem McKenzie River. Those downstream from the Cougar and Blue River dams provide for fish passage.

The McKenzie is considered to contain the least degraded habitat among the Willamette River sub-basins, and e-flows are consistently met (Wallick et al. 2018). This is, in part, due to the fact that consumptive use (agricultural and municipal withdrawals) is less than in other sub-basins (Risley et al. 2010). Although the WVS here has retained more floodplain characteristics, flood flows and sediment transport have decreased (Risley et al. 2010). Bull trout populations existing in McKenzie and the Middle Fork (Altman et al. 1997, Zymonas et al. 2021).

The WVS in the McKenzie impacts ESA-listed UWR spring Chinook and bull trout primarily through blocked passage at Cougar Dam (the reach above Blue River dam did not historically support salmonids), changes to channel morphology, habitat degradation, and predation impacts on juveniles from the summer steelhead and rainbow trout stocking program. The McKenzie UWR spring Chinook salmon population is considered to be a “genetic legacy” population (NMFS & ODFW 2011). The full expression of Chinook juvenile life history migratory strategies has been documented in the McKenzie sub-basin (i.e., fry, sub-yearling, and yearling outmigrants) (NMFS & ODFW 2011). NWFSC estimates that about 11% of the usable spawning habitat is above the WVS dams in the McKenzie Sub-Basin (Bond et al. 2017).

ESA-listed bull trout occur throughout the McKenzie. The 2008 USFWS Biological Opinion determined that the continued operation and maintenance of the WVS would adversely impact bull trout critical habitat through impoundment, habitat fragmentation and a general decline in water quality (USFWS 2008). The recovery plan for bull trout identifies non-anadromous populations of UWR bull trout within the Coastal Recovery Unit (USFWS 2015). This unit includes populations in the McKenzie and Middle Fork sub-basins. The bull trout population in the South Fork of the McKenzie was formally considered a “genetic legacy” unit, but this delineation was revised in the last bull trout recovery plan (see USFWS 2015). Populations above the project appear to be isolated due to passage barriers and water quality (USFWS 2008, Ratliff and Howell 1992). Bull trout also require cooler temperatures and greater habitat complexity (Ratliff and Howell 1992), which may be in conflict with operations that target Chinook and steelhead life stages. The bull trout population above Cougar Dam has remained stable following reintroduction (Zymonas et al. 2021).

##### *3.8.1.8.1 Cougar Dam*

The construction of Cougar Dam blocked access to historic spawning and critical habitat for UWR spring Chinook and bull trout along the South Fork of the McKenzie River. Although the dam was built with up and downstream fish passage facilities, these were found ineffective and abandoned. A water temperature control tower was constructed in 2005 and allows for temperature management of discharged water downstream, particularly applied for UWR spring Chinook. An adult fish facility was also constructed in 2010 to collect upstream migrating adult spring Chinook and bull trout. Unmarked adult spring Chinook passed above Cougar Dam are supplemented with hatchery origin Chinook according to a hatchery genetic management plan (Corps and ODFW 2016). Pre-spawn mortality in returning adult Chinook above Cougar Dam is low (<10%), but is between 30% and 40% in the lower McKenzie River below Leaburg Dam. Downstream migrating fish must pass through existing routes, which include the regulating outlet or turbine penstocks. Passage and survival rates of juvenile Chinook through these routes under existing operations have not resulted in the re-establishment of a sustainable population above the dam (e.g., Sard et al. 2015).

##### *3.8.1.8.2 Blue River Dam*

There is no fish passage above Blue River Dam and there were no historic populations of anadromous salmon or steelhead above the project location. Today, the reservoir contains mostly stocked rainbow trout. Although effects are similar to those observed at other WVS projects, Blue River Dam operations have impacts on downstream habitats through regulated discharge (Risley et al. 2010). Similar to other WVS projects, controlled releases at Blue River Dam result in non-normative temperatures. With the exception of e-flows, the Corps has not conducted operations for temperature control at Blue River Dam.

##### *3.8.1.8.3 Hatcheries and Wild Salmonids in the McKenzie*

USACE's hatchery program in the McKenzie River affects natural-origin UWR spring Chinook salmon to varying degrees primarily through increased pHOS, and increased risk of pre-spawn mortality of the UWR spring Chinook. The NMFS 2008 Biological Opinion and the Upper Willamette River Conservation and Recovery Plan (ODFW and NOAA 2011) identify a goal of <10% pHOS for the McKenzie sub-basin spring Chinook population. Currently pHOS both below Leaburg and above Cougar ranges from ~70-90%. Routine monitoring is conducted to assess spring Chinook spawner abundance, distribution, PSM and pHOS. PHOS, and spawning distribution, may not change until actions are taken to increase abundance of wild spring Chinook or reduce abundance of hatchery spring Chinook spawners. Returning adult hatchery Chinook are either collected at McKenzie or Leaburg Hatchery, trapped and removed by hand from the Leaburg Dam fish ladder by ODFW, trapped at Cougar Dam adult fish facility, or spawn naturally in the McKenzie River or its tributaries.

ODFW maintains a summer steelhead program exclusively for harvest opportunities, per contract. The McKenzie is not part of the winter steelhead DPS and summer steelhead do not directly impact reintroduction efforts.

#### *3.8.1.9 Middle Fork/Coast Fork Willamette River*

The Willamette River originates in the Middle and Coast Forks (Altman et al. 1997). ESA-listed spring Chinook salmon and bull trout, as well as Oregon chub, (delisted in 2015) are present in the Middle Fork Willamette (MFW) sub-basin. The four projects (Dexter Dam-DEX; Lookout Point Dam—LOP; Hills Creek Dam—HCR; Fall Creek Dam—FCR) in the Middle Fork form a complete barrier to upstream fish passage, requiring adult fish facilities at the base of DEX and FCR dams that are used for collection of hatchery brood and/or transport of adult Chinook upstream. The older adult collection facility at DEX does meet NOAA fish passage guidelines, and a new facility is currently being designed. A new adult fish facility was completed at Fall Creek Dam in 2018. NWFSC estimates about 65% of the usable spawning habitat for Chinook is upstream of LOP Dam, 24% above HCR, and about 3% above Fall Creek.

ODFW began transferring excess hatchery-origin adult spring Chinook Salmon above DEX and FCR in 1993. The NMFS 2008 Biop included continuation of this program as an experimental aide to Chinook salmon reintroduction, including above HCR. Since 2009, only unmarked Chinook salmon have been transported above Fall Creek Dam due to operational changes providing for improved downstream passage (as discussed below), and leading to a sustainable population above Fall Creek Dam. Naturally produced juvenile offspring migrate into these reservoirs annually (Romer et al. 2013).

The WVS in the Middle Fork affects ESA-listed spring Chinook salmon and bull trout and has blocked passage along several reaches. Other impacts include altered hydrology and water temperatures and habitat degradation through blocked access to spawning grounds by inundation of headwaters. The accessible reach of the Middle Fork is lower in elevation than the other three sub-basins, and typically experiences high temperatures where returning adult fish hold below dams prior to moving upstream to spawn. This contributes to high rates of pre-spawn mortality and predation rates in project reservoirs. Furthermore, habitat degradation downstream of Corps projects may not provide suitable rearing habitat for juvenile Chinook. In its evaluation of alternatives to address the NMFS 2008 RPA, USACE identified the Middle Fork as having the greatest uncertainty around establishing a sustainable population above DEX, LOP and HCR dams due to high adult pre-spawn mortality, high juvenile mortality in reservoirs and uncertainty around adequate downstream passage solutions (USACE 2015).

##### *3.8.1.9.1 Lookout Point/Dexter Dam Complex*

Adult Chinook are collected below Dexter Dam at an outdated facility optimized for collection of hatchery broodstock in conditions where temperatures and densities of hatchery origin fish are high, contributing to high rates of pre-spawn mortality (Bowerman et al. 2018). The NMFS 2008 Biological Opinion RPA recommended that the facility below Dexter Dam be updated (NMFS 2008). Currently, designs for a new adult facility are being completed.

The combined length of Lookout Point Reservoir and Dexter Pool is about 20 linear miles, creating a challenge to downstream migrants. Recent research has estimated high reservoir mortality of juvenile spring Chinook (Kock et al. 2019). This is expected in part to be due to predation (Brandt et al. 2016).

Several alternatives have been examined to evaluate downstream passage in the Middle Fork, particularly at Lookout Point Dam. In 2010, AECOM completed a feasibility study of in-tributary, mid-reservoir, and at-dam passage solutions for Lookout Point Dam. The study concluded that several uncertainties were associated with the Middle Fork that precluded a decision point for Middle Fork Passage (AECOM 2010). In 2011, a follow-up study by AECOM indicated that a head of reservoir collector could improve downstream passage but was technologically complicated and would require the construction of new dams at collection points (AECOM 2011). A study by the University of British Columbia (2020) similarly concluded that while a head of reservoir collector could prove beneficial, the risk to population viability if the collector could not perform or if downstream habitat was not available to fry, were much higher than at-dam solutions (McAllister et al. 2020).

##### *3.8.1.9.2 Hills Creek Dam*

HCR Dam blocks access for spring Chinook to historic salmonid habitat. A reintroduced population of bull trout existing above the dam has grown significantly and steadily over nearly the last decade (Zymonas et al. 2021). The bull trout population spawns in tributaries to Hills Creek Reservoir and rears and forages in upstream tributaries and within Hills Creek Reservoir. Periodically hatchery spring Chinook salmon are translocated by truck above the dam for the purposes of research. There are no fish passage facilities at HCR. Downstream migrating fish must pass through existing routes which include the regulating outlet and turbine penstocks. Rigorous study of passage rates and survival rates for downstream passing fish has not be conducted at HCR Dam, but are assumed to be similar to Cougar Dam based on results from rotary screwtraps reported by Larson (2000) and Keefer et al. (2013).

##### *3.8.1.9.3 Fall Creek Dam*

FCR Dam on Fall Creek (river mile 7.9) was completed in 1965. Only wild ESA-listed spring Chinook salmon return to the adult trap. A new Fall Creek adult trap was completed in 2018 and downstream passage is achieved by a deep drawdown to streambed in late November or early December, annually, which allows juvenile Chinook and other fish to safely and effectively exit downstream through lower outlets. Successful passage operations have resulted in a sustainable population of UWR Chinook above Fall Creek to be re-established; however, the effective population size of genetic contributors remains small (O'Malley and Bohn 2018) and has demonstrated variable pre-spawn mortality (Bowerman et al. 2018). Due to the small effective population size, survival of their progeny to adulthood is assumed to be relatively high. Most juveniles enter Fall Creek Reservoir in February and March after emergence, and then rear until the fall reservoir draft. After rearing between spring and fall annually, spring Chinook juveniles achieve an exceptional size in Fall Creek Reservoir. This size at emigration is likely contributing to adult survival rates, as observed in other Chinook populations. Pre-spawn mortality research is ongoing to elucidate the factors driving pre-spawn mortality and a post-construction evaluation of the newly constructed trap is ongoing. In 2020, adult returns exceeded 800 individuals; well, above the historic estimate for this population despite high pre-spawn mortality (WFPOM team meeting minutes, October 28, 2020).

There are no hatchery origin spring Chinook translocated above Fall Creek Dam. The population is sustained by transport of natural origin adult Chinook upstream annually.

#### *3.8.19.4 Hatcheries and Wild Chinook Salmon in the Middle Fork*

USACE's hatchery program in the Middle Fork Willamette River affects natural origin UWR spring Chinook to varying degrees primarily through increased pHOS at low elevation, increased risk of pre-spawn mortality, and increased fish transport delays. With the exception of above Fall Creek Dam, production of natural-origin Chinook salmon is at extremely low levels in the Middle Fork. A portion of hatchery production mitigation is currently released in the Coast Fork Willamette to support sport harvest opportunities, but these juvenile Chinook salmon are limited by poor rearing conditions and are not considered viable.

Adult hatchery-origin Chinook salmon are transported above Lookout Point Dam and Hills Creek Dam to increase production in the Middle Fork, provide foraging opportunities for bull trout above Hills Creek Dam, support fish passage and pre-spawn mortality RM&E, and support re-establishing a sustainable natural population in the Middle Fork. Between 2002 and 2015, the number of adult hatchery Chinook salmon transported annually above Lookout Point Dam ranged from 555 to 3,765, and from 0 to 3,328 above Hills Creek Dam. In the last 7 years, the number transported above each of these dams ranged from approximately 1,000 to 2,000 annually. Since fish passage conditions are poor, with natural return rates well below those needed to achieve a cohort replacement rate of $\geq$ 1, mostly hatchery-origin adult Chinook salmon will continue to be outplanted above Dexter Dam until fish passage conditions improve.

Prespawn mortality rates continue to remain at moderate (>25%) to high (>50%) levels for adult Chinook salmon trapped and transported from the Dexter Dam adult trapping facility (Sharpe et al. 2016). Keefer et al. (2010) modeled adult Chinook salmon returns, varying the pre-spawn mortality rates across the range of observed rates, and holding juvenile and ocean survival rates constant. They concluded that "unless juvenile survival is exceptionally high, the North Fork (Middle Fork) population model results indicate that the high pre-spawn mortality rates we recorded in some years are likely to have a significant negative effect on reintroduction efforts and establishment of self-sustaining populations".

The abundance of hatchery-origin Chinook salmon on the spawning grounds may influence pre-spawn mortality above Lookout Point Dam. Currently only hatchery-origin adults are outplanted due to the very low number of natural-origin (unmarked) Chinook salmon returning to Dexter Dam. These fish do not originate in the habitat above Lookout Point Dam, which may reduce their propensity to spawn naturally. However, this seems unlikely given that pre-spawn mortality rates for hatchery and natural origin adult Chinook salmon are very similar above Santiam dams and above Cougar Dam in the McKenzie in recent years (e.g., Sharpe 2016 WFSR presentation). Pre-spawn mortality has also been linked to how quickly females are able to establish redds once on the spawning grounds (Hruska et al. 2011), again suggesting that the duration of exposure to high temperatures at high spawner densities may increase pre-spawn mortality rates.

USACE's hatchery program is implemented to meet mitigation obligations and ESA requirements. There are varying degrees of negative impacts of hatchery production on wild origin fish. NMFS determined these impacts to be negligible in light of the fact that wild origin fish lack sufficient passage (both upstream and downstream) around the dams and reservoirs to be self-sustaining. Nonetheless, at current production levels, the hatchery program will likely result in increased impacts to the Corps' ESA mission without reevaluation and adaptive adjustments to decrease population level impacts to UWR spring Chinook salmon and winter steelhead as passage is improved.

### 3.8.2 Environmental Consequences

This section describes the analytical approaches used to evaluate UWR spring Chinook and winter steelhead. The population models each produce the performance metrics while the sub-models are treated as inputs to the population models. Non-salmonid species are evaluated qualitatively as described in the Methodology. In this section of the PEIS, duration (length of time that an effect lasts) and extent (geographic area over which the effect occurs) are not explicitly identified under each of the predicted effects because this would be unnecessarily repetitive. For each alternative, the duration of effects would be the entire period of study to 2050 and the extent would be the entire sub-basin under discussion.

#### *3.8.2.1 Methodology*

The area of analysis for aquatic species and ESA-listed resources is defined broadly as the geographic boundaries of the WRB. The Willamette River is located entirely within the state of Oregon, beginning south of Cottage Grove and extending approximately 187 miles to the north where it flows into the Columbia River.

This Draft PEIS evaluates fish and aquatic habitat using a quantitative (ESA-listed salmon and steelhead and critical habitat) and qualitative (bull trout and habitat) framework. The quantitative framework relies on output from a suite of models developed for ESA-listed salmon and steelhead. This process is similar to the quantitative and peer reviewed process of Ensemble modeling. This approach typically involves using multiple models to come to a more informed management decisions given the known limitations and advantages of each model. While broadly applied in many disciplines, it has not been implemented for UWR salmon or steelhead for the purpose of describing biological benefits and impacts from hydrosystem management. Ideally, each model should cover a spectrum of assumptions about the system that the others do not. In this way, risks and consequences of each assumption are explicitly exposed and transparent to process participants. The EIS process does not require the use of multiple models; however, the process greatly benefits from the exercise and informs an overall better- decision based on tradeoffs.

USACE utilized three population models to assess ESA-listed salmon. The Ecological Diagnosis Treatment (EDT) model was developed through the collective efforts of many biologists, modelers and users in over two decades to assess effects of management actions on habitat conditions, fish abundance, and distribution, including the impact of hatchery management strategies on ESA-listed fish and fishery objectives. The University of British Columbia has developed a Bayesian Integrated Passage Assessment (IPA) approach which uses prior probability distributions (i.e., prior information) to inform abundance trends based on a portfolio of proposed management operations and fish passage structures. In contrast to the other two models, the IPA model only accounts for the performance of populations above WVS dams. Lastly, the NOAA Life Cycle Model has previously been used to analyze management action benefits to salmon and steelhead for the Corps' Configuration and Operations Plan (USACE 2015). The details of these models are described in the Effects Analysis Section.

These three approaches cover a broad spectrum of assumptions and utilize a range of frameworks from deterministic to probabilistic approaches. The use of three models promotes explanation of contrasting results that must be explained by a) the range of assumptions of each model, and b) the risks associated with each wrong or incomplete assumption. By comparing these results, assumptions and consequences are explicitly exposed. Those weaker assumptions that are of smaller consequence to participants may be preferred over model assumptions that carry higher consequences if wrong. In this way, the process becomes more transparent to participants, which instills objectivity in the EIS process. In the description that follows, each population model is supplemented where data are scarce or where management operations have never previously been attempted. These include the Fish Benefits Workbook to describe dam passage and a flow-survival model to characterize downstream responses to flow management.

Each model predicts aspects of the NOAA Viable Salmonid Population (VSP) framework (McElhaney et al. 2000). A VSP is one that meets threshold criteria for spatial structure, diversity, productivity, abundance, and risk of extinction. To maintain consistency with how NOAA evaluates project actions, explicit consideration of VSP is the evaluation framework for this Draft PEIS. Each of the VSP metrics are weighted based on performance, availability of data, and the quality and availability of data. In general, higher VSP scores indicate greater viability. VSP scores are calculated from the output of salmonid population models. These models tend to cover all or most of the salmonid life cycle. Most information comes from the hydrosystem because the ocean phase of the life cycle is less understood. Although VSP is used to evaluate salmonid population resilience, this analysis considers additional criteria specific to USACE. First, USACE must explicitly consider aspects of the hydrosystem that it most affects such as downstream passage and downstream water quality effects. Though not an explicit VSP consideration, these metrics are also considered in the suite of effects analysis models. Second, while VSP describes the viability of a salmonid population, USACE considers replacement potential (i.e., whether each generation produces enough juveniles to at least replace itself) to mitigate for the effects of the project without consideration of factors outside of its authority to address (e.g., ocean conditions). Table 3.8-9 summarizes the metrics produced in this analysis.

**Table 3.8-9. Summary effects analysis metrics for ESA-listed UWR spring Chinook and winter steelhead**

| Primary attributes | Description | Primary data sources sought | Units of measure |
|---|---|---|---|
| Productivity | Population Growth Rate | Recruits/Spawner (R/S), Smolt-to-adult-return rates (SAR), counts or indices of abundance for adults and juveniles | Estimated change in the geometric mean R/S, SAR, and A/P |
| Abundance | Geomean of naturally producing adults | Empirical counts, retrospective analysis, and simulations of adult return counts and redds | Estimated trends in geomean abundance of natural origin spawners over several salmon generations (forecasted period will depend on data available to support given expected uncertainty of prospective analyses) |
| Extinction Risk | Quasi extinction risk (QET) | Empirical counts and prospective analysis of adult return counts and redds | Probability that abundance is less than threshold over several salmon generations (forecasted period will depend on data available to support given expected uncertainty of prospective analyses) |
| Diversity | Number of surviving trajectories | Life history strategies that survived under a management alternative | Proportion of surviving life history strategies |
| Bull Trout Habitat | Increase in bull trout habitat | The amount of habitat and relative risk that is improved under an alternative | Percent increase over the No Action Alternative |

The primary performance metrics (Table 3.8-9) for the population models are: 1. Equilibrium abundance which describes the adult abundance predictions once the population stabilizes at some point in the future (30-100 years), 2. Productivity describes the number of successful juveniles that are produced per adult spawner either in the first 10 years or as an average over 100 years, 3. Extinction Risk is the probability that a population will fall below a given number of adults at some point into the future (30-100 years), 4. Diversity is the percentage of life history strategies that succeed (i.e., demonstrate a productivity greater than 1) once the population reaches equilibrium (5-10 years), and 5.Bulltrout metrics include: the increase in rearing and foraging habitat access and the risk of exposure to limiting factors (5-10 years). The performance metrics inform the evaluation criteria (Table 3.8-10).

The performance metrics 1-4 describe salmonid viability. Impacts are characterized by whether or not a given population is "viable" or "not viable" for a given performance metric. The alternatives are evaluated based upon: 1. The number of populations that have a low extinction risk, 2. The number of populations that demonstrate a productivity (i.e., recruits per spawner) close to or greater than 1.0 (i.e., whether or not the population is able to replace itself), and 3. Whether or not the McKenzie Core Legacy population is likely to go extinct. If any one of these criteria is not met, then the population is at risk according to the impact description below (Table 3.8-10). The EDT output: Diversity, productivity, and equilibrium abundance are ranked in terms of performance in a given water year type (wet, dry, and normal). A lower ranking indicates a better performance. If the water years receive the same ranking, it is an indication that the alternative is robust to differences in annual hydrology. If water years receive different rankings, it is an indication that the alternative is sensitive to changes in hydrology.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.8-10. Evaluation Criteria for Potential Effects for Spring Chinook and Winter Steelhead**

| Effect Scale | Criteria |
|---|---|
| None/negligible | Sub-basin extinction risk during the period covered by this PEIS would be very low (<1%). Maximum productivity would be greater than 1; equilibrium abundance would be above the levels recommended to sustain the population. For Chinook, 3 of 4 populations would persist and at least one of those populations would include McKenzie, a Core Legacy population. For steelhead, both populations in the North and South Santiam would persist. An alternative that demonstrates negligible effects in these categories is considered to MEET THRESHOLDS for viability. |
| Minor | Sub-basin extinction risk would be low (>1%≤5%). Maximum productivity is greater than 1; equilibrium abundance would be above the levels recommended to enable recovery. For Chinook, 3 of 4 populations would persist and at least one of those populations include McKenzie, a Core Legacy population. For steelhead, both populations in the North and South Santiam would persist. An alternative that demonstrates minor effects in these categories is considered to meet all thresholds for viability. |
| Moderate | Sub-basin extinction risk would be moderate (>5%<10%. Maximum productivity would be near 1; equilibrium abundance would be above the levels recommended to enable recovery. For Chinook, 3 of 4 populations |

| Effect Scale | Criteria |
|---|---|
| | would persist at the moderate extinction level and at least one of those populations would include McKenzie, a Core Legacy population. For steelhead, both populations in the North and South Santiam would persist. Mitigation measures would be necessary and would reduce potential adverse effects. An alternative that demonstrates moderate effects in these categories is considered to meet most thresholds for viability. |
| Major | Extinction risk would be high (>10%). Maximum productivity would be less than 1; equilibrium abundance would be below the levels recommended to enable recovery. For Chinook, less than 3 populations persist and would not include McKenzie, a Core Legacy population. For steelhead, less than 2 populations would persist. Mitigation measures to offset the adverse effects may be required in accordance with Corps policies to reduce effects from long-term changes to the resource. An alternative that demonstrates major effects in these categories meets few or no thresholds for viability. |

The qualitative approach for aquatic resources and aquatic habitat uses a weight of evidence approach, that is, while there is no quantitative analysis, conclusions may be reasonably drawn from multiple sources of information in the peer reviewed literature. Many of the habitat attributes considered by EDT can also inform habitat quality over the Alternatives.

In this section of the Draft PEIS, duration (length of time that an effect lasts) and extent (geographic area over which the effect occurs) are not explicitly identified under each of the predicted effects because this would be unnecessarily repetitive. For each alternative, the duration of effects would be the entire period of study to 2050 and the extent would be the entire sub-basin under discussion.

##### *3.8.2.1.1 Population Model 1: Ecosystem Diagnosis and Treatment (EDT)*

EDT is an approach to decision analysis that provides information on population performance under any number of habitat conditions. The tool was developed to account for continuity and quality of habitat under alternative management strategies, particularly in riverine environments. Lestelle et al. (2004) provide a comprehensive overview of EDT and its application to most Pacific salmon species. In brief, the approach is driven by fish capacity (the number of fish that can be supported by the habitat) and productivity (benchmark survival) at each life stage. The total population capacity and productivity is then the integration over all life stages such that habitat quality is accessible at varying time and spatial resolutions (Lestelle et al. 2004). This latter point is of relevance for anadromous fish management where conditions in the freshwater environment impact specific life stages. These impacts must be known both at the life-stage and population levels to inform decision-makers.

EDT has been used to inform decisions on salmon management in the Chehalis River system (ENVIRON International 2011), the Interior Columbia Basin (Wooster et al. 2019), and the Puget Sound (Paquet et al. 2011). The approach utilizes an underlying basin geometry using Geographic Information Systems (GIS) and overlays habitat attributes that may impact a benchmark survival of a fish in a given reach at a given life stage. Fish may have numerous life history pathways or "trajectories" that they express under a given set of habitat attributes (ICF 2019). Habitat attributes are linked to the expression of life history trajectories through a Beverton-Holt stock-recruitment function (i.e., the number of juveniles expected to survive to adulthood given the number of adult parents that produced them and their intrinsic productivity) (Figure 3.8-11).

The trajectories that successfully navigate the basin geometry to complete their life cycle, given the habitat attributes that exist or are proposed to exist (e.g., downstream passage solutions) contribute to "persistence." Life history trajectories that persist contribute to the population performance (e.g., productivity, capacity, equilibrium abundance) (Figure 3.8-11). EDT does not aim to predict abundance as a statistical model would but predicts the abundance that the population may be expected to replace itself in the next generation given the habitat conditions (Figure 3.8-12) that exist, i.e., at what abundance a population may be considered stabilized given the management actions implemented.

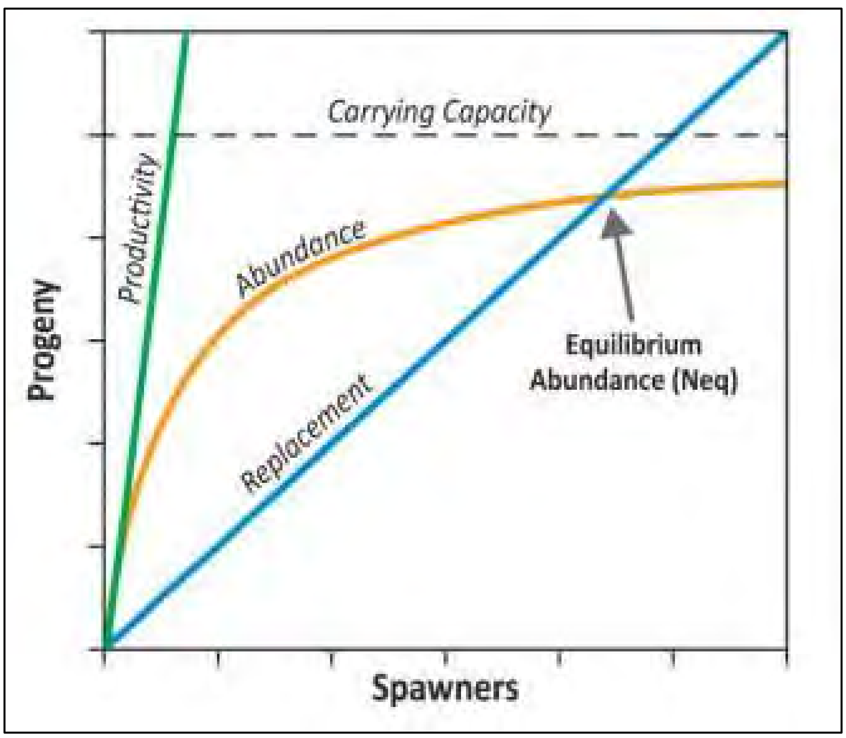

**Figure 3.8-11. Attributes of a Beverton-Holt function**

Note: Figure adapted from ICF (2019). EDT predicts equilibrium abundance (i.e., replacement) given the carrying capacity under a set of habitat attributes and the productivity (i.e., the number of juveniles per spawners at low abundance).

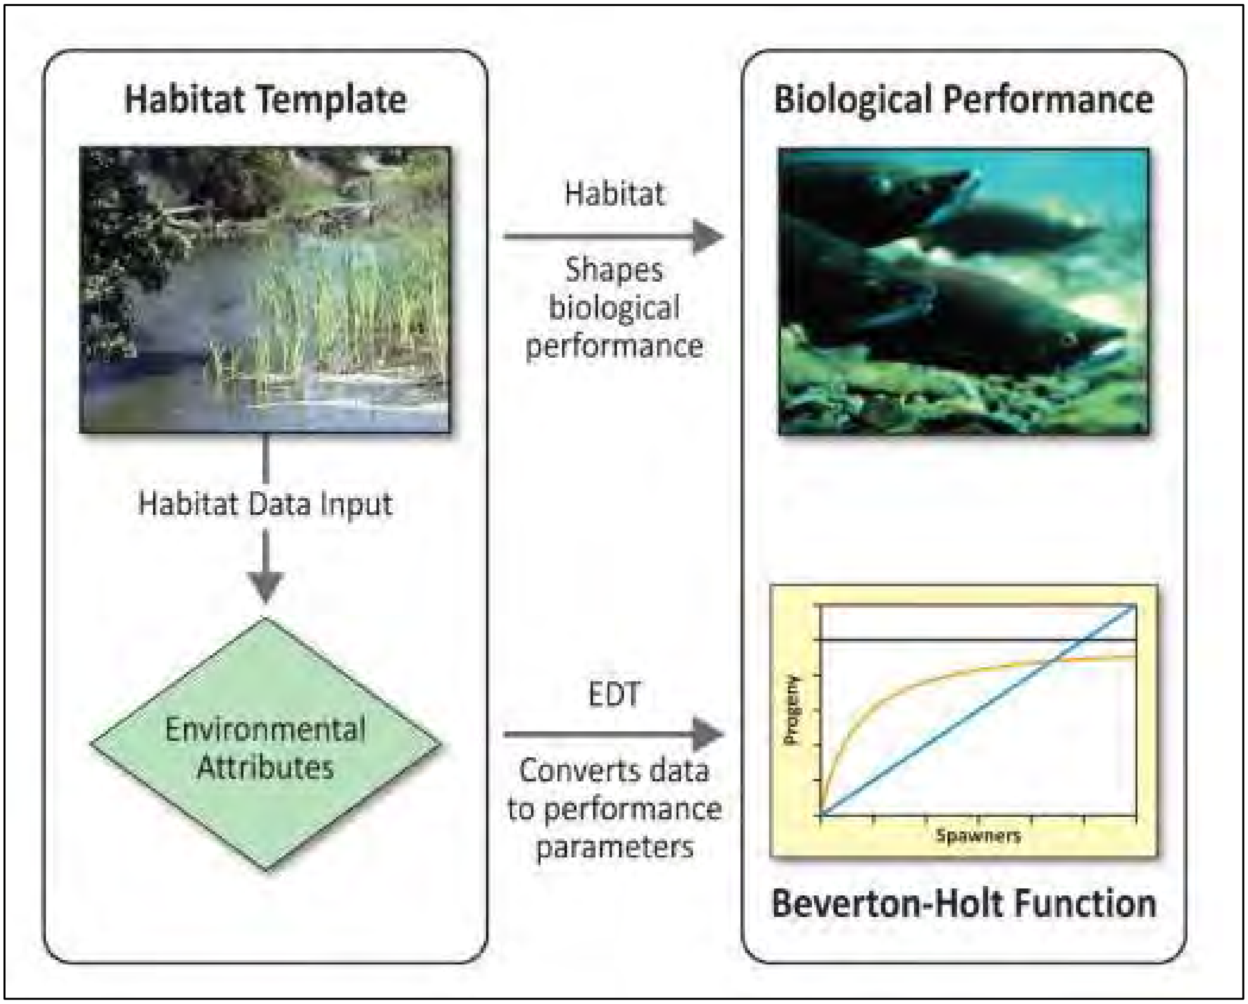

**Figure 3.8-12. A conceptual overview of the EDT process. Figure adapted from ICF (2019).**

There are several key assumptions in this modeling approach:

Modeled changes in temperature, flow, fish passage, etc. reflect habitat quantity/quality differences between current conditions and alternative scenarios under different water year conditions.

Abundance, capacity, productivity, and diversity are primary EDT outputs.

Differences in physical habitat (width and depth of reaches; spatial extent of reservoirs) between scenarios was not explored in this exercise.

##### *3.8.2.1.2 Population Model 2: Integrated Passage Assessment (IPA)*

The IPA framework describes three goals: to describe a passage action evaluation for ESA-listed spring Chinook salmon and winter steelhead, to determine how well each of the proposed alternatives meets management objectives, and to develop an analytical framework that can address uncertainty. The IPA uses several operating models within the same framework. Each operating model has been previously developed for similar applications but have been refined to support the Draft PEIS. These are: the NOAA Life Cycle Model, the Corps' Fish Benefit Workbook, and the Oregon State University flow-survival model/structured decision analysis. Each component model is used to inform evaluation of the alternatives (Figure 3.8-13).

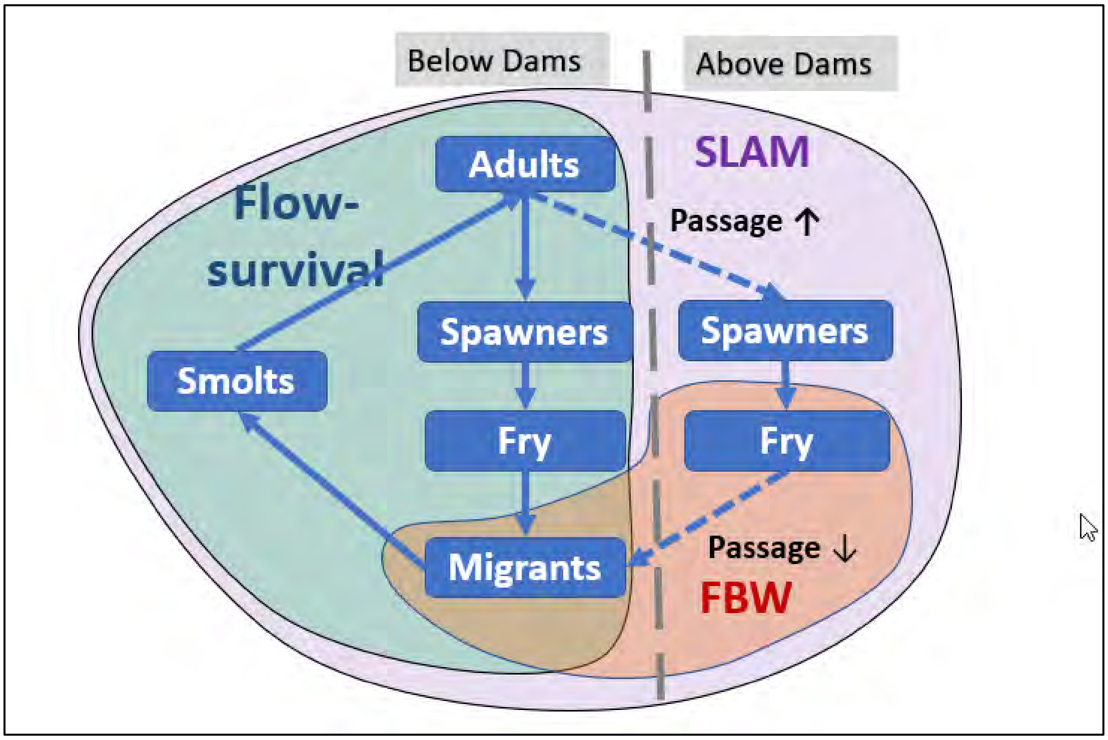

**Figure 3.8-13. Conceptual overview of the Integrated Passage Assessment Model**

Note: The IPA uses attributes of existing models to characterize aspects of the hydrosystem with respect to passage actions. Figure adapted from the UBC Integrated Passage Assessment presentation given at the EIS Cooperators Meeting February 10, 2021.

Using information from these models, the IPA includes an apparent survival (mark-recapture) model to inform survival within a reach of interest. The reaches are representative of habitat above dams, downstream dam passage, downstream habitat conditions, ocean conditions, and upstream migration. Survival in one reach implies transition to the next and the survival probabilities in each reach are estimated simultaneously (Figure 3.8-14).

$$\text{Reservoir} \xrightarrow{S_1} \text{Dam} \xrightarrow{S_2} \text{Lower River} \xrightarrow{S_3} \text{Ocean} \xrightarrow{S_4} \text{River}$$

**Figure 3.8-14. The Integrated Passage Assessment considers how conditions may influence survival in five broad reaches**

Note: The probability of survival in each reach is estimated simultaneously. Figure adapted from the UBC Integrated Passage Assessment presentation given at the EIS Cooperators Meeting February 10, 2021.

Fry-adult survival and productivity are informed by using existing telemetry data to generate a survival and detection probability for each reach and integrating over all reaches. Where data are scarce or unavailable, these estimates can be driven by “prior” information. In this context, “prior” information can be based on information from other similar systems, accepted peer reviewed research, or scientific intuition. Computer routines allowing prior information then allow the user to simulate different management scenarios thousands or even millions of times to reasonably predict an outcome. This is the mechanism that allows for explicit estimation of *survival and the degree of uncertainty about the prediction*. The goal of this approach is not only to arrive at a number but to also describe how certain the estimate is given the available data and prior knowledge. To capitalize on this quantitative information about uncertainty, the integrated passage model includes a structured decision-making process, whereby data gaps are easily identified and described in terms of relative importance. For example, growth rates may not be precisely known for a given reach at a given time but may be of less consequence than not having data on the availability of juvenile rearing habitat to support growth. Therefore, while growth may not be precisely known, information about available habitat to support growth may be of greater relevance to, and could have greater impact on, the outcome. This would not be known without explicitly quantifying the amount of uncertainty in several dimensions. In this way uncertainties, and their relative importance across time and space, can be integrated over all reaches to describe the confidence around a given passage action to provide biological benefit.

The IPA provides several performance metrics for juvenile and adult life stages. Importantly, it predicts productivity, which is defined as the number of surviving juveniles per successful parent spawner. Productivity is measured at low abundance i.e., when the population would be expected to demonstrate maximum growth rate following a management action. This metric allows decision makers to know how productive a given population will be. The second important performance metric is the equilibrium abundance, or the abundance at which the population is stable and not significantly increasing or decreasing annually. Lastly, the quasi-extinction risk (QET) is simply the probability that the population will be above a population abundance threshold number for the duration of given management actions (2020 – 2050).

There are several key modeling assumptions that must be made using this approach:

The model considers only above dam populations, i.e., those populations directly impacted by blocked passage.

The model only considers the length of the proposed management action (28 years into the future).

Egg-fry survival rate as a function of eggs deposited and follows a Beverton-Holt function.

There are six juvenile migrant types above dams within three main groups (fry, fall subyearlings, yearlings).

Reservoir survival rate of juveniles is invariant to the downstream dam passage measure applied.

Splits for juvenile migration groups above dams are invariant to downstream dam passage measure applied.

In two-dam models juveniles originating above and passing down through Hills Creek and Green Peter will try to pass directly through downstream dams without stopping.

Dam passage survival and dam passage efficiency were bootstrapped from fish benefits workbook.

Future marine survival reflects historical variation in early ages (to age-3) marine survival.

At sea fishing mortality rates and incidental mortality rates in terminal fisheries from CTC 2021 mortality rate assessment approximate long-term average mortality rates.

Upstream passage has 100% survival.

Spawning success of hatchery origin fish is less than natural origin fish.

Juvenile reservoir survival does not change under different management scenarios.

The telemetry data used to predict downstream survival is representative of long-term averages.

The proportion of adults in each age class remains the same in the ocean phase of the life history.

Previously measured harvest rates are representative of the long-term average.

Juveniles can depth compensate during periods of high TDG.

###### *3.8.2.1.3 Population Model 3: NOAA Life Cycle Model (LCM)*

The NOAA LCM uses multiple sources of information to characterize downstream emigration, ocean survival, and upstream migration of spring Chinook and winter steelhead (Myers et al. 2018). The LCM is characterized by a number of phases, splits, life history variations, and origin (wild steelhead and Chinook and hatchery Chinook). Juveniles will die or leave the hydrosystem based on a number of factors. As they enter the ocean, several factors impact their successful navigation back to the river to spawn in their natal stream and contribute to overall production of their Evolutionarily Significant Unit (ESU; spring Chinook) or Designated Population Segment (DPS; winter steelhead). The overall status of the ESU or DPS is the basis for determining viability. NMFS describes the viability of a species using the Viable Salmonid Population (VSP) metric (McElhany et al. 2000). The VSP metric considers several aspects of population performance (abundance, productivity, diversity, and spatial structure) that the LCM attempts to predict.

While the LCM is initiated using returning adults, it is helpful to consider the model description starting from the juvenile stage. It is assumed that a proportion of deposited eggs will survive to emergence in the spring. Juvenile fish above dams enter a reservoir based on timing information from empirical data such as telemetry, information from similar systems, or justifiable hypotheses based on historic observations (ref). It is assumed that reservoir rearing juveniles are subject to some degree of reservoir mortality, which again is either hypothetical or informed by empirical data when available (e.g., Kock et al. 2019). As fish approach the dam, their availability to pass, passage effectiveness, and survival is determined using prescribed passage measures in the Fish Benefit Workbook (see section 3.10…). Fish passage and timing is determined by the proposed passage action and an emigration life history type. For spring Chinook, these are broadly characterized as spring fry, fall sub-yearlings, or spring yearlings. For winter steelhead, the life history types are sub-yearlings, yearlings, and age 2 juveniles (Malone et al. 2014). In general, survival upstream of a given dam is characterized by emergence, movement into the reservoir, and availability of fish to pass. Each of these components are informed by empirical data where it exists, justifiable hypotheses, or historical information.

The LCM then posits that survivors that have passed the dam are subject to mortality factors such as total dissolved gas (TDG). Below Willamette Falls, juveniles become smolts and enter the ocean at age 2. Upon ocean entry, several outcomes are possible. A spring Chinook adult can be removed by harvest, die, return to the river, or remain in the ocean as a four, five, or six-year-old. Similarly, winter steelhead can return as a three, four, or five-year-old. For fish that return to the river to spawn, they are subject to a number of mortality factors including harvest and pre-spawn mortality (PSM). Returning adults are allocated to their natal stream based upon the proportions of juveniles that left as emigrants. A proportion of winter steelhead outmigrate as kelts (a spawned fish) and may return as repeat spawners. The LCM is represented conceptually in Figure 3.8-15.

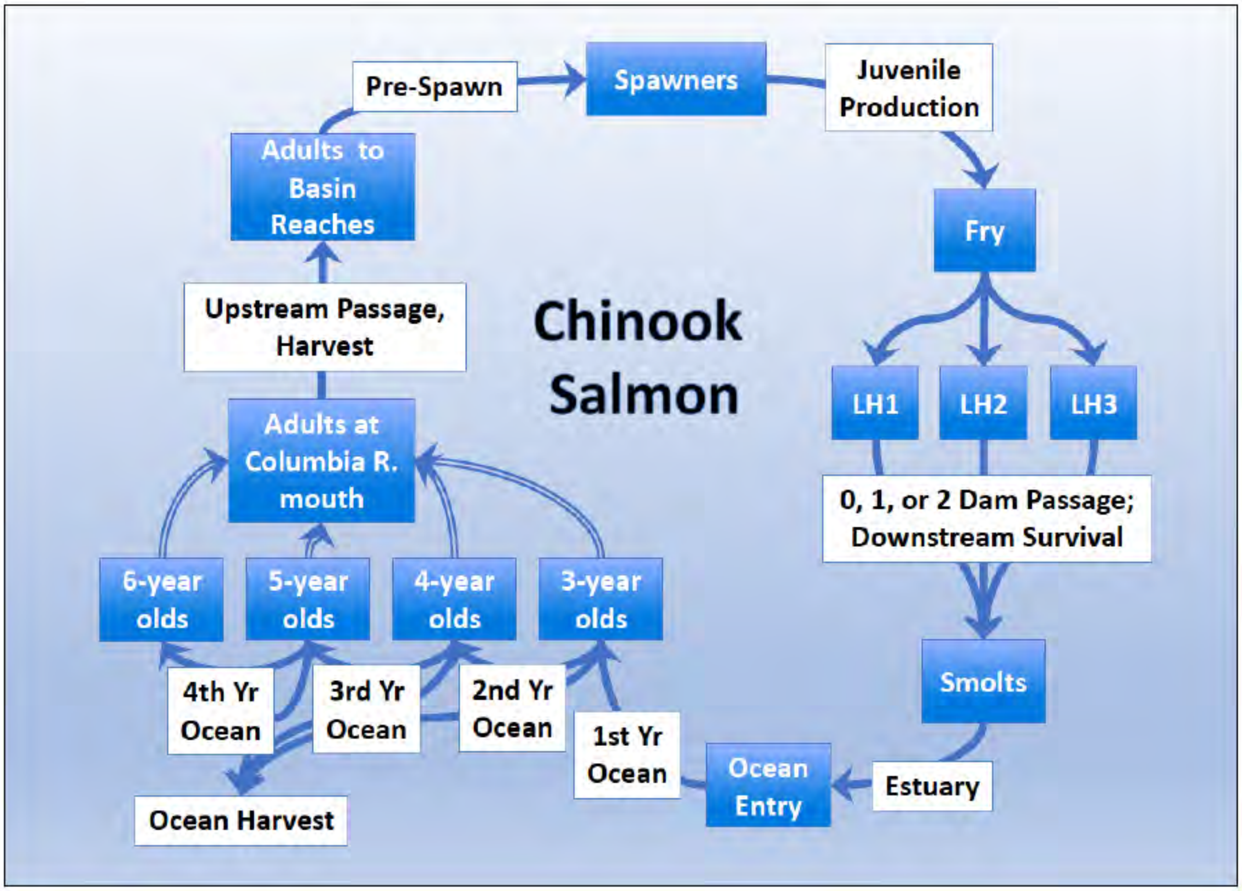

**Figure 3.8-15. Conceptual representation of the Life Cycle Model adapted from Myers et al. 2018.**

Output from the LCM is used to compute VSP metrics. Productivity is defined as the recruits (juveniles that successfully transition to the standing population) per spawner (the parent stock) averaged over a timeline of interest (Note that this approach is different from that of the Integrated Passage Assessment that measures the maximum productivity of a population). Abundance is expressed as equilibrium abundance, or the abundance at which the population is considered stable, evaluated over a number of years. These metrics inform the quasi-extinction risk (QET), or the probability of the population declining below an identified threshold abundance in 100 years or less. The threshold abundance is defined relative to historic population size (Zabel et al. 2014, COPII App C). (Note that the timeline used for this projection into the future differs from that of the Integrated Passage Assessment). Spatial structure and diversity are more difficult to quantify and are generally given less weight in the VSP calculation (ref). Juvenile emigration, and adult upstream migration is calibrated using empirical data where they exist, and informed assumptions where data are limited. The adult ocean phase is informed using observed and monitored correlates (ie, conditions in the ocean that correspond to salmon success) (ref). The aim of the Life Cycle model is to describe viability with respect to historic conditions and current management actions.

There are several key assumptions that must be made using this approach:

1. The model considers above and below dam populations, i.e., it includes both populations directly and indirectly impacted by the dam.
2. The model projects beyond the management action (100 years into the future).
3. The model assumes productivity is based on the long-term average of the projection over 100 years.
4. Spawner-to-fry production is dependent of the number of other individuals in the system, and follows a Beverton-Holt relationship.
5. Juvenile freshwater rearing success is independent from the number of juveniles in the system, i.e., there is no competition for resources
6. The No Action Alternative is reflected of actual conditions
7. Fish are subject to variable ocean survival.
8. Effects of temperatures due to actions are assumed from USGS modeling of three water years: 2011, 2015, 2016; The differences between years are applied to reaches below dams according to FBW-characterized water years (Abundant (2011), Adequate (2016), insufficient (2015), deficit (2015)).
9. Other than effects directly related to the No Action Alternative and Action Alternatives, there is an assumption of stationarity for parameters related to FW habitat, ocean conditions (and variability), and climate.
10. Assuming stationarity in proportions of juvenile outmigrant trajectories going to the ocean.

#### *3.8.2.1.4 Bull Trout Assessment Model*

To assess the effects of the WVS EIS alternatives on bull trout, a habitat assessment framework was developed following the principles and approaches applied by Schaller et al. (2014), with additional considerations of reservoir and fish passage conditions at large dams, and limiting factors documented in the Oregon Bull Trout Recovery Strategy (USFWS and others 2015).

Schaller et al. (2014) surveyed biologists with knowledge of bull trout to identify and weight variables affecting aquatic habitat conditions for bull trout. Scores were defined for assessing each of the variables for different life stage needs of bull trout, and then applied with the weighting factors to assess habitat conditions in river reaches of interest.

The highest weighted variables identified by Schaller et al. (2014) were surface flow, water temperature and passage impediments (see Table 3.17 in Schaller et al. 2014), indicating these were considered the most important variables by the biologists surveyed. Other viable weightings were much smaller, indicating they would have much less of an influence when comparing effects among alternatives in an assessment. We therefore focused the habitat assessment for the WVS EIS on surface flow, water temperature and passage conditions.

For purposes of the WVS EIS bull trout assessment, habitat reaches were defined consistent with those recently applied by ICF (2022) when modeling habitat conditions using the Ecosystem Diagnostic and Treatment (EDT) model. This allowed for the application of information on habitat conditions for variables of interest already summarized by ICF to be used.

We assumed all bull trout would utilize reservoirs that are located downstream of each impounded river reach being assessed. This is based on Zymonas et al. (2021) reporting that most bull trout populations in the Willamette Basin are adfluvial (spawn in streams; rear and forage in lakes or reservoirs).

Additional variables not explicitly considered by Schaller et al. (2014) which are important when assessing reservoir use by bull trout are predation and fisheries. Barrows et al. (2016) assessed available information on habitat changes from large dams on the Columbia mainstem and concluded it is unknown whether or not changes in the river system with the addition of reservoirs are beneficial for bull trout growth and survival. Both predation and harvest are included as primary threats to recovery of bull trout in the Upper Willamette. Reservoirs of the WVS include piscivorous fishes known to prey on salmonids, including pike minnow, walleye and smallmouth bass. Predation risk was scored based on the piscivorous fish species present in each reservoir. Local sport fisheries increase the risk of stress, injury, and mortality. Evidence of injury from hook and line capture of bull trout has been reported for bull trout in Hills Creek and South Fork McKenzie (ODFW 2021; Zymonas et al. 2021). Since USACE does not have any authority to change sport fishing regulations, we assumed current fisheries regulations and level of fishing effort (pressure) would continue under each WVS EIS alternatives. Predation risk and fisheries variable scores were used to decrement the value of the habitat scores.

We did not explicitly incorporate risks from catastrophic events (e.g. wildfires or landslides) into the assessment of bull trout since these events would in most cases result in negative effects for bull trout populations in the Willamette regardless of fish passage conditions. Bull trout are dependent on high elevation streams. If bull trout move downstream of WVS dams to rear and a catastrophic event occurs affecting habitat and/or survival of bull trout below the dam, we assume this scenario would be a negative impact on population performance with loss of potential spawners from the population. If bull trout move downstream of WVS dams to rear and a catastrophic event occurs above the dam, we also assume this scenario would be a negative impact on population performance with loss or degradation of habitat and/or survival of bull trout occupying habitat above the dam. Only in the case where a catastrophic event occurs effecting habitat conditions below a WVS dam, but most/all of the population does not have access to habitat below the dams, we would assume would result in limited impact to bull trout population performance in addition to reduced exposure to downstream limiting factors.

Compared to Schaller et al. 2014 we modified how passage impediments were considered in order to better account for conditions found at WVS dams currently and under each WVS EIS alternative. We characterized passage at dams for bull trout as either not available, partially available or fully available. Under the no passage available category, we assumed poor downstream passage conditions and no upstream passage are provided. For passage to be fully available, we assumed both effective up and downstream passage is present. Other conditions were assumed to fall in the partially available passage category. For the WVS EIS, operational downstream passage with upstream passage would be in this category. Passage condition categories were scored and used as an adjustment factor for scoring habitat conditions available below WVS dams where bull trout currently reside upstream (Cougar Dam and Hills Creek) or where they are being considered for reintroduction (Detroit Dam). This qualitative approach does not account for uncertainty in the effectiveness of different passage conditions for bull trout. Considering that passage facilities being considered among the WVS EIS alternatives are designed for anadromous salmonids, it is unknown whether these facilities are entirely suitable for migratory bull trout. As assumed for Columbia River mainstem dams (Barrows et al. 2016), they may delay or possibly discourage bull trout from freely moving throughout critical habitat in the mainstem, and they may also impede bull trout dispersal between subbasins.

Three bull trout populations were included in the bull trout assessment: populations that currently exist in headwater tributaries above Cougar and Hills Creek dams, and an assumed reintroduced bull trout population above Detroit Dam. We included a population above Detroit Dam since USFWS also plans to reintroduce bull trout above Detroit Dam (Hudson 2017). We assumed bull trout had been reintroduced above Detroit Dam, given the 30-year time horizon of the EIS effects analysis.

**Bull trout habitat score** = [above principal dam hydrology score + temperature score * reach length * predation risk factor * fisheries risk factor] + [below principal dam hydrology score + temperature score * reach length * predation risk factor * fisheries risk factor * passage condition factor]

<u>**Exposure to Limiting Factors and Risks Under Different Dam Passage Conditions**</u>

In order for access to additional habitat to be beneficial it must lead to increases in abundance, productivity (adult recruitment), and diversity. Expanded distribution could also reduce risks from catastrophic events (e.g., large wildfires or landslides), if spawning can still occur, and the expansion in distribution does not reduce productivity or spawner abundance over time for the primary population.

Bull trout collected at the Cougar adult fish facility demonstrates that some individuals will move downstream of the dam then return upstream to the base of the dam where they are effectively collected and moved back upstream (e.g., Zymonas et al. 2021). Most of those returning are mature adults, based on their size. However, data are lacking on the growth and survival for bull trout that move below WVS dams and it is not possible to determine if the rate of mortality for individuals moving below principal dams is greater than the rate of return and spawning in the principal population. Benefits of providing passage and access to habitat below WVS dams could include access to additional rearing/foraging habitat or spawning habitat, access to other spawning populations, increase in distribution reducing risks from catastrophic events (e.g., wildfires, large landslides). However, there are also many risks for bull trout that move downstream which act to diminish the potential benefits of accessing additional habitat below dams. These include injury or mortality from passage at large dams or diversion dams, the inability to move back upstream of dams lacking effective passage facilities, delay in passage where facilities exist, exposure to poor habitat conditions (e.g., higher water temperatures), injury or mortality from predators or angling. We also did not find any evidence of satellite populations having resulted from bull trout volitionally moving below principal dams, however this may be due to limited data availability.

The Oregon Bull Trout Recovery Strategy prepared by USFWS and others lists the following statewide limiting factors (Table 3.8-11), and those specifically identified for bull trout in the Upper Willamette. Exposure to all of these known limiting factors would be expected to increase with access below dams for bull trout below Cougar, Hills Creek and Detroit/Big Cliff dams.

**Table 3.8-11. Limiting factors identified in the Oregon Bull Trout Recovery Strategy**

| Statewide Limiting Factors | Upper Willamette Limiting Factors |
|---|---|
| Temperature | Altered flow and geomorphic processes |
| Flow | Entrainment and fish passage |
| Barriers | Illegal harvest |
| Human development | Prey base |
| | Hybridization and competition |
| | Predation |

Source:S. Gunkel, personal communication, 06 OCT 2021. Slide presentation to USACE on the Oregon Bull Trout Recovery Strategy

To assess the value of improving access to habitat downstream of primary dams, effects on population abundance, productivity, diversity and distribution should be considered. It is not known if the current downstream emigration rate for bull trout below dams is equal to or greater than their return rate at Cougar and Hills Creek dams. In the Deschutes River, where cool water temperatures are maintained by significant ground water inputs, return rates of bull trout passing downstream of Round Butte Dam have been high (unpublished data emailed from Chris Allen and Peter Lickwar, USFWS to Rich Piaskowski, USACE, 2.17.22). However, higher water temperatures and multiple other limiting factors exist below WVS dams, as referenced above from the Oregon Bull Trout Recovery Strategy. If emigration rates leads to a decline in the number of spawning bull trout over time, then the existing populations will decline unless satellite spawning areas are established downstream.

There is not any evidence that spawning below WVS dams is occurring, nor locations where spawning below WVS dams could potentially occur. Zymonas et al. (2021) assessed conditions in the North Santiam and Middle Fork Willamette Sub-basins. They referred to "McKenzie Basin reference" water temperature criteria for reintroduction assessments in the Willamette Basin that would include spawning and early juvenile rearing habitat having summer temperatures < 8°C and incubation temperatures averaging < 5°C, although numeric criteria may be flexible and influenced by other abiotic and biotic factors. Among locations water temperatures were monitored in the Middle Fork Sub-basin, Fisher Creek may provide the most suitable site for spawning and early rearing in the portion of the NFMF watershed accessible to migratory fish. Fisher Creek did not meet the McKenzie Basin reference criteria however. Due to the marginal temperature conditions observed, Zymonas et al. (2021) recommended "a preliminary experimental approach to assess survival of Upper Willamette Bull Trout in a warmer thermal regime". Skookum Creek was the only other stream reach noted by Zymonas et al. (2021) in the accessible portion of the NFMF watershed that provided colder temperatures and greater discharge, but this was an extremely short reach of potential spawning habitat (~50 m) between extreme high gradient cascades and dispersal into a large wetland populated by Brook Trout. Given the uncertainty that spawning could occur below Hills Creek Dam, it may be most prudent to first attempt to establish spawning below Hills Creek Dam before providing passage. If successful spawning is demonstrated below Hills Creek, it would reduce risks from a population sink occurring from increased rates of downstream fish passage, as well as risks from catastrophic events above Hills Creek Dam. If, however, establishing spawning below Hills Creek Dam is not successful, it would be important to assess recruitment rates back upstream from individuals passing downstream of the dam before providing long-term passage downstream, especially when considering climate change will further increase water temperatures and reduce summer base flows at rates greater at lower elevations.

In the North Santiam Sub-basin, Zymonas et al. (2021) documented suitable spawning and rearing areas upstream from Detroit Reservoir, but did not survey stream reaches below Detroit and Big Cliff dams. For purposes of assessing potential spawning and early rearing potential in stream reaches in the North Santiam Sub-basin below these dams, we considered water temperature data from USGS monitoring sites and elevation. Streams meeting the McKenzie Basin reference water temperature criteria were not apparent in the USGS temperate gauge data reviewed. It would therefore be important to assess recruitment rates back upstream from individuals passing downstream of Detroit Dam before providing long-term passage downstream of bull trout downstream once they are re-established above Detroit Dam, especially when considering climate change will further increase water temperatures and reduce summer base flows at rates greater at lower elevations.

We also considered that areas below dams are predicted to significantly degrade with respect to habitat suitability for bull trout due to climate change and land use impacts, and in some cases become definitively unsuitable (e.g., Wenger et al. 2013). Habitat quality below dams is assumed to further degrade over the 30-year time period of the WVS EIS, due to predicted climate change effects on precipitation and air temperatures, leading to changes in hydrology, water temperatures, fire, competition with warmwater and exotic fishes, changing land use and increasing development, among other factors.

Lacking emigration and upstream return rates of bull trout at WVS dams, we assume that risks of mortality is high for emigrants passing below dams due to the numerous limiting factors present, the prediction of further habitat degradation, and that there would not be spawning below dams. Since existing bull trout populations above Cougar and Hills Creek dams, which are currently stable or increasing, rely on reservoirs for rearing and foraging, we also considered the extent that reservoir conditions would change in each alternative. A fish passage measure which results in a reservoir pool which is largely drained would be expected to significantly affect rearing and forage opportunity. Passage measures which maintain a reservoir year-round were assumed not to significantly affect rearing and forage opportunity.

Structural downstream passage solutions could provide managers flexibility given uncertainty in the value of dispersal of bull trout below WVS dams. Structural passage would allow collected individuals to be marked, and then either passed downstream or returned to WVS reservoirs above dams. Monitoring would allow determination if the recruitment rate back into the spawning population above a WVS dam is equal to or less than the rate of individuals passing downstream and used to guide ongoing management. However, additional investigation could also inform the effects and risks of providing passage downstream passage prior to investing in passage for bull trout. Available technology allows for marking and recapture studies to estimate emigration and return rates without the need to physically recapture fish once marked.

Based on the above, we categorized risks for bull trout populations residing above Detroit and Hills Creek dams as high for those providing increased access to habitat below dams (improved passage at dams). For Cougar, due to the maintenance of cooler water below Cougar Dam and the Upper McKenzie watershed, we scored the risk level for WVS EIS alternatives with improved dam passage as moderate if the reservoir is maintained, and high if the reservoir is significantly reduced.

For alternatives where fish passage is not changed from existing conditions, we categorized the risks as low. This is primarily based on available information showing existing populations of bull trout above Cougar and Hills Creek as stable or increasing, and the assumption that habitat conditions will degrade and known limiting factors will be exacerbated below dams with climate change.

##### *3.8.2.1.5 Supporting Model 1: Fish Benefits Workbook*

The Fish Benefits Workbook is used to inform downstream passage for all three population models. It characterizes fish passage conditions given dam operations and fish behavior. It was created as a tool for the Configuration and Operation Plan (COP). While information to populate The Life Cycle model was available for upstream passage and downstream effects on spawning and rearing, downstream passage success under the alternative actions remained uncertain, particularly for structures that had not yet been designed or successfully implemented in other basins. Passage at Willamette high head dams is complicated due to fluctuations in pool elevation to mitigate flood risk during winter storms. Downstream passage alternatives needed to include consideration of pool elevation changes, juvenile attraction to flow, and the ability to find and survive passage outlets.

In response, the Corps created the Fish Benefits Workbook: a spreadsheet application that uses the hydrological period of record, flow information, available water, and importantly, the ability of a fish to find and use a passage route. These flow-passage relationships are described in Appendix K of the COP (USACE 2015). The relationships rely primarily on the concepts of "fish bearing flow" and the effectiveness at a given dam outlet. To inform the Fish Benefits Workbook passage rates, the Corps proposed completion of a synthesis of downstream passage data across several species in the region to inform performance of alternative structures (COP 2015). The model only encompasses what is occurring from the forebay of a dam to the tailrace. It does not include information about reservoir survival or what happens after survival to the tailrace. The output from Fish Benefit workbook is downstream passage survival, given the ability of a fish to use and survive a route/outlet. Downstream passage survival is passed to the NOAA LCM, the IPA, and EDT population models. Each of these models uses downstream passage survival to simulate the number of survivors to the next reach.

There are a number of key assumptions in the Fish Benefit Workbook:

Fish are available to pass if they are in the forebay of a dam.

There are generally three types of fish that will pass: fry that leave in their first spring, sub-yearlings that leave in the fall, and yearlings that leave in their second spring. These types are not constrained. For example, fry may leave in other months of the year up to becoming a sub-yearling.

The yearling stage begins January 1.

Fish timing to the arrival at a dam comes from Alden et al. (2014) with adjustment given the new availability of a passage route. For example, it is assumed that the arrival timing may change if juveniles are provided a year-round route as opposed to a seasonal route.

Dam passage efficiency, or the proportion of fish from the forebay of a dam that pass, was based on available data where it existed. Dam passage efficiency for novel fish passage structures was calculated using the methodology of Kock et al. (2019).

Fish passage structure designs were based on existing design information previously developed for Cougar and Detroit.

Where fish must pass a high head dam followed by a reregulation dam (for example, Detroit and Big Cliff), the mortality between the two dams is assumed to be between 15%-20%.

For a complete list of assumptions by project, refer to the FBW parameter documentation supporting information included in Appendix E.

#### *3.8.2.1.6 Supporting Model 2: Flow-Survival Relationships*

Juvenile and adult fish survival below the dam is affected by downstream factors including TDG, flow, and the availability of habitat. Often, water management decisions involve tradeoffs among multiple objectives or legal authorities. The US Geological Survey, Oregon Cooperative Fish and Wildlife Research Unit, Department of Fish and Wildlife, and Oregon State University have developed a series of decision support sub-models for UWR spring Chinook and winter steelhead to characterize water management tradeoffs and effects on key habitat features (Peterson et al. 2022). The decision sub-models, dependent on a given hydrology and water temperature regime, predict four different life history outcomes: 1) the number of Chinook reaching emergence and surviving to swim-up, 2) the number of Chinook adult equivalents, 3) the number of outmigrating winter steelhead, and 4) the survival rate of age-1 juvenile steelhead. Model predictions were driven by a number of life history and habitat inputs such as temperature, habitat-discharge relationships, and territory size.

Descriptions and assumptions of the four sub-models can be found in Peterson et al. (2022). All models operated on a weekly time step that began in the eighth week of the year and ran through April of the following year. Models are only assessing below dam spawning and juvenile rearing. Hydrology inputs were based on ResSim model results provided by the Corps for the NAA and action alternatives. Water temperature inputs were based on CE-QUAL-W2 model results provided by the Corps for the NAA and action alternatives. The sub-models produced predictions for each sub-basin, for the NAA and each EIS action alternative, in each year of three representative water years in which water temperatures and hydrology inputs were applied (2011, 2015 and 2016). Sub-model predictions (using median habitat criteria results provided by Peterson) for each action alternative were compared to the No Action Alternative (BiOp flows). Due to the multiple survival models, and differences in output units from each model, survival results were ranked for each model, using the RANK.EQ function in Excel, to prepare a comparison of results for the two species and across alternatives.

The results of this Draft PEIS are presented by sub-basin and across alternatives. Performance metrics are presented for the NOAA LCM and the IPA. The overall basin performance under each alternative is demonstrated by the EDT output. The LCM and IPA produce similar performance metrics that are dependent on the projected performance over a given timeline in the future:

**Table 3.8-12. Summary of performance metrics for each sub-basin population model**

| Performance Metric | LCM | IPA |
|---|---|---|
| Future timeline | 100 years | 30 years |
| Spawner abundance | Mean geomean of adult spawners over 100 years | Median geomean of adult spawners from year 16-30 in the projection |
| Mean recruits per spawner (R/S) | Mean recruits per spawner over 100 years | Median recruits per spawner from years 1-5 (maximum productivity) |

| Performance Metric | LCM | IPA |
|---|---|---|
| Mean quasi-extinction risk (QET) | The probability of population extinction over 100 years | The probability of population extinction over 30 years |

There are a few key differences in how both models output the performance metrics, mainly the timeline under consideration. First, the LCM predicts 100 years in the future while the IPA predicts 30 years into the future. This difference arises from differences in how the outputs are used for Willamette System project management (IPA) versus purposes explicitly for salmon conservation (LCM). The LCM requires 100 years to compute VSP. Conversely, the IPA only considers the probable timeline of the proposed management action (30 years). This is because the selected management action is likely to change as the system changes in the future.

The second major difference arises from the point in the future where recruits per spawner is measured. In the LCM, recruits per spawner is averaged over the entire 100 years. Therefore, the value should remain close to 1.0 if the population is stable under a given alternative. The IPA produces the median recruits per spawner in years 1-5 of the projection. This time period represents when the population is most likely to respond to a management action and represents the maximum productivity of a population under a given alternative. Recruits per spawner values in the IPA should be substantially greater than 1.0 if the population is viable under a given alternative.

Lastly, while the LCM predicts future abundance of above and below dam populations, the IPA only tracks the above-dam populations.

EDT does not produce a projection into the future. Instead, it uses current or expected habitat features to predict salmon success or failure under a given alternative. It is a simulation based on the expected habitat condition under each alternative. EDT produces performance metrics for each alternative and three representative year types: 2011 (wet), 2015 (dry), and 2016 (normal).

The total Alternative effects are given at the end of the results description.

**Table 3.8-13. EDT performance metrics at the sub-basin level**

| Performance metric (PM) | EDT |
|---|---|
| Diversity | The percentage of life history strategies that are successful under a given alternative |
| Productivity | The expected recruits per spawner basin-wide under a given alternative |
| Equilibrium Abundance | The population size once the population has stopped increasing or decreasing |

### *3.8.2.2 Environmental Consequences Summary*

The NAA would represent the current management direction of the WVS. Specific measures included in the NAA are described in Section 2.4.1. The NAA is predicted to have MAJOR adverse impacts on UWR Chinook salmon and winter steelhead. Life cycle models predict high extinction risk in all sub-basins for both species. Adverse impacts on bull trout are predicted to be MINOR. Bull trout above Cougar have been stable for several years and have been increasing above Hills Creek. Habitat scores for bull trout are reasonable, with one hundred percent of the spawning habitat available, and 70% of the rearing/foraging habitat available. The WVS passage conditions at dams limit bull trout access to below dam rearing/foraging habitat. Climate change is predicted to further degrade habitat for bull trout particularly below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature objectives below dams for Chinook and steelhead.

Alternative 1 is the storage focused alternative. Specific measures included in the Alternative 1 are described in Section 2.4.3. Large floating fish passage structures would be implemented compatible with water storage needs in the North, South Santiam, and the Middle Fork. A fall deep drawdown at Fall Creek will continue. Minimum below-dam flow values support capturing water in reservoirs during spring. Alternative 1 implementation is predicted to have MAJOR impacts on Chinook salmon and MINOR adverse impacts on winter steelhead in the North and South Santiam. Lifecycle models predict low extinction risk for Chinook in the North and South Santiam, and high risk of extinction in the McKenzie and Middle Fork. The downstream passage structure at Lookout Point is dependent on the dam operations and predicted to perform poorly likely due to the storage theme of Alternative 1. Both life cycle models predict low extinction risk in Santiam winter steelhead populations, although one model predicted low recruits per spawning for the South Santiam. The EDT output indicates that Alternative 1 is somewhat resilient to different hydrology year types with respect to life history diversity. Scores and risks for bull trout would be ranked similar to the No Action Alternative, with MINOR effects predicted. Habitat scoring for bull trout is only marginally better than in the No Action Alternative with rearing/forage habitat increases for North Santiam bull trout below Detroit. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, McKenzie and Middle Fork sub-basins.

Alternative 2A has an integrated management strategy theme. Specific measures included in the Alternative 2A are described in Section 2.4.4. This alternative includes structural downstream passage at Detroit, Foster, Cougar and Lookout Point dams, and operational passage at Green Peter Dam. A fall deep reservoir drawdown at Fall Creek Dam will continue. Alternative 2A would have MODERATE adverse effects on Chinook salmon, predicted to produce the most viable populations compared to other alternatives and retains the McKenzie core legacy population. For Chinook and steelhead, there was agreement in most cases found from assessing population performance with lifecycle models. One exception was for the South Santiam. The IPA predicts low extinction risk in the South Santiam with a viable population above Foster, whereas the LCM does not. Alternative 2A produces the most optimistic outcomes for Chinook salmon in the Middle Fork among the alternatives, accomplished with a downstream passage structure at Lookout Point exclusive of passage at Hills Creek. Alternative 2A would have MINOR adverse impacts to Santiam winter steelhead populations, with good performance in all metric dimensions in both life cycle models except for the South Santiam under the LCM. EDT results shows resiliency with respect to recruits per spawner. Bull trout habitat scores and risks are comparable to Alternative 1, with a fish passage addition providing access to habitat below Cougar Dam. Alternative 2A would have MINOR adverse impacts for bull trout. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, and Middle Fork sub-basins.

Alternative 2B also has an integrated management strategy theme. Specific measures included in the Alternative 2B are described in Section 2.4.5. The only difference with Alternative 2A is that 2B has an operational downstream fish passage measure at Cougar Dam (deep drawdown to near the diversion tunnel in spring and fall) instead of a structural measure. Cougar Reservoir would largely be drained in spring and only partially refilled in summer due to summer inflow, resulting in most juvenile Chinook moving downstream of Cougar Dam and a significant reduction in rearing/foraging opportunity within the reservoir for bull trout. Many bull trout would be expected to move upstream into the South Fork McKenzie, or below Cougar Dam during spring and fall reservoir drawdowns. Suitable habitat for bull trout exists above and below Cougar Dam and Reservoir, however carry capacity and other effects of redistribution on survival and spawning is uncertain. The deep draft in spring will also eliminate conservation water storage, resulting in lower summer stream flows and changes in water temperatures below Cougar Dam. These differences will affect fish rearing/foraging patterns both above and below Cougar Dam. Compared to Alternative 2A, 2B results in increased adverse impacts to Chinook (moderate) and bull trout (moderate) in the McKenzie, otherwise impacts are predicted to be the same as for Alternative 2A. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, and Middle Fork sub-basins.

Alternative 3A has an operational theme (i.e., fish passage, water quality and other missions are accomplished by operation of existing structures). Specific measures included in the Alternative 3A are described in Section 2.4.6. Reservoir drawdowns will occur in spring and fall at Detroit, Cougar (to RO), and Lookout dams. Spring surface spill and fall deep drawdowns will occur at Green Peter and Hills Creek. A fall deep drawdown at Fall Creek will continue. Alternative 3A would have Major adverse impacts for Chinook and steelhead. Predicted performance for these species is very similar to the NAA, with some improvement in North Santiam Chinook and South Santiam steelhead. Alternative 3A would have Major adverse impacts for Bull trout. Reservoir rearing/foraging area is significantly reduced in both Detroit and Cougar reservoirs and expected to result in increased movement into more degraded rearing/foraging habitat below Detroit and Hills Creek dams where spawning habitat does not exist and human disturbance is high. Climate change is predicted to further degrade habitat for bull trout below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature targets below dams for Chinook and steelhead.

Alternative 3B also has an operational theme, with a different combination of fish passage measures. Specific measures included in the Alternative 3B are described in Section 2.4.7. Reservoir drawdowns will occur in spring and fall at Green Peter (to RO), Cougar (to DT), and Hills Creek dams (to RO). Spring surface spill and fall drawdowns (to RO) will occur at Detroit and Lookout Point dams. A fall deep drawdown at Fall Creek will continue. Alternative 3B would have Moderate to Major adverse impacts for Chinook and steelhead. Performance for Chinook in the North Santiam and McKenzie is predicted as viable to nearly viable, and the same for steelhead in the North and South Santiam. Alternative 3B would have Moderate to Major adverse impacts for bull trout. Reservoir rearing/foraging area is reduced in Cougar Reservoir, and passage will result in increased movement into more degraded rearing/foraging habitat below Detroit and Hills Creek dams where spawning habitat does not exist and human disturbance is high. Climate change is predicted to further degrade habitat for bull trout below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature targets below dams for Chinook and steelhead.

Alternative 4 is a structural focused alternative and includes large floating fish passage structures coupled to temperature structures in the North, McKenzie, and the Middle Fork. Smaller structures are included at Foster Dam in the South Santiam. A fall deep drawdown at Fall Creek will continue. Specific measures included in the Alternative 4 are described in Section 2.4.8. Alternative 4 adverse effects are predicted to be Moderate for Chinook salmon and MINOR for winter steelhead. Life cycle models predicts low extinction risk for Chinook for the North and South Santiam, and for the McKenzie. Only one model predicts low extinction risk for Middle Fork Chinook. Life cycle models predict low extinction risk for North Santiam winter steelhead, but only one model predicts low extinction risk for South Santiam steelhead. The EDT output also indicates Alternative 4 is somewhat resilient to different hydrology year types with respect to life history diversity. Alternative 4 is predicted to have Moderate adverse impacts for bull trout. Habitat scoring for bull trout is improved in all three sub-basins due to passage actions, however access to below dam habitat increases demographic risks especially below Hills Creek and secondarily below Detroit where spawning habitat does not exist, and human disturbance is high. Climate change is predicted to further degrade habitat for bull trout below dams. Structures for fish passage and temperatures will increase resiliency to climate change by improving operational flexibility.

Alternative 5 is the same as Alternative 2B but includes different minimum flows. Specific measures included in the Alternative 5 are described in Section 2.4.9. Despite the change in minimum flows, little to no difference between 2B and 5 is predicted regarding reservoir volumes or flows below dams, since reservoir drafting during the conservation use season and early flood seasons result in stream flows remaining above minimums. Therefore, the same impacts to Chinook, steelhead and bull trout are predicted from Alternative 5 as for Alternative 2B. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, McKenzie and Middle Fork sub-basins.

### *3.8.2.3 No Action Alternative*

#### *3.8.2.3.1 North Santiam*

Under the No Action Alternative, no downstream passage is implemented for juvenile downstream passage at Detroit.

**Chinook Salmon**

The summarized performance metrics for Chinook under the NAA for the LCM and IPA models are described in Table 3.8-14. Under the No Action Alternative, no downstream passage is implemented for juvenile downstream passage at Detroit. This results in few juveniles surviving to emigrate from above Detroit Dam, and therefore too few natural origin adults returning from the ocean to maintain the population above Detroit Dam. The life cycle models are in agreement with respect to spawner abundance, but disagree with respect to recruits per spawner and quasi-extinction risk. This may arise from differences in assumptions about TDG under the No Action Alternative. EDT output indicates some robustness to water year type with respect to diversity but poorer performance for spawner abundance and Recruit per Spawner. Under the No Action Alternative, spring Chinook in the North Santiam would not demonstrate substantial population growth but may persist at very a very small population size. Based on the EDT, it is likely that annual water year variability would have observable effects on Chinook. Evaluation Criteria: The No Action Alternative under both life cycle models predicts unacceptable risks to viability in two of three performance metrics. Therefore, the NAA would have MAJOR adverse impacts on Chinook salmon in the North Santiam.

**Table 3.8-14. North Santiam NAA spring Chinook performance across each model**

| North Santiam | | | | |
|---|---|---|---|---|
| **Model** | **Spawner Abundance** | **Recruit per Spawner** | **Quasi-extinction Risk** | **Diversity** |
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 3 | NA | 1 |
| EDT Dry | 3 | 1 | NA | 2 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The summarized performance metrics for steelhead under the No Action Alternative for the LCM, IPA, and EDT are given in Table 3.8-15. Under the No Action Alternative, no downstream passage is implemented for juvenile downstream passage at Detroit. However, about half of the steelhead spawning habitat exists in the North Santiam Sub-basin below Detroit Dam, and therefore lifecycle models predict somewhat better performance in comparison to Chinook.

The LCM predicts viability in one of three categories while the IPA predicts non-viability in all categories. The EDT output suggests robustness across normal and wet years with respect to diversity but poorer performance in dry years. With respect to equilibrium abundance and productivity, EDT predicts better performance in normal and dry years and worse performance in wet years. Under the No Action Alternative, steelhead in the North Santiam may persist at low population sizes; however, the uncertainty about population performance indicates that steelhead could still be at high risk, particularly in variable water years. Evaluation Criteria: Given that both life cycle models predict non-viability in at least one of the performance metrics, the NAA is expected to have MAJOR adverse impacts on winter steelhead in the North Santiam.

**Table 3.8-15. North Santiam NAA winter steelhead performance across each model**

| North Santiam | | | | |
|---|---|---|---|---|
| **Model** | **Spawner Abundance** | **Recruit per Spawner** | **Quasi-extinction Risk** | **Diversity** |
| LCM | Meets | Fails | Fails | NA |
| IPA | Fails | Fails | Fails | NA |
| EDT Wet | 3 | 3 | NA | 1 |
| EDT Dry | 2 | 2 | NA | 2 |
| EDT Normal | 1 | 1 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The summarized performance metrics for bull trout under the No Action Alternative are given in Table 3.8-16. Habitat scores are reasonable for the NAA with very limited passage under existing conditions. Although passage increases would provide access to habitat below dams, this passage increases demographic risks for each population currently residing above WVS dams by exposure to lower quality habitat and requires individuals to return and be trucked back above the dams to spawn and contribute to the population due to the lack of spawning habitat below dams. However, the facility at Minto may be used to collect adult bull trout to move them upstream of Detroit. Given available habitat and the possibility to use existing facilities to translocate adult bull trout upstream, effects on bull trout under the No Action Alternative in the North Santiam are predicted to be MINOR adverse.

**Table 3.8-16. Summary of bull trout habitat scoring and relative risk under the No Action Alternative in the North Santiam.**

| NAA | | | |
|---|---|---|---|
| **Sub-basin** | **Region** | **Score** | **Risk** |
| North Santiam | Above Detroit (rearing/foraging and spawning) | 41.52 | Low |
| | Below Detroit (rearing/foraging only) | 19.79 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.3.2 South Santiam*

Under the NAA, a continued spill operation would occur for downstream juvenile passage at Foster and there would be no downstream passage implemented at Green Peter. Upstream passage for adult fish would be provided by the existing adult fish facility at the base of Foster Dam. The combination of up and downstream passage allows Chinook and steelhead to access habitat above Foster Dam but not above Green Peter Dam.

**Chinook salmon**

The performance metrics for spring Chinook salmon in the South Santiam under the NAA are summarized in Table 3.8-17. In general, both life cycle models predicts that none of the performance metrics meet the minimum thresholds for viability. This likely in part due to the constraints on downstream fish passage survival by using existing water discharge routes at Foster Dam, given declining natural origin returns in recent years. The EDT outputs suggest that the No Action Alternative is sensitive to hydrology (i.e., year type) with dry years performing the worst in the South Santiam. This result likely reflects few days of spillway use in dry years resulting in poorer downstream fish passage survival. Under the No Action Alternative, spring Chinook are at high risk of extinction and negative population growth, likely due to the lack of effective passage, particularly in dry years. Evaluation Criteria: Given that the life cycle models predict non-viability in at least two of the three categories, it is predicted that the No Action Alternative would have MAJOR adverse impacts to spring Chinook in the South Santiam.

**Table 3.8-17. South Santiam NAA spring Chinook salmon performance across each model**

| South Santiam | | | | |
|---|---|---|---|---|
| **Model** | **Spawner Abundance** | **Recruit per Spawner** | **Quasi-extinction Risk** | **Diversity** |
| LCM | Fails | Fails | Fails | NA |
| IPA | Fails | Fails | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |

| South Santiam | | | | |
|---|---|---|---|---|
| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
| EDT Dry | 3 | 3 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The winter steelhead performance metrics under the NAA are summarized in Table 3.8-18. In general, both life cycle models indicate that very few of the performance metrics meet the minimum thresholds for viability. The EDT output suggests that the NAA is sensitive to hydrology with the exception of the Diversity metrics where wet and normal years perform comparably. Under the No Action Alternative, steelhead would be at high risk primarily due to the lack of adequate downstream passage and may demonstrate varied performance under different water year types. Evaluation Criteria: Given that both life cycle models predict non-viability in at least two of the three categories, it is predicted that the NAA would have MAJOR impacts on winter steelhead in the South Santiam.

**Table 3.8-18. South Santiam NAA winter steelhead performance across each model**

| South Santiam | | | | |
|---|---|---|---|---|
| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
| LCM | Meets | Fails | Fails | NA |
| IPA | Fails | Fails | Fails | NA |
| EDT Wet | 3 | 3 | NA | 1 |
| EDT Dry | 2 | 2 | NA | 2 |
| EDT Normal | 1 | 1 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

#### *3.8.2.3.3 McKenzie*

Under the NAA, no downstream passage would be implemented at Cougar Dam. Adult Chinook (primarily hatchery origin) and bull trout collected at the Cougar adult fish facility at the base of the dam and trucked upstream of the dam to spawn. Downstream fish passage would occur through the regulating outlet or turbine penstocks with the reservoir pool operated between the minimum and maximum conservation pool elevations. In this case fish many fish will exit when water depths to the dam outlets is high, increasing risk of injury and mortality. Survival through these routes as operated has been shown inadequate for re-establishing a Chinook population above Cougar Dam.

**Chinook Salmon**

The spring Chinook performance metrics in the McKenzie under the NAA are given in Table 3.8-19. In general, both models indicate that the performance metrics do not meet the minimum thresholds for viability, in general, but differ in the mechanism. The LCM predicts adequate spawner abundance; however, the LCM accounts for up and downstream populations whereas the IPA only accounts for upstream populations. Since wild populations exist below Cougar, they contribute to overall spawner abundance, even though productivity overall is predicted to be low. The EDT output indicate that the NAA is sensitive to hydrology except with respect to Diversity where all water year types performed similarly, i.e., the NAA in the McKenzie is resilient to water year type with respect to life history diversity. Under the No Action Alternative, spring Chinook in the McKenzie are unlikely to persist at levels adequate to avoid demographic risk. While initial replacement rates may be above 1.0 in some cases, the population growth rate would not be high enough to sustain the population in the long term primarily due to the lack of effective downstream passage. Evaluation Criteria: Given that the life cycle models predicted non-viability in two of three categories, the NAA is predicted to have MAJOR adverse impacts on spring Chinook in the McKenzie.

**Table 3.8-19. McKenzie NAA spring Chinook salmon performance across each model**

| McKenzie | | | | |
|---|---|---|---|---|
| **Model** | **Spawner Abundance** | **Recruit per Spawner** | **Quasi-extinction Risk** | **Diversity** |
| LCM | Meets | Fails | Fails | NA |
| IPA | Fails | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 1 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

Although habitat score for bull trout in the McKenzie under the NAA are below values for Detroit (Table 3.8-20), bull trout populations above Cougar have been stable for several years (Zymonas et al. 2021). This indicates that even with limited downstream fish passage conditions to below dam habitat, this population is sustainable under the NAA. For bull trout that do survive downstream passage, the existing adult fish facility at the base of the dam would be used to collected and transport those migrating upstream back above the dam to re-enter the spawning population. It is predicted that the NAA would have a NEGLIGIBLE adverse impact on the bull trout population above Cougar Dam.

**Table 3.8-20. Summary of bull trout habitat scoring and relative risk under the No Action Alternative in the McKenzie**

| McKenzie | | | |
|---|---|---|---|
| **Sub-basin** | **Region** | **Score** | **Risk** |
| McKenzie | Above Cougar (rearing/foraging and spawning) | 11.83 | Low |
| | Below Cougar (rearing/foraging only) | 7.13 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.3.4 Middle Fork*

Under the NAA, no downstream passage would be implemented at Lookout Point or Hills Creek dams. Adult hatchery Chinook in excess of hatchery brood stock needs collected at Dexter Adult Fish Facility are trucked upstream of Lookout Point and Hills Creek dams to spawn. Downstream passage at Hills Creek, Lookout, and Dexter Dam occurs through existing outlets where on average downstream fish passage survival is low under the NAA dam operational regime. The existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam.

**Chinook Salmon**

The performance metrics for spring Chinook in the Middle Fork under the NAA are summarized in Table 3.8-21. The performance metrics in both models are not predicted to meet the minimum thresholds for viability. This is not unexpected given the high prespawn mortality risk, high pHOS below Dexter dam, and lack of effective passage under the NAA. The EDT output indicates poor resiliency of UWR spring Chinook under the NAA in the Middle Fork, with dry years demonstrating the lowest performance in all dimensions. Under the No Action Alternative, spring Chinook would remain at high risk without significant natural production. While model results indicate that natural origin populations could sustain at low abundance levels, productivity is predicted to remain low and below threshold levels for viability. The lack of effective downstream passage and adequate temperature control in the Middle Fork produces higher overall risk for spring Chinook. Evaluation Criteria: Given that the IPA predicts non-viability in all categories, the NAA is predicted to have MAJOR adverse impacts to spring Chinook salmon in the Middle Fork.

**Table 3.8-21. Middle Fork NAA spring Chinook salmon performance across each model**

| Middle Fork | | | | |
|---|---|---|---|---|
| **Model** | **Spawner Abundance** | **Recruit per Spawner** | **Quasi-extinction Risk** | **Diversity** |
| LCM | Meets | Fails | Fails | NA |

| Middle Fork | | | | |
|---|---|---|---|---|
| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
| IPA | Fails | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The bull trout performance metrics under the NAA in the Middle Fork are summarized in Table 3.8-22. The habitat score above Hills Creek is low relative to the McKenzie and North Santiam, but high above Hills Creek relative to the below dam component. This is because the below dam component experiences higher temperatures than in other sub-basins. Even without passage, the population above Hills Creek has increased in recent years (Zymonas et al. 2021), which indicates that this population performs reasonably well under the NAA. It is expected that climate change will only worsen habitat conditions particularly downstream of Hills Creek and other dams, and the habitat score is not expected to increase with passage below Hills Creek. Bull trout that move downstream as not able to re-enter the spawning population above the dam, however given the population has been growing under operational conditions assumed for the NAA, the population performance would not be expected to change. Since most bull trout remain upstream of Hills Creek Dam, they are not exposed to risks associated with poorer habitat conditions, angling, passage at other dams and other human-related factors. The NAA is expected to have NEGLIGIBLE impacts on bull trout in the Middle Fork.

**Table 3.8-22. Summary of bull trout habitat scoring and relative risk under the No Action Alternative in the Middle Fork**

| Middle Fork | | | |
|---|---|---|---|
| Sub-basin | Region | Score | Risk |
| Middle Fork | Above Hills Creek (rearing/foraging and spawning) | 10.06 | Low |
| | Below Hills Creek (rearing/foraging only) | 0 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.4 Alternative 1*

#### *3.8.2.4.1 North Santiam*

Under Alternative 1, construction of structural downstream fish passage (#392) would be implemented at Detroit Dam. Upstream fish passage for Detroit and Big Cliff dams would be provided using the existing Minto Adult Fish Facility. The combination of structural passage provides effective access to upstream habitat for Chinook and steelhead, leading to increased abundance and productivity. Passage improvements would also support passage of a re-introduced bull trout population above Detroit Dam to access habitat below the dam and return back upstream to re-enter the spawning population, but there are a greater number of limiting factors downstream increasing potential for mortality for individuals that move downstream. Since there is not any spawning habitat available downstream of the dam, individuals must survival and migrate back upstream, be collected and trucked above Detroit Dam, in order to re-enter the spawning population.

**Chinook salmon**

The performance metrics for Chinook in the North Santiam under Alternative 1 are summarized in Table 3.8-23. In general, both life cycle models are closely aligned. Alternative 1 indicates good performance in all categories. In nearly all Action Alternatives, the North Santiam demonstrated the best performance in all models. The EDT shows Alternative 1 resiliency with respect to recruit per spawner but not for equilibrium abundance or life history diversity. This suggests that while the alternative performs well overall, it may perform worse in drier years. Under Alternative 1, spring Chinook in the North Santiam would experience lower risk than under the No Action Alternative, primarily due to effective downstream passage and adequate temperature control to manage prespawn mortality. However, the different assumptions about TDG induced mortality among the two life cycle models may result in performance slightly less than expected. Given the reasonable performance across life cycle models with the exception of quasi-extinction risk, and the level of resiliency across different year types, it is expected that Alternative 1 will have MINOR adverse impacts on spring Chinook salmon in the North Santiam.

**Table 3.8-23. North Santiam Alternative 1 spring Chinook salmon performance across each model**

| North Santiam | | | | |
|---|---|---|---|---|
| **Model** | **Spawner Abundance** | **Recruit per Spawner** | **Quasi-extinction Risk** | **Diversity** |
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 2 | NA | 1 |
| EDT Dry | 3 | 1 | NA | 3 |
| EDT Normal | 2 | 1 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the North Santiam are summarized in Table 3.8-24. Unlike the spring Chinook metrics, winter steelhead performance demonstrate general concurrence except with respect to quasi-extinction risk. In general, the LCM predicted a higher average abundance under Alternative 1, whereas abundance in the IPA was an order of magnitude smaller. While predicted productivity in both models met the minimum threshold for viability, the IPA predicted a lower overall productivity than the LCM. EDT shows resiliency across recruit per spawner. Under Alternative 1, steelhead would experience lower risk due to effective downstream passage and adequate temperature control. The migration timing when compared to Chinook may also limit effects of TDG. Given the high performance and resiliency in recruit per spawner, it is expected that Alternative 1 would have MINOR adverse impacts to winter steelhead in the North Santiam.

**Table 3.8-24. North Santiam Alternative 1 winter steelhead performance across each model**

| North Santiam | | | | |
|---|---|---|---|---|
| **Model** | **Spawner Abundance** | **Recruit per Spawner** | **Quasi-extinction Risk** | **Diversity** |
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the North Santiam under Alternative 1 are summarized in Table 3.8-25. In general, more habitat is available once bull trout pass downstream of Detroit as compared to the No Action Alternative but there are a greater number of limiting factors downstream. It is also expected that climate change would only exacerbate these factors. Therefore, while habitat could be increased under Alternative 1, so to would the impacts from limiting factors. It is expected that Alternative 1 would have MODERATE adverse impacts to bull trout reintroduced to the North Santiam.

**Table 3.8-25. Summary of bull trout habitat scoring and relative risk under Alternative 1 in the North Santiam**

| North Santiam | | | |
|---|---|---|---|
| **Sub-basin** | **Region** | **Score** | **Demographic Risk** |
| North Santiam | Above Detroit (rearing/foraging and spawning) | 41.32 | High |
| | Below Detroit (rearing/foraging only) | 38.08 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.4.2 South Santiam*

Under Alternative 1, construction of structural downstream fish passage (#392) occurs at Foster and Green Peter. Upstream migrating fish are collected at the existing Foster Adult Fish Collection Facility, and a new adult collection facility would be constructed and operated at the base of Green Peter Dam. The structural fish passage improvements allow Chinook and steelhead to access habitat above Foster and Green Peter dams, supporting increased abundance ad productivity compared to the NAA. However habitat available above these dams is limited and at lower elevation, influencing hydrology and water temperatures, when compared to that above WVS dams in other sub-basins where Chinook occur. These differences can affect fish survival and population performance.

**Chinook**

The performance metrics for spring Chinook in the South Santiam under Alternative 1 are summarized in Table 3.8-26. The IPA was consistently more optimistic for Chinook in the South Santiam under Alternative 1. This is likely related to each model's relative sensitivity to the downstream passage measure implemented under a given alternative. In general, the LCM is more sensitive to structural downstream passage and populations tend to perform better under the LCM than the IPA, when downstream passage facilities are assumed. Under Alternative 1, downstream passage at Green Peter is accomplished using a combination of seasonal operations. Downstream passage operations in the IPA are almost exclusively informed by the assumptions in Fish Benefits Workbook for a given passage alternative, whereas in the LCM, other factors may influence the effectiveness of operational passage when compared to structural passage (eg, reservoir mortality, or the fate of fish who do not passage the dam under a given operational passage scenario). In general, both models assume that if adult returns fall below a threshold in four consecutive years within the timeline, it is presumed extinct. It is possible that the population did not go extinct in the IPA because the model only considers the timeline of the management action (30 years) whereas the LCM considers a timeline beyond the management action (100 years). Otherwise, the IPA predicted high performance for Alternative 1 because it represents the most optimistic scenario for spring Chinook in the South Santiam. Alternative 1 included structural passage at both Foster and Green Peter dams, which was assumed to provide the best downstream passage survival. EDT suggests there could be differences in performance under a given hydrology year, but the magnitude of these differences may be smaller given the structural solutions proposed for downstream passage. Therefore, Alternative 1 is expected to have MINOR adverse impacts on spring Chinook salmon in the South Santiam despite the fact that the LCM predicts extinction, because it is assumed that the duration of the management action more closely aligns with the IPA assumption of 30 years.

**Table 3.8-26. South Santiam Alternative 1 spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead under Alternative 1 in the South Santiam are summarized in Table 3.8-27. Both life cycle models agree with respect to equilibrium spawner abundance and quasi-extinction risk but did not agree with respect to spawner abundance only. The LCM predicted no production in the South Santiam for any alternative (i.e., Recruit per spawner = 0). This is an unexpected result given that a population with a low extinction risk should demonstrate a productivity at least near 1.0 to consistently escape extinction. At the time of this writing, this result cannot be explained. Therefore, we relied primarily on the IPA for South Santiam winter steelhead. Again, structural downstream passage at both Foster and Green Peter is assumed to convey the highest possible benefit for outmigrating juveniles, therefore, the performance metrics reflect high viability scores. The EDT output also indicates that Alternative 1 is somewhat resilient to different hydrology year types with respect to life history diversity, but not for equilibrium abundance or productivity. Alternative 1 is expected to have MINOR adverse impacts on winter steelhead in the South Santiam.

**Table 3.8-27. South Santiam Alternative 1 winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 3 | 3 | NA | 1 |
| EDT Dry | 2 | 2 | NA | 2 |
| EDT Normal | 1 | 1 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

#### *3.8.2.4.3 McKenzie*

Under Alternative 1, no passage would be implemented at Cougar Dam. Fish passing upstream can be safely collected and trucked upstream using the existing adult facility completed in 2015. Fish passing downstream must use either the regulating outlet or turbine penstocks. Survival through these routes as operated has been shown inadequate for re-establishing a Chinook population above Cougar Dam.

**Chinook**

The performance metrics for spring Chinook in the McKenzie under Alternative 1 are summarized in Table 3.8-28. Under Alternative 1, no passage would be implemented at Cougar Dam. The life cycle models are in agreement with respect to equilibrium spawner abundance. This is not unexpected. The McKenzie sub-basin has populations of natural origin spawners below Cougar and the LCM takes that production into account. It assumes these populations are allowed to persist. The IPA only considers above dam natural origin components but considers only the lifespan of the management action (30 years). The EDT output indicates resiliency in all hydrology year types with respect to diversity but not equilibrium spawner abundance or productivity. This is also expected given that the McKenzie produces a wide spectrum of life history types even under the No Action Alternative due to above and below dam components. Given the lack of viability across the performance metrics, it is expected that Alternative 1 would have MAJOR adverse impacts to spring Chinook in the McKenzie.

**Table 3.8-28. McKenzie Alternative 1 spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 1 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the McKenzie under Alternative 1 are summarized in Table 3.8-29. Bull trout populations above Cougar have been stable for several years under the existing passage conditions at Cougar Dam (Zymonas et al. 2021). This indicates that the population is sustainable under Alternative 1. It is predicted that the NAA would have MINOR impacts on the bull trout population above Cougar.

**Table 3.8-29. Summary of bull trout habitat scoring and relative risk under Alternative 1 in the McKenzie**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| McKenzie | Above Cougar (rearing/foraging and spawning) | 11.86 | Moderate |
| | Below Cougar (rearing/foraging only) | 7.14 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.4.4 Middle Fork*

Under Alternative 1, The existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam. Construction of structural downstream fish passage (#392) would be implemented at Lookout Point and no passage would be implemented at Hills Creek. Adult Chinook would be collected at the base of Dexter Dam in the adult fish facility and trucked upstream of Lookout Point Reservoir. The structural fish passage improvements allow Chinook to access habitat above Lookout Point Dam, support increased abundance and productivity compared to the NAA. However, high pre-spawn mortality, poor reservoir survival, and low smolt to adult survival impact the ability to achieve a population at a low extinction risk. The bull trout population above Hills Creek Dam has been growing under existing passage conditions. Under Alternative 1, individuals that move downstream of Hills Creek Dam would not be able to re-enter the spawning population above the dam. However, given the population has been growing, the population performance would not be expected to change under this Alternative. Since most bull trout remain upstream of Hills Creek Dam, they are not exposed to risks associated with poorer habitat conditions, angling, passage at other dams and other human-related factors.

**Chinook**

The performance metrics for spring Chinook under Alternative 1 in the Middle Fork are summarized in Table 3.8-30. Under Alternative 1, structural passage would be implemented at Lookout Point and no passage would be implemented at Hills Creek. The LCM and IPA results are consistent in predicted performance in the Middle Fork. Due to passage at Lookout, Alternative 1 is likely to meet a lower population risk for Chinook than under the NAA, however, lack of adequate temperature control could contribute to ongoing prespawn mortality and low intrinsic productivity. The EDT results showed that Alternative 1 was not resilient to different hydrology year types probably due to the inability to substantially manipulate temperature in this low elevation sub-basin. It is expected that Alternative 1 would have MAJOR adverse impacts to spring Chinook in the Middle Fork.

**Table 3.8-30. Middle Fork Alternative 1 spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

<u>**Bull Trout**</u>

The performance metrics for bull trout in the Middle Fork under Alternative 1 are summarized in Table 3.8-31. Similar to the No Action Alternative, there is no passage at Hills Creek. However, the population above Hills Creek has been increasing in recent years without passage (Zymonas et al. 2021). The demographic risk to this population is low without implementation of passage at Hills Creek. Since most bull trout remain upstream of Hills Creek Dam, they are not exposed to risks associated with poorer habitat conditions, angling, passage at other dams and other human-related factors. Therefore, Alternative 1 would have NEGLIGIBLE adverse impact on bull trout in the Middle Fork.

**Table 3.8-31. Summary of bull trout habitat scoring and relative risk under Alternative 1 in the Middle Fork**

<table>
<tr><th>Sub-basin</th><th>Region</th><th>Score</th><th>Demographic Risk</th></tr>
<tr><td rowspan="2">Middle Fork</td><td>Above Hills Creek<br>(rearing/foraging and spawning)</td><td>10.03</td><td rowspan="2">Low</td></tr>
<tr><td>Below Hills Creek<br>(rearing/foraging only)</td><td>0</td></tr>
</table>

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.5 Alternative 2A*

#### *3.8.2.5.1 North Santiam*

Under Alternative 2A, construction of structural downstream fish passage (#392) would be implemented at Detroit Dam. For upstream passage, fish would be collected at the existing Minto adult fish facility and trucked upstream. The structural fish passage improvements allow Chinook and steelhead to access habitat above Detroit Dam, and support increased abundance and productivity compared to the NAA. Passage improvements would also support passage of a re-introduced bull trout population above Detroit Dam to access habitat below the dam and return back upstream to re-enter the spawning population, but there are a greater number of limiting factors downstream increasing potential for mortality for individuals that move downstream. Since there is not any spawning habitat available downstream of the dam, individuals must survival and migrate back upstream, be collected and trucked above Detroit Dam, in order to re-enter the spawning population.

**Chinook**

The performance metrics for spring Chinook salmon under Alternative 2A in the North Santiam are summarized in Table 3.8-32. Alternative 2A performs well in both life cycle models likely due to the implementation of structural downstream passage at Detroit. The EDT output does indicate some lack of resiliency over different hydrology year types but interestingly, recruits per spawner is highest in wet and dry years and lower in normal years. This may indicate small differences in performance or could be driven by a functional relationship in EDT. Overall, Alternative 2A presents lower risk to spring Chinook, due to effective downstream passage, improved downstream flow management which provided rearing and holding opportunities below dam, and adequate temperature control, which would likely reduce prespawn mortality. Alternative 2A would be expected to have MINOR adverse impacts on spring Chinook salmon in the North Santiam.

**Table 3.8-32. North Santiam Alternative 2A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 1 | NA | 2 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the North Santiam under Alternative 2A are summarized in Table 3.8-33. Similar to Chinook salmon, winter steelhead perform well in most performance metric dimensions in both life cycle models. Winter steelhead would likely be at lower risk due to effective downstream passage, increased rearing and holding opportunities downstream, and reduced prespawn mortality. The IPA predicts a much higher quasi-extinction risk than the LCM (above 35% higher risk). EDT shows resiliency with respect to recruits per spawner where Alternative 2A performs best under wet year times and comparably well under dry and normal year types. Alternative 2A would have MINOR adverse impacts to winter steelhead in the North Santiam.

**Table 3.8-33. North Santiam Alternative 2A winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the North Santiam are summarized in Table 3.8-34. Habitat scores are high above and below Detroit under 2A. However, Alternative 2A carries high demographic risks if bull trout are not able to migrate back upstream of the dam to contribute to the above Detroit population. It is expected that Alternative 2A would have MODERATE adverse impacts on bull trout in the North Santiam.

**Table 3.8-34. Summary of bull trout habitat scoring and relative risk under Alternative 2A in the North Santiam**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| North Santiam | Above Detroit (rearing/foraging and spawning) | 42.47 | High |
| | Below Detroit (rearing/foraging only) | 39.07 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

#### *3.8.2.5.2 South Santiam*

Under Alternative 2A, construction of structural downstream fish passage (#392) would be implemented at Foster. At Green Peter Dam upstream of Foster, a deeper fall reservoir drawdowns for fish passage (#40) and spring spill would be implemented to provide downstream fish passage. An adult fish facility would also be constructed at the base of Green Peter Dam. These fish passage improvements allow Chinook and steelhead to access habitat above both Foster and Green Peter dams, supporting the potential for increased abundance and productivity compared to the NAA. Compared to above other WVS dams, the relatively lower elevation habitat above these dams may constrain productivity and survival.

**Chinook**

The performance metrics for spring Chinook salmon under Alternative 2A are summarized in Table 3.8-35. The life cycle models agree with respect to equilibrium spawner abundance but not with respect to recruits per spawner or quasi-extinction risk. Again, this could reflect the complexity of the two-dam system in South Santiam where downstream passage at Green Peter in Alternative 2A is accomplished by operations and downstream passage and at Foster is accomplished using a structural solution. Given rates previously observed at Foster using structures and operations (Liss et al. 2020, Deng et al. 2019), it is likely that even if a population cannot be established above Green Peter, that the population above Foster would be successful through structural passage options. Therefore, the IPA may be more representative of performance in the South Santiam under 2A. Similar as mentioned under previous alternatives, the LCM tends to predict poorer performance when operational downstream passage is implemented compared to structural downstream passage. The implementation of operational downstream passage at Green Peter likely results in a lower performance weighting in the LCM when compared to the IPA. The EDT output show variable resilience to water year type by performance metric. Interestingly, the normal year type performed worse with respect to spawner abundance than the dry year type. This may be driven by an underlying functional relationship in EDT. For example, channel widths were not assumed to change with water management type because there is no information on how widths would change by reach. This may result in normal and dry years performing similarly. With respect to recruits per spawner, EDT predicted that Alternative 2A performed similarly in normal and dry years but best in wet years. With respect to diversity, dry years performed the worst, normal slightly better, and wet years the best. It is predicted that Alternative 2A would have MINOR adverse impacts on spring Chinook salmon in the South Santiam.

**Table 3.8-35. South Santiam Alternative 2A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 2 | 2 | NA | 3 |
| EDT Normal | 3 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the South Santiam under Alternative 2A are summarized in Table 3.8-36. Steelhead performance between both models demonstrated similar patterns as Chinook predictions. The LCM predicted non-viability with respect to productivity and quasi-extinction risk while the IPA predicted meeting viability thresholds for median spawner abundance and productivity. Recall that the LCM predicted 0.0 productivity in the South Santiam in all alternatives despite demonstrating low extinction risk in some alternatives (see section 3.8.2.4.2 Chinook). The IPA produced results similar to those for Chinook. This likely reflects improved downstream passage, improved habitat opportunities below dam, and reduced prespawn mortality with temperature control measure. EDT produced identical patterns with respect to Alternative 2A resiliency by water year type (see Chinook). It is expected that Alternative 2A would have MINOR adverse impacts on winter steelhead in the South Santiam.

**Table 3.8-36. South Santiam Alternative 2A winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

### *3.8.2.5.3 McKenzie*

Under Alternative 2A, construction of structural downstream fish passage (#392) would be implemented at Cougar. Upstream passage would occur using the existing adult fish collection facility at the base of Cougar Dam. The structural fish passage improvements allow Chinook and bull trout to access habitat above and below Cougar Dam, supporting increased Chinook abundance and productivity compared to the NAA, and increased survival of bull trout seeking to pass downstream.

**Chinook**

The performance metrics for spring Chinook in the McKenzie under Alternative 2A are summarized in Table 3.8-37. Alternative 2A proposes a structure at Cougar which assumes more optimistic downstream survival, particularly in the LCM. Both life cycle models predict viability in all performance metric dimensions. Similar to Alternative 1, EDT predicts similar performance over hydrology year type with respect to diversity which is likely due to the presence of multiple life history types above and below Cougar. However, Alternative 2A performs worse in dry and normal year types as opposed to wet years. Alternative 2A presents reduced overall risk due to effective downstream passage, adequate temperature control, and the presence of self-sustaining population downstream of Cougar. It is expected that Alternative 2A would have MINOR adverse impacts on spring Chinook salmon in the McKenzie.

**Table 3.8-37. McKenzie Alternative 2A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 1 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the McKenzie under Alternative 2A are summarized in Table 3.8-38. In general, bull trout are able to take advantage of habitat above and below Cougar due to structural downstream passage at Cougar dam and the adult facility in the tailrace of Cougar. However, given that the population above Cougar has been stable for many years, there is a moderate risk from passage if adults that are moved downstream. The rate of downstream passage of bull trout will not be understood until the structural passage improvement is operated for several years. Regardless, individual bull trout moved below the dam must be collected and moved back above the dam to contribute to the spawning population above the dam, otherwise these individuals are a loss to the population, reducing abundance and productivity. Bull trout that moved below Cougar would be subject to downstream effects and limiting factors. It is expected that Alternative 2A would have MODERATE impacts on bull trout in the McKenzie.

**Table 3.8-38. Summary of bull trout habitat scoring and relative risk under Alternative 2A in the McKenzie**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| McKenzie | Above Cougar (rearing/foraging and spawning) | 12.15 | Moderate |
| | Below Cougar (rearing/foraging only) | 14.73 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.5.4 Middle Fork*

Under Alternative 2A, the existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam. Construction of structural downstream fish passage (#392) would be implemented at Lookout Point Dam but not Hills Creek Dam. Upstream passage would occur using the existing adult fish facility at the base of Dexter Dam. The structural fish passage improvements allow Chinook to access habitat above Lookout Point Dam, supporting increased abundance and productivity compared to the NAA. The existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam. At Hills Creek Dam, downstream passage occurs through existing outlets where on average downstream fish passage survival is low under the NAA dam operational regime. The existing bull trout population above Hills Creek Dam would be expected to perform the same as under the NAA.

**Chinook**

The performance metrics for spring Chinook salmon in the Middle Fork under Alternative 2A are summarized in Table 3.8-39. The IPA and LCM predict viability with respect to equilibrium spawner abundance and recruits per spawner but not with respect to quasi-extinction risk. This pattern occurs when a population is productive but only at extremely low abundance. This indicates that the population may never meet the abundance threshold required to limit demographic risk. It is important to note that Alternative 2A produced low mean persistence in both the IPA and the LCM and these estimates are well below acceptable thresholds for viability, despite demonstrating improvement over the No Action Alternative. The EDT output produced typical results with respect to equilibrium spawner abundance and quasi-extinction risk (i.e., the alternative performed better in wet years than in normal or dry). Surprisingly, dry years performed better than normal years with respect to recruit per spawner. It is likely that effective downstream passage improves performance somewhat but lack of adequate temperature control may contribute to ongoing prespawn mortality above and below the project. It is expected that Alternative 2A would have MAJOR adverse impacts on spring Chinook salmon in the Middle Fork.

**Table 3.8-39. Middle Fork Alternative 2A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the Middle Fork under Alternative 2A are summarized in Table 3.8-40. Alternative 2A does not propose up or downstream passage at Hills Creek Dam. Given that the population above Hills Creek Dam has been increasing in recent years (Zymonas et al. 2021), the demographic risk to the bull trout population above Hills Creek is low. Although bull trout that move downstream are not able to re-enter the spawning population above the dam, the population has been growing under similar operational conditions as assumed for this alternative. Therefore the population performance would not be expected to change. Since most bull trout remain upstream of Hills Creek Dam, they are not exposed to risks associated with poorer habitat conditions, angling, passage at other dams and other human-related factors. It is expected that Alternative 2A would have NEGLIGIBLE impacts to bull trout in the Middle Fork.

**Table 3.8-40. Summary of bull trout habitat scoring and relative risk under Alternative 2A in the Middle Fork**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| Middle Fork | Above Hills Creek (rearing/foraging and spawning) | 10.11 | Low |
| | Below Hills Creek (rearing/foraging only) | 0 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.5.5 Near-term Operations Measure for Alternatives 2A, 2B, 3A, 3B, 4, 5*

The descriptions of the near-term operations measure can be found within Chapter 2. The analysis of impacts of the near-term operations measure on ESA-listed fish is broken down into subbasins.

**North Santiam Subbasin**

The near-term operations measure within the North Santiam Basin includes Fall/Winter downstream fish passage through the upper regulating outlets and spring fish passage through strategic use of spillway and turbines at Detroit Dam and spreading spill to reduce total dissolved gas at Big Cliff Dam.

***Effects on UWR Steelhead from spring/summer spill operation:***

UWR steelhead are not currently passed upstream of Detroit Dam, and there would be no plans to begin doing so until the long-term downstream passage solution is implemented. Therefore, effects of this action would be limited to steelhead downstream of Big Cliff Dam in the North Santiam River.

Upstream Passage Rates and Survival: Under this action, upstream migrating fish will continue to be collected at the Minto Adult Fish Collection Facility, where they can be loaded onto a truck and translocated to the North Santiam River Reach between Minto and Big Cliff dams. There are no changes from the NAA expected with implementation of this near term action on adult collection rates. Exposure to elevated TDG levels could increase for adults translocated between Minto and Big Cliff dams, however this would be expected to be minimal since adults are highly mobile and can avoid prolonged exposure.

Incubation and rearing: Natural origin adult winter steelhead will continue to be released into the Minto Dam to Big Cliff Dam reach of the North Santiam to spawn. Incubation periods overlap with this operation. The NAA also assumes surface spill occurs in the spring and summer for temperature control purposes. Since spill under this action may begin sooner than those in the NAA for temperature control, effects from elevated TDG on incubating eggs and fry may be somewhat higher in comparison to the NAA. Juveniles rearing below Big Cliff Dam could be exposed to high TDG however this is expected to be minimal since juvenile are highly mobile and can avoid exposure by moving within the local river channel, or moving downstream where high TDG levels are known to dissipate.

***Effects on UWR Chinook from spring/summer spill operation:***

Upstream Passage Rates and Survival: Under this action, upstream migrating marked (hatchery) adult fish will continue to be collected at the new Minto Adult Fish Collection Facility, where they can be loaded onto a truck and translocated above Detroit Dam. Unmarked (natural origin) adult Chinook would continue to be released above Minto Dam. There are no changes from the NAA expected with implementation of this near term action on adult collection rates. Exposure to elevated TDG levels could increase for adults migrating upstream to Minto, and particularly for natural origin adults released into the reach between Minto and Big Cliff. This exposure is not expected to increase pre-spawn mortality rates since adults are highly mobile and can avoid prolonged exposure.

Incubation and rearing: Natural origin adult spring Chinook will continue to be released into the Minto Dam to Big Cliff Dam reach of the North Santiam to spawn. Surface spill is not expected to occur during or after the Chinook spawning season from Detroit Dam. Therefore, the effect on incubation and rearing is expected to be the same as assumed for the NAA.

Downstream passage rates and survival: Beeman and Adams (2015) estimated survival from the forebay of Detroit Dam to Big Cliff forebay as 71.6% based on detections of acoustic tagged juvenile Chinook. Their study did not account for route of passage, however most of the fish passage events detected occurred during the period when surface spill was occurring and those fish with known routes of passage nearly all used the spillway.

In 2021, rotary screw traps were used to collect fish moving downstream from Big Cliff Dam when Detroit and Big Cliff dams' operations were similar to the near-term operations were conducted. Catch rates of juvenile Chinook salmon were low during spring when some surface spill occurred, and then highest during the month of July in a period when no spill occurred (Cramer Fish Sciences 2022). This may be related to the timing of juvenile Chinook entering the forebay, given previous reservoir distribution studies by ODFW show most juveniles remain very close to shore in the upper half of the reservoir until summer (Monzyk et al. 2014), and therefore few may be available to pass downstream until they become more dispersed in the reservoir during early summer. Catch rates reported from screwtraps need to be interpreted with caution since they vary considerably within and between years, and typically the catch rates of screwtraps are extremely low (<5%). Monitoring data from screwtraps also rarely permit an estimate of the numbers of fish passing downstream during the targeted operational period due to the extremely low catch rates, do not permit an assessment of which routes through the dam that were used to pass, or the survival of those passing.

The number of days that surface spill can occur depends on the annual hydrology. In some years surface spill may continue into July or August. In those years, more juvenile Chinook would be expected to pass downstream and survive at a higher rate compared to years when spill duration is less. Downstream flow minimum targets per Measure 30 will increase the reservoir refill rate in spring and increase the probability of surface spill occurring among years and the duration it occurs.

Juvenile fish passing downstream of Detroit Dam must also pass-through Big Cliff Reservoir and Dam. Beeman and Adams (2015) estimated juvenile Chinook survival from Detroit Dam tailrace downstream to Minto Dam as 67-74 percent, or inversely a mortality of 26-33 percent. We assume this estimate includes mortality occurring below Big Cliff Reservoir. Fischer et al. 2019 estimated mortality through Dexter Reservoir (which reregulates flows below Lookout Point Dam), at about 2%. Big Cliff Reservoir is smaller than Dexter. Oligher and Donaldson (1966) conducted Big Cliff Kaplan turbine unit tests to determine what effect various operating conditions would have on survival of fish passing through this type of turbine. Average survival from all tests in Oct. 1964 was 91.1 percent at 91 ft. head, 94.5 percent at 81 ft. head, and 89.7 percent at 71 ft. head. Average survival from all tests in May 1966 was 92.2 percent at 91 ft. head, 89.8 percent at 81 ft. head, and 90.6 percent at 71 ft. head. Therefore, we expect the 26-

33 percent mortality rate range is likely high since it also includes mortality occurring below Big Cliff.

Based on review of the recent monitoring collected using screwtraps and previous screwtrapping results, it is assumed the near-term action will result in an increase in surface spill and consequently downstream passage rates and survival for juvenile Chinook in comparison to the NAA.

Hatchery Program and effects on ESA-listed natural origin production: The HGMP (2016) for the North Santiam hatchery spring Chinook program indicates until the long-term juvenile fish passage solution past Detroit is implemented and approved by NMFS that only hatchery UWR Chinook salmon will be transported above Detroit Dam unless genetic pedigree indicates there is greater than a 1:1 ratio of recruits to spawners in the pedigree data for adults released above the dams for five complete years of data, or if fish managers determine there are special circumstances leading to a decision to outplant natural origin adults above Detroit Dam (e.g., lower survival of adults or their progeny is expected due to weather or habitat conditions below dams). Therefore, we conclude that pHOS will in most, if not all years, remain at 100% above the dam during implementation of this near-term action, and will remain the same as below Minto Dam as under the NAA.

***Effects on UWR Steelhead during the fall/winter operation:***

UWR steelhead are not currently passed upstream of Detroit Dam, and there would be no plans to begin doing so until long-term downstream passage is implemented. Therefore, effects of this action would be limited to steelhead downstream of Big Cliff Dam in the North Santiam River.

Upstream Passage Rates and Survival: Under this action, upstream migrating fish will continue to be collected at the new Minto Adult Fish Collection Facility, where they can be loaded onto a truck and translocated and released into the river between Minto and Big Cliff dams. There are no changes from the NAA expected with implementation of this near-term action on adult collection rates. Exposure to elevated TDG levels could increase for adults translocated between Minto and Big Cliff dams, however this would be expected to be minimal since adults are highly mobile and can avoid prolonged exposure.
