Compared to NAA, Alternative 2A resulted in minor to major beneficial water temperature effects in the North and South Santiam sub-basins due to the proposed temperature control structure at Detroit dam and the Green Peter fall deep drawdown. Minor to moderate beneficial TDG effects are expected in the North Santiam due to the proposed temperature control structure at Detroit that removes the need for operational temperature control with non-turbine outlets. Moderate to major adverse TDG effects are expected in the South Santiam due to the Green Peter fall deep drawdown that relies on more spill flow in in Alternative 2A when compared to the NAA.

This alternative includes structural downstream passage at Detroit, Foster, Cougar and Lookout Point dams, and operational passage at Green Peter Dam. A fall deep reservoir drawdown at Fall Creek Dam will continue. Alternative 2A would have MODERATE adverse effects on UWR spring Chinook salmon and is predicted to produce the most viable populations compared to any other alternative while retains the McKenzie core legacy population. For the South Santiam the LCM does not predict a viable population above Foster. Alternative 2A produces the most optimistic outcomes for UWR spring Chinook salmon in the Middle Fork among all the alternatives.

Alternative 2A would have MINOR adverse impacts to Santiam UWR steelhead populations when compared to the NAA, with good performance in all metric dimensions in both life cycle models except for the South Santiam under the LCM. EDT results shows resiliency with respect to recruits per spawner. Bull trout habitat scores and risks are comparable to Alternative 1, with a fish passage addition providing access to habitat below Cougar Dam. Alternative 2A would have MINOR adverse impacts for bull trout compared to the NAA. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, and Middle Fork sub-basins.

Alternative 2A would include adding a WTC tower at Detroit (Measure 105); lamprey passage at Green Peter (Measure 52); and downstream passage structures (Measure 392) at Detroit, Foster, Cougar, and Lookout Point. Measures included are focused on improving water quality and fish passage. This should improve lamprey populations in the South Santiam subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins compared to the NAA. Improving fish populations will provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, racoons, weasels, eagles, osprey, great blue herons, etc.

Like the NAA and Alterative 1, Alternative 2A follows a rule curve that results in one major cycle of draft and fill per water year. This cycle impacts 369 (80%) of known archaeological sites. Alternative 2A proposes a deeper fall reservoir drawdown at Green Peter and Fall Creek as opposed to just Fall Creek (with the NAA and Alternative 1). A deep fall drawdown would increase erosion at Green Peter and Fall Creek reservoirs, but the adverse effect to documented archaeological sites is not fully measurable. The number of reservoirs impacted on a project-level doubles in this Alternative and results in a higher number of documented archaeological sites that would be subject to this increased erosion as compared to the NAA.

Alternative 2A includes lamprey passage measures, has moderate to major water quality benefits (with the exception of moderate to major adverse effects to TDG expected at Green Peter), has minor benefits to piscivorous species, and there are minor to moderate adverse effects to UWR spring Chinook salmon and UWR steelhead as compared to the NAA. This alternative predicts the most positive outcomes for population survival of any alternative. Alternative 1 and 2A have similar adverse impacts to Bull Trout. This alternative is more beneficial to fisheries resources when compared to the NAA and Alternative 1. However, Alternative 2A has major adverse impacts to tribal resources, increased from the NAA and Alternative 1.

##### *3.24.3.3.1 Near-term operations Measures*

Throughout Chapter 3, each resources section considers the impacts of the near-term operations measure. Please refer to these sections. Overall, the operations are in place to improve anadromous fish passage, which is a positive effect to fisheries tribal resources. Adverse effects to wildlife and other fish are anticipated to be minor. Most of the operations in the measure have irreversible adverse impacts to cultural resources as compared to the NAA. These impacts are the same under every alternative as they were analyzed for the full temporal scope of the PEIS.

#### *3.24.3.4 Alternative 2B -- Hybrid Alternative*

The primary difference between Alternatives 2A and 2B is at Cougar dam, the diversion tunnel will be used for fish passage for Alternative 2B whereas for Alternative 2A, an FSS will be used. Specific measures included in Alternative 2B are described in Section 2.4.5.

Compared to NAA, Alternative 2B resulted in minor to major beneficial water temperature effects in the North Santiam, South Santiam, and South Fork McKenzie sub-basins due to the proposed temperature control structure at Detroit dam, Green Peter fall deep drawdown with operational temperature control, and a deep drawdown at Cougar. Minor to moderate beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins due to a reduced number of days with spill (at Detroit, the proposed temperature control structure removed the need for operational temperature control with non-turbine outlets). Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 2B due to the deep drawdown at Cougar that involves use of the diversion tunnel, which is expected to have lower TDG than the regulating outlet. Moderate to major adverse TDG effects are expected in the South Santiam due to the Green Peter autumn deep drawdown that relies on more spill flow in Alternative 2A than the NAA.

The only difference between Alternative 2A and Alternative 2B is that 2B has an operational downstream fish passage measure at Cougar Dam (deep drawdown to near the diversion tunnel in spring and fall) instead of a structural measure. Cougar Reservoir would largely be drained in spring and only partially refilled in summer due to summer inflow, resulting in most juvenile Chinook moving downstream of Cougar Dam and a significant reduction in rearing/foraging opportunity within the reservoir for bull trout. Many bull trout would be expected to move upstream into the South Fork McKenzie, or below Cougar Dam during spring and fall reservoir drawdowns. Suitable habitat for bull trout exists above and below Cougar Dam and Reservoir, however carry capacity and other effects of redistribution on survival and spawning is uncertain. The deep draft in spring will also eliminate conservation water storage, resulting in lower summer stream flows and changes in water temperatures below Cougar Dam. These differences will affect fish rearing/foraging patterns both above and below Cougar Dam as compared to the NAA. Compared to Alternative 2A, 2B results in increased adverse impacts to UWR spring Chinook salmon (moderate) and bull trout (moderate) in the McKenzie, otherwise impacts are predicted to be the same as for Alternative 2A. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, and Middle Fork sub-basins.

Alternative 2B would include adding a WTC tower at Detroit (Measure 105); lamprey passage at Green Peter (Measure 52); and downstream passage structures (Measure 392) at Detroit, Foster, and Lookout Point. As previously mentioned, downstream passage at Cougar is provided through the spring and fall drawdowns to the diversion tunnel (Measures 40 and 720). Measures included are focused on improving water quality and fish passage. This should improve lamprey populations in the South Santiam subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins. Improving fish populations will provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, racoons, weasels, eagles, osprey, great blue herons, etc. when compared to the NAA.

Alterative 2B as well as the NAA, Alternative 1, and Alternative 2A follows a rule curve that results in one major cycle of draft and fill per water year. Alternative 2B proposes a deep spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) at Cougar (1330 feet) and fall deep drawdown at Green Peter and Fall Creek. Overall, the WVS would see a 4% system-wide increase in site exposure with Alternative 2B as compared to the NAA. Alternative 2B has the potential to cause moderate to major effects to six of the 13 historic districts with proposed measures that support water quality, downstream and upstream fish passage. The overall effect from Alternative 2B to cultural resources would be irreversible, adverse, and major within the WVS when compared to the NAA.

Alternative 2B includes lamprey passage measures at multiple projects and would result in minor to major water quality improvements (except TDG levels at Green Peter) when compared to the NAA. There are reduced adverse impacts to UWR spring Chinook salmon and UWR steelhead when compared to the NAA and Alternative 1, and similar but slightly increased adverse effects when compared to Alternative 2A. Alternative 1 and 2A have similar adverse impacts to Bull Trout. This alternative has less adverse effects to fisheries resources when compared to the NAA and Alternative 1, but slightly more adverse effects that Alternative 2A. Alternative 2B has major adverse impacts to tribal resources compared to the NAA.

##### *3.4.3.4.1 Near-Term Operations Measures*

See Section 3.24.3.3.1.

#### ***3.24.3.5 Alternative 3A – Operations-Focused Fish Passage Alternative***

Alternative 3A proposes to improve fish passage through operations-focused measures including downstream passage at Cougar through deep drawdown to lowest regulating outlets. Specific measures included in the Alternative 3A are described in Section 2.4.6.

Compared to NAA, Alternative 3A resulted in minor to major beneficial water temperature effects in the Middle Fork Willamette (between Hills Creek dam and Lookout Point Dam) and South Santiam sub-basins due to the proposed deep drawdowns at Hills Creek and Green Peter dams. In the North Santiam sub-basin, minor beneficial effects to water temperature are expected during the autumn while moderate adverse effects are expected during the spring-summer due to deep drawdown at Detroit Dam in Alternative 3A. In the South Fork McKenzie sub-basin, minor adverse effects to water temperature are expected during the fall due to a partial drawdown at Cougar Dam in Alternative 3A. Minor to major adverse TDG effects are expected in the North Santiam, South Santiam, and Middle Fork Willamette as compared to the NAA due to the deep drawdowns at Detroit, Green Peter (autumn) and Lookout Point that rely on higher outflows and/or spill flow in Alternative 3A.

Reservoir drawdowns will occur in spring and fall at Detroit, Cougar (to RO), and Lookout dams. Spring surface spill and fall deep drawdowns will occur at Green Peter and Hills Creek. The fall deep drawdown at Fall Creek from the NAA will continue. Alternative 3A would have Major adverse impacts for UWR spring Chinook salmon and UWR steelhead when compared to the NAA. Predicted performance for these species is very similar to the NAA, with some improvement in North Santiam UWR spring Chinook salmon and South Santiam UWR steelhead. Alternative 3A would have Major adverse impacts for Bull trout compared to the NAA. Reservoir rearing/foraging area is significantly reduced in both Detroit and Cougar reservoirs and expected to result in increased movement into more degraded rearing/foraging habitat below Detroit and Hills Creek dams where spawning habitat does not exist and human disturbance is high. Climate change is predicted to further degrade habitat for bull trout below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature targets below dams for UWR spring Chinook salmon and UWR steelhead.

Alternative 3A will also provide lamprey passage at Blue River, Green Peter, and Hills Creek dams; downstream spillway fish passage at Big Cliff, Dexter, Fall Creek, Green Peter, and Hills Creek dams. This should improve lamprey populations in the McKenzie, South Santiam, and Middle Fork Willamette subbasins and salmonid populations in the North Santiam, South Santiam, and Middle Fork Willamette subbasins. Improving fish populations will provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, raccoons, weasels, eagles, osprey, great blue herons, etc. that use habitat upstream of the dams in these subbasins when compared to the NAA.

Alterative 3A deviates strongly from the NAA as well as Alternative 1, Alternative 2A, and Alternative 2B in regard to the increase in potential impacts to archaeological resources. Fall deep drawdowns are proposed for six reservoirs including Blue River, Hills Creek, Green Peter, Detroit, Lookout Point, and Cougar beyond the annual cycle of draw and fill. Spring deep drawdowns are proposed at three of those reservoirs including Detroit, Lookout Point, and Cougar. At all of these reservoirs accelerated erosion will impact slope stability and the archaeological sites present, but at much larger scale than the NAA. Nearly 50% of reservoirs and present sites will be vulnerable to increased erosion from the fall deep drawdowns, and nearly 25% of reservoirs will experience additional erosion by doubling the cycle of draft and fill that occur in one water year. The WVS would experience a 44% increase in site exposure from the NAA. Adverse effects specifically to archaeological sites at seven reservoirs would be substantially high.

Alternative 3A would also greatly lengthen the amount of time that sites at Detroit, Lookout Point, and Cougar Reservoir will be exposed to human-induced impacts. Alternative 3A has the potential to cause moderate to major effects to four of the 13 historic districts with proposed measures that support water quality, downstream and upstream fish passage. The overall effect from Alternative 3A to Cultural Resources would be irreversible, adverse, and major within the WVS as compared to the NAA.

Alternative 3A has major adverse impacts to cultural resources, which greatly increase compared to the NAA, Alternative 1, Alternative 2A, and Alternative 2B. The alternative does include lamprey passage measures at multiple projects, but moderate to major adverse effects are increased for UWR spring Chinook salmon, UWR steelhead and Bull Trout. While there are some benefits to water quality, overall this alternative has the most adverse effects to water quality compared to the NAA, Alternative 1, 2A, and 2B. This alternative has the most adverse effects to tribal resources.

##### *3.24.3.5.1 Near-Term Operations Measures*

See Section 3.24.3.3.1.

#### ***3.24.3.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)***

Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)

Alternative 3B is similar to Alternative 3A in that it proposes to improve fish passage through operations-focused measures, but it includes downstream passage at Cougar through the diversion tunnel. Specific measures included in the Alternative 3B are described in Section 2.4.7.

Compared to NAA, Alternative 3B resulted in minor to moderate beneficial water temperature effects in the Middle Fork Willamette, McKenzie, and South Santiam sub-basins due to the proposed drawdowns at Hills Creek, Lookout Point, Cougar, and Green Peter dams. Minor to major adverse TDG effects are expected in the North Santiam, South Santiam, and Middle Fork Willamette (below Dexter Dam) as compared to the NAA, due to the deep drawdowns at Detroit (autumn), Green Peter, and Lookout Point (autumn) that rely on high outflows, thereby increasing the number of days with spill in Alternative 3B. Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 3B due to the deep drawdown at Cougar that involves use of the diversion tunnel, which is expected to have lower TDG than the regulating outlet when compared to the NAA.

Reservoir drawdowns will occur in spring and fall at Green Peter (to RO), Cougar (to DT), and Hills Creek dams (to RO). Spring surface spill and fall drawdowns (to RO) will occur at Detroit and Lookout Point dams. A fall deep drawdown at Fall Creek will continue as under the NAA. Alternative 3B would have Moderate to Major adverse impacts for UWR spring Chinook salmon and UWR steelhead. Performance for Chinook in the North Santiam and McKenzie is predicted as viable to nearly viable, and the same for steelhead in the North and South Santiam. Alternative 3B would have Moderate to Major adverse impacts for bull trout. Reservoir rearing/foraging area is reduced in Cougar Reservoir, and passage will result in increased movement into more degraded rearing/foraging habitat below Detroit and Hills Creek dams where spawning habitat does not exist and human disturbance is high. Climate change is predicted to further degrade habitat for bull trout below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature targets below dams for UWR spring Chinook salmon and UWR steelhead.

There are also differences in terms of fish passage improvements between 3A and 3B. Alternative 3B will improve fish passage by providing downstream passage through the spillways at Big Cliff, Detroit, Dexter, and Lookout Point dams as well as through the drawdowns previously discussed. Lamprey passage will be provided at Hills Creek, Blue River, and Green Peter. Improving lamprey and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins will provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including but not limited to river otters, snakes, raccoons, weasels, eagles, osprey, great blue herons, etc. upstream of the dams in these subbasins compared to the NAA.

Alterative 3B shares similarities with 3A, but is quite different from the NAA, Alternative 1, Alternative 2A, and Alternative 2B. Deeper fall reservoir drawdowns (#40) are proposed for the same seven reservoirs including Fall Creek, Blue River (1165 feet), Hills Creek (1446 feet), Green Peter (780 feet), Detroit (1375 feet), Lookout Point (761 feet), and Cougar (1517 feet). Spring reservoir drawdowns (#720), however, are proposed at Hills Creek, Cougar, and Green Peter. In both of these alternatives, Cougar would have a spring and fall deep drawdown. In Alternative 3B, the fall deep drawdown at Cougar would pass through the diversion tunnel. The WVS would experience a 31% higher site exposure rate than the NAA.

Adverse effects specifically to archaeological sites at seven of the reservoirs are substantially high. Like with Alternative 3A, accelerated erosion would impact slope stability and the archaeological sites present in the reservoirs, at a similar scale, but with slightly different locations. Again, more than 50% of reservoirs and associated archaeological sites would be vulnerable to increased erosion from the fall deep drawdowns, and nearly 25% of reservoirs would experience additional erosion by doubling the cycle of draft and fill that occur in one water year compared to the NAA. Alternative 3A has the potential to cause moderate to major effects to four of the 13 historic districts with proposed measures that support water quality, downstream and upstream fish passage. The overall effect from Alternative 3B to Cultural Resources would be irreversible, adverse, and major within the WVS.

Like Alternative 3A, Alternative 3B has major adverse impacts to cultural resources compaired the NAA, Alternative 1, Alternative 2A, and Alternative 2B. The alternative does include lamprey passage measures at multiple projects, but moderate to major adverse effects would occur for UWR spring Chinook salmon, UWR steelhead, and Bull Trout. Overall this alternative has adverse effects to water quality similar to those of 3A (and more adverse than the NAA, Alternative 1, Alternative 2A, and Alternative 2B), but it is improved from Alternative 3A due to the lower TDG anticipated through the use of the Cougar diversion tunnel. This alternative has a similar level of adverse effects as Alternative 3A to tribal resources.

##### *3.24.3.6.1 Near-Term Operations Measures*

See Section 3.24.3.3.1.

#### ***3.24.3.7 Alternative 4 – Structures-Based Fish Passage Alternative***

Alternative 4 proposes to improve fish passage through a structure-based approach. Specific measures included in the Alternative 4 are described in Section 2.4.8.

Compared to NAA, Alternative 4 resulted in minor to major beneficial water temperature effects in the Middle Fork Willamette (between Hills Creek Dam and Lookout Point Dam), South Santiam, and North Santiam basins due to the proposed temperature control structures at Hills Creek, Lookout Point, and Detroit Dams as well as operational temperature control at Green Peter Dam. Minor to Major beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins based on the proposed TDG abatement structures below Detroit and Big Cliff Dams and the reduced number of spill days at Cougar Dam in Alternative 4.

Alternative 4 is a structural focused alternative and includes large floating fish passage structures coupled to temperature structures in the North, McKenzie, and the Middle Fork. Smaller structures are included at Foster Dam in the South Santiam. A fall deep drawdown at Fall Creek will continue. Alternative 4 adverse effects are predicted to be Moderate for UWR spring Chinook salmon and MINOR for UWR steelhead compared to the NAA. Life cycle models predict low extinction risk for UWR spring Chinook salmon for the North and South Santiam, and for the McKenzie. Only one model predicts low extinction risk for Middle Fork Chinook. Life cycle models predict low extinction risk for North Santiam UWR steelhead, but only one model predicts low extinction risk for South Santiam steelhead. The EDT output also indicates Alternative 4 is somewhat resilient to different hydrology year types with respect to life history diversity.

Alternative 4 is predicted to have Moderate adverse impacts for bull trout. Habitat scoring for bull trout is improved in all three sub-basins due to passage actions, however access to below dam habitat increases demographic risks especially below Hills Creek and secondarily below Detroit where spawning habitat does not exist, and human disturbance is high. Climate change is predicted to further degrade habitat for bull trout below dams. Structures for fish passage and temperatures will increase resiliency to climate change by improving operational flexibility.

This alternative would include adding WTC towers (Measure 105) at Detroit, Hills Creek, and Lookout Point; lamprey passage (Measure 52) at Hills Creek; up and downstream passage at Fern Ridge (Measure 639); and downstream passage structures (Measure 392) at Cougar, Detroit, Foster, Hills Creek, and Lookout Point (fish collection around Dexter). Measures included are focused on improving water quality and fish passage. This would improve lamprey populations in the Middle Willamette subbasin and salmonid populations in the North Santiam, South Santiam, Long Tom, and Middle Willamette Fork subbasins. Improving fish populations will provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, raccoons, weasels, eagles, osprey, great blue herons, etc. upstream of the dams in these subbasins compared to the NAA.

Alterative 4 follows a rule curve that results in one major cycle of draft and fill per water year and is similar to Alternative 1 in regard to impacts to archaeological resources. The impacts are also similar to the NAA. Alternatives 4, however, does not propose any deep drawdowns or spring spills over the spillway. Rather this alternative focuses heavily on structure-based measures to accomplish downstream fish passage. Like Alternative 1, Alternative 4 would result in a minor increase in system-wide site exposure (3% increase from NAA). As with the NAA, the WVS cycle of draft and fill will continue to adversely affect 369 (80%) of the archaeological sites present. Alternative 4 has the potential to cause moderate to major effects to seven of the 13 historic districts through measures that support water quality, downstream and upstream fish passage. The overall effect from Alternative 4 to Cultural Resources would be irreversible, adverse, and major within the WVS.

The alternative provides minor benefits to piscivorous species and does include some lamprey passage, but at limited projects compared to the NAA. Water quality has minor to major improvements on par with Alternative 1 though improved from the NAA and Alternatives 2A, 2B, 3A, and 3B. Overall the impacts to UWR spring Chinook salmon, UWR steelhead, and Bull Trout are similar to those for Alternatives 2A and 2B and improved from the NAA and Alternatives 1, 3A, and 2B. Alternative 4 and the NAA have similar adverse effects to archaeological sites, improved from Alternatives 2A, 2B, and greatly improved from Alternatives 3A and 3B. Alternative 4 has the greatest adverse impacts to the built environment resources and slightly more than Alternatives 1, 2A, and 2B. Alternative 4 has a range of beneficial to adverse effects to tribal resources compared to the NAA.

##### *3.24.3.7.1 Near-term operations measures*

See Section 3.24.3.3.1.

#### ***3.24.3.8 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Alternative 5 is nearly identical to Alternative 2B except that the integrated temperature and habitat flow regime (Measure 30a) has been replaced by the refined integrated temperature and habitat flow regime (Measure 30b). Specific measures included in the Alternative 5 are described in Section 2.4.9.

Compared to NAA, Alternative 5 would likely result in minor to major beneficial water temperature effects in the North Santiam, South Santiam, and South Fork McKenzie sub-basins due to the proposed temperature control structure at Detroit dam, Green Peter deep autumn drawdown with operational temperature control, and a deep drawdown at Cougar. Minor to moderate beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins due to a reduced number of days with spill (at Detroit, the proposed temperature control structure removed the need for operational temperature control with non-turbine outlets). Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 5 due to the deep drawdown at Cougar that involves use of the diversion tunnel, which is expected to have lower TDG than the regulating outlet. Moderate adverse TDG effects are expected below Green Peter Dam (above Foster Lake) due to the Green Peter autumn deep drawdown that relies on more spill flow in Alternative 5 compared to the NAA.

Despite the change in minimum flows, little to no difference between 2B and 5 is predicted regarding reservoir volumes or flows below dams, since reservoir drafting during the conservation use season and early flood seasons result in stream flows remaining above minimums. Therefore, the same impacts to Chinook, steelhead and bull trout are predicted from Alternative 5 as for Alternative 2B. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, McKenzie and Middle Fork sub-basins.

Alternative 5 would include adding a WTC tower at Detroit (Measure 105); lamprey passage at Green Peter (Measure 52); and downstream passage structures (Measure 392) at Detroit, Foster, and Lookout Point. As previously mentioned, downstream passage at Cougar is provided through the spring and fall drawdowns to the diversion tunnel (Measures 40 and 720). Measures included are focused on improving water quality and fish passage. This should improve lamprey populations in the South Santiam subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins. Improving fish populations will provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, racoons, weasels, eagles, osprey, great blue herons, etc. compared to the NAA.

Alterative 5 follows a rule curve that results in one major cycle of draft and fill per water year. Alternative 5 proposes a deep spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) at Cougar (1330 feet) and fall deep drawdown at Green Peter and Fall Creek. Overall, the WVS would see a 4% system-wide increase in site exposure with Alternative 5 compared to the NAA. Alternative 5 has the potential to cause moderate to major effects to six of the 13 historic districts with proposed measures that support water quality, downstream and upstream fish passage. The overall effect from Alternative 5 to Cultural Resources would be irreversible, adverse, and major within the WVS.

Alternative 5 effects are on par with Alternative 2B. Alternative 5 includes lamprey passage measures at multiple projects and would result in minor to major water quality improvements (except moderate adverse impacts to Green Peter TDG levels) that are similar to Alternatives 2A and 2B compared to the NAA that has none. Water quality would be improved compared to Alternatives 3A and 3B but have more adverse effects than Alternative 4. There are reduced adverse impacts to UWR spring Chinook salmon and UWR steelhead when compared to the NAA and Alternatives 1, 3A, and 3B, but increased adverse effects when compared to Alternative 2A and 4. Alternative 1, 2A, 2B, and 4 have similar adverse impacts to Bull Trout. This alternative has less adverse effects to fisheries resources when compared to the NAA and Alternatives 1, 3A, 3B, and 4, but slightly more adverse effects that Alternative 2A. Alternative 5 has major adverse impacts to cultural resources, increased from the NAA, Alternative 1, and Alternative 2A, but reduced from Alternatives 3A and 3B.

#### *3.24.3.8.1 Near-term operations measures*

See Section 3.24.3.3.1.

## 3.25 UNAVOIDABLE ADVERSE EFFECTS

Unavoidable adverse effects are those effects that cannot be avoided or fully mitigated should the alternatives be implemented. The effects of the Alternatives are described in Chapter 3 and some of them may not be fully avoided, as identified in CEQ regulations (40 C.F.R. § 1502.16). Location and intensity of unavoidable effects would vary by alternative. Physical laws and processes make erosion and sedimentation unavoidable. If storage reservoirs are operated according to their intended function, with drafting and refilling cycles, the reservoir elevations may fluctuate substantially, reservoir shorelines would be exposed, and islands could be bridged. Unavoidable effects from storage reservoir operations include blowing dust from exposed sediments, diminished visual quality, damage to archaeological sites, and some degree of disruption to resident fish spawning and food availability. Seasonal limitations on use of recreation facilities could be avoided by modifying the facilities, but it would be impractical to eliminate all elevation-based recreation effects. Several types of effects are unavoidable with the current configuration of the system, such as some degree of disruption to anadromous and resident fish spawning and food availability. Projected effects at the WVS projects would result from operational changes that disrupt established uses dependent upon certain elevation patterns. If operations change those elevation patterns, some degree of effect to the established uses is unavoidable.

## 3.26 RELATIONSHIP BETWEEN SHORT-TERM USES AND LONG-TERM PRODUCTIVITY

This analysis looks at the relationship between short-term uses of environmental resources and the maintenance and enhancement of long-term productivity. WVS operations may cause both short-term and long-term effects to the affected environment that cannot be mitigated. All of the alternatives would cause some mix of short-term effects, including soil erosion, dust generation, degradation of water quality, loss of riparian or wetland vegetation, disruption of fish and wildlife habitat, disruption of recreational use, degradation of visual quality, and effects to cultural resources. In general, the extent these would be long-term effects would depend upon how long a given operation was continued. Some of the short-term changes could soon lead to long-term decreases in productivity. For example, dam releases that contribute to downstream flow levels going below those required for irrigation pumps could result in long-term agricultural productivity losses, if irrigators do not modify their pumps. The short-term and long-term uses of the environment for WVS operations could have some beneficial effects on long-term productivity. The continued availability of power should help maintain the region's reliability. Operations intended to benefit anadromous and resident fish should contribute to the survival and recovery of ESA-listed species and to the maintenance of other stocks. Some of the alternatives would improve conditions for anadromous and resident fish and wildlife, and this could improve the long-term productivity of these resources.

## 3.27 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

Irreversible and irretrievable commitments generally affect environmental resources such as soils, wetlands, and riparian areas, but can involve financial resources. Such commitments are considered irreversible and irretrievable because their implementation would affect a resource that has deteriorated to the point that renewal can occur only over a long period or at a great expense, or because they would cause the resource to be destroyed or removed. Few of the operational effects resulting from operation of existing facilities would be irreversible or irretrievable. Loss of soil due to erosion is an irreversible and irretrievable commitment. The construction of new facilities would result in irreversible and irretrievable commitments of upland and blow ordinary highwater areas as well as financial resources. As this is a PEIS and the detailed locations and designs for these structures have been developed, the irreversible and irretrievable commitment of resources will not be known until future tiered NEPA is performed, as discussed in Chapter 7.

Because all of the alternatives, including current operations, involve reservoir fluctuation at some of the projects, erosion would occur at these projects under all of the alternatives. The abundance and quality of wetland and riparian habitat depend on water levels and timing. The desiccation of wetland plants due to drafting at storage reservoirs in some cases would be an irreversible commitment. The desiccation of submerged aquatic plants and mud-dwelling fauna and gradual loss of emergent marsh and riparian vegetation is also an irreversible and irretrievable commitment. These resources could conceivably be restored with higher water levels, but the existing resources would be lost.

Loss of cultural resources resulting from accidental damage or vandalism would be an irreversible and irretrievable commitment. All of the alternatives, including current operations, would expose substantial percentages of known archaeological sites to such damage or vandalism.

## 3.28 INTENTIONAL DESTRUCTIVE ACTS

Intentional destructive acts are acts of vandalism, theft, burglary, sabotage, and terrorism that can disrupt or destroy infrastructure or threaten human health and safety. The area of analysis for intentional destructive acts is the WRB. Although the Bonneville Power Administration (BPA) services areas outside of the WRB, those areas are outside of the scope of this EIS and should not be affected by intentional destructive acts in the area of analysis due to the redundancies[59] and resilience[60] built into the power transmission system.

### 3.28.1 Background

BPA is a division of the U.S. Department of Energy (DOE) and is a cooperating agency for this Draft EIS. Explicit inclusion of intentional destructive acts in NEPA analysis is required for both nuclear and non-nuclear actions proposed by DOE (United States Court of Appeals, 2006).

[59] Redundance is provided by the inclusion of additional critical components in the power grid system in case primary components fail.

[60] Resilience is the ability of a system to withstand disasters (low-frequency, high-impact incidents). For example, if a region's hydropower electricity were to be temporarily shut off, power to the region would still be provided by other sources such as fossil fuels, wind, and nuclear energy.

### 3.28.2 Types of Intentional Destructive Acts

Intentional destructive acts considered in this section include vandalism, theft, burglary, sabotage, and terrorism. While relatively infrequent, these acts have either occurred in the area of analysis in the past or are reasonably foreseeable. Intentional destructive acts generally result in adverse financial effects. Damage to the natural environment can also occur but is less likely.

#### *3.28.2.1 Vandalism, Theft, and Burglary*

Vandalism is the deliberate destruction of property. Theft involves the non-consensual taking of property, whereas burglary involves entering a building with the intent to commit a crime inside. Burglary is often committed with the intent of theft (Mince-Didier, 2022).

According to data collected between 2016 and 2018, the intentional destructive acts that occur most frequently at USACE-managed facilities within the WRB are vandalism, theft, and burglary (Table 3.32-2). The most common intentional destructive act was vandalism, which made up over half of all total reported incidents.

**Table 3.28-1. Intentional Destructive Acts Reported to USACE Within the WRB (2016-2018)**

| Incident Type | Number of Incidents | Percent of Total Incidents[1] |
|---|---|---|
| Vandalism | 102 | 53% |
| Theft | 10 | 5% |
| Burglary | 1 | <1% |
| **Total** | 108 | 56% |

[1]Other incidents recorded by USACE that are not considered intentional destructive acts include but are not limited to vehicle collisions, illegal dumping, and wildfires.

Source: USACE, 2018

According to data collected by BPA, approximately 128 incidents of vandalism, theft, and burglary occurred at BPA-managed facilities between 2007 and 2009. Theft of valuable materials such as metal was the most common crime documented. To deter criminal activity such as unauthorized access to facilities, BPA utilizes physical measures including security fencing and cameras. BPA is currently in the process of replacing solid copper wire with copper-clad steel wire at electrical substations, which is much less expensive and more difficult to cut, in order to prevent future thefts (KGW, 2011). The Bonneville Security and Emergency Response Office works closely with federal law enforcement agencies as well as local and state police to ensure that all incidents are appropriately reported, investigated, and prosecuted. Through its Crime Witness Program, BPA offers up to $25,000 for confidential information that leads to the arrest and conviction of individuals committing crimes against Bonneville facilities. This program has resulted in the return of BPA property and in court-ordered restitutions paid by convicted parties (BPA, 2014).

#### *3.28.2.2 Terrorism and Sabotage*

Terrorism and sabotage are defined similarly and are both carried out in pursuit of political objectives: terrorism is the use of violence and intimidation, while sabotage is the deliberate damage of equipment or structures. Since September 11$^{th}$, 2001, terrorism has been recognized as one of the biggest problems facing the United States. Terrorism and sabotage are more significant threats than vandalism, theft, or burglary because, while far less common, their effects are greater in magnitude and extent. Terrorism and sabotage have not occurred at USACE-managed facilities within the WRB but have occurred at BPA-managed facilities throughout BPA's service area. These acts have generally targeted electrical transmission structures and facilities. In Bend, Oregon in 1999, a large steel transmission tower was toppled, and in Eugene, Oregon in 2011, over $1 million in damages was incurred after substation equipment was damaged in an attempt to disrupt electrical service. BPA maintains close liaisons with federal law enforcement agencies, the Department of Homeland Security, and local jurisdictions to ensure effective communication of information and intelligence to prevent such acts.

# CHAPTER 4 - CUMULATIVE EFFECTS

Council on Environmental Quality (CEQ) regulations for implementing the National Environmental Policy Act (NEPA) require an assessment of cumulative effects. CEQ defines a cumulative effect as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions" (40 CFR § 1508.7). This chapter describes the methods for identification of cumulative actions and presents the results of the cumulative effects analysis.

Cumulative effects may be additive or interactive. Additive effects are the sum of the effects on a resource; for example, groundwater pumping for agricultural irrigation, domestic consumption, and industrial cooling and process activities all contribute incrementally and additively to groundwater aquifer drawdown. Interactive effects may be either countervailing – where the net adverse cumulative effect is less than the sum of the individual effects – or synergistic – where the net adverse cumulative effect is greater than the sum of the individual effects. An example of a countervailing effect is when particulate matter and aerosol air pollutants, which tend to block or reflect sunlight or incoming solar radiation and thus cool the planet surface, counteract the warming effect of carbon dioxide emitted at the same time. A synergistic effect can be demonstrated by the discharge of nutrients and heated water (from use in cooling at thermal power plants) to a river that combine to cause a harmful algal bloom (HAB) and subsequent loss of dissolved oxygen (DO); the combined effects of the HAB and loss of DO are greater than the individual effects added together.

CEQ recommends that cumulative effects analysis be narrowed as much as possible to focus on important issues at a national, regional, or local level (CEQ 1997). The first step in cumulative impact analysis is to identify past, present, and reasonably foreseeable future cumulative actions. The second step is to analyze how, if at all, the effects of the Proposed Action and alternatives may contribute to the effects of the cumulative actions thereby resulting in cumulative effects.

## 4.1 ANALYSIS APPROACH

Methods for cumulative effects analysis are based on the policy guidance and methodology originally developed by CEQ (1997). This method involves identifying affected resources and the associated direct/indirect effects, establishing the geographic and temporal boundaries of the analysis, identifying applicable cumulative actions, and analyzing the cumulative effects of all actions considered.

The effects of all past actions on resources are summarized below in Section 4.1.2.1. The Affected Environment sections of Chapter 3 describe the ongoing effects to each resource or the effects of present actions to each resource. The Environmental Consequences sections of Chapter 3 present the direct and indirect effects of the Proposed Action and alternatives on each resource. This chapter considers the direct and indirect effects on each resource of the Proposed Action and alternatives together with the past, present, and reasonably foreseeable future actions (RFFAs) of other projects. For example, the existing and projected future climate of the Willamette River Basin (WRB) can be considered an effect of past, present, and future actions, all of which may result in further cumulative effects on certain resources in the analysis area. Note that the direct and indirect effects of climate change on all affected resources are also analyzed and discussed and qualitatively analyzed in Chapter 3.

### 4.1.1 Geographical and Temporal Scope

The geographic boundary for each resource considered in these cumulative effects analysis is referred to as the cumulative effects analysis area (CEAA). The CEAA follows the geographic boundaries of direct and indirect effects for each resource identified in Chapter 3 unless noted otherwise for specific resources.

The temporal boundaries for cumulative effects in this analysis have three components – past, present, and future. Past cumulative effects are generally captured under each resource's Affected Environment section in Chapter 3, given that past actions and their effects have contributed to the current condition of a resource. A brief description of relevant past actions is provided below, and generally include past cumulative effects dating back to approximately the year 1969 – or the year that all 13 WVS dams and reservoirs were completed. Present and reasonably foreseeable future cumulative actions are included in this chapter if they are expected to overlap in space and time with the scope of this PEIS, which unless otherwise noted is approximately the year 2050.

### 4.1.2 Cumulative Actions Scenario

The following sections discuss the past, present, and reasonably foreseeable future actions within the WRB.

#### *4.1.2.1 Past Actions*

According to CEQ, a cumulative effects analysis may assess past actions in the project area by focusing on the "current aggregate effects of past actions without delving into the historical details of individual past actions" (CEQ 2005). While all past actions do not need to be identified for the cumulative effects analysis, this section presents a brief description of the effects from past actions – including WVS dams and reservoirs and development and population growth – to the extent that they are relevant and useful in analyzing cumulative effects. Human actions and development have substantially influenced the CEAA for nearly all of the resources analyzed in this Draft PEIS. The history of the Willamette Valley System (WVS) and its component dams, reservoirs, riverbank protection, fish hatcheries, and other facilities as relevant to the proposed project is discussed in Chapters 1 and 2.

##### *4.1.2.1.1 WVS and Other Dams and Reservoirs in the WRB*

Within the analysis area, aquatic, riparian, and floodplain habitat has changed continuously throughout history through habitat loss, modification, degradation, and restoration, as a result of both natural forces and events and human activities. Central to these changes have been the alteration of the Willamette River Basin's hydrology, or how water movement has changed over time. Before dams existed in the WRB, the Willamette River was a natural, free-flowing riverine system. River flows, naturally augmented by rainfall and snowmelt, tended to be higher in the winter months and lower in the summer months.

As a result of construction of the WVS, scores of miles of free-flowing, riverine habitat in Willamette River tributaries have been converted to 13 dams and reservoirs which moderate overall flows and have changed water currents or flows. WVS operations have led to winter flows that are lower on average than historic flows because WVS reservoirs reduce high flows by capturing runoff and releasing it gradually. Average summer flows are now higher than historical summer flows as a result of intentional releases of stored water from reservoirs.

In addition to the 13 USACE-built and managed dams in the WRB, according to USACE's National Inventory of Dams, there are 247 other dams dispersed throughout the WRB managed by entities other than the USACE (USACE, 2020h). Most of these non-USACE dams are more than 50 years old, and most are small to medium-sized, with relatively few large dams and reservoirs. The majority of dams are below 30 feet in height, and only a relative few have water storage capacity that exceeds 1,000 acre-feet. Most have under 500 ac-ft of storage capacity, and many less than 100 ac-ft. (In contrast, the largest of the WVS reservoirs – Lookout Point – contains more than 400,000 ac-ft of storage.). More than 90 percent of these 247 dams are earth-fill.

Most of the dams are privately owned; some are owned by municipalities, public utilities, and the U.S. Fish and Wildlife Service or U.S. Forest Service. None of the 247 dams have flood control listed as a purpose, in contrast with the WVS dams, all but two of which have flood control as an authorized purpose. Most on the non-USACE dams were built for irrigation, recreation, fish and wildlife, and to a smaller extent, hydroelectricity and M&I water supply. Of the 247 non-USACE dams in the WRB in its entirety, only 38 dams are located in WRB sub-basins containing WVS dams/reservoirs. Along with USACE's dams and reservoirs, these widely dispersed impoundments – and more often located in the headwaters of tributaries rather mainstems of Willamette tributaries – affect the WRB's hydrology and salmon runs by obstructing migration and submerging spawning and rearing habitat. They also support the basin's increasing human population and economic activity by supplying water for both agricultural irrigation and municipal/industrial users, generating electricity, and furnishing water-based recreational opportunities for the basin's residents and visitors.

Implementation of this large suite actions has had cumulative adverse effects to resources within the WRB, including direct mortality to species and habitat loss and degradation. Examples of the various ways that habitat can be lost or degraded include the creation of barriers to fish passage both upstream and downstream; overharvest of aquatic species; introduction of invasive and predatory species; modification of flow and water temperature to suboptimal conditions; and pollution of water.

Relevant past cumulative actions also include the voluntary and federal- and state-mandated actions of private and public parties to provide beneficial and offsetting effects for salmonids, other aquatic species, and other wildlife. These offsetting actions include but are not limited to managing hatcheries and fisheries; water quality; and land, including fish and wildlife habitat. Chapters 1 and 2 of this Draft PEIS describe the ongoing collaborative efforts undertaken over the decades by the U.S. Army Corps of Engineers (USACE), Bonneville Power Administration (BPA), and the Bureau of Reclamation (Reclamation) with partnering federal, tribal, and state agencies and non-governmental organizations (NGOs) to conserve and manage fish and wildlife and mitigate the adverse effects of WVS operations. The 2008 U.S. Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS) Biological Opinions (2008 BiOps) obligate USACE, BPA, and Reclamation to develop and implement procedures and measures to protect Endangered Species Act (ESA)-listed species. These measures must be concurrent with continued operations and maintenance (O&M) of the WVS in accordance with its authorized purposes.

###### *4.1.2.1.2 WRB Population Growth and Development*

In the recent past, the WRB has experienced substantial population growth and development, as shown in Figure 4.1-1. This is especially true in the lower elevations of the WRB closer to the mainstem Willamette River and its major tributaries. Other past cumulative actions related to WRB population growth and development include the following:

- Agricultural, urban, and transportation corridor development, which converts and permanently alters natural habitats;
- Water withdrawals for irrigation, municipal, and industrial uses to support human development in the Willamette Valley;
- Floodplain development;
- Logging and mining within the watershed;
- Dredging and sediment management;
- Commercial and recreational fish harvesting;
- Increase in recreational use and visitation of public lands;
- Proliferation of invasive species (both plants and animals); and
- Point and non-point source water pollution.

This growth and development have had adverse effects to resources within the WRB, including salmonids, other aquatic organisms, and other wildlife and their habitats.

**Figure 4.1-1. Population and Urban Development Increasing Throughout the WRB (Eugene, OR) (Maciek Lulko, licensed under CC BY-NC 2.0)**

According to data from the National Resources Inventory (NRI) of the U.S. Department of Agriculture's (USDA's) Natural Resources Conservation Service (NRCS), in the 35-year span between 1982 and 2017, the area of developed land in the 10 counties comprising almost all of the geographic area of the WRB grew from 519,800 acres (812 square miles) to 747,100 acres (1,167 square miles), an increase of 44 percent as shown in Table 4.1-1 (NRCS 2020). During the same time period, the combined populations of these 10 counties grew by 59 percent (USCB 1992; USCB 2020). Primarily as a result of this population growth and the associated demand for additional developed land, cropland in the 10 WRB counties listed in Table 4.1-2 decreased by 12 percent from 1982 to 2017, from 1,085,200 acres (1,696 square miles) to 955,300 acres (1,493 square miles).

**Table 4.1-1. Increase in Developed Land in WRB Counties, 1982 – 2017**

| County | 1982 Developed Land Area (1,000 acres) | 2017 Developed Land Area (1,000 acres) | Percentage Change 1982 to 2017 |
|---|---|---|---|
| Benton | 24.4 | 30.2 | 24% |
| Clackamas | 70.4 | 114.3 | 62% |
| Douglas | 57.5 | 72.8 | 27% |
| Lane | 110.7 | 141.7 | 28% |
| Linn | 40.2 | 60.5 | 50% |

| County | 1982 Developed Land Area (1,000 acres) | 2017 Developed Land Area (1,000 acres) | Percentage Change 1982 to 2017 |
|---|---|---|---|

#### *4.1.2.2 Ongoing and Present Actions*

As discussed in Chapter 1, Section 1.8.10, in September 2021, the U.S. District Court for the District of Oregon issued an interim injunction concerning USACE's management and operation of the WVS and effects on ESA-listed salmonids. The U.S. District Court for the District of Oregon ordered USACE to implement interim actions intended to improve conditions for fish passage and water quality in the WVS to avoid irreparable harm to ESA-listed salmonids until the completion of the reinitiated Section 7 ESA consultation with NMFS and USFWS.

These interim actions include 16 Near-Term Operations Measures that require changes to how one or more of the WVS dams are currently operated and three projects that modify existing WVS structures. The 16 Near-Term Operations Measures are included in each of the action alternatives described in Chapter 2, and their direct and indirect environmental effects are assessed in Chapter 3.

The three projects that modify existing WVS structures include:

- **Dexter** – Design and construct upgrades to the existing Dexter adult fish facility (AFF).
- **Big Cliff** – Determine whether operational measures alone are sufficient to maintain acceptable TDG levels below Big Cliff Dam and, if not, design and construct a structural solution for mitigating excess TDG levels during spill operations.
- **Cougar** – Determine whether structural improvements/modifications need to be made to Cougar Dam's ROs to ensure safer fish passage and reduce TDG levels and, if so, design and construct a structural solution.

The District Court ordered that the design, construction, and operation of these three structural improvement projects be expedited. Therefore, these three structural Court-ordered projects have or are currently undergoing separate NEPA processes that will assess their direct, indirect, and cumulative impacts on the human environment. Since the direct and indirect of these projects is being fully assessed by their individual NEPA documents, they are not included in Chapter 3 of this PEIS. However, this chapter includes the construction, operations, and maintenance of these reasonably foreseeable projects in the cumulative effects analysis.

As part of its comprehensive dam safety program, USACE is continuously assessing its dams to better understand dam safety risks and inform future actions. The USACE Dam Safety Program periodically assesses and reassesses risks to all our dams on a 5-year cycle. When risks are identified there is a proscribed process for elevating them for more detailed analysis and design to ensure they are adequately addressed. The assessment process identifies and analyzes many risks using the latest science and engineering methods and standards. This process is described in more detail in Appendix H. Many of the risks analyzed end up being either not consequential or probable enough to merit further action.

However, in 2020, after completing a detailed analysis of the seismic risk at Detroit and Lookout Point Dams, it was concluded that immediate action to mitigate the risk at these dams was necessary. Per Engineering Regulation, ER 1110-2-1156 (USACE Publications), "USACE has specific public safety responsibility, when a project has known safety issues, to take appropriate interim risk reduction measures including reservoir releases. USACE statutory responsibilities require operation of dams in a manner that reduces the project's probabilities of failure when there are known issues with the integrity of the project." This determination resulted in the development of Interim Risk Reduction Measures (IRRM) to address these risks until a permanent solution could be assessed and designed. IRRMs at these dams required pool restriction on the maximum pool elevation. In other words, the maximum elevation the associated reservoirs are allowed to reach each summer is lower than the authorized maximum.

The effects of these IRRMs were assessed in Environmental Assessments and are incorporated by reference. However, the measures proposed under the action alternatives do not require these reservoirs to reach the authorized maximum conservation pool elevation and, in fact, generally further restrict maximum elevations below the IRRM restrictions. Therefore, the measure in the action alternatives make it more likely that operations will meet the IRRM requirements. For this reason, the effects of the IRRMs and the measures in the action alternatives are not additive and will not be assessed further in the cumulative effects analysis.

In addition to USACE's ongoing management and operation of the WVS, present actions have already been incorporated into the affected environment for each resource analyzed in this Draft PEIS. Non-USACE actions include the operation of hydroelectric dams; recreation; timber and logging industry operations; mining operations; ongoing non-point source pollution; and management, conservation, and protection of the environment by federal and state agencies.

The alternatives analysis of this Draft PEIS assumes that existing laws, policies, agency jurisdictions, rulings, BiOps, and other elements of the regulatory environment will remain in place for their stated duration.

Likewise, while the adequacy and status of existing regional coordination, alignment, and planning actions will not be assessed in this PEIS, they nonetheless merit mention for context. For example, efforts are underway to create more integrated and regional approaches to salmon and steelhead challenges that require collaboration across federal, state and tribal government jurisdictions (e.g., Columbia Basin Partnership Taskforce, Willamette Fish Passage Operations & Maintenance coordination team, Flow Management and Water Quality Team). Anticipated future effects of these activities are included in this chapter where applicable and cumulative effects are analyzed for reasonably foreseeable future actions (RFFAs).

#### *4.1.2.3 Reasonably Foreseeable Future Actions*

RFFAs are anticipated future environmental trends or specific proposed activities that could cause similar effects in the same space and time as the no action alternative and action alternatives, but that are proposed by or involve outside entities such as other federal, state, or local agencies, or private sector interests. RFFAs can also be trends or actions that are not yet implemented. In order to be deemed reasonably foreseeable, RFFAs must typically be budgeted for and included under formal proposals or decisions (such as an official agency decision document or a county land use plan).

The RFFAs for the WVS and WRB have been grouped into eleven categories as shown in Table 4.1-3 below and are numbered for reference throughout this chapter. These cumulative actions and trends are focused on the management of fish and wildlife (primarily fish); environmental management and implementation of current and new laws, and policies; water quality and quantity management; industrial and agricultural development; regional population growth; energy development; climate change; and resource extraction.

**Table 4.1-3. Reasonably Foreseeable Future Actions Affecting the WVS and WRB**

| RFFA Number | RFFA Description |
|---|---|
| RFFA 1 | Future population growth and accompanying urban, industrial, and commercial development |
| RFFA 2 | Reduced agricultural production |
| RFFA 3 | Water withdrawals for municipal, industrial, and agricultural uses |
| RFFA 4 | Decarbonizing the energy sector with renewable energy sources |
| RFFA 5 | Federal and state wildlife and lands management |
| RFFA 6 | Fishery management and killer whales |
| RFFA 7 | Tribal, state, and local fish and wildlife improvement |
| RFFA 8 | Invasive species management |
| RFFA 9 | Climate change |
| RFFA 10 | Mining operations |
| RFFA 11 | Timber and logging industry operations |

#### *4.1.2.3.1 RFFA 1 – Future Population Growth and Accompanying Urban, Industrial, and Commercial Development*

Within the counties that compose the WRB, human populations are continuing to increase. This growth is occurring primarily in urban metropolitan areas with smaller increases in rural areas. The State of Oregon Office of Economic Analysis, responsible for making official demographic projections for Oregon, anticipates this increase to continue at least through 2050 (State of Oregon 2013). Population projections from 2020 to 2050 are shown in Table 4.1-4 for the 10 counties that compose almost the entire WRB.

**Table 4.1-4. Population Projections for WRB Counties, 2020 – 2050**

| County | 2020 Population Estimate | 2050 Population Estimate | Percentage Increase 2020 to 2050 |
|---|---|---|---|
| Benton | 91,379 | 111,666 | 22% |
| Clackamas | 422,576 | 583,814 | 38% |
| Douglas | 116,113 | 139,675 | 20% |
| Lane | 378,335 | 464,839 | 23% |
| Linn | 128,454 | 168,189 | 31% |
| Marion | 331,643 | 498,624 | 50% |
| Multnomah | 807,198 | 982,504 | 22% |
| Polk | 88,081 | 135,877 | 54% |
| Washington | 570,672 | 915,979 | 61% |
| Yamhill | 113,611 | 167,300 | 47% |

| County | 2020 Population Estimate | 2050 Population Estimate | Percentage Increase 2020 to 2050 |
|---|---|---|---|
| **Total** | **3,048,061** | **4,168,466** | **37%** |

Source: State of Oregon 2013

Projected population increases for these WRB counties range from 20 percent to 61 percent and average 37 percent. If the relationship between the increase in population and the increase in developed land continues into the future, and mirrors the trend that existed from 1982 to 2017, developed land area of the WRB from 2020 to 2050 would be estimated to increase by 28 percent, or approximately 206,150 acres (322 square miles).

A larger population in the WRB would cause a number of cascading effects throughout the basin. Municipal water demands may increase, which may be met by increased withdrawals from the WVS. Increased urban development would decrease upland habitat and increase impervious surface in the area, changing the physical, chemical, hydrological, and ecological characteristics of stream ecosystems. In most cases, such changes are detrimental to native fish and wildlife. The rate of exurban (area just beyond denser suburbs) development also appears to be increasing. Exurban development is generally associated with direct habitat conversion and loss for fish and wildlife species. Human population growth and development often leads to increased discharges of non-point source pollutants in stormwater runoff from residential, commercial, industrial, agricultural, recreational, and transportation land uses.

A variety of population-driven factors external to the WRB can also cause effects within the basin. Growing international trade through shipping has led to modifications to the lower Columbia and Willamette rivers through dredging, port development, and increasing boat traffic. Projects to deepen channels or modify ports in Portland, OR may necessitate increasing numbers of ships and cargo tonnage on the lower Willamette and increasing rail freight and truck traffic on transportation corridors in the WRB that are linked to that port. Increased volumes of materials such as hazardous products and fuels that power trains, vessels, and trucks will likely move through the WRB in response to the demands of a growing population. With increased movement of raw materials and manufactured goods via all three modes, more accidents and spills would be likely. Mining, logging, trade, and transportation projects also influence the hydrology, water quality, and land use in the WRB and WVS. Overall, this RFFA interacts cumulatively with all of the resources listed in Table 4.1-6**.**

##### *4.1.2.3.4 RFFA 2 – Reduced Agricultural Production*

Human population growth and related development have contributed to the decline of agricultural lands within the WRB. The NRCS identifies and inventories three categories of farmland or agricultural land: cropland, pastureland, and rangeland. Cropland includes cultivated row crops and orchards. Range and pasture lands are where the primary vegetation is herbaceous plants and shrubs, which provide forage for domestic livestock. As shown in Table 4.1-2, cropland in the 10 counties that compose most of the geographic area of the WRB declined by 12 percent from 1982 to 2017. Farmland seen in Figure 4.1-2 was converted to developed land to accommodate population growth.

Given the population projections shown in Table 4.1-4 that show strong growth for each of the 10 counties, land conversion and development pressures are likely to continue and the area of cropland within the WRB will likely continue to diminish. Reduced cropland acreage may reduce demands for agricultural irrigation water withdrawn from the WRB. Less cropland could also result in less soil erosion from wind and rain. Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.1-6, including but not limited to land use, soils, wetlands, listed species and critical habitat, socioeconomics, water supply, and visual resources.

**Figure 4.1-2. Willamette Valley Cropland (jim.choate59 licensed under CC BY-NC-ND 2.0)**

#### *4.1.2.3.3 RFFA 3 – Water Withdrawals for Municipal, Industrial, and Agricultural Uses*

Water usage within the WRB is likely to increase in the future, especially as human population growth, associated development, and climate change continue to affect water availability and scarcity in the region. The Willamette Water 2100 project identifies and quantifies linkages and feedbacks among human, hydrological, and ecological dimensions within the WRB, and makes predictions about where and when human activities and climate change would impact future water scarcities. Figure 4.1-3 illustrates their model's prediction on basin-wide water allocation regarding irrigation, municipal, and residential usage from 2010 to 2100. It suggests that water demand for irrigation usage (as seen in green) would remain relatively stable over the course of the 21st century; whereas water demand for municipal and residential usage (as seen in blue) would increase, likely linked to factors such as increasing human population projections and the evolving effects of climate change (WW2100 No Date).

By reducing the amount of water flowing through the WVS, increased withdrawals have implications for instream flow and for maintenance of riparian and aquatic habitats for fish and wildlife. New water withdrawals are typically subject to regulatory restrictions which might partially offset their negative effects. In the model's scenario, urban areas in general would be able to meet water needs with existing water rights, which would also include maintaining important water sources from outside the basin, such as the Bull Run watershed that supplies the City of Portland (WW2100 No Date). Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.1-6, including but not limited to water supply, socioeconomics, listed species and critical habitat, water quality, and hydrological processes.

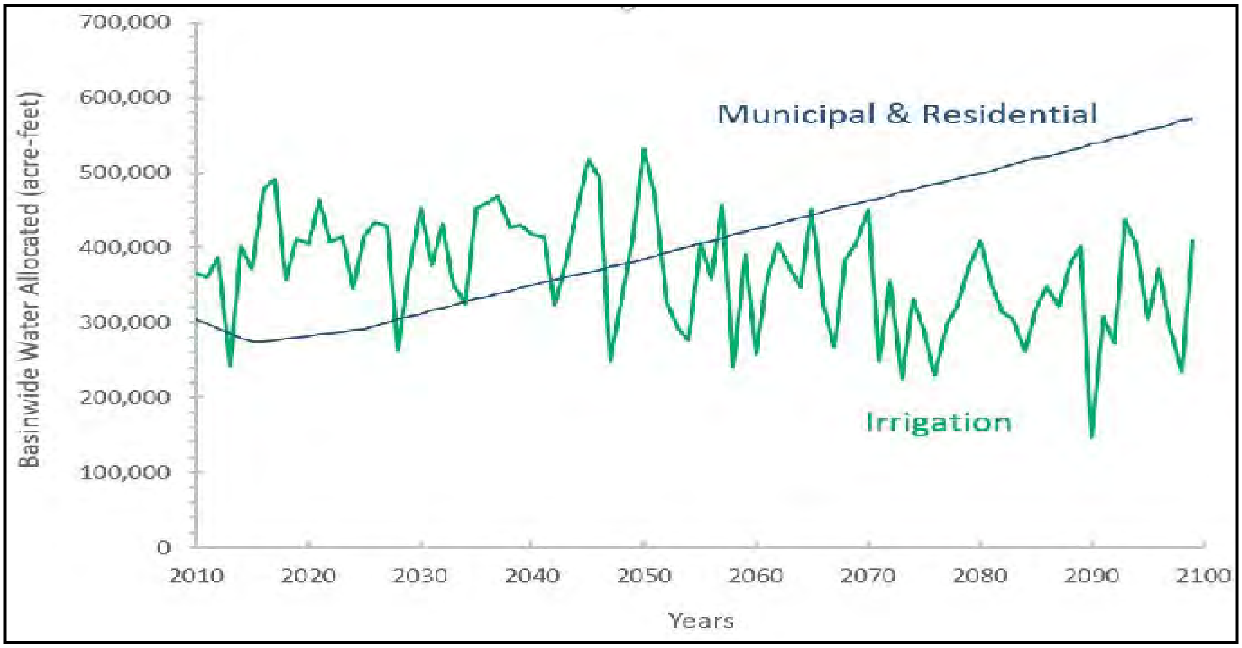

**Figure 4.1-3. WRB Water Usage Projections, 2010 – 2100 (WW2100 No Date)**

#### *4.1.2.3.4 RFFA 4 – Decarbonizing the Energy Sector with Renewable Energy Sources*

Decarbonization of the energy sector is a national trend that continues to surge in Oregon. Oregon's Renewable Portfolio Standard sets the requirement for how much of the state's electricity must come from renewable sources. In March 2016, this standard was set to require 50 percent of Oregon's electricity to come from renewables by 2040 (ODOE No Date-b). Hydropower facilities typically provide more than half of the electricity generated in Oregon; natural gas fuels the second-largest share of Oregon's electricity generation, while non-hydroelectric renewable resources, including wind, biomass, solar, and geothermal power, provide almost the rest of Oregon's generation. Coal no longer supplies any in-state generation because Oregon's only coal-fired power plant in Morrow County closed in October 2020. There are also no commercial nuclear power plants in the state (EIA 2021). Therefore, natural gas contends as the main energy generator of GHG emissions; however, no new natural gas plants have been proposed within the counties of the WRB. The Troutdale Reynolds Industrial Park in Multnomah County was terminated in 2016 when the developer withdrew the application for site certification (ODOE No Date-a). Oregon has only minor fossil energy reserves (EIA 2021), which would likely reduce the propensity for the fuel source into the future.

Renewable energy infrastructure and projects such as wind turbines and solar arrays are expanding in Oregon as throughout the nation. In the WRB and the rest of Oregon, there are federal and state wind energy incentives, including state tax credits and large cash rebates, for installing wind turbines and generators (Dasolar.com 2021; Energy Trust 2014; ODOE No Date-c). Electricity generated by renewable sources at locations outside the WRB could also potentially help meet some of the region's growing energy needs (Musial et al. 2019). However, other land use planning and regulation make it difficult to site utility-scale solar projects in the densely populated Willamette Valley, despite the fact that the high-population-growth WRB has the greatest and fastest growing electricity demand in the state (Poehler 2020). These rules do not interfere with the installation of rooftop solar arrays on existing buildings, however, which do not take up additional space in areas with competing land uses. While there are multiple renewable energy projects proposed throughout Oregon, there are currently no proposed renewable energy projects within the counties representing the WRB (ODOE No Date-a). Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.1-6, including but not limited to soils, vegetation, socioeconomics, power and transmission, land use, cultural resources, and visual resources.

#### *4.1.2.3.5 RFFA 5 – Federal and State Wildlife and Lands Management*

Public lands in Oregon continue to be managed in a way that balances economic interest with the need for wildlife conservation and land preservation. Oregon's Department of Land Conservation and Development (ODLCD) guide these decisions using the Oregon Statewide Planning Goals and Guidelines, which was recently amended in July 2019. This most recent revision includes goals to preserve forest lands, agricultural lands, scenic and historic areas; maintain air, water, and land resource quality; project urban growth boundaries for future urbanization growth; create a 300-mile Willamette Greenway that protects the Willamette River; and classify Oregon's 22 major estuaries based on their biological, economic, recreational, and aesthetic benefits to better inform future developments or alterations. Local city and county land use plans must be consistent with the statewide planning goals, thereby becoming the controlling document for land use in the area covered by that plan (ODLCD 2019).

The WRB contains abundant public lands, especially in the headwaters and higher elevations. These lands would continue to be managed for multiple purposes, such as watershed protection, wildlife and habitat conservation, recreation, livestock grazing, resource extraction (e.g., logging, mining), and other public uses. The 1.7-million-acre Willamette National Forest as shown in Figure 4.1-4 contains eight Congressionally-designated national wilderness areas and stretches for 110 miles along the eastern edge of the WRB and western slopes of the Cascade Range. The forest extends from the upper reaches of the Santiam River in the north and past the McKenzie River, to the Middle and North Forks of the Willamette and the 8,743-ft. Diamond Peak in the south. Among other functions, its wooded slopes provide the cities of Salem, Eugene, and Springfield, and other communities in the WRB with clear, clean water by serving as a sponge and protecting soils from erosion (USFS No Date-b). Mt. Hood National Forest extends from the northern boundary of the Willamette National Forest northward towards the City of Portland and the Columbia River. It contains more than a million acres of forested mountains, lakes, and streams (USFS No Date-a).

**Figure 4.1-4. Willamette National Forest**

The Oregon Department of Fish and Wildlife (ODFW) and the U.S. Fish and Wildlife Service (USFWS) would continue to implement management activities at the Willamette Valley National Wildlife Refuge Complex. The three refugees that make up the complex include William L. Finley National Wildlife Refuge, Ankeny National Wildlife Refuge, and Baskett Slough National Wildlife Refuge, located in Benton, Marion, and Polk counties, respectively. The three refuges in the complex provide protection for historically abundant oak savanna, native prairie, riparian forest, and wetland habitats. These protected areas allow endangered plant populations to grow, summer songbirds to nest, and wintering waterfowl to find sanctuary in the vast wetlands. Refuges are grouped and managed as a "complex" because they occur in a similar ecological region, such as a watershed or specific habitat type (USFWS 2014). In addition to conserving and managing wildlife habitats and populations, national wildlife refuges foster six priority public uses, namely hunting, fishing, wildlife observation, wildlife photography, environmental education, and interpretation.

The way that these lands are managed within the WRB can have cumulative effects when added to the actions proposed in this Draft PEIS. In particular, water management, soil management, vegetation management, and fire management can have important additive effects that could be either beneficial or adverse depending on the nature of the management action.

Section 3.9 of this EIS refers to a number of species currently listed as threatened or endangered under the federal Endangered Species Act, some of whom for which critical habitat has been designated. Also mentioned are certain candidate species, species petitioned for listing, and species of concern. In the future, if any of these other species are formally listed under the ESA and afforded additional protections (such as critical habitat designation), this could potentially constrain certain proposed operational or structural measures at specific projects in the WVS.

Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.1-6, including but not limited to land use, water and air quality, socioeconomics, flood risk management, water supply, recreation, listed species and critical habitat, hazardous algal blooms, tribal and cultural resources, and environmental justice.

##### *4.1.2.3.6 RFFA 6 – Fishery Management and Killer Whales*

The management of killer whales and the fisheries they depend on are expected to continue into the future based on the efforts taken by the Pacific Fishery Management Council (PFMC) and other stakeholders concerned about their survival. PFMC, one of eight regional fishery management councils established by Congress in 1976, manages ocean populations of Upper Willamette River (UWR) Chinook salmon, which are the focus of multi-agency endangered species preservation efforts in the WVS. The PFMC prepares fisheries harvest plans known as Pacific Salmon Fishery Management Plans for Chinook (including UWR Chinook), coho, and pink salmon; these plans are implemented and enforced by NMFS in federal offshore waters (i.e., 3 to 200 miles offshore). NMFS promulgates regulations for how many salmon can be caught offshore based on PFMC plans. Overall, the PFMC and NMFS are studying ways to better manage the catch of salmon in offshore ocean waters.

PFMC established the Southern Resident Killer Whale (SRKW) Workgroup to reassess the effects of federal ocean salmon fisheries on southern resident killer whales as seen in Figure 4.1-5. The goal of the workgroup was to potentially recommend conservation measures or management protocols that limit the effects on Chinook salmon, including UWR Chinook, in federal waters, and thereby indirectly help ensure the survival of the highly endangered SRKW. The southern resident killer whales compose the smallest of the three “resident” populations of killer whales in the eastern North Pacific Ocean. As of September 2020, they numbered just 74 individuals in three pods, down from 96-98 individuals in the mid-1990s. Southern resident killer whales are found mostly off British Columbia, Washington and Oregon, but also travel to forage widely along the outer coast. Southern residents specialize in preying on Chinook salmon. They feed on Chinook year-round, and this species is their main prey in the spring and summer when they occupy inland waters (MMC 2021).

**Figure 4.1-5. Pod of Killer Whales (*Orcinus orca*)**

The SRKW Workgroup is composed of representatives from West Coast tribes; the states of California, Idaho, Oregon, and Washington; PFMC; and NMFS. In November 2020, the workgroup provided recommendations for ocean salmon fisheries management via a final report to PFMC members (PFMC 2020). Under the plan adopted by PFMC, the management threshold was set as the arithmetic mean of the seven lowest years of pre-fishing Chinook salmon abundance in the area north of Cape Falcon, Oregon (1994-1996, 1998-2000, and 2007, currently estimated at 966,000). When any given year's preseason Chinook abundance projection falls below the established threshold of 966,000, a number of management actions (time and area fishery closures) are implemented through annual regulations. These management efforts interact cumulatively with the number of UWR Chinook salmon able to return each year to spawn in Willamette River tributaries via the Columbia River and the mainstem Willamette.

In other words, ocean fisheries have an effect (a reduction) on adult salmon returns via removal of fish by harvest. However, in the case of UWR Chinook in PFMC fisheries, only minimally so given an average exploitation rate in PFMC fisheries of less than 0.5%. Actions in the PFMC ocean fishery management areas have very low effects on the return abundance of UWR Chinook. Therefore, the magnitude of effect on SRKW of ocean fishery actions on UWR Chinook is also very small. However, UWR Chinook are important to SRKW due to the timing of their return to the mouth of the Columbia and energetic need for SRKW in that time period. In contrast to PFMC fisheries management actions, measures that improve production of the salmon stock in freshwater areas can have a potentially large effect on the strength of the return, and thereby would be expected to accrue larger benefits to SRKW in comparison. Furthermore, in the absence of significant improvements in smolt-to-adult ratios of natural-origin fish, any reductions in Willamette Valley hatchery production would directly reduce key food resources available to the SRKW.

Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.1-6, including socioeconomics, recreation, tribal resources, listed species and critical habitat, wetlands, and water quality.

#### *4.1.2.3.7 RFFA 7 – Tribal, State, and Local Fish and Wildlife Improvement*

State and local agencies, tribes, environmental organizations, and private communities are expected to continue non-federal habitat activities and projects focused on improving general habitat and ecosystem function or species-specific conservation objectives. ODFW created their Strategic Plan in February 2018 to establish their long-term goals of managing and protecting the state's fish and wildlife resources, both game and nongame. One of their main goals is to expand stewardship and support of Oregon's fish, wildlife, and their habitats. To accomplish this, ODFW plans to continue effective stewardship of Oregon's fish, wildlife, and their habitats through sound science and by addressing constituents' needs, providing leadership on five focal fish and wildlife issues with progress reports and solutions by 2022, aligning budgets with ODFW conservation and management priorities, and expanding ODFW overall funding efforts (ODFW 2018).

The Confederated Tribes of Grand Ronde Community of Oregon collaborates with USACE to improve fish habitat and populations in Reservation streams, in part for subsistence fishing purposes. Members of the Confederated Tribes of Warm Springs harvest Pacific lamprey at Willamette Falls and work with USACE to ensure that cumulative effects from other ongoing projects or mitigation efforts in the WRB are taken into account. Members also coordinate with USACE to consider potential effects of the WVS on water quality, climate change, streamflow for fish and wildlife, and tribal cultural resources, in particular on Pacific salmon and lamprey.

The Nature Conservancy (TNC) carries out a number of projects in the WRB oriented toward protecting imperiled species, management of habitats and ecosystems, and adapting to climate change. One of their most recent projects was the restoration of the Willamette River at the confluence of the middle fork of the Willamette River and the coastal fork, east of Eugene. TNC removed a series of gravel pits and barriers acting as levees and allowed the river to return to its natural, free-flowing state, which provided crucial resting spots for salmon, wetland habitat for wildlife, and fertile floodplains for trees, shrubs, and other plants. The McKenzie River Trust owns and manages the property, and continues to collaborate with TNC on preservation projects and ecotourism programs (TNC 2021). Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.1-6, including but not limited to water and air quality, socioeconomics, recreation, land use, visual resources, tribal and cultural resources, hydrologic processes, and environmental justice.

#### *4.1.2.3.8 RFFA 8 – Invasive Species Management*

Non-native and invasive plants and animals are damaging biological diversity and ecosystem integrity across the WRB. Aquatic species such as water primrose and yellow floating heart are of particular concern because they can spread rapidly and can quickly alter the function of an ecosystem. Within the Willamette Valley National Wildlife Refuge Complex, several invasive species pose a serious threat to native species through competition and predation. Reed canarygrass out-compete native wetland emergent plants; Himalayan blackberry thickets alter upland prairies and woodlands, nutria degrade aquatic habitats and displace native species; and bullfrogs, bass, and bluegill fish disrupt aquatic ecosystems by preying on native fish, amphibians, and reptiles (USFWS No Date).

Throughout the WRB, USACE, BPA, and Reclamation, the cooperating agencies listed in Chapter 1, and other federal land managers such as the USFWS and USFS cooperate on weed management, invasive species prevention and eradication, and vegetation treatments. To the extent that these efforts are successful, they improve habitats for and the survival of native plants and animals. Several other planning efforts and regulations are underway to provide a comprehensive framework for addressing invasive species in Oregon (Oregon Conservation Strategy No Date). These include:

- Oregon Statewide Strategic Plan for Invasive Species, 2017 – 2027
- ODFW Wildlife Integrity Administrative Rules
- ODFW Aquatic Invasive Species Prevention Plan
- Oregon Department of Agriculture Noxious Weed Strategic Plan
- Oregon Aquatic Nuisance Species Management Plan
- Ballast Water Management Administrative Rules

In general, USACE anticipates that invasive species management will increase in the future in the WRB generally and WVS specifically as changes in climatic conditions may favor invasive species (both native and non-native) that are early colonizers after disturbance, more resistant to climate perturbations, or favored by emerging climate regimes (such as those flora and fauna migrating northward).

Overall, this RFFA interacts cumulatively with some of the resources listed in Table 4.1-6, including but not limited to water quality, wetlands, listed species, recreation, land use, hazardous algal blooms, and drinking water.

##### *4.1.2.3.9 RFFA 9 – Climate Change*

Climate change continues to be an evolving, complex phenomena that is causing multiple, and at times intersecting, environmental effects that are occurring within the WRB, the state of Oregon, and the planet as a whole. Appendix F2, Supplemental Climate Change Information, provides a relatively detailed assessment of the potential effects of climate change on the WRB and WVS using the most recent available science and modeling. This appendix includes the results of a 4-year research project completed by the University of Washington and Oregon State University, with resource support and technical expertise provided by the River Management Joint Operating Committee (RMJOC) agencies (USACE, BPA, and Reclamation). The RMJOC-II report (2018) found the following for the 2020 to 2049 time period:

- Temperatures in the region have already warmed about 1.5 degrees Fahrenheit (°F) since the 1970s. Temperatures are expected to warm another 1 to 4°F by the 2030s.
- Future precipitation trends are more uncertain, but higher precipitation is likely for the rest of the 21st century, particularly in the winter months. Already-dry summers could become drier.
- The incidence of large forest fires as seen in Figure 4.1-6 has increased since the early 1980s and is projected to continue increasing through the 21$^{st}$ century as air surface temperatures continue to rise. Wildfire alters the land surface and can have strong influences on runoff, vegetation dynamics, erosion and sediment transport, and ecosystem processes. Strong seasonality and dependence on spring snowmelt positions the WRB to be at risk for increased fires due to the effects of climate change.
- Average winter snowpacks in the mountains surrounding the Willamette Valley are very likely to decline over time as more winter precipitation falls as rain instead of snow.
- By the 2030s, higher average fall and winter flows on WRB streams and rivers, earlier peak spring runoff, and longer periods of low summer flows are very likely.
- Overall, this RFFA interacts cumulatively with all of the resources listed in Table 4.1-6.

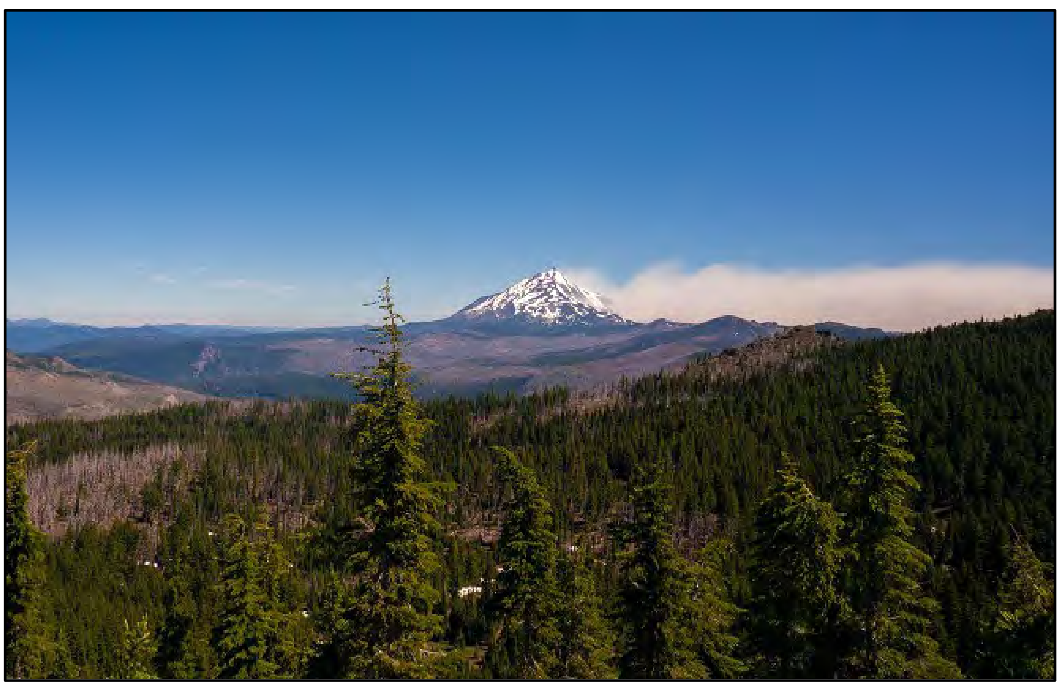

**Figure 4.1-6. Wildfires on the slopes of Mt. Jefferson in the Oregon Cascades (Travis Simpson from Pixabay)**

#### *4.1.2.3.10 RFFA 10 – Mining Operations*

Mining operations within the WRB continue to be of growing interest due to the area's diverse mineral resources and the large number of identified mines and active mining claims. The Oregon-Washington Bureau of Land Management (BLM) is responsible for a wide variety of activities within the minerals program, including decision-making regarding mining claims and providing guidance for surface use management and use and occupancy under the mining laws (BLM No Date-a). As of 2021, the WRB has a total of 462 identified mines, most of which are located within Lane, Douglas, Linn, and Clackamas counties as seen in Table 4.1-5. A majority of these mines are for minerals including but not limited to gold, silver, copper, zinc, lead, mercury, antimony, barium-barite, silica, manganese, clary, and construction sand and gravel. Of those mines, 171 (37 percent) are in production, and another 199 (43 percent) are prospect mines, meaning there has been some degree of development such as surface trenching, shafts, drill holes, or geophysical, geochemical, or geological surveys to estimate grade and tonnage (The Diggings 2022). These are likely indications of future mining activities in these counties.

Furthermore, the WRB has 691 active mining claims (The Diggings 2022), which are parcels of land that the claimant has asserted a right of possession, and the right to develop and extract a discovered, valuable, mineral deposit. The overwhelming majority of these sites are located in Douglas and Lane counties. Claimants are required to maintain their sites by paying an annual maintenance fee every year to continue to hold their mining claims, or they must perform assessment work such as drilling, excavations, driving shafts and tunnels, or geophysical, geochemical, or geological surveys (BLM No Date-b). While there is no guarantee the active claims will transition into production mines, these ongoing maintenance requirements do indicate the probability that these sites could transition to production mines in the future. Overall, this RFFA interacts cumulatively with some of the resources listed in Table 4.1-6, including but not limited to land use, hazardous materials, visual resources, noise, water and air quality, and socioeconomics.

**Table 4.1-5. Mining Sites in WRB Counties, 2021**

| County | Identified Mines | Production Mines | Prospect Mines | Active Claims |
|---|---|---|---|---|
| Benton | 1 | 0 | 0 | 0 |
| Clackamas | 52 | 22 | 21 | 3 |
| Douglas | 111 | 53 | 39 | 351 |
| Lane | 170 | 58 | 90 | 233 |
| Linn | 88 | 37 | 35 | 53 |
| Marion | 15 | 0 | 7 | 49 |
| Multnomah | 13 | 1 | 4 | 0 |
| Polk | 5 | 0 | 0 | 0 |
| Washington | 3 | 0 | 0 | 0 |
| Yamhill | 4 | 0 | 3 | 2 |

| County | Identified Mines | Production Mines | Prospect Mines | Active Claims |
|---|---|---|---|---|
| **Total** | 462 | 171 | 199 | 691 |

*4.1.2.3.11 RFFA 11 – Timber and Logging Industry Operations*

While Oregon is in one of the world's great tree-growing regions (the Pacific Northwest), trends indicate that growth has slowed recently in the timber and logging industry state wide, especially in the WRB. Oregon's soils and climate provide ideal conditions for growing commercially viable trees – which can be made into products such as paper, lumber, particle board, firewood, and oak barrels – and forests cover more than 30 million of Oregon's 62 million acres – almost half the state's landmass. However, timber harvests have fluctuated from 1990s to 2020 and decreased overall. From 1990 to 2020, annual timber harvests declined from 6.2 billion board feet to 3.6 billion board feet. Jobs from 1990 to 2019 declined by almost 41 percent from 15,774 statewide to 9,353. Projections for the Oregon logging industry predict a relatively stable but gradual decline of the industry, losing about 100 jobs, or two percent, between 2020 and 2030 (Rooney 2021).

Western Oregon is classified as one of the top timber regions of the country. Of Western Oregon's 19.2 million acres, 15.3 million acres are forested, or 80 percent. Forests in this region have about 78 billion cubic feet of standing timber. About 71 percent of this volume is in federal ownership, all of which is not available for production due to the expansion of riparian and wildlife preserves and forest conservation efforts. The other 29 percent is in nonfederal ownership, such as private industry (Campbell, Azuma, and Weyermann 2002).

The ecological units in Western Oregon include the Willamette Valley, the Oregon Coast Range, the Western Cascades, and the Klamath Mountains. The Willamette Valley would not likely be the focus of timber and logging operations into the foreseeable future. It has the lowest percentage of forest lands (35 percent) among other ecological units and also has the highest number and concentration of people (Campbell, Azuma, and Weyermann 2002). Although the WRB is not expected to be a major focus for the timber and logging industry in the future, it is included as an RFFA because of cumulative interactions with some of the resources listed in Table 4.1-6, including land use, vegetation, listed species and critical habitat, soils, visual resources, noise, and socioeconomics.

#### *4.1.2.4 RFFA Interaction with Resources*

Table 4.1-6 lists the 11 RFFAs and indicates each resource topic with which there would be a potential cumulative effect interaction.

**Table 4.1-6. Reasonably Foreseeable Future Actions and Potentially Affected Resources Matrix**

| Resource Topic | RFFA 1 | RFFA 2 | RFFA 3 | RFFA 4 | RFFA 5 | RFFA 6 | RFFA 7 | RFFA 8 | RFFA 9 | RFFA 10 | RFFA 11 |

Note: RFFA 1 = Future population growth and accompanying urban, industrial, and commercial development
RFFA 2 = Reduced agricultural production
RFFA 3 = Water withdrawals for municipal, industrial, and agricultural uses
RFFA 4 = Decarbonizing the energy sector with renewable energy sources
RFFA 5 = Federal and state wildlife and lands management
RFFA 6 = Fishery management and killer whales
RFFA 7 = Tribal, state, and local fish and wildlife improvement
RFFA 8 = Invasive species management
RFFA 9 = Climate change
RFFA 10 = Mining operations
RFFA 11 = Timber and logging industry operations

## 4.2 HYDROLOGIC PROCESSES

### 4.2.1 Cumulative Effects Analysis Methodology for Hydrologic Processes

The cumulative effects on hydrologic processes are analyzed qualitatively across the WVS and within each alternative with respect to its differences from the NAA. This section considers how the cumulative actions discussed below would alter the hydrologic processes results and analysis in Chapter 3. The period of analysis is the same as this PEIS (to the 2050s).

#### *4.2.1.1 Cumulative Actions Applicable to Hydrologic Processes*

Past actions, present actions, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on hydrologic processes, include:

- WVS and other Dams and Reservoirs in the WRB: construction and past operations and maintenance
- WRB Population Growth and Development: altered land use within to the Willamette River
- WVS Dams and Reservoirs: ongoing operations and maintenance
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 5: Federal and state wildlife and lands management
- RFFA 7: Tribal, state, and local fish and wildlife improvement
- RFFA 9: Climate change

Some of the other RFFAs discussed in Section 4.1.2.3 would not interact with the hydrology of the Willamette Basin or only negligibly alter the WVS dam and reservoir operations and as such would not have a cumulative effect on Hydrologic Processes.

- RFFA 2: Reduced agricultural production. While decreased projected cropland may marginally affect Willamette Basin hydrology, the main driver of this interaction is more properly placed in RFFA 1.
- RFFA 4: Decarbonizing the energy sector with renewable energy sources. There is minimal variation in total flow due to outlet choice, such as whether to run the WVS dam’s hydroelectric turbines.
- RFFA 6: Fishery management and killer whales. The flow targets in the WVS are specific to the river reaches and habitat where they occur. They are not variable based on Pacific Ocean salmon returns.
- RFFA 8: Invasive species management. Does not affect flow or regulation decisions for the WVS dams.

- RFFA 10: Mining operations. Negligible cumulative changes to total flow in the Willamette Basin from the status quo.
- RFFA 11: Timber and logging industry operations. Negligible cumulative changes to total flow in the Willamette Basin from the status quo.

Therefore, these RFFAs are dismissed from further analysis.

#### *4.2.1.2 Cumulative Effects to Hydrologic Processes by Alternative*

The existing regulated hydrology is changed from the natural condition by the construction and operation of the WVS and other dams and reservoirs. The imposition of regulated hydrology moderated the natural hydrology in the Willamette Basin. Regulated peak flows are lower in the winter due to flood risk management operations. Flows are also lower during spring while the reservoirs store water, and higher during the summer and fall when they release that stored water. The volume and height of each reservoir and dam or system or dams and reservoirs generally determines its potential cumulative effect on the hydrology of the WRB.

Past WRB population growth and development has altered land use in the WVS watershed and next to the rivers that the WVS dams and reservoirs regulate. This development has affected the construction and operation of the WVS dams and reservoirs, with the Corps historically seeking the maximize their net benefits to the downstream population.

The WVS dams and reservoirs are currently authorized for flood control, hydropower, pollution abatement, fish and wildlife conservation, recreation, irrigation, municipal and industrial water supply, and water quality. The revetments are typically designed for riverbank stabilization, though features and functions vary by location. The typical operations within WVS have changed since their construction and continue to change with ongoing operations and actions currently in development. While each individual water year may have a minor effect on the basin-wide hydrology, ongoing changes will alter the system permanently.

Future population grow and accompanying urban, industrial, and commercial development (RFFA 1) would increase local inflow into river reaches downstream of the WVS dams and increase demand for water withdrawals consumptive uses (see RFFA 3 analysis below). The increased runoff would present flood management challenges to the WVS during flood season as there would be no increase in storage available to operate to the additional downstream inflow. The increased demand for water withdrawals would occur across all seasons. Since total flow is lower in the summer, the increase would be a greater portion of the total flow in that season. Both the flood management challenges and the increased demand for consumptive withdrawals would be additive effects.

Water withdrawals for municipal, industrial, and agricultural uses (RFFA 3) would decrease water availability and operational adaptability across many reaches of Willamette Valley basin. Increased demand would have the effect of either decreasing reservoir water surface elevation, decreasing instream flows, or a combination of both. Water withdrawals would be additive effects.

Federal and state wildlife and lands management (RFFA 6) refers to areas both upstream and downstream of the WVS reservoirs. Upstream of the reservoirs, as with the timber and mining effects (RFFAs 11 and 12), there are unlikely to be future change large enough to appreciably alter the inflow to the reservoirs. Downstream of the dams, the restoration project would increase floodplain storage at the margin, potentially altering the local inflows. This would potentially alter flood management operations and the effect would be additive.

Tribal, state, and local fish and wildlife improvement (RFFA 8) would primarily alter the Willamette Basin hydrology with the fish flow targets downstream of the WVS dams and the combined targets on the mainstem Willamette River. This PEIS contains measures that would redefine these targets. The spring and summer regulated hydrology of the Willamette River, particularly in dry years, is defined by these flow operations and any changes would be immediately noticeable. These effects would be additive.

Climate change (RFFA 10) would increase winter inflows to the Willamette basin, both upstream and downstream of the WVS dams and reservoirs, which would alter flood risk management operations during the winter and generally increase instream flows regardless of Corps actions. In late spring, basin-wide flows would drop earlier, leading to lower reservoir water surface elevations to meet ongoing and increasing flow demands. See the climate change sections of each alternative in section 3.2 for more information. Effects would be additive with the other RFFAs within their respective seasons.

In general, the combination of the RFFAs with an effect on Hydrologic Processes would increase overall flow and reservoir water surface elevations in the winter. This could either be inflow to reservoirs and streams or changes in reservoir operations as a direct consequence of those same increases. This same set of RFFAs would decrease available instream flows and reservoir water surface elevations starting in the late spring through the summer and fall.

#### *4.2.1.3 No Action Alternative*

There could be substantial changes to the existing conditions hydrologic processes in the Willamette River Basin under the No Action Alternative from the cumulative effects listed above. The combined cumulative effects in the Willamette Basin would mean higher reservoir water surface elevations and an increase in flows across all river reaches in the winter and early spring. The late spring and summer would bring lower reservoir water surfaces and lower flow in dry years, when accumulated stored water could run out more often and earlier in the year. However, the contribution of the NAA to the combined cumulative effects would be minor or negligible on its own since the NAA maintains the hydrology of the Willamette Basin consistent with existing conditions.

#### *4.2.1.4 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

The cumulative effects to hydrologic processes for Alterative 1 are divided by Willamette River subbasin based on the effects described at the top of this section. Overall, the cumulative effects to hydrologic processes would be expected to be moderate when applied to Alternative

1. During the PEIS analysis period, Alternative 1 would alter the hydrology of the WVS to a greater extent than the cumulative actions, though climate change and water withdrawals would measurably change certain aspects of the WVS operations.

#### *4.2.1.4.1 Santiam Subbasin*

The cumulative actions would decrease reservoir elevations at Detroit and Green Peter in the conservation season. Because Alternative 1 increases total storage as compared the NAA, downstream flows would remain similar even with cumulative actions such as increased downstream flow demands.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Detroit due to higher-than-average expected increases in inflow.

#### *4.2.1.4.2 Long Tom Subbasin*

Fern Ridge reservoir water surface elevations and downstream flows would moderately decrease during conservation season (spring to early fall) and increase during flood season (winter) from cumulative actions, including climate change and future population growth.

#### *4.2.1.4.3 McKenzie Subbasin*

Predicted conservation season reservoir water surface elevation increases at Cougar and Blue River would be offset by cumulative actions, including climate change and water withdrawals. Flow releases would also decrease in dry years but remain relatively stable in average and wetter years.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Cougar due to higher-than-average expected increases in inflow.

#### *4.2.1.4.4 Middle Fork of the Willamette Subbasin*

At Lookout Point and Hills Creek, increased conservation season storage would be decreased by cumulative actions, decreasing dry year flows when the reservoirs already reach their minimum water surface elevations to meet mainstem flow targets. Fall Creek reservoir water surface elevations and releases would be lower.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Hills Creek due to higher-than-average expected increases in inflow.

#### *4.2.1.4.5 Coast Fork of the Willamette Subbasin*

Both Dorena and Cottage Grove water surface elevations would decrease during conservation season. Since Alternative 1 increases total storage, downstream flows would remain similar.

Winter would see both increased instream flows and increased reservoir water surface elevations due to climate change, but less so than in higher elevation basins.

##### *4.2.1.4.6 Mainstem Willamette River*

Instream flows would decrease during conservation season – from late spring through early fall – due to cumulative actions including climate change and water withdrawals. Although the addition of stored water from the WVS reservoirs would offset some of this reduction, the flow targets at Albany and Salem would be missed more often during the summer and fall.

Winter flows would increase in the mainstem Willamette River in all except the driest years with climate change and population growth. The WVS operations may be able to increase average reservoir elevations during flood risk management operations to limit this increased flow. However, since most of the tributary area to the mainstem Willamette River is unregulated and increased inflows to the reservoirs would likely be coincident with the increased instream flows, the potential for winter-time reservoir management to offset increasing flows would be very limited in scope.

#### ***4.2.1.5 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

The cumulative effects to hydrologic processes for Alterative 2A are divided by Willamette River subbasin based on the effects described at the top of this section. Overall, the cumulative effects to hydrologic processes would be expected to be moderate within the framework of Alternative 2A. During the PEIS analysis period, Alternative 2A would alter the hydrology of the WVS to a greater extent than the cumulative actions, though climate change and water withdrawals would measurably change certain aspects of the WVS operations.

##### *4.2.1.5.1 Santiam Subbasin*

The cumulative actions would decrease reservoir elevations at Detroit and Green Peter in the conservation season. Since Alternative 2A increases total storage as compared the NAA, downstream flows would likely remain similar for all but the driest years even with actions such as increased downstream flow demands.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Detroit due to higher-than-average expected increases in inflow. The cumulative effects would reduce any additional winter-time flexibility after the fall drawdown at Green Peter by increasing inflows.

##### *4.2.1.5.2 Long Tom Subbasin*

Fern Ridge reservoir water surface elevations and downstream flows would moderately decrease during conservation season (spring to early fall) and increase during flood season (winter) from cumulative actions, including climate change and future population growth.

#### *4.2.1.5.3 McKenzie Subbasin*

Predicted conservation season reservoir water surface elevation increases at Cougar and Blue River would be offset by cumulative actions, including climate change and water withdraws. Summer and fall flow releases would decrease in dry years and the variability in summer flows would continue to decrease.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Cougar due to higher-than-average expected increases in inflow.

#### *4.2.1.5.4 Middle Fork of the Willamette Subbasin*

At Lookout Point and Hills Creek, increased conservation season storage would be decreased by cumulative actions, decreasing dry year flows when the reservoirs already reach their minimum water surface elevations to meet mainstem Willamette River flow targets. Fall Creek reservoir water surface elevations and releases would be lower.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Hills Creek due to higher-than-average expected increases in inflow.

#### *4.2.1.5.5 Coast Fork of the Willamette Subbasin*

Both Dorena and Cottage Grove water surface elevations would decrease during conservation season and would likely reach minimum conservation elevation in the driest years. Although Alternative 2A increases total storage, downstream flows would decrease in late fall when the reservoirs exhaust their stored water.

Winter would see both increased instream flows and increased reservoir water surface elevations due to climate change, but less so than in higher elevation basins.

#### *4.2.1.5.6 Mainstem Willamette River*

Instream flows would decrease during conservation season – from late spring through early fall – due to cumulative actions including climate change and water withdrawals. Although the additional stored water from the WVS reservoirs would offset some of this reduction, the flow targets at Albany and Salem would be missed during the driest years. Summer flow variability would further decrease.

Winter flows would increase in the mainstem Willamette River in all except the driest years with climate change and population growth. The WVS operations may be able to increase average reservoir elevations during flood risk management operations to limit this increased flow. However, since most of the tributary area to the mainstem Willamette River is unregulated and increased inflows to the reservoirs would likely be coincident with the increased instream flows, the potential for winter-time reservoir management to offset increasing flows would be very limited in scope.

#### *4.2.1.6 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

The cumulative effects to hydrologic processes for Alterative 2b are divided by Willamette River subbasin based on the effects described at the top of this section. Overall, the cumulative effects to hydrologic processes would be expected to be moderate within the framework of Alternative 2B. During the PEIS analysis period, Alternative 2B would alter the hydrology of the WVS to a greater extent than the cumulative actions, though climate change and water withdrawals would measurably change certain aspects of the WVS operations.

##### *4.2.1.6.1 Santiam Subbasin*

The cumulative actions would decrease reservoir elevations at Detroit and Green Peter in the conservation season. Since Alternative 2B increases total storage as compared the NAA, downstream flows would likely remain similar for all but the driest years even with actions such as increased downstream flow demands.

Winter would see both increased instream flows and increased reservoir water surface elevations, with Detroit seeing higher-than-average expected increases in inflow. The cumulative effects would reduce any additional winter-time flexibility after the fall drawdown at Green Peter by increasing inflows.

##### *4.2.1.6.2 Long Tom Subbasin*

Fern Ridge reservoir water surface elevations and downstream flows would moderately decrease during conservation season (spring to early fall) and increase during flood season (winter) from cumulative actions, including climate change and future population growth.

##### *4.2.1.6.3 McKenzie Subbasin*

Cougar reservoir would lose the minimal conservation season store water realized in Alternative 2B due to cumulative actions, including climate change and water withdraws, while Blue River would also see decreases from its increased stored water. Summer and fall flows downstream would decrease from their reduced levels and the variability in summer flows would continue to decrease.

During the winter, Cougar and Blue River would see both increased instream flows and increased reservoir water surface elevations. Although Cougar could mitigate some of this coming out of its fall drawdown, higher-than-average expected increases in inflow and lower storage volumes deeper in the reservoir mean that any such actions would likely be very limited in scope.

##### *4.2.1.6.4 Middle Fork of the Willamette Subbasin*

At Lookout Point and Hills Creek, conservation season storage would be decreased by cumulative actions, decreasing dry year flows when the reservoirs already reach their minimum water surface elevations to meet mainstem flow targets. The reservoirs would reach their minimum water surface elevations more often and earlier in the year to make up for the lack of stored water at Cougar reservoir. Fall Creek reservoir water surface elevations and releases would be lower.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Hills Creek due to higher-than-average expected increases in inflow.

##### *4.2.1.6.5 Coast Fork of the Willamette Subbasin*

Both Dorena and Cottage Grove reservoir water surface elevations would decrease during conservation season and would likely reach minimum conservation elevation in the driest years. Although Alternative 2B increases total storage, downstream flows would decrease in late fall when the reservoirs exhaust their stored water.

Winter would see both increased instream flows and increased reservoir water surface elevations due to climate change, but less so than in higher elevation basins.

##### *4.2.1.6.6 Mainstem Willamette River*

Instream flows would decrease during conservation season – from late spring through early fall – due to cumulative actions including climate change and water withdrawals. Although some additional stored water from the Santiam reservoirs would offset some of this reduction at Salem, the flow target at Albany would be missed more often during dry years. Summer flow variability would further decrease.

Winter flows would increase in the mainstem Willamette River in all except the driest years with climate change and population growth. The WVS operations may be able to increase average reservoir elevations during flood risk management operations to limit this increased flow. However, since most of the tributary area to the mainstem Willamette River is unregulated and increased inflows to the reservoirs would likely be coincident with the increased instream flows, the potential for winter-time reservoir management to offset increasing flows would be very limited in scope.

#### ***4.2.1.7 Alternative 3A – Operations-Focused Fish Passage Alternative***

The cumulative effects to hydrologic processes for Alterative 3a are divided by Willamette River subbasin based on the effects described at the top of this section. Overall, the cumulative effects to hydrologic processes would be expected to be major within the framework of Alternative 3A. Though Alternative 3A would alter the hydrology of the WVS to a greater extent than the cumulative actions during the PEIS analysis period, climate change would compound those changes across the Willamette River basin.

#### *4.2.1.7.1 Santiam Subbasin*

Detroit Reservoir would be even lower throughout conservation season due to cumulative actions, including climate change and increases in downstream flow demands. Typical instream flows would decrease, meeting flow targets in only the wettest years. Green Peter would also see its increased conservation storage diminish though from a higher level than at Detroit and likely has capacity to maintain similar downstream flows in the South Santiam River.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Detroit due to higher-than-average expected increases in inflow. The cumulative effects would reduce any additional winter-time flexibility after the fall drawdowns at both reservoirs by increasing inflows.

#### *4.2.1.7.2 Long Tom Subbasin*

Fern Ridge reservoir water surface elevations and downstream flows would moderately decrease during conservation season (spring to early fall) and increase during flood season (winter) from cumulative actions, including climate change and future population growth.

#### *4.2.1.7.3 McKenzie Subbasin*

Cougar reservoir would lose the minimal stored water realized during conservation season in Alternative 3A due to cumulative actions, including climate change and water withdraws. Blue River would also see decreases from its increased stored water, reaching minimum water surface elevation more often and earlier in the year. Summer and fall flows downstream would decrease from their reduced levels and the variability in summer flows would decrease.

During the winter, Cougar and Blue River would see both increased instream flows and increased reservoir water surface elevations, particularly at Cougar due to higher-than-average expected increases in inflow.

#### *4.2.1.7.4 Middle Fork of the Willamette Subbasin*

Conservation season storage would be reduced at Hills Creek and Lookout Point due to cumulative actions. Since Lookout Point comes out its spring drawdown in June, decreasing inflows will mean less storage in conservation season. The decreased downstream flows in Alternative 3A would be exacerbated and further decease flow variability in the subbasin. Fall Creek reservoir water surface elevations and releases would be lower.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Hills Creek due to higher-than-average expected increases in inflow.

#### *4.2.1.7.5 Coast Fork of the Willamette Subbasin*

Both Dorena and Cottage Grove reservoir water surface elevations would decrease during conservation season and would likely reach minimum conservation elevation in dry years.

Although Alternative 3A increases peak storage, the reservoirs would have to release maintain flows and see less conservation season inflow due to cumulative actions.

Winter would see both increased instream flows and increased reservoir water surface elevations due to climate change, but less so than in higher elevation basins.

##### *4.2.1.7.6 Mainstem Willamette River*

Instream flows would decrease during conservation season – from late spring through early fall – from already minimum levels due to cumulative actions including climate change and water withdrawals. The Albany flow target would rarely, if ever, be met from July through September. Additional flow from Green Peter would help meet the Salem flow target more regularly than the Albany flow target. However, the limited and decreasing storage at Detroit would mean that long summer and fall periods below the Salem flow target would be inevitable.

Winter flows would increase in the mainstem Willamette River in all except the driest years with climate change and population growth. The WVS operations may be able to increase average reservoir elevations during flood risk management operations to limit this increased flow. However, since most of the tributary area to the mainstem Willamette River is unregulated and increased inflows to the reservoirs would likely be coincident with the increased instream flows, the potential for winter-time reservoir management to offset increasing flows would be very limited in scope.

#### ***4.2.1.8 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)***

The cumulative effects to hydrologic processes for Alterative 3b are divided by Willamette River subbasin based on the effects described at the top of this section. Overall, the cumulative effects to hydrologic processes would be expected to be major within the framework of Alternative 3B. Though Alternative 3B would alter the hydrology of the WVS to a greater extent than the cumulative actions during the PEIS analysis period, climate change would compound those changes across the Willamette River basin.

##### *4.2.1.8.1 Santiam Subbasin*

Cumulative actions, including climate change and increases in downstream flow demands, would offset some water surface elevation increases at Detroit reservoir throughout conservation season. However, typical instream flows directly downstream of the dam would likely remain similar due to the remaining storage. Green Peter would not likely fill to minimum conservation pool in the summer and Foster would exhaust its smaller storage capacity more often and earlier in the year. Flow targets downstream of Foster would only be met in the wettest years, with dry years only passing the inflow from the South Santiam reservoirs for many months.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Detroit due to higher-than-average expected increases in inflow. The cumulative effects would reduce any additional winter-time flexibility after the fall drawdowns at both reservoirs by increasing inflows.

##### *4.2.1.8.2 Long Tom Subbasin*

Fern Ridge reservoir water surface elevations and downstream flows would moderately decrease during conservation season (spring to early fall) and increase during flood season (winter) from cumulative actions, including climate change and future population growth.

##### *4.2.1.8.3 McKenzie Subbasin*

Cougar reservoir would lose the minimal stored water realized during conservation season in Alternative 3B due to cumulative actions, including climate change and water withdraws, while Blue River would also see decreases from its increased stored water. Summer and fall flows downstream would decrease from their reduced levels and the variability in summer flows would continue to decrease.

During the winter, Cougar and Blue River would see both increased instream flows and increased reservoir water surface elevations. Although Cougar could mitigate some of this coming out of its fall drawdown, higher-than-average expected increases in inflow and lower storage volumes deeper in the reservoir mean that any such actions would likely be very limited in scope.

##### *4.2.1.8.4 Middle Fork of the Willamette Subbasin*

Conservation season storage would be reduced at Hills Creek and Lookout Point due to cumulative actions. Since the Hills Creek average basin elevation is higher, decreasing inflows would occur earlier in the year, likely reducing the already low conservation storage in Alternative 3B. Since Lookout Point reaches its minimum water surface elevation only in the driest years, it would be able to supplement downstream flows somewhat. Fall Creek reservoir water surface elevations and releases would be lower.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Hills Creek due to higher-than-average expected increases in inflow.

##### *4.2.1.8.5 Coast Fork of the Willamette Subbasin*

Both Dorena and Cottage Grove reservoir water surface elevations would decrease during conservation season and would likely reach minimum conservation elevation in the driest years. Although Alternative 2B increases total storage, downstream flows would decrease in late fall when the reservoirs exhaust their stored water.

Winter would see both increased instream flows and increased reservoir water surface elevations due to climate change, but less so than in higher elevation basins.

##### *4.2.1.8.6 Mainstem Willamette River*

Instream flows would decrease during conservation season – from late spring through early fall – due to cumulative actions including climate change and water withdrawals. The flow target at Albany would be missed more often and for longer periods during dry years. The Salem flow target would be missed more often during the same periods as low flow at Albany.

Winter flows would increase in the mainstem Willamette River in all except the driest years with climate change and population growth. The WVS operations may be able to increase average reservoir elevations during flood risk management operations to limit this increased flow. However, since most of the tributary area to the mainstem Willamette River is unregulated and increased inflows to the reservoirs would likely be coincident with the increased instream flows, the potential for winter-time reservoir management to offset increasing flows would be very limited in scope.

#### ***4.2.1.9 Alternative 4 – Structures-Based Fish Passage Alternative***

The cumulative effects to hydrologic processes for Alterative 4 are divided by Willamette River subbasin based on the effects described at the top of this section. Overall, the cumulative effects to hydrologic processes would be expected to be moderate within the framework of Alternative 4. During the PEIS analysis period, Alternative 4 would alter the hydrology of the WVS to a greater extent than the cumulative actions, though climate change and water withdrawals would measurably change certain aspects of the WVS operations.

##### *4.2.1.9.1 Santiam Subbasin*

The cumulative actions would decrease reservoir water surface elevations at Detroit and Green Peter in the conservation season. Since Alternative 4 increases total storage at Detroit, downstream flows would remain similar even with actions such as increased downstream flow demands. Foster would occasionally miss its flow target due to Green Peter exhausting its storage in the driest years.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Detroit due to higher-than-average expected increases in inflow.

##### *4.2.1.9.2 Long Tom Subbasin*

Fern Ridge reservoir water surface elevations and downstream flows would moderately decrease during conservation season (spring to early fall) and increase during flood season (winter) from cumulative actions, including climate change and future population growth.

##### *4.2.1.9.3 McKenzie Subbasin*

Predicted conservation season reservoir water surface elevation increases at Cougar and Blue River would be offset by cumulative actions, including climate change and water withdraws. Flow releases would also decrease in dry years but remain relatively stable in average years.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Cougar due to higher-than-average expected increases in inflow.

##### *4.2.1.9.4 Middle Fork of the Willamette Subbasin*

At Lookout Point and Hills Creek, increased conservation season storage would be decreased by cumulative actions, decreasing dry year flows when the reservoirs already reach their minimum water surface elevations to meet mainstem flow targets. Fall Creek reservoir water surface elevations and releases would be lower.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Hills Creek due to higher-than-average expected increases in inflow.

##### *4.2.1.9.5 Coast Fork of the Willamette Subbasin*

Both Dorena and Cottage Grove reservoir water surface elevations would decrease during conservation season. Since Alternative 4 increases total storage, downstream flows would remain similar.

Winter would see both increased instream flows and increased reservoir water surface elevations due to climate change, but less so than in higher elevation basins.

##### *4.2.1.9.6 Mainstem Willamette River*

Instream flows would decrease during conservation season – from late spring through early fall – due to cumulative actions including climate change and water withdrawals. Although the addition of stored water from the WVS reservoirs would offset some of this reduction, the flow targets at Albany and Salem would be missed more often during the summer and fall.

Winter flows would increase in the mainstem Willamette River in all except the driest years with climate change and population growth. The WVS operations may be able to increase average reservoir elevations during flood risk management operations to limit this increased flow. However, since most of the tributary area to the mainstem Willamette River is unregulated and increased inflows to the reservoirs would likely be coincident with the increased instream flows, the potential for winter-time reservoir management to offset increasing flows would be very limited in scope.

#### ***4.2.1.10 Alternative 5 – Revised Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

The cumulative effects to hydrologic processes for Alternative 5 are divided by Willamette River subbasin based on the effects described at the top of this section. Overall, the cumulative effects to hydrologic processes would be expected to be moderate with the framework of Alternative 5. During the PEIS analysis period, Alternative 5 would alter the hydrology of the WVS to a greater extent than the cumulative actions, though climate change and water withdrawals would measurably change certain aspects of the WVS operations.

#### *4.2.1.10.1 Santiam Subbasin*

The cumulative actions would decrease reservoir elevations at Detroit and Green Peter in the conservation season. Since Alternative 5 increases total storage as compared the NAA, downstream flows would likely remain similar for all but the driest years even with actions such as increased downstream flow demands.

Winter would see both increased instream flows and increased reservoir water surface elevations, with Detroit seeing higher-than-average expected increases in inflow. The cumulative effects would reduce any additional winter-time flexibility after the fall drawdown at Green Peter by increasing inflows.

#### *4.2.1.10.2 Long Tom Subbasin*

Fern Ridge reservoir water surface elevations and downstream flows would moderately decrease during conservation season (spring to early fall) and increase during flood season (winter) from cumulative actions, including climate change and future population growth.

#### *4.2.1.10.3 McKenzie Subbasin*

Cougar reservoir would lose the minimal conservation season store water realized in Alternative 5 due to cumulative actions, including climate change and water withdraws, while Blue River would also see decreases from its increased stored water. Summer and fall flows downstream would decrease from their reduced levels and the variability in summer flows would continue to decrease.

During the winter, Cougar and Blue River would see both increased instream flows and increased reservoir water surface elevations. Although Cougar could mitigate some of this coming out of its fall drawdown, higher-than-average expected increases in inflow and lower storage volumes deeper in the reservoir mean that any such actions would likely be very limited in scope.

#### *4.2.1.10.4 Middle Fork of the Willamette Subbasin*

At Lookout Point and Hills Creek, conservation season storage would be decreased by cumulative actions, decreasing dry year flows when the reservoirs already reach their minimum water surface elevations to meet mainstem flow targets. The reservoirs would reach their minimum water surface elevations more often and earlier in the year to make up for the lack of stored water at Cougar reservoir. Fall Creek reservoir water surface elevations and releases would be lower.

Winter would see both increased instream flows and increased reservoir water surface elevations, particularly at Hills Creek due to higher-than-average expected increases in inflow.

#### *4.2.1.10.5 Coast Fork of the Willamette Subbasin*

Both Dorena and Cottage Grove reservoir water surface elevations would decrease during conservation season and would likely reach minimum conservation elevation in the driest years. Although Alternative 5 increases total storage, downstream flows would decrease in late fall when the reservoirs exhaust their stored water.

Winter would see both increased instream flows and increased reservoir water surface elevations due to climate change, but less so than in higher elevation basins.

#### *4.2.1.10.6 Mainstem Willamette River*

Instream flows would decrease during conservation season – from late spring through early fall – due to cumulative actions including climate change and water withdrawals. Although some additional stored water from the Santiam reservoirs would limit the frequency of missing the flow target at Salem, the flow target at Albany would be missed more often and for longer periods during dry years. Summer flow variability would further decrease.

Winter flows would increase in the mainstem Willamette River in all except the driest years with climate change and population growth. The WVS operations may be able to increase average reservoir elevations during flood risk management operations to limit this increased flow. However, since most of the tributary area to the mainstem Willamette River is unregulated and increased inflows to the reservoirs would likely be coincident with the increased instream flows, the potential for winter-time reservoir management to offset increasing flows would be very limited in scope.

## 4.3 RIVER MECHANICS AND GEOMORPHOLOGY

### 4.3.1 Cumulative Effects Analysis Methodology for River Mechanics and Geomorphology

This analysis is a qualitative assessment of the anticipated trends to River Mechanics and Geomorphology resource.

#### *4.3.1.1 Cumulative Actions Applicable to River Mechanics and Geomorphology*

Past, present, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on River Mechanics and Geomorphology include:

- WVS and Other Dams and Reservoirs in the WRB: construction and past operations and maintenance (see section 4.2.1.1) and ongoing operations and maintenance (see section 4.2.2)
- WRB Population Growth and Development: altered land use within to the Willamette River basin (see section 4.2.1.2)
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development
- RFFA 2: Future agricultural development
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 5: Federal and state wildlife and lands management
- RFFA 7: Tribal, state, and local fish and wildlife improvement
- RFFA 9: Climate change
- RFFA 10: Mining operations
- RFFA 11: Timber and logging industry operations

Some of the other RFFAs discussed in Section 4.2.3 would not change sediment processes or geomorphology of the Willamette Basin or only negligibly alter the WVS dam and reservoir operations and as such would not have a cumulative effect on river mechanics and geomorphology. These include:

- RFFA 4: Decarbonizing the energy sector with renewable energy sources. There is minimal variation in total flow due to outlet choice, such as whether to run the WVS dam's hydroelectric turbines.
- RFFA 6: Fishery management and killer whales. The flow targets in the WVS are specific to the river reaches and habitat where they occur. They are not variable based on Pacific Ocean salmon returns.
- RFFA 8: Invasive species management. Does not affect flow or regulation decisions for the WVS dams.

Therefore, these RFFAs are dismissed from further analysis.

### 4.3.2 Cumulative Effects to River Mechanics and Geomorphology by Alternative

The WVS dams and reservoirs are currently authorized for flood control, hydropower, pollution abatement, fish and wildlife conservation, recreation, irrigation, municipal and industrial water supply, and water quality. Existing river processes and geomorphology are changed from the natural condition by construction and operation of the WVS dams and reservoirs, public and private bank protection and river training, land use both urban and rural, resource extraction, transportation infrastructure development, river navigation both recreational and commercial, and past visions of flood risk management including large scale removal of large wood. The cumulative effect of these large scale past actions is conversion of river to inland lakes in the form of reservoirs and a simplified river form in the regulated river reaches that are less dynamic and experience less connection with their historical floodplain. Cumulative effects described in this section are relative to the existing condition in order to highlight differences between alternatives. Other dams and reservoirs within the WRB are more numerous (estimated to be 247 additional non-USACE dams) but generally much smaller in height and volume. Few of these projects have flood control operations or storage capacity and do not attempt to reduce peak flows that are drivers for morphological activity. The primary driver for peak flow reduction in the WVS remains the USACE WVS flood control projects. The non-USACE dams to impound sediment but likely offset increased sediment supply from development and land management. The cumulative actions would create adverse, additive, and minor to moderate effects to river mechanics and geomorphology.

Future population growth and accompanying urban, industrial, and commercial development (RFFA 1) occurring in historical floodplains would lock the landscape into a developed condition and encourage river and bank stabilization to ensure property protection. Floodplain fill, likely to the 100-year FEMA base flood elevation, and subsequent floodplain disconnection from the river would simplify the river form and future morphological processes. Additionally, sediment supplied to the river from the converted lands would change in nature from crop or pasture fines and intermittent coarser sediments from bank erosion to predominately urbanized and industrial fines. Potential for increased deep draft port traffic in the lower Willamette may result in increased dredging to maintain port and navigation channel depth. Hydrologic changes due to RFFA 1 actions are negligible to subreach scale sediment processes. Given extents of existing development in the WVS and limitations put on development through Oregon's urban growth boundary laws, the cumulative actions would create adverse, additive, and minor effects to river mechanics and geomorphology.

Future agricultural development (RFFA 2) occurring in historical floodplains would encourage stabilization of the river and riparian landscape into a developed condition and encourage bank stabilization to ensure property protection. Outside of the urban growth boundaries, floodplain development would likely be in the form of larger ranchettes or properties that take advantage of the river and riparian amenities. Floodplain fill, likely to the 100-year FEMA base flood elevation, and flood water management through the development of training berms or levees would further disconnect the river from the floodplain and simplify the river form and future morphological processes. Bank protection would limit re-mobilization of stored coarse sediments and encourage further vertical river incision. The cumulative actions would create adverse, additive, and minor effects to river mechanics and geomorphology.

Water withdrawals for municipal, industrial, and agricultural uses (RFFA 3) would have the effect of either decreasing reservoir water surface elevation, decreasing instream flows, or a combination of both. Decreased water surface elevation would increase reservoir bank exposure and potential for scour and suspension of fine sediments from the reservoir banks. The cumulative actions would create adverse, additive, and minor effects to sediment supply.

Federal and state wildlife and lands management (RFFA 5) and timber and logging industry operations (RFFA 11) happen throughout the regulated and unregulated portions of the watershed and are conservation focused or expected to occur at similar rates to the recent past. Rates of surface erosion and sediment supply due to land management are expected to remain unchanged. Increased awareness of the value of riparian corridors and preservation of future large wood sources during resource extraction would improve river and riparian complexity. The cumulative actions would be additive and minor effects to sediment supply and geomorphology.

Tribal, state, and local fish and wildlife improvement (RFFA 7) would include river and floodplain restoration actions and potentially environmental flows to inundate habitats and mobilize bed sediments. Restoration actions would directly and locally modify river and riparian form and function; however, the scale of most restoration actions limit the river mechanics and geomorphology impacts to the local project area. Environmental flows have been performed historically in the Willamette system but have been limited in magnitude to non-damaging peak flows similar to smaller regulated flood events. The cumulative actions would create beneficial, additive, and minor effects to overall system river mechanics and geomorphology.

Climate change (RFFA 9) would increase winter inflows and sediment supply to the Willamette basin, both upstream and downstream of the WVS dams and reservoirs. Additionally, there is causal relationship between wildfires and increased sediment supply. Expected increases in very high fire danger days and associated increases in forest fire acreages are expected to increase basin sediment yields due to climate change. Reservoirs act as sediment traps and would partially mitigate increases in sediment supply in regulated reaches by trapping additional sediment. Additionally, climate change generally decreases conservation season flows and therefore conservations season reservoir stages (Section 4.3). This could increase bank exposure, decrease reservoir storage and increase fine grained suspended sediment concentrations in the reservoirs and sediment releases downstream. As climate change does not increase operational range, but only stages within the operational rage, this conservation season change is expected to be negligible to minor. See the climate change sections in section 3.3 for more information. Effects would be additive with the other RFFAs within their respective seasons.

Mining operations (RFFA 10) would include gravel and sand extraction from river adjacent floodplain pits. Existing and proposed new pits or expansions are subject to current environmental protection laws and are typically separated from the river by levees or natural high land limiting sediment releases to the river. Levees and associated river training and bank protection to enforce the isolation in turn simplify morphological processes in the adjacent river, disconnect the river the floodplain and permanently modify the landscape by extraction. The cumulative actions would create adverse, additive, and minor effects to sediment supply and morphology.

In general, the combination of the RFFAs with an effect on river mechanics and geomorphology minorly changes the current trajectory of the basin. Restoration and land use that view the river as an amenity may partially offset future development and resource extraction demands in the continued simplification of the river and river processes. Many of the RFFAs would have varying but localized minor effects to river mechanics and geomorphology. Of the RFFAs, climate change and its associated hydrological and sediment supply changes, particularly in unregulated tributaries and regulated reaches with large unregulated contributing areas, has the most potential to affect large scale changes with increased sediment supply, winter flows and associated morphologic activity.

General trends described in this section apply to all subbasins within the WVB. It is unknown to what magnitude climate change, increased development, and other cumulative actions may impact future trends in sediment processes. Many of the RFFAs offset each other to some degree for the river mechanics and geomorphology resource at the subbasin scale, for example development may seek to harden and bank from erosion while restoration may seek to modify or remove an existing revetment. Location, extents, and timing of these actions are unknown. Climate change and associated winter flow and sediment supply increases are likely the largest additive driver for cumulative changes to WVS river mechanics and geomorphology. To that end, and to prevent undue repetition of general trends in alternative analysis, general trends apply to all alternatives and subbasins with impacts being long-term and basin-wide by default unless otherwise noted.

#### *4.3.2.1 No Action Alternative*

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to sediment processes (changes from existing condition) under the No Acton Alternative. As discussed in section 3.3.3.1, the effects of the No Action Alternative do not appreciably change the geomorphology and sediment processes, or the closely related hydrology and hydraulics, of the WVS from the existing conditions. Overall cumulative effects would be additive, with negligible to minor increases, in the effect and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. Effects as discussed in section 3.3.3.1 of the NAA.

#### *4.3.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

RFFAs with the potential to contribute to cumulative effects to geomorphology and sediment transport are described in section 4.3.1. General trends described in this section apply to all subbasins within the WSV. Overall cumulative effects would be additive, with negligible to minor increases in the effect, and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. The direct/indirect effects of Alternative 1 compared to the No Action Alternative are summarized in Table 3.3-2.

##### *4.3.2.2.1 Santiam Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Santiam Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.2). Higher-than-average winter flows in Detroit and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.2.2 Long Tom Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Long Tom Subbasin, both upstream and downstream of the WVS dams and reservoirs, and reservoirs as well as a decrease in conservation season reservoir stages (Section 4.3.3.2).

##### *4.3.2.2.3 McKenzie Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the McKenzie Subbasin, both upstream and downstream of the WVS dams and reservoirs (Section 4.3.3.2). Higher-than-average winter flows in Cougar and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.2.4 Middle Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Middle Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs (Section 4.3.3.2). Higher-than-average winter flows in Hills Creek and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.2.5 Coast Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Coast Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.2).

##### *4.3.2.2.6 Mainstem Willamette River*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Mainstem Willamette River. The source the increased sediment is likely headwaters making uncertain the magnitude in increase transported to the mainstem river. The mainstem Willamette is the subbasin most likely to see development (RFFAs 1 and 2) and restoration (RFFA 7) offsets that have uncertainty in location and magnitude. It is unknown to what magnitude cumulative actions would impact future sediment processes.

#### ***4.3.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

RFFAs with the potential to contribute to cumulative effects to geomorphology and sediment transport are described in section 4.3.1. General trends described in this section 4.3.1apply to all subbasins within the WSV. Overall cumulative effects would be additive, with negligible to minor increases in the effect, and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. The direct/indirect effects of Alternative 2A compared to the No Action Alternative are summarized in Table 3.3-3.

##### *4.3.2.3.1 Santiam Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Santiam Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.3). Higher-than-average winter flows in Detroit and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.3.2 Long Tom Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Long Tom Subbasin, both upstream and downstream of the WVS dams and reservoirs, and reservoirs as well as a decrease in conservation season reservoir stages (Section 4.3.3.3).

##### *4.3.2.3.3 McKenzie Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the McKenzie Subbasin, both upstream and downstream of the WVS dams and reservoirs (Section 4.3.3.3). Higher-than-average winter flows in Cougar and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.3.4 Middle Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Middle Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs (Section 4.3.3.3). Higher-than-average winter flows in Hills Creek and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.3.5 Coast Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Coast Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.3).

##### *4.3.2.3.6 Mainstem Willamette River*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Mainstem Willamette River. The source the increased sediment is likely headwaters making uncertain the magnitude in increase transported to the mainstem river. The mainstem Willamette is the subbasin most likely to see development (RFFAs 1 and 2) and restoration (RFFA 7) offsets that have uncertainty in location and magnitude. It is unknown to what magnitude cumulative actions of would impact future sediment processes.

#### ***4.3.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

RFFAs with the potential to contribute to cumulative effects to geomorphology and sediment transport are described in section 4.3.1. General trends described in this section apply to all subbasins within the WSV. Overall cumulative effects would be additive, with negligible to minor increases in the effect, and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. The direct/indirect effects of Alternative 2B compared to the No Action Alternative are summarized in Table 3.3-4.

##### *4.3.2.4.1 Santiam Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Santiam Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4). Higher-than-average winter flows in Detroit and Green Peter associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoirs. A higher-than-average increase in depositional rates within the reservoirs may occur.

##### *4.3.2.4.2 Long Tom Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Long Tom Subbasin, both upstream and downstream of the WVS dams and reservoirs, and reservoirs as well as a decrease in conservation season reservoir stages (Section 4.3.3.4).

##### *4.3.2.4.3 McKenzie Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the McKenzie Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4).

##### *4.3.2.4.4 Middle Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Middle Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4). Higher-than-average winter flows into Hills Creek and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.4.5 Coast Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Coast Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4).

##### *4.3.2.4.6 Mainstem Willamette River*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Mainstem Willamette River. The source the increased sediment is likely headwaters making uncertain the magnitude in increase transported to the mainstem river. The mainstem Willamette is the subbasin most likely to see development (RFFAs 1 and 2) and restoration (RFFA 7) offsets that have uncertainty in location and magnitude. It is unknown to what magnitude cumulative actions of would impact future sediment processes.

#### ***4.3.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative***

RFFAs with the potential to contribute to cumulative effects to geomorphology and sediment transport are described in section 4.3.1. General trends described in this section apply to all subbasins within the WSV. Overall cumulative effects would be additive, with negligible to minor increases in the effect, and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. The direct/indirect effects of Alternative 3A compared to the No Action Alternative are summarized in Table 3.3-5.

##### *4.3.2.5.1 Santiam Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Santiam Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.5). Higher-than-average winter flows in Detroit associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoirs may occur. Lower than average pool stages in Detroit reservoir during the conservation season increase the potential for fine grained sediment suspension in the pool and downstream sediment releases to Big Cliff reservoir.

##### *4.3.2.5.2 Long Tom Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Long Tom Subbasin, both upstream and downstream of the WVS dams and reservoirs, and reservoirs as well as a decrease in conservation season reservoir stages (Section 4.3.3.5).

#### *4.3.2.5.3 McKenzie Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the McKenzie Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.5). Higher-than-average winter flows in Cougar and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

#### *4.3.2.5.4 Middle Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Middle Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.5). Higher-than-average winter flows in Hills Creek and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

#### *4.3.2.5.5 Coast Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Coast Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.5).

#### *4.3.2.5.6 Mainstem Willamette River*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Mainstem Willamette River. The source the increased sediment is likely headwaters making uncertain the magnitude in increase transported to the mainstem river. The mainstem Willamette is the subbasin most likely to see development (RFFAs 1 and 2) and restoration (RFFA 7) offsets that have uncertainty in location and magnitude. It is unknown to what magnitude cumulative actions of would impact future sediment processes.

### *4.3.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

RFFAs with the potential to contribute to cumulative effects to geomorphology and sediment transport are described in section 4.3.1. General trends described in this section apply to all subbasins within the WSV. Overall cumulative effects would be additive, with negligible to minor increases in the effect, and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. The direct/indirect effects of Alternative 3B compared to the No Action Alternative are summarized in Table 3.3-6.

###### *4.3.2.6.1 Santiam Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Santiam Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.6). Higher-than-average winter flows in Detroit associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoirs may occur.

###### *4.3.2.6.2 Long Tom Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Long Tom Subbasin, both upstream and downstream of the WVS dams and reservoirs, and reservoirs as well as a decrease in conservation season reservoir stages (Section 4.3.3.6).

###### *4.3.2.6.3 McKenzie Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the McKenzie Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.6).

###### *4.3.2.6.4 Middle Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Middle Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.6). Higher-than-average winter flows in Hills Creek and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

###### *4.3.2.6.5 Coast Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Coast Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.6).

##### *4.3.2.6.6 Mainstem Willamette River*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Mainstem Willamette River. The source the increased sediment is likely headwaters making uncertain the magnitude in increase transported to the mainstem river. The mainstem Willamette is the subbasin most likely to see development (RFFAs 1 and 2) and restoration (RFFA 7) offsets that have uncertainty in location and magnitude. It is unknown to what magnitude cumulative actions of would impact future sediment processes.

#### *4.3.2.7 Alternative 4 – Structures-Based Fish Passage Alternative*

RFFAs with the potential to contribute to cumulative effects to geomorphology and sediment transport are described in section 4.3.1. General trends described in this section apply to all subbasins within the WSV. Overall cumulative effects would be additive, with negligible to minor increases in the effect, and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. The direct/indirect effects of Alternative 4 compared to the No Action Alternative are summarized in Table 3.3-7.

##### *4.3.2.7.1 Santiam Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Santiam Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.7). Higher-than-average winter flows in Detroit and Green Peter associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoirs. A higher-than-average increase in depositional rates within the reservoirs may occur.

##### *4.3.2.7.2 Long Tom Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Long Tom Subbasin, both upstream and downstream of the WVS dams and reservoirs, and reservoirs as well as a decrease in conservation season reservoir stages (Section 4.3.3.7).

##### *4.3.2.7.3 McKenzie Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the McKenzie Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.7).

##### *4.3.2.7.4 Middle Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Middle Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.7). Higher-than-average winter flows into Hills Creek and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.7.5 Coast Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Coast Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.7).

##### *4.3.2.7.6 Mainstem Willamette River*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Mainstem Willamette River. The source the increased sediment is likely headwaters making uncertain the magnitude in increase transported to the mainstem river. The mainstem Willamette is the subbasin most likely to see development (RFFAs 1 and 2) and restoration (RFFA 7) offsets that have uncertainty in location and magnitude. It is unknown to what magnitude cumulative actions of would impact future sediment processes.

#### ***4.3.2.8 Alternative 5***

RFFAs with the potential to contribute to cumulative effects to geomorphology and sediment transport are described in section 4.3.1. General trends described in this section apply to all subbasins within the WVS. Overall cumulative effects would be additive, with negligible to minor increases in the effect, and long-term to the WVB as affected by cumulative actions, which are largely influenced by anticipated climate change and continued development. For example, a minor increase in sediment supply to a reach due to changes in operation may be a minor to moderate increase when cumulative effects are considered. A negligible effect may remain negligible or pass the threshold into a minor effect. Major effects would remain major. The direct/indirect effects of Alternative 5 compared to the No Action Alternative are summarized in Table 3.3-8.

##### *4.3.2.8.1 Santiam Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Santiam Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4). Higher-than-average winter flows in Detroit and Green Peter associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoirs. A higher-than-average increase in depositional rates within the reservoirs may occur.

##### *4.3.2.8.2 Long Tom Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Long Tom Subbasin, both upstream and downstream of the WVS dams and reservoirs, and reservoirs as well as a decrease in conservation season reservoir stages (Section 4.3.3.4).

##### *4.3.2.8.3 McKenzie Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the McKenzie Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4).

##### *4.3.2.8.4 Middle Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Middle Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4). Higher-than-average winter flows into Hills Creek and associated higher sediment inflows would be offset by higher reservoir water surface elevations resulting in negligible change in sediment releases from the reservoir. A higher-than-average increase in depositional rates within the reservoir may occur.

##### *4.3.2.8.5 Coast Fork of the Willamette Subbasin*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Coast Fork of the Willamette Subbasin, both upstream and downstream of the WVS dams and reservoirs, as well as a decrease in conservation season reservoir stages (Section 4.3.3.4).

##### *4.3.2.8.6 Mainstem Willamette River*

The anticipated trends of cumulative actions would see an increase in winter inflows and sediment supply to the Mainstem Willamette River. The source the increased sediment is likely headwaters making uncertain the magnitude in increase transported to the mainstem river. The mainstem Willamette is the subbasin most likely to see development (RFFAs 1 and 2) and restoration (RFFA 7) offsets that have uncertainty in location and magnitude. It is unknown to what magnitude cumulative actions of would impact future sediment processes.

## 4.4 GEOLOGY AND SOILS

### 4.4.1 Cumulative Effects Analysis Methodology for Geology and Soils

The cumulative effects analysis for Geology and Soils is qualitative and examines effects within the WVB over the period of analysis. This analysis focuses on anticipated impacts to landslides from hydrologic process trends based upon the relevant cumulative actions discussed in the scenario.

#### *4.4.1.1 Cumulative Actions Applicable to Geology and Soils*

Past, present, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on Geology and Soils, include:

- WVS and Other Dams and Reservoirs in the WRB: construction and past operations and maintenance (see section 4.1.2.1.1)
- WVS Dams and Reservoirs: ongoing operations and maintenance (see section 4.1.2.2)
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 8: Tribal, state, and local fish and wildlife improvement
- RFFA 10: Climate change
- RFFA 11: Mining operations
- RFFA 12: Timber and logging industry operations.

Effects on soils due to past and future factors that impact land use (WRB Population Growth and Development and RFFA 1 and 2) are generally better described in terms of geomorphology (section 4.4). Some of the other RFFAs discussed in Section 4.2.3 would not occur at or in close proximity to the WVS dams and reservoirs and as such would not have a cumulative effect on geology and soils within the area of interest. These include:

- WRB Population Growth and Development: altered land use within to the Willamette River (see section 4.2.1.2). While the increase in population and resulting urban, commercial, and industrial development that has occurred in the recent past may increase water demand, which could mean that minimum reservoir elevations are reached more frequently, which is the mechanism of concern for landslide initiation, the main driver of this change is more accurately described by RFFA 3.
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development. Although an increase in population and resulting urban, commercial, and industrial may increase water demand, which could mean that minimum reservoir elevations are reached more frequently, which is the mechanism of concern for landslide initiation, the main driver of this change is more properly placed in RFFA 3.

- RFFA 2: Future agricultural development. While decreased projected cropland may marginally affect Willamette Basin hydrology and decrease water use, which has indirect effects on geology and soils, the main driver of this change is more properly placed in RFFA 3.
- RFFA 4: Decarbonizing the energy sector with renewable energy sources. Reduced demand for the extraction of fossil fuels is more properly described by RFFA 10, mining operations. Decarbonation of the energy sector would not change reservoir operations in a way that would influence landslide formation.
- RFFA 5: Federal and state wildlife and lands management. Based on the hydrologic cumulative effects assessment (section 4.3.3) changes to land management upstream of the WV projects is unlikely to cause changes large enough to alter flow into the reservoirs, therefore it is unlikely to affect the probability of deep reservoir drawdown which is the mechanism of concern for initiating landslide formation.
- RFFA 6: Fishery management and killer whales. The flow targets in the WVS are specific to the river reaches and habitat where they occur. They are not variable based on Pacific Ocean salmon returns. Therefore deep drawdowns to meet flow targets that could impact geologic deposits are not impacted by this factor.
- RFFA 8: Invasive species management. Does not affect reservoir regulation decisions for the WVS dams or removal of geologic materials.

Therefore, these RFFAs are dismissed from further analysis.

### 4.4.2 Cumulative Effects to Geology and Soils by Alternative

Construction of the Willamette Valley projects altered local geology because several necessary tasks for dam construction require removal of geologic materials. Foundation preparation at many locations involved stripping of overburden and unsuitable rock until competent rock was reached. Construction of the dam spillway and core trench often require blasting and excavation. Additionally, materials for the dam embankments are often excavated from local borrow areas. Initial filling and drawdown of the reservoir and activities associated with construction of the dam sometimes initiate landslides or steepen slopes so that rockfall and landslides are more likely. For example, at Lookout Point relocation of the highway and railroad during construction reactivated the Minnow slide deposit and the first drawdown of the reservoir formed the Voss slide (see section 3.4.1.6). Activities related to construction and the first fill and drawdown cycle of the reservoir-initiated soil creep and landslides at Cougar, Detroit, Dorena, Fall Creek, Green Peter, Hills Creek, Lookout Point. These landslides are likely to continue to occur during periods of very wet weather or reduction of the reservoir stage. Construction of other dams and reservoirs in the Willameete River Basin are unlikely to directly effect the formation of landslides at the Willamette Valley projects.

As discussed in section 3.3.3.1, there are several near-term operations related to the injunction that are expected to require deep drawdown of the reservoir that could result in moderate landslide effects at Lookout Point and Cougar, minor landslide effects at Green Peter, and negligible effects to landslides at Fall Creek. There are also projects may result in excavation of geologic materials. These effects are additive.

An increase to water withdrawals to meet municipal, industrial, and agricultural demand (RFFA 3) would result in more stored water being released from the reservoir to meet downstream flow targets, which may mean that in dry years reservoir levels will decrease more quickly to minimal pool elevations in order to meet flow targets. Water withdrawals would be additive effect on landslide formation.

This PEIS contains measures that would alter the flow targets downstream of the WVS dams to meet tribal, state, and local fish and wildlife improvement goals (RFFA 7). Under some alternatives during spring and summer of dry years reservoirs would need to be lowered more rapidly and would be drawn down deeper than the current minimum elevation in order to meet these targets. This effect would be additive for landslide formation.

Climate change (RFFA 9) is anticipated to reduce the amount of precipitation that falls as snow in the winter, which would cause basin-wide flows to be reduced earlier in spring than when it has historically occurred. This leads to an earlier reduction in reservoir water surface elevations starting in late spring through summer and fall. This increases the probability that the reservoir will be drawn down to its minimum elevation during dry years. This increases shoreline exposure and is an additive effect for landslide formation. Additionally, climate change is anticipated to increase the risk of forest fire. Because tree roots bind soil together, loss of trees due to forest fires increases the erodibility of soils and reduces the strength of slopes, allowing for otherwise stable slopes to initiate failure.

Removal of material associated with mining (RFFA 10) can result in over steepened slopes. Mining in areas where landslides are already present exacerbates existing slope stability issues. Green Peter and Lookout Point have mining claims located on mapped landslide areas that would have an additive effect on the environmental consequences of near-term operations and proposed alternatives.

The roots of trees have a stabilizing effect on soils and removing trees during timber and logging industry operations (RFFA 11) kills the roots, which can result in slope instability, especially in areas that have existing landslides and are already prone to slope failure. Cougar and Lookout Point have historic logging operations in areas containing landslides that would have an additive synergistic effect to landslide formation.

#### *4.4.2.1 No Action Alternative*

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under the No Acton Alternative due to landslide formation. As discussed in section 3.4.3.1, the effects of the NAA do not appreciably change the geomorphology and sediment processes, or the closely related hydrology and hydraulics, of the WVS from the existing conditions. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under the NAA, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.3.1.

##### *4.4.2.1.1 Santiam Subbasin*

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under the NAA. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir. Near term operations at Detroit and Green Peter would cause deeper drawdowns and increase the probability of landslide formation. Because no operations are proposed to meet flow targets that would cause a reduction in reservoir elevations in the Santiam Subbasin projects, no differential effects on landslide formation from fish and wildlife improvement is expected to occur. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit (ODF, 2022) have occurred in areas with landslides, which would potentially destabilize slopes. Both increased water withdrawals due to demand and climate change have additive effects for Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under the NAA are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

##### *4.4.2.1.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

##### *4.4.2.1.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the NAA. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Near term operations at Cougar would cause deeper drawdowns and increase the probability of landslide formation. Because no operations are proposed to meet flow targets that would cause a reduction in reservoir elevation at Cougar no differential effects on landslide formation from fish and wildlife improvement is expected to occur. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would reduce slope stability. Both increased water withdrawals due to demand and climate change have effects for at Cougar. In summary, cumulative effects due to past, current, and future actions under the NAA are anticipated for Cougar, but not at Blue River, since it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

##### *4.4.2.1.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin several RFFA's have an additive effect on environmental consequences under the NAA. Construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs. Near-term operations at Hills Creek and Lookout point would influence landslide formation. Because no operations are proposed to meet flow targets that would cause a reduction in reservoir elevation at Hills Creek and Lookout Point no differential effects on landslide formation from fish and wildlife improvement is expected to occur. Mining claim activity and timber harvesting at Lookout Point have occurred in areas with landslides (Causey, J.D., 2011; DOGAMI, 2022; ODF, 2022). Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. In summary, cumulative effects due to past, current, and future actions under the NAA are anticipated for Hills Creek and Lookout Point, but not at Dexter or Fall Creek, since they do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

##### *4.4.2.1.5 Coast Fork of the Willamette Subbasin*

Under the NAA, no Coast Fork subbasin projects are expected to have environmental consequences due to landslides.

#### ***4.4.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures***

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under Alternative 1 due to conditions that increase the probability of landslide formation occurring. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under Alternative 1, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.4.1.

##### 4.4.2.2.1 Santiam Subbasin

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under Alternative 1. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir. Near term operations at Detroit and Green Peter would cause deeper drawdowns and increase the probability of landslide formation. Because all measures that cause a reduction in reservoir elevation at Detroit and Green Peter are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit (ODF, 2022) have occurred in areas with landslides. Both increased water withdrawals due to demand and climate change would have effects at Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under Alternative 1 are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.2.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.2.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 1. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Deep drawdowns at Cougar related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Cougar are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would further destabilize slopes. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Cougar. In summary, cumulative effects due to past, current, and future actions under Alternative 1 are anticipated for Cougar, but not at Blue River because it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.2.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 1. Construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs. Deep drawdowns at Lookout Point related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Hills Creek and Lookout Point are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Mining claim activity and timber harvesting at Lookout Point have occurred in areas with landslides (Causey, J.D., 2011; DOGAMI, 2022; ODF, 2022). Both increased water withdrawals due to demand and climate change would have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. In summary, cumulative effects due to past, current, and future actions under Alternative 1 are anticipated for Hills Creek and Lookout Point, but not at Dexter or Fall Creek, since they do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

##### *4.4.2.2.5 Coast Fork of the Willamette Subbasin*

In the Coast Fork subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 1. Construction associated with Dorena Dam initiated landslides that are in contact with the reservoir. Because all measures that cause a reduction in reservoir elevation at Dorena are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Dorena (ODF, 2022). Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Dorena. Based on the cumulative effects of past, current, and future actions under alternative 1 are anticipated for Dorena, but not at Cottage Grove, since it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### ***4.4.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under Alternative 2A due to conditions that increase the probability of landslide formation occurring. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under Alternative 2A, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.4.1.

##### *4.4.2.3.1 Santiam Subbasin*

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under Alternative 2A. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 2A. Near term operations at Detroit would cause deeper drawdowns and increase the probability of landslide formation. Near term operations at Green Peter are the same as the deeper fall reservoir drawdown for downstream fish passage under alternative 2A, so no incremental difference due to near term operations is expected for this project. Changes to flow targets under alternative 2A means that drawdowns down to above the RO at Green Peter are more likely to occur compared with the NAA. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit (ODF, 2022) have occurred in areas with landslides. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under Alternative 2A are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.3.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.3.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 2A. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Deep drawdowns at Cougar related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Cougar are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would further destabilize slopes. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Cougar. In summary, cumulative effects due to past, current, and future actions under Alternative 2A are anticipated for Cougar, but not at Blue River because it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.3.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin several RFFA's have an additive effect on environmental consequences under the alternative 2A. Construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs. Deep drawdowns at Lookout Point related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Hills Creek and Lookout Point are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Mining claim activity and timber harvesting at Lookout Point have occurred in areas with landslides (Causey, J.D., 2011; DOGAMI, 2022; ODF, 2022). Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. Based on the cumulative effects of past, current, and future actions under alternative 2A are anticipated for Hills Creek and Lookout Point, but not at Dexter or Fall Creek, since they do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.3.5 Coast Fork of the Willamette Subbasin*

Under alternative 2A no Coast Fork Willamette subbasin projects are expected to have environmental consequences due to landslides.

### *4.4.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under Alternative 2B due to conditions that increase the probability of landslide formation occurring. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under Alternative 2B, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.4.1.

#### *4.4.2.4.1 Santiam Subbasin*

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under Alternative 2b. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 2B. Near term operations at Detroit would cause deeper drawdowns and increase the probability of landslide formation. Near term operations at Green Peter are the same as the deeper fall reservoir drawdown for downstream fish passage under alternative 2B, so no incremental difference due to near term operations is expected for this project. Changes to flow targets under alternative 2B means that drawdowns down to above the RO at Green Peter are more likely to occur compared with the NAA, changes to flow targets have an additive effect to the environmental consequences due to landslides. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit have occurred in areas with landslides (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under Alternative 2B are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.4.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.4.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 2b. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Deep drawdowns at Cougar related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Cougar are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would further destabilize slopes. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Cougar. In summary, cumulative effects due to past, current, and future actions under Alternative 2B are anticipated for Cougar, but not at Blue River because it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

##### *4.4.2.4.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin several RFFA's have an additive effect on environmental consequences under the alternative 2B. Construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs. Deep drawdowns at Lookout Point related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Hills Creek and Lookout Point are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Mining claim activity and timber harvesting at Lookout Point (Causey, J.D., 2011; DOGAMI, 2022; ODF, 2022) have occurred in areas with landslides. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. Based on the cumulative effects of past, current, and future actions under alternative 2B are anticipated for Hills Creek and Lookout Point, but not at Dexter or Fall Creek, since they do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

##### *4.4.2.4.5 Coast Fork of the Willamette Subbasin*

Under alternative 2B no Coast Fork subbasin projects are expected to have environmental consequences due to landslides.

#### ***4.4.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative***

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under Alternative 3A due to conditions that increase the probability of landslide formation occurring. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under Alternative 3A, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.4.1

#### *4.4.2.5.1 Santiam Subbasin*

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under Alternative 3a. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir. Near term operations at Detroit would cause deeper drawdowns and increase the probability of landslide formation. Near term operations at Green Peter are the same as the deeper fall reservoir drawdown for downstream fish passage under alternative 3A, so no incremental difference due to near term operations is expected for this project. Changes to flow targets under alternative 3A means that drawdowns down to above the RO at Detroit and Green Peter are more likely to occur compared with the NAA, changes to flow targets have an additive effect to the environmental consequences due to landslides. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit have occurred in areas with landslides (ODF, 2022). Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under Alternative 3A are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.5.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.5.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 3a. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Deep drawdowns at Cougar related to near term operations would increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides, but because the near term operation is the same as the deeper fall reservoir drawdown for downstream fish passage under alternative 3A, no incremental difference due to near term operations is expected for this project. Changes to flow targets under alternative 3A means that drawdowns down to above the RO at Cougar are more likely to occur compared with the NAA, changes to flow targets have an additive effect to the environmental consequences on landslides. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would further destabilize slopes. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Cougar. In summary, cumulative effects due to past, current, and future actions under Alternative 3A are anticipated for Cougar, but not at Blue River because it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.5.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin several RFFA's have an additive effect on environmental consequences under the alternative 3A. Construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs. Near term operations at Lost Creek are the same as the deeper fall reservoir drawdown for downstream fish passage under alternative 3A, so no incremental difference due to near term operations is expected for this project. Changes to flow targets under alternative 3A means that drawdowns down to above the RO at Hills Creek and Lookout Point are more likely to occur compared with the NAA, changes to flow targets have an additive effect to the environmental consequences due to landslides. Mining claim activity (Causey, J.D., 2011; DOGFAMI, 2022) and timber harvesting at Lookout Point have occurred in areas with landslides (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. Based on the cumulative effects of past, current, and future actions under alternative 3A are anticipated for Lookout Point, but not at Hills Creek, Dexter, or Fall Creek. Hills Creek does not have anticipated environmental consequences under this alternative and Dexter and Fall Creek do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.5.5 Coast Fork of the Willamette Subbasin*

In the Coast Fork subbasin, construction associated with Dorena Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 3A. Because all measures that cause a reduction in reservoir elevation at Dorena are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Dorena (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Dorena. Based on the cumulative effects of past, current, and future actions under alternative 3A are anticipated for Dorena, but not at Cottage Grove, since it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

### ***4.4.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)***

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under Alternative 3B due to conditions that increase the probability of landslide formation occurring. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under Alternative 3B, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.4.1

#### *4.4.2.6.1 Santiam Subbasin*

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under Alternative 3b. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 3B. Near term operations at Detroit would cause deeper drawdowns and increase the probability of landslide formation. Near term operations at Green Peter are the same as the deeper fall reservoir drawdown for downstream fish passage under alternative 3B, so no incremental difference due to near term operations is expected for this project. Changes to flow targets under alternative 3B means that drawdowns down to above the RO at Detroit and Green Peter are more likely to occur compared with the NAA, changes to flow targets have an additive effect to the environmental consequences due to landslides. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit have occurred in areas with landslides (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under Alternative 3A are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.6.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.6.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 3B. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Deep drawdowns at Cougar related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Changes to flow targets under alternative 3B means that drawdowns down to above the RO at Cougar are more likely to occur compared with the NAA, which would potentially initiate landslide formation. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would decrease slope stability. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Cougar. In summary, cumulative effects due to past, current, and future actions under Alternative 3A are anticipated for Cougar, but not at Blue River because it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.6.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin, construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs and would have an additive effect on environmental consequences due to landslides under alternative 3B. Near term operations at Lost Creek are the same as the deeper fall reservoir drawdown for downstream fish passage under alternative 3B, so no incremental difference due to near term operations is expected for this project. Because all measures that cause a reduction in reservoir elevation at Hills Creek and Lookout Point are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Mining claim activity and timber harvesting at Lookout Point have occurred in areas with landslides (Causey, J.D., 2011; DOGAMI, 2022; ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. Based on the cumulative effects of past, current, and future actions under alternative 3B are anticipated for Lookout Point, but not at Hills Creek, Dexter, or Fall Creek. Hills Creek does not have anticipated environmental consequences under this alternative and Dexter and Fall Creek do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.6.5 Coast Fork of the Willamette Subbasin*

In the Coast Fork subbasin, construction associated with Dorena Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 3B. Because all measures that cause a reduction in reservoir elevation at Dorena are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Dorena (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Dorena. Based on the cumulative effects of past, current, and future actions under alternative 3B are anticipated for Dorena, but not at Cottage Grove, since it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

### ***4.4.2.7 Alternative 4 – Structures-Based Fish Passage Alternative***

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under Alternative 4 due to conditions that increase the probability of landslide formation occurring. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under Alternative 4, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.4.1

#### *4.4.2.7.1 Santiam Subbasin*

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under Alternative 4. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 4. Near term operations at Detroit and Green Peter would cause deeper drawdowns and increase the probability of landslide formation. Because all measures that cause a reduction in reservoir elevation at Detroit and Green Peter are directly related to meeting flow targets, no differential effects on landslide formation would occur. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit have occurred in areas with landslides (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under Alternative 4 are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.7.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.7.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 4. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Deep drawdowns at Cougar related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Cougar are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Cougar. In summary, cumulative effects due to past, current, and future actions under Alternative 3A are anticipated for Cougar, but not at Blue River because it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.7.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin several RFFA's have an additive effect on environmental consequences under the alternative 4. Construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs. Deep drawdowns at Lookout Point related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Hills Creek and Lookout Point are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Mining claim activity and timber harvesting at Lookout Point (Causey, J.D., 2011; DOGAMI, 2022; ODF, 2022) have occurred in areas with landslides. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. Based on the cumulative effects of past, current, and future actions under alternative 4 are anticipated for Hills Creek and Lookout Point, but not at Dexter or Fall Creek, since they do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.7.5 Coast Fork of the Willamette Subbasin*

In the Coast Fork subbasin, construction associated with Dorena Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 4. Because all measures that cause a reduction in reservoir elevation at Dorena are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Timber harvesting has occurred in areas with landslides at Dorena (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Dorena. Based on the cumulative effects of past, current, and future actions under alternative 4 are anticipated for Dorena, but not at Cottage Grove, since it does not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

### *4.4.2.8 Alternative 5 – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Combined with the effects of the RFFAs including climate change, there would likely be additional effects to geology (changes from existing condition) under Alternative 2B due to conditions that increase the probability of landslide formation occurring. For all subbasins that are expected to have cumulative effects on the probability of landslides occurring due to past, current, and future actions under Alternative 2B, the expected cumulative effect is additive, synergistic, indirect, and of unknown magnitude. However, any cumulative effect that increases the probability of landslide formation is not expected to change the scale of the effect from activation of landslides within the Santiam basin based on the criteria in section 3.4.1

#### *4.4.2.8.1 Santiam Subbasin*

In the Santiam subbasin several RFFA's have an additive effect on environmental consequences under Alternative 5. Construction associated with Green Peter Dam initiated landslides that are in contact with the reservoir and would have an additive effect on environmental consequences due to landslides under alternative 5. Near term operations at Detroit and Green Peter would cause deeper drawdowns and increase the probability of landslide formation. Changes to flow targets under alternative 5 means that drawdowns down to above the RO at Green Peter are more likely to occur compared with the NAA, changes to flow targets have an additive effect to the environmental consequences due to landslides. Mining claim activity at Green Peter (Causey, J.D., 2011; DOGAMI, 2022) and timber harvesting at Detroit have occurred in areas with landslides (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Detroit and Green Peter. In summary, cumulative effects due to past, current, and future actions under Alternative 5 are anticipated for Detroit and Green Peter, but not at Big Cliff or Foster. Big Cliff does not have existing landslide areas and Foster is not anticipated to have increased shoreline exposure, and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.8.2 Long Tom Subbasin*

There are no landslides in contact with the reservoir at Fern Ridge, therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.8.3 McKenzie Subbasin*

In the McKenzie subbasin several RFFA's have an additive effect on environmental consequences under the Alternative 5. Construction associated with Cougar Dam initiated landslides that are in contact with the reservoir. Deep drawdowns at Cougar related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Changes to flow targets under alternative 5 means that drawdowns down to above the RO at Cougar are more likely to occur compared with the NAA, changes to flow targets have an additive effect to the environmental consequences on landslides. Timber harvesting has occurred in areas with landslides at Cougar (ODF, 2022), which would have an additive effect on environmental consequences. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Cougar. Based on the cumulative effects of past, current, and future actions under alternative 5, an additive indirect effect of unknown magnitude on the probability of landslides occurring is expected. However, this probability increase is not expected to change the scale of the effect from activation of landslides within the McKenzie subbasin based on the criteria in section 3.3.1.

#### *4.4.2.8.4 Middle Fork of the Willamette Subbasin*

In the Middle Fork subbasin several RFFA’s have an additive effect on environmental consequences under the alternative 5. Construction associated with Hills Creek and Lookout Point Dams initiated landslides that are in contact with the reservoirs. Deep drawdowns at Lookout Point related to near term operations are anticipated to increase shoreline exposure and may decrease slope stability due to erosion and small-scale slope failures in areas that have existing landslides. Because all measures that cause a reduction in reservoir elevation at Hills Creek and Lookout Point are directly related to meeting flow targets, no differential effects on landslide formation are expected to occur. Mining claim activity and timber harvesting at Lookout Point (Causey, J.D., 2011; DOGAMI, 2022; ODF, 2022) have occurred in areas with landslides. Both increased water withdrawals due to demand and climate change have synergistic additive effects for environmental consequences at Hills Creek and Lookout Point. Based on the cumulative effects of past, current, and future actions under alternative 5 are anticipated for Hills Creek and Lookout Point, but not at Dexter or Fall Creek, since they do not have existing landslide areas and therefore no environmental consequences due to landslides are expected under any alternative.

#### *4.4.2.8.5 Coast Fork of the Willamette Subbasin*

Under Alternative 5 no Coast Fork subbasin projects are expected to have environmental consequences due to landslides.

## 4.5 WATER QUALITY

### 4.5.1 Cumulative Effects Analysis Methodology for Water Quality

#### *4.5.1.1 Cumulative Actions Applicable to Water Quality*

Past, present, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on Water Quality, include:

- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development.
- RFFA 2: Reduced agriculture production
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 4: Decarbonizing the energy sector with renewable energy sources.
- RFFA 5: Federal and state wildlife and lands management
- RFFA 7: Tribal, state, and local fish and wildlife improvement.
- RFFA 8: Invasive species management.
- RFFA 9: Climate change
- RFFA 10: Mining operations.

Some of the other RFFAs discussed in Section 4.2.3 would not occur at or in close proximity to the WVS dams and reservoirs and as such would not have a cumulative effect on Water Quality. Had they occurred at or in close proximity to the WVS dams and reservoirs, they would have contributed to cumulative effects for Water Quality.

- RFFA 6: Fishery management and Killer Whales. No direct effect to Water Quality as this is managing effects of fisheries on Chinook, including UWR Chinook, and survivability of Killer Whales.
- RFFA 11: Timber and logging industry operations. Water Quality would not be affected as the Willamette Valley is not projected to be a focus of timber and logging operations in the foreseeable future.

Therefore, these RFFAs are dismissed from further analysis.

### 4.5.2 Cumulative Effects to Water Quality by Alternative

Construction of the Willamette Valley dams has changed downstream water temperatures to be unnaturally cool in the summer and warm in the winter. As water is released over the spillway this creates Total Dissolved Gas (TDG) which can be detrimental to aquatic species. Increased turbidity levels typically occur due to drawdown operations of the reservoir or high flow events due to precipitation. During construction of the WVS dams' contaminants may have been introduced which may require removal.

Future population growth, urban, industrial, and commercial development (RFFA 1) may cause adverse effects due to an increase in water demand and potential runoff downstream of the WVS dams. An increase in runoff may introduce non-point and point source pollution which would affect water quality. An increase in the source pollution inputs may contain contaminants and nutrient inputs. Increased nutrient inputs may also facilitate harmful algae bloom growth. Water demand from population growth and development could cause an increase in water temperatures due to a decrease of instream flow.

Reduced agricultural production (RFFA 2) would decrease cropland and potentially reduce water demands for irrigation although conversely this is due to an increase population growth and accompanying urban, industrial, and commercial development (RFFA 1). A reduction of agricultural development is beneficial to water quality whereas an increase in population growth would adversely affect water quality.

There could be adverse effects from increased volumes of water withdrawals for Municipal, Industrial, and Agricultural Uses (RFFA 3). An increase in water withdrawals would likely affect instream water temperatures as less water would be available in water segments to keep temperatures cool. This would likely create unsuitable habitat for aquatic species.

There may be possible adverse effects due to Decarbonizing the energy sector with renewable energy sources (RFFA 4) due to the potential for an increase in lack-of-market/lack-of-turbine-capacity spill, which could lead to higher TDG levels. Conversely, decarbonizing, and electrifying transportation and other sectors could reduce involuntary spill from lack-of-market spill.

A cumulative effect of Federal and State Wildlife and Land Management (RFFA 5) with the actions proposed in this Draft PEIS may benefit Water Quality. Watershed protection and conservation projects may provide an improvement to aquatic habitat and species. Water Quality parameters, such as water temperature, may also benefit depending on the wildlife and land management strategies.

Tribal, state, and local fish and wildlife improvement (RFFA 7) may be beneficial to water quality. Conservation and restoration efforts may provide a benefit to water quality by providing an improvement to aquatic habitat and species. Water Quality parameter such as temperature may also benefit due to land management strategies.

Invasive species management (RFFA 8) would assist in removal of non-native species that are a detriment to native species by predation or competition for food sources. Invasive plant species, such as milfoil, have the potential to decrease dissolved oxygen levels in a water body. Low dissolved oxygen can adversely affect fish and aquatic species. Removal and replacement of native species would thereby have a positive effect on Water Quality.

Climate change (RFFA 9) would affect water quality due to an increase in air temperature which would increase water temperatures. Greenhouse gas emissions are comprised of carbon dioxide, nitrous oxide, methane, and ozone. An increase in air temperature due to greenhouse gases may cause an increase water temperature. These gases can also potentially lower pH levels in waters which can cause an unsuitable environment for aquatic species.

Mining operations (RFFA 11) has the potential to adversely affect water quality by introducing minerals and contaminants via runoff downstream of dams. Majority of identified mines occur in Douglas and Lane counties. Mines occurring in Lane County may adversely affect water quality for the Coast Fork Willamette, Middle Fork Willamette, and McKenzie subbasins.

**Table 4.5-1. Summary of Reasonably Foreseeable Future Actions Relevant to Water Quality**

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| RFFA 1 | Future population growth and urban, industrial, and commercial development | There may be adverse effects from increased water demand which cause an increase of instream water temperatures and pollution due to increased stormwater runoff from these sectors [All Alternatives]. |
| RFFA 2 | Reduced agricultural production | Potential beneficial effect to water quality due to decrease in cropland and water demand [All Alternatives]. |
| RFFA 3 | Water withdrawals for municipal, industrial, and agricultural uses | An increase in water withdrawals may cause adverse effects for instream water temperatures [All Alternatives]. |
| RFFA 4 | Decarbonizing the energy sector with renewable energy sources | Possible adverse effects due to potential increase in lack-of-market/lack-of-turbine capacity spill, which may lead to higher TDG levels. Decarbonizing and utilizing electrical transportation may reduce involuntary spill from lack-of-market spill [All Alternatives]. |
| RFFA 5 | Federal and state wildlife and lands management | Potential beneficial effect to water quality due to habitat restoration and land use management [All Alternatives]. |
| RFFA 7 | Tribal, State, and local fish and wildlife improvement | Potential beneficial effect to water quality due to habitat restoration [All Alternatives]. |
| RFFA 8 | Invasive Species Management | Potential benefit in removal of oxygen depleting plant species. An adverse effect if chemicals are utilized for removal management [All Alternatives]. |
| RFFA 9 | Climate change | Potential adverse effects from increased air temperature may result in increased water temperatures. There is potential for higher winter water volumes and lower summer water volumes. Potential increased water volumes may necessitate increase spill causing elevated |

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| | | TDG levels. A decrease in flow and water volumes in the summer may cause elevated instream water temperatures [All Alternatives]. |
| RFFA 11 | Mining Operations | Potential adverse effects due to contaminants entering waters via runoff [All Alternatives]. |

#### *4.5.2.1 No Action Alternative*

Within the Willamette Valley System water quality parameters include water temperature, TDG, Turbidity, HABs, and Mercury (Coast Fork Willamette). Under the No Action Alternative, the RFFA including Climate change has the greatest potential to alter these water quality parameters, please refer to section 3.6.3.1. As stated above, population growth along with municipal and industrial has the potential to increase instream water demand and stormwater run-off pollution. An increase of TDG exceedances may occur with decarbonizing the energy sector and lack of turbine capacity spill for hydropower generation. Non-point and point source pollution occurrence may increase in the due to mining operations and population growth. The summary of direct/indirect effects of the No Action Alternative are summarized in Table 3.5-9.

#### *4.5.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Cumulative effects to water quality for Alternative 1 measures and RFFA’s are described by Willamette Valley subbasins based on effects described in section 4.2.2. The summary of direct/indirect effects of Alternative 1 compared to the No Action Alternative are summarized in Table 3.5-13.

##### *4.5.2.2.1 North Santiam Subbasin*

Big Cliff downstream water temperatures observes a negligible effect of days below 18C during the summer and moderate benefit of days near temperature target from April through August with the inclusion of a Water Temperature Control tower at Detroit dam.

Structural improvements to reduce TDG at Detroit would have a major benefit at Big Cliff. Annual differences in number of days above 110% of TDG exceedances and below Detroit is reduced as compared to the NAA.

Turbidity has the potential to increase as there is a moderate change downstream of Detroit Dam in fine grained sediments entering Big Cliff run-of-reservoir. Turbidity may also increase with higher precipitation events anticipated due to Climate change.

HABs have the potential to increase as there is a major change in shoreline exposure and sediment re-entrainment at Detroit reservoir. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure at Detroit reservoir, which creates the potential for an increase in methylation due to water fluctuations. However, there are no foreseeable increases in anoxic waters. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for the shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.2.2 South Santiam Subbasin*

Foster observes major adverse effects to downstream water temperatures of days below 18C during the summer, moderate beneficial effect from April through August, and negligible effect from September through March as compared to the NAA. Alternative 1 includes a water temperature control tower at Green Peter.

Structural improvements to reduce TDG at Green Peter and Foster would have a negligible effect as compared to the NAA.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine grained sediments entering Foster reservoir which may partially settle. Turbidity may also increase with higher precipitation events anticipated due to Climate change.

HABs has the potential to increase as there is a major change for shoreline exposure and sediment re-entrainment at Green Peter reservoir. Foster reservoir has the potential for negligible changes for shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation.

Mercury has the potential to increase as there is a major change in shoreline exposure at Green Peter reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Foster reservoir would be negligible for shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.2.3 McKenzie Subbasin*

Cougar downstream water temperatures would observe a negligible effect as there is already a water temperature control tower on site. However, cumulative actions including Climate change, water demands and mainstem flow targets may minor additive adverse cumulative effects to water temperatures in the subbasin. Blue River is low priority for water temperature control.

A beneficial effect to TDG is observed when including structural improvement at Cougar. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change.

Turbidity has the potential to increase as fine-grained sediment supply passing downstream of Cougar observes a minor change and Blue River would observe a moderate change.

A major change in shoreline exposure is observed at Cougar and Blue River which may increase the potential for HAB growth. Sediment Re-entrainment has the potential for a moderate change at Cougar and major change for Blue River. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Cougar and Blue River reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.2.4 Middle Fork Willamette Subbasin*

Hills Creek would have a minor adverse effect to water temperature targets in the summer which would mean an increase of the days of cooler (<18C or 64F) released downstream water temperatures. The inclusion of a water temperature control tower at Lookout Point would affect Dexter downstream water temperatures as Dexter is a reregulating dam. Downstream water temperatures at Dexter would have a moderate adverse effect of days below 18C in the summer, although a minor benefit is observed for days near the target temperature from April through August.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments compared to the NAA passing out of Hills Creek into the Middle Fork Willamette above Lookout Point. Dexter reservoir would have potential for minor change in fine grained sediment and negligible potential for change in sediment supply downstream of Dexter Dam.

HABs have the potential to increase as a major change in shoreline exposure compared to the NAA is observed at Hills Creek and Lookout Point. Sediment Re-entrainment results in a major change for Hills Creek and minor change for Lookout Point. Fall Creek would observe negligible change and Dexter reservoir is a run-of-river project and is not included in these metrics. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Hills Creek and Lookout Point reservoirs there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Fall Creek reservoir would see negligible change relative to the NAA. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.2.5 Coast Fork Willamette and Long Tom Subbasin*

There are no measures for water temperature or TDG at Cottage Grove, Dorena or Fern Ridge as such conditions are expected to remain similar to the NAA. A decrease of water surface elevations at Cottage Grove and Dorena during conservation season may increase fine-grained sediment release which may affect Turbidity levels. Cumulative actions of operations and deeper drafts at Cottage Grove and Dorena would have a major change to shoreline exposure relative to the NAA which may affect the mercury methylation process and increase the potential for algal blooms by resuspension of sediment with nutrients. As the reservoir would fill in the fall and winter, the exposed shoreline would expect to increase the likelihood of the methylation process.

##### *4.5.2.2.6 Mainstem Willamette*

Mainstem Willamette at Albany and Salem water temperatures observe minor adverse temperature effects in the summer. A decrease of instream flows during conservation season, from late spring through early fall, along with cumulative actions of instream water withdrawals and Climate change may exacerbate water temperatures. The additional water storage at WVS reservoirs may alleviate the increase in summer water temperatures. Currently there are only summer water temperature targets for the Mainstem Willamette. Water quality parameters such as TDG, Turbidity, HABs are negligible or have not been reported as a concern.

#### ***4.5.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Cumulative effects to water quality for Alternative 2A measures and RFFA’s are described by Willamette Valley subbasins based on effects described in section 4.2.2. The summary of direct/indirect effects of Alternative 2A compared to the No Action Alternative are summarized in Table 3.5-12.

##### *4.5.2.3.1 North Santiam Subbasin*

Big Cliff downstream water temperatures observes a negligible effect of days below 18C during the summer and moderate benefit of days near temperature target from April through August with the inclusion of a Water Temperature Control tower at Detroit dam.

A moderate benefit is observed at Detroit and Big Cliff for TDG levels as the annual difference in number of days above 110% TDG levels is less as compared to the NAA.

Turbidity has the potential to increase as there is a moderate change downstream of Detroit Dam in fine grained sediments entering Big Cliff reservoir and minor change of the fine-grained sediments passing downstream into the North Santiam. Adverse effects from RFFA's (section 4.2.2) may increase the potential for Turbidity.

HABs have the potential to change as there is a negligible change in head-of-reservoir sediment mobilization and a major change in shoreline exposure. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure at Detroit reservoir, which creates the potential for an increase in methylation due to water fluctuations. However, there are no foreseeable increases in anoxic waters. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for the shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.3.2 South Santiam Subbasin*

Foster observes negligible effects to downstream water temperatures with days below 18C (64.4F) during the summer with the use of the spillway for surface spill in the summer at Green Peter reservoir. Moderate beneficial effects to downstream water temperatures from April through August which may be due to the modifications to increase warm water releases through a Foster Warm Water Supply (FWWS) pipe and fish weir at Foster Dam. A minor beneficial effect from September through March may be due to the use the RO's discharge of colder water during fall and winter drawdown operations at Green Peter reservoir.

There are no measures for TDG abatement at Green Peter and Foster. Adverse effects to TDG levels are observed for both reservoirs which may be due to the increase of spill as compared to the NAA. A measure to use the spillway for surface spill in the summer at Green Peter may contribute to the increase of TDG levels.

Turbidity has the potential to increase as there is potential for major change of sediment supply in fine grained sediments entering Foster reservoir which may partially settle and may pass a moderate change of the fine-grained sediments downstream into the South Santiam. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase turbidity as winter precipitation is projected to increase this may increase sediment downstream of the dams.

HABs have the potential to increase as there is a major change for shoreline exposure and sediment re-entrainment at Green Peter reservoir. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Green Peter reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Foster reservoir would be negligible for shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.3.3 McKenzie Subbasin*

Cougar downstream water temperatures would observe a negligible effect as there is already a water temperature control tower on site although cumulative actions including Climate change, water demands and mainstem flow targets may alter this effect.

A negligible effect to TDG is observed as there are no TDG measures at Cougar. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change.

Turbidity has the potential to increase as fine-grained sediment supply passing downstream of Cougar would observe a minor change and Blue River would observe a moderate change.

A major change in shoreline exposure is observed at Cougar and Blue River which may increase the potential for HAB growth. Sediment Re-entrainment has the potential for a moderate change at Cougar and major change for Blue River. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Cougar and Blue River reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.3.4 Middle Fork Willamette Subbasin*

There are no Water Temperature measures for the Middle Fork Willamette. Cumulative effects at Hills Creek and Lookout Point storing more water in the spring and increasing water surface elevations. Hills Creek would have a moderate adverse effect to water temperature targets in the summer which would mean an increase of the days of cooler (<18C or 64F) released downstream water temperatures. Downstream water temperatures at Dexter would have a negligible effect of downstream water temperatures as compared to the NAA.

TDG level effects would be negligible for Hills Creek and Dexter as there are no TDG measures and has no reduction of days of TDG exceedances for the year (Appendix D, Figure 2-35). Fall Creek reservoir does not have a TDG gage and effects would be similar to the NAA and Affected Environment.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments passing out of Hills Creek into the Middle Fork Willamette above Lookout Point. Dexter reservoir would have potential for minor change in fine grained sediment and negligible potential for change in sediment supply downstream of Dexter Dam.

HABs have the potential to increase as a major change in shoreline exposure is observed at Hills Creek and Lookout Point. Sediment Re-entrainment results in a major change for Hills Creek and minor change for Lookout Point. Fall Creek would observe negligible change and Dexter reservoir is a run-of-river project and is not included in these metrics. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Hills Creek and Lookout Point reservoirs there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Fall Creek reservoir would see negligible change relative to the NAA. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.3.5 Coast Fork Willamette and Long Tom Subbasin*

There are no water temperature or TDG measures at Cottage Grove, Dorena or Fern Ridge as such conditions are expected to remain similar to the NAA. Negligible effects are expected for Turbidity, HABs and Mercury. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

##### *4.5.2.3.6 Mainstem Willamette*

Mainstem Willamette at Albany and Salem water temperatures observes negligible effects to water temperature in the summer. A decrease of instream flows during conservation season, from late spring through early fall, along with cumulative actions of instream water withdrawals and Climate change may exacerbate water temperatures. Currently there are only summer water temperature targets for the Mainstem Willamette. TDG gages are not located on the Willamette River as TDG concerns are typically located downstream of WVS dams. There is a negligible potential for changes in sediment supply relative to the NAA in the Middle Willamette free-flowing reach as such Turbidity is not expected to increase. HABs are not expected as there are no OHA advisories near Albany and Salem in public records. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

#### ***4.5.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Cumulative effects to water quality for Alternative 2B measures and RFFA's are described by Willamette Valley subbasins based on effects described in section 4.2.2. The summary of direct/indirect effects of Alternative 2B compared to the No Action Alternative are summarized in Table 3.5-16.

#### *4.5.2.4.1 North Santiam Subbasin*

Big Cliff downstream water temperatures observes a negligible effect of days below 18C (64.4F) during the summer and moderate benefit of days near temperature target from April through August and major benefit for days near temperature target from September through March with the inclusion of a Water Temperature Control tower at Detroit dam.

No TDG measures are included in Alternative 2B although a moderate benefit is observed at Detroit and Big Cliff for TDG levels as the annual difference in number of days above 110% TDG levels is less as compared to the NAA.

Turbidity has the potential to increase as there is a moderate change downstream of Detroit Dam in fine grained sediments entering Big Cliff reservoir and minor change of the fine-grained sediments passing downstream into the North Santiam. Adverse effects from RFFA's (section 4.2.2) may increase the potential for Turbidity.

HABs have the potential to increase at Detroit Reservoir as there is a major change in shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Detroit reservoir, which creates the potential for an increase in methylation due to water fluctuations. However, there are no foreseeable increases in anoxic waters. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for the shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.4.2 South Santiam Subbasin*

Foster observes negligible effects to downstream water temperatures with days below 18C (64.4F) during the summer with the use of the spillway for surface spill in the summer at Green Peter reservoir. Moderate beneficial effects to downstream water temperatures from April through August which may be due to the modifications to increase warm water releases through a Foster Warm Water Supply (FWWS) pipe and fish weir at Foster Dam. A minor beneficial effect from September through March may be due to the use the RO's discharge of colder water during fall and winter drawdown operations at Green Peter reservoir.

There are no measures for TDG abatement at Green Peter and Foster. Major adverse effects to TDG levels are observed at Green Peter and moderate adverse effect at Foster reservoirs which may be due to the increase of spill as compared to the NAA. A measure to use the spillway for surface spill in the summer at Green Peter may contribute to the increase of TDG levels.

Turbidity has the potential to increase as there is potential for major change of sediment supply in fine grained sediments entering Foster reservoir which may partially settle and may pass a moderate change of the fine-grained sediments downstream into the South Santiam. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase this may increase sediment downstream of the dams.

HABs have the potential to increase as there is a major change for head-of-reservoir sediment mobilization, shoreline exposure and sediment re-entrainment at Green Peter reservoir. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Foster reservoir has a minor change for potential head-of-reservoir sediment mobilization and negligible change for shoreline exposure and sediment re-entrainment. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Green Peter reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Foster reservoir would be negligible for shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.4.3 McKenzie Subbasin*

Cougar downstream water temperatures would observe a negligible to minor beneficial effect as there is a water temperature control tower on site although cumulative actions including Climate change, water demands and mainstem flow targets may alter this effect.

A minor beneficial effect to TDG at Cougar although there are not TDG measures for Alternative 2B. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change.

Turbidity has the potential to increase as fine-grained sediment supply passing downstream of Cougar would observe a major change and Blue River would observe a moderate change.

A major change at Cougar and negligible change at Blue River in the potential head-of-reservoir sediment mobilization and major change in shoreline exposure may increase the potential for HAB growth. Sediment Re-entrainment has the potential for a moderate change at Cougar and major change for Blue River. A resuspension and scour of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Cougar and Blue River reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.4.4 Middle Fork Willamette Subbasin*

There are no Water Temperature measures for the Middle Fork Willamette. Cumulative effects at Hills Creek and Lookout Point storing more water in the spring and increasing water surface elevations. Hills Creek would have a major adverse effect to water temperature targets in the summer which would mean an increase of the days of cooler (<18C or 64F) released downstream water temperatures. Downstream water temperatures at Dexter would have a negligible effect of downstream water temperatures as compared to the NAA.

TDG level effects would be negligible for Hills Creek, Lookout Point and Dexter as there are no TDG measures and has no reduction of days of TDG exceedances for the year (Appendix D Figure 2-35). Fall Creek reservoir does not have a TDG gage and effects would be similar to the NAA and Affected Environment.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments passing out of Hills Creek into the Middle Fork Willamette above Lookout Point. Dexter reservoir would have potential for minor change in fine grained sediment and negligible potential for change in sediment supply downstream of Dexter Dam.

HABs have the potential to increase as a major change in shoreline exposure is observed at Hills Creek and Lookout Point. Sediment Re-entrainment results in a major change for Hills Creek and minor change for Lookout Point. Fall Creek would observe negligible change and Dexter reservoir is a run-of-river project and is not included in these metrics. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Hills Creek and Lookout Point reservoirs there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Fall Creek reservoir would see negligible change relative to the NAA. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.4.5 Coast Fork Willamette and Long Tom Subbasin*

There are no water temperature or TDG measures at Cottage Grove, Dorena or Fern Ridge as such conditions are expected to remain similar to the NAA. Negligible effects are expected for Turbidity, HABs and Mercury. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

#### *4.5.2.4.6 Mainstem Willamette*

Mainstem Willamette at Albany and Salem water temperatures observes negligible effects to water temperature in the summer. A decrease of instream flows during conservation season, from late spring through early fall, along with cumulative actions of instream water withdrawals and Climate change may exacerbate water temperatures. Currently there are only summer water temperature targets for the Mainstem Willamette. Water quality parameters such as TDG, Turbidity, HABs are negligible or have not been reported as a concern. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

#### *4.5.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Cumulative effects to water quality for Alternative 3A measures and RFFA's are described by Willamette Valley subbasins based on effects described in section 4.2.2. The summary of direct/indirect effects of Alternative 3A compared to the No Action Alternative are summarized in Table 3.5-22.

##### *4.5.2.5.1 North Santiam Subbasin*

Big Cliff downstream water temperatures would observe a major adverse effect of days below 18C (64.4F) during the summer which may be due to utilizing the spillway for surface spill in the summer at Detroit. A moderate adverse effect of days near temperature target from April through August which may be due to utilizing the spill way for surface spill in the summer at Detroit. A minor benefit for days near temperature target from September through March which may be due to use of the RO's discharging colder water during drawdown operations in the fall and winter to reduce water temperatures below Detroit. A measure to line the lower RO tunnels to limit cavitation effects and to assist in temperature control at Detroit may provide a benefit.

TDG measure included in Alternative 3A include an operation of spreading of water over the spillway in order to reduce TDG % exceedances at Detroit and Big Cliff. Major Adverse effects are observed at Detroit and Big Cliff for TDG levels as the annual difference in number of days above 110% TDG levels as compared to the NAA. This is likely due to an increase in utilizing the spillway for surface spill.

Turbidity has the potential to increase as there is a major change of fine-grained sediments passing into Big Cliff fun-of-reservoir and moderate change of the fine-grained sediments passing downstream into the North Santiam. Adverse effects from RFFA's (section 4.2.2) may increase the potential for Turbidity.

HABs have the potential to increase at Detroit Reservoir as there is a major change in head-of-reservoir, shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Detroit reservoir, which creates the potential for an increase in methylation due to water fluctuations. However, there are no foreseeable increases in anoxic waters. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for the shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.5.2 South Santiam Subbasin*

Foster observes negligible effects to downstream water temperatures with days below 18C (64.4F) during the summer which may be attributed to Green Peter and Foster spillway use for surface spill in the summer. Moderate beneficial effects to downstream water temperatures from April through August with the use of the Green Peter and Foster spillways for surface spill in the summer. Minor beneficial effect from September through March with the use the RO's to discharge colder water during fall and winter drawdown operations at Green Peter reservoir.

There are no measures for TDG abatement at Green Peter and Foster. Major adverse effects to TDG levels is observed at Green Peter and moderate adverse effect at Foster. A measure to use the spillway for surface spill in the summer at Green Peter and Foster may contribute to the increase of TDG levels.

Turbidity may increase as there is potential for major change of sediment supply in fine grained sediments entering Foster reservoir which may partially settle and may pass a moderate change of the fine-grained sediments downstream into the South Santiam. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase which may increase sediment downstream of the dams.

HABs have the potential to increase as there is a major change for head-of-reservoir sediment mobilization, shoreline exposure and sediment re-entrainment at Green Peter reservoir. Foster reservoir has a minor change for potential head-of-reservoir sediment mobilization and negligible change for shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Green Peter reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Foster reservoir would be negligible for shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.5.3 McKenzie Subbasin*

Cougar downstream water temperatures would observe a negligible effect for days below 18C (64.4) in the summer, negligible effect for days near temperature target from April through

August, and minor adverse effect for days near temperature target from September through March. Cougar reservoir has a spring and fall drawdown which may limit ability to store water during conservation season. Blue River would store more water in the spring. Alternative 3A includes a measure to modify the spillway at Blue River dam to provide better water temperature management. Cumulative actions including Climate change, water demands and mainstem flow targets may alter water temperatures.

A negligible effect to TDG is observed at Cougar although as there are no TDG measures for Alternative 3A.

Turbidity has the potential to increase as fine-grained sediment supply passing downstream of Cougar and Blue River would observe a moderate change. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase which may increase sediment downstream of the dams.

Cougar observes a major change and Blue River a minor change for potential head-of-reservoir sediment mobilization. A major change in shoreline exposure at Cougar and Blue River may increase the potential for HAB growth. Sediment Re-entrainment has the potential for a moderate change at Cougar and Blue River. A resuspension and scour of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Cougar and Blue River reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.5.4 Middle Fork Willamette Subbasin*

Hills Creek would have a major adverse effect to water temperature targets in the summer which would mean an increase of the days of cooler (<18C or 64F) released downstream water temperatures. Beneficial effects are observed for Days near temperature targets for April through August and September through March at Hills Creek. Downstream water temperatures at Dexter would have a major adverse effect to water temperature targets in the summer with increase of the days of cooler released downstream water temperatures as compared to the NAA. Hills Creek will modify the spillway to use the spillway for surface spill in the summer.

TDG level effects would be negligible for Hills Creek and Lookout Point while Dexter would have minor adverse effects to TDG levels. A measure for spreading of spill across the dam for TDG management is included at Dexter. Fall Creek reservoir does not have a TDG gage and effects would be similar to the NAA and Affected Environment.

Turbidity has the potential to increase as there is a major change of sediment supply in fine-grained sediments into Dexter reservoir passing out of Lookout Point run-of-river reservoir.

Dexter reservoir would have potential for moderate change in fine grained sediment supply passing into the Middle Fork Willamette downstream of Dexter Dam.

HABs have the potential to increase with a minor change at Hills Creek and major change at Lookout Point for head-of-reservoir sediment mobilization relative to the NAA. A minor change at Hills Creek and major change at Lookout Point for shoreline exposure is observed. Sediment Re-entrainment results in a negligible effect for Hills Creek and major change for Lookout Point. Fall Creek would observe negligible change for head-of-reservoir, shoreline exposure and sediment re-entrainment metrics. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a minor change in shoreline exposure compared to the NAA at Hills Creek and major change at Lookout Point reservoirs there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Fall Creek reservoir would see negligible change relative to the NAA. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.5.5 Coast Fork Willamette and Long Tom Subbasin*

There are no water temperature or TDG measures at Cottage Grove, Dorena or Fern Ridge as such conditions are expected to remain similar to the NAA.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments passing into the Coast Fork Willamette and Row River from Cottage Grove dams.

HABs have the potential to increase with a major change for shoreline exposure and moderate change for sediment re-entrainment at Cottage Grove and Dorena dams. Fall creek would have a negligible change to the above metrics.

Mercury has the potential to increase with a major change to shoreline exposure which may affect the mercury methylation process at Cottage Grove and Dorena.

Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

##### *4.5.2.5.6 Mainstem Willamette*

Mainstem Willamette at Albany and Salem water temperatures observes minor adverse effects to water temperature in the summer. A decrease of instream flows during conservation season, from late spring through early fall, along with cumulative actions of instream water withdrawals and Climate change may exacerbate water temperatures. Currently there are only summer water temperature targets for the Mainstem Willamette. Water quality parameters such as

TDG, Turbidity, HABs are negligible or have not been reported as a concern. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

#### *4.5.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Cumulative effects to water quality for Alternative 3B measures and RFFA's are described by Willamette Valley subbasins based on effects described in section 4.2.2. The summary of direct/indirect effects of Alternative 3B compared to the No Action Alternative are summarized in Table 3.5-22.

##### *4.5.2.6.1 North Santiam Subbasin*

Big Cliff downstream water temperatures would observe negligible effects for all temperature targets. Measures include utilizing the spillway for surface spill in the summer at Detroit, lining of the lower RO tunnels to limit cavitation effects and to assist in temperature control at Detroit, utilizing the RO's to discharge cold water during drawdown operations in the fall and winter to reduce water temperatures below Detroit.

Alternative 3B includes a measure for operation of spreading of water over the spillway in order to reduce TDG % exceedances at Detroit and Big Cliff. Moderate Adverse effects are observed at Detroit and Big Cliff for TDG levels as the annual difference in number of days above 110% TDG levels as compared to the NAA. This is likely due to an increase in utilizing the spillway for surface spill.

Turbidity has the potential to increase as there is a moderate change of fine-grained sediments passing into Big Cliff fun-of-reservoir and minor change of the fine-grained sediments passing downstream into the North Santiam. Adverse effects from RFFA's (section 4.2.2) may increase the potential for Turbidity.

HABs have the potential to increase at Detroit Reservoir as there is a major change in head-of-reservoir, shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Detroit reservoir, which creates the potential for an increase in methylation due to water fluctuations. However, there are no foreseeable increases in anoxic waters. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for the shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.6.2 South Santiam Subbasin*

Foster observes major adverse effects to downstream water temperatures with days below 18C (64.4F) during the summer. Moderate beneficial effects to downstream water temperatures from April through August with the use of the Green Peter and Foster spillways for surface spill in the summer. Negligible effect from September through March with the use the RO's to discharge colder water during fall and winter drawdown operations at Green Peter reservoir.

Alternative 3B measure for TDG abatement is observed at Foster reservoir with spreading of spill. Green Peter has no TDG measure. Both reservoirs observe a minor adverse effect.

Turbidity may increase as there is potential for major change of sediment supply in fine grained sediments entering Foster reservoir which may partially settle and may pass a moderate change of the fine-grained sediments downstream into the South Santiam. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase which may increase sediment downstream of the dams.

HABs have the potential to increase as there is a major change for head-of-reservoir sediment mobilization, shoreline exposure and sediment re-entrainment at Green Peter reservoir. Foster reservoir has a minor change for potential head-of-reservoir sediment mobilization and negligible change for shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Green Peter reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Foster reservoir would be negligible for shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.6.3 McKenzie Subbasin*

Cougar downstream water temperatures would observe a negligible effect for days below 18C (64.4) in the summer, minor benefit for days near temperature target from April through August, and minor benefit effect for days near temperature target from September through March. Cougar reservoir includes a measure within Alternative 3B to modify a diversion tunnel for water temperature control. Blue River reservoir includes measures to modify the spillway for better water temperature management and use of the spillway in the summer for surface spill. Cumulative actions including Climate change, water demands and mainstem flow targets may alter water temperatures.

A minor beneficial effect to TDG is observed at Cougar although there are no TDG measures for Alternative 3B.

Turbidity has the potential to increase as fine-grained sediment supply passing downstream of Cougar and Blue River would observe a major and moderate change. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase which may increase sediment downstream of the dams.

Cougar observes a major change and Blue River a minor change for potential head-of-reservoir sediment mobilization. A major change in shoreline exposure at Cougar and Blue River may increase the potential for HAB growth. Sediment Re-entrainment has the potential for a major and moderate change at Cougar and Blue River. A resuspension and scour of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Cougar and Blue River reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.6.4 Middle Fork Willamette Subbasin*

Hills Creek would have a major adverse effect to water temperature targets in the summer which would mean an increase of the days of cooler (<18C or 64F) released downstream water temperatures. Moderate beneficial effects are observed for Days near temperature targets for April through August and September through March at Hills Creek. A negligible effect for days near temperature target from September through March is observed at Hills Creek. Downstream water temperatures at Dexter would have a minor adverse effect to water temperature targets in the summer with increase of the days of cooler released downstream water temperatures as compared to the NAA. Dexter downstream water would observe a moderate benefit for days near temperature target from April through August and negligible effect for days near temperature target from September through March. Hills Creek will modify the spillway to use the spillway for surface spill in the summer.

TDG level effects would be negligible for Hills Creek and Lookout Point while Dexter would have minor adverse effects to TDG levels. A measure for spreading of spill across the dam for TDG management is included at Lookout Point and Dexter. Fall Creek reservoir does not have a TDG gage and effects would be similar to the NAA and Affected Environment.

Turbidity has the potential to increase as there is a major change of sediment supply in fine-grained sediments into Dexter reservoir passing out of Lookout Point run-of-river reservoir. Dexter reservoir would have potential for moderate change in fine grained sediment supply passing into the Middle Fork Willamette downstream of Dexter Dam.

HABs have the potential to increase with a major change at Hills Creek and Lookout Point for head-of-reservoir sediment mobilization relative to the NAA. A major change at Hills Creek and major change at Lookout Point for shoreline exposure is observed. Sediment Re-entrainment results in a negligible effect for Hills Creek and major change for Lookout Point. Fall Creek would observe negligible change for head-of-reservoir, shoreline exposure and sediment re-entrainment metrics. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Hills Creek and Lookout Point reservoirs there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Fall Creek reservoir would see negligible change relative to the NAA. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.6.5 Coast Fork Willamette and Long Tom Subbasin*

There are no water temperature or TDG measures at Cottage Grove, Dorena or Fern Ridge as such conditions are expected to remain similar to the NAA.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments as compared to the NAA passing into the Coast Fork Willamette and Row River from Cottage Grove dams. There is negligible change in sediment supply relative to the NAA in the Long Tom River.

HABs have the potential to increase with a major change for shoreline exposure as compared to the NAA and moderate change for sediment re-entrainment at Cottage Grove and Dorena dams. Fern Ridge would have a negligible change to the above metrics.

Mercury has the potential to increase with a major change to shoreline exposure as compared to the NAA which may affect the mercury methylation process at Cottage Grove and Dorena.

Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

##### *4.5.2.6.6 Mainstem Willamette*

Mainstem Willamette at Albany and Salem water temperatures observe negligible effects to water temperature in the summer. A decrease of instream flows during conservation season, from late spring through early fall, along with cumulative actions of instream water withdrawals and Climate change may exacerbate water temperatures. Currently there are only summer water temperature targets for the Mainstem Willamette. Water quality parameters such as TDG, Turbidity, HABs are negligible or have not been reported as a concern. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

### 4.5.2.7 Alternative 4 – Structures-Based Fish Passage Alternative

Cumulative effects to water quality for Alternative 4 measures and RFFA's are described by Willamette Valley subbasins based on effects described in section 4.2.2. The summary of direct/indirect effects of Alternative 4 compared to the No Action Alternative are summarized in Table 3.5-25.

#### *4.5.2.7.1 North Santiam Subbasin*

Big Cliff downstream water temperatures would observe negligible effects for days below 18C (64.4F; summer) temperature targets as compared to the NAA. A moderate benefit for days near temperature target from April through August, and major benefit for days near temperature target from September through March. The inclusion of a water temperature control at Detroit reservoir may provide the beneficial effect that is observed.

Alternative 4 includes a measure for TDG structural improvement in the design of the Detroit water temperature control tower which results in a moderate beneficial effect. Big Cliff includes a measure for structural improvement to reduce TDG and mechanical degassing at the adult fish facility which results in a major beneficial effect.

Turbidity has the potential to increase as there is a moderate change of fine-grained sediments passing into Big Cliff fun-of-reservoir and minor change of the fine-grained sediments passing downstream into the North Santiam. Adverse effects from RFFA's (section 4.2.2) may increase the potential for Turbidity.

HABs have the potential to increase at Detroit Reservoir as there is a negligible change in head-of-reservoir, major change for shoreline exposure and major change for sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Detroit reservoir, which creates the potential for an increase in methylation due to water fluctuations. However, there are no foreseeable increases in anoxic waters. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for the shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.7.2 South Santiam Subbasin*

Foster observes major beneficial effects to downstream water temperatures with days below 18C (64.4F) during the summer as compared to the NAA. Minor beneficial effects to downstream water temperatures from April through August with the use of the Green Peter spillways for surface spill in the summer. Negligible effect from September through March with the use the RO's to discharge colder water during fall and winter drawdown operations at Green Peter reservoir.

Alternative 4 measure for TDG abatement is a structural improvement at the Foster adult fish collection facility. Foster observes a negligible effect. There are no TDG abatement measure at Green Peter and a major adverse effect is observed.

Turbidity may increase as there is potential for moderate change of sediment supply in fine grained sediments as compared to the NAA entering Foster reservoir which may partially settle and may pass a minor change of the fine-grained sediments downstream into the South Santiam. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase which may increase sediment downstream of the dams.

HABs have the potential to increase as there is a negligible change for head-of-reservoir sediment mobilization at Green Peter and Foster. Green Peter reservoir observes in a major change for shoreline exposure and sediment re-entrainment as compared to the NAA. Foster reservoir has a negligible change for sediment mobilization, shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Green Peter reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Foster reservoir would be negligible for shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.7.3 McKenzie Subbasin*

Cougar downstream water temperatures observes negligible effects as there no water temperature measures within Alternative 4. Cumulative actions including Climate change, water demands and mainstem flow targets may alter water temperatures.

A minor beneficial effect to TDG is observed at Cougar with the inclusion of structural improvement measure for TDG within Alternative 4.

Turbidity has the potential to increase as fine-grained sediment supply passing downstream of Cougar and Blue River would observe a minor and moderate change. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase which may increase sediment downstream of the dams.

A major change at Cougar and negligible change at Cougar and Blue River in the potential head-of-reservoir sediment mobilization. A major change in shoreline exposure at Cougar and Blue River may increase the potential for HAB growth. Sediment Re-entrainment has the potential for a moderate change at Cougar and major change at Blue River. A resuspension and scour of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Cougar and Blue River reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.7.4 Middle Fork Willamette Subbasin*

Hills Creek would have a major adverse effect to water temperature targets in the summer which would mean an increase of the days of cooler (<18C or 64F) released downstream water temperatures. Major beneficial effects are observed for Days near temperature targets for April through August and moderate benefit during September through March at Hills Creek. The effects observed at Hills Creek may be due to the inclusion of a water temperature control tower to better regulate downstream water temperatures. Downstream water temperatures at Dexter would have a major adverse effect to water temperature targets in the summer with increase of the days of cooler released downstream water temperatures as compared to the NAA. Dexter downstream water would observe a negligible effect for days near temperature target from April through August and September through March. Dexter has no TDG measures included in Alternative 4 although a water temperature control tower is included at Lookout Point. There are no water temperature measures for Fall Creek.

TDG level effects would be negligible for Hills Creek, Lookout Point and Dexter. Alternative 4 includes a measure for a water temperature control tower at Lookout Point. Dexter Reservoir includes a structural improvement to reduce TDG and mechanical degassing method in the fish collection and hatchery area downstream of the dam. Fall Creek reservoir does not have a TDG gage and effects would be similar to the NAA and Affected Environment.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments into Hills Creek reservoir. A minor change in fine-grained sediment supply to the Dexter run-of-river reservoir.

All Middle Fork Willamette dams have a negligible change for head-of-reservoir sediment mobilization relative to the NAA. A major change at Hills Creek and Lookout Point for shoreline exposure is observed. Sediment Re-entrainment results in a major effect for Hills Creek and minor change for Lookout Point. Fall Creek would observe negligible change for head-of-reservoir, shoreline exposure and sediment re-entrainment metrics. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Hills Creek and Lookout Point reservoirs there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Fall Creek reservoir would see negligible change relative to the NAA. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

##### *4.5.2.7.5 Coast Fork Willamette and Long Tom Subbasin*

There are no water temperature or TDG measures at Cottage Grove, Dorena or Fern Ridge as such conditions are expected to remain similar to the NAA.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments passing into the Coast Fork Willamette and Row River from Cottage Grove dams. There is negligible change in sediment supply relative to the NAA in the Long Tom River free-flowing reach.

A Negligible change to potential for head-of-reservoir sediment mobilization is observed at all WVS storage projects. HABs have the potential to increase with a major change for shoreline exposure at Cottage Grove and Dorena reservoirs. A moderate change for sediment re-entrainment at Cottage Grove and Dorena dams. Fern Ridge would have a negligible change to the above metrics.

A major change to shoreline exposure relative to the NAA is observed at Cottage Grove and Dorena. Fern Ridge results in negligible change. Exposed sediment may affect the mercury methylation process at Cottage Grove and Dorena.

Cumulative effects of RFFA’s with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

##### *4.5.2.7.6 Mainstem Willamette*

Mainstem Willamette at Albany observe negligible effects to water temperature in the summer, while Salem observes minor adverse effects relative to the NAA. A decrease of instream flows during conservation season, from late spring through early fall, along with cumulative actions of instream water withdrawals and Climate change may exacerbate water temperatures. Currently there are only summer water temperature targets for the Mainstem Willamette. Water quality parameters such as TDG, Turbidity, HABs are negligible or have not been reported as a concern. Cumulative effects of RFFA’s with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

### *4.5.2.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Cumulative effects to water quality for Alternative 4 measures and RFFA's are described by Willamette Valley subbasins based on effects described in section 4.2.2. The summary of direct/indirect effects of Alternative 5 compared to the No Action Alternative are summarized in Table 3.5-28.

#### *4.5.2.8.1 North Santiam Subbasin*

Big Cliff downstream water temperatures observes a negligible effect of days below 18C (64.4F) during the summer and moderate benefit of days near temperature target from April through August and major benefit for days near temperature target from September through March with the inclusion of a Water Temperature Control tower at Detroit dam.

No TDG measures are included in Alternative 2B although a moderate benefit is observed at Detroit and Big Cliff for TDG levels as the annual difference in number of days above 110% TDG levels is less as compared to the NAA.

Turbidity has the potential to increase as there is a moderate change downstream of Detroit Dam in fine grained sediments entering Big Cliff reservoir and minor change of the fine-grained sediments passing downstream into the North Santiam. Adverse effects from RFFA's (section 4.2.2) may increase the potential for Turbidity.

HABs have the potential to increase at Detroit Reservoir as there is a major change in shoreline exposure and sediment re-entrainment. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Detroit reservoir, which creates the potential for an increase in methylation due to water fluctuations. However, there are no foreseeable increases in anoxic waters. Big Cliff reservoir is a run-of river project that operates in a small range of pool elevations and is not included for the shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.8.2 South Santiam Subbasin*

Foster observes negligible effects to downstream water temperatures with days below 18C (64.4F) during the summer with the use of the spillway for surface spill in the summer at Green Peter reservoir. Moderate beneficial effects to downstream water temperatures from April through August which may be due to the modifications to increase warm water releases through a Foster Warm Water Supply (FWWS) pipe and fish weir at Foster Dam. A minor beneficial effect from September through March may be due to the use the RO's discharge of colder water during fall and winter drawdown operations at Green Peter reservoir.

There are no measures for TDG abatement at Green Peter and Foster. Major adverse effects to TDG levels are observed at Green Peter and moderate adverse effect at Foster reservoirs which may be due to the increase of spill as compared to the NAA. A measure to use the spillway for surface spill in the summer at Green Peter may contribute to the increase of TDG levels.

Turbidity has the potential to increase as there is potential for major change of sediment supply in fine grained sediments entering Foster reservoir which may partially settle and may pass a moderate change of the fine-grained sediments downstream into the South Santiam. RFFA's with Adverse effects (section 4.2.2) and Climate change may increase Turbidity as winter precipitation is projected to increase this may increase sediment downstream of the dams.

HABs have the potential to increase as there is a major change for head-of-reservoir sediment mobilization, shoreline exposure and sediment re-entrainment at Green Peter reservoir. A resuspension of sediment may make nutrients available and facilitate algae bloom growth. Foster reservoir has a minor change for potential head-of-reservoir sediment mobilization and negligible change for shoreline exposure and sediment re-entrainment. Cumulative actions including Climate change with increased air and water temperatures may increase the likelihood of bloom formation. Adverse effects from RFFA's (section 4.2.2) may increase the potential growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Green Peter reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Foster reservoir would be negligible for shoreline exposure metric. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.8.3 McKenzie Subbasin*

Cougar downstream water temperatures would observe a negligible to minor beneficial effect as there is a water temperature control tower on site although cumulative actions including Climate change, water demands and mainstem flow targets may alter this effect.

A minor beneficial effect to TDG at Cougar although there are not TDG measures for Alternative 2B. Blue River is not expected to change as the RO's are utilized and TDG levels would not be expected to change.

Turbidity has the potential to increase as fine-grained sediment supply passing downstream of Cougar would observe a major change and Blue River would observe a moderate change.

A major change at Cougar and negligible change at Blue River in the potential head-of-reservoir sediment mobilization and major change in shoreline exposure may increase the potential for

HAB growth. Sediment Re-entrainment has the potential for a moderate change at Cougar and major change for Blue River. A resuspension and scour of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Cougar and Blue River reservoir there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.8.4 Middle Fork Willamette Subbasin*

There are no Water Temperature measures for the Middle Fork Willamette. Cumulative effects at Hills Creek and Lookout Point storing more water in the spring and increasing water surface elevations. Hills Creek would have a major adverse effect to water temperature targets in the summer which would mean an increase of the days of cooler (<18C or 64F) released downstream water temperatures. Downstream water temperatures at Dexter would have a negligible effect of downstream water temperatures as compared to the NAA.

TDG level effects would be negligible for Hills Creek, Lookout Point and Dexter as there are no TDG measures and has no reduction of days of TDG exceedances for the year (Appendix D, Figure 2-35). Fall Creek reservoir does not have a TDG gage and effects would be similar to the NAA and Affected Environment.

Turbidity has the potential to increase as there is a moderate change of sediment supply in fine-grained sediments passing out of Hills Creek into the Middle Fork Willamette above Lookout Point. Dexter reservoir would have potential for minor change in fine grained sediment and negligible potential for change in sediment supply downstream of Dexter Dam.

HABs have the potential to increase as a major change in shoreline exposure is observed at Hills Creek and Lookout Point. Sediment Re-entrainment results in a major change for Hills Creek and minor change for Lookout Point. Fall Creek would observe negligible change and Dexter reservoir is a run-of-river project and is not included in these metrics. A resuspension of sediment may make nutrients available and facilitate algae bloom growth.

Mercury has the potential to increase as there is a major change in shoreline exposure compared to the NAA at Hills Creek and Lookout Point reservoirs there is potential for an increase for the methylation process to occur with water fluctuations. However, there are no foreseeable increases in anoxic waters. Fall Creek reservoir would see negligible change relative to the NAA. Cumulative actions including Climate Change with increased air and water temperatures and precipitation events may increase the likelihood of mercury.

#### *4.5.2.8.5 Coast Fork Willamette and Long Tom Subbasin*

There are no water temperature or TDG measures at Cottage Grove, Dorena or Fern Ridge as such conditions are expected to remain similar to the NAA. Negligible effects are expected for Turbidity, HABs and Mercury. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

#### *4.5.2.8.6 Mainstem Willamette*

Mainstem Willamette at Albany and Salem water temperatures observes negligible effects to water temperature in the summer. A decrease of instream flows during conservation season, from late spring through early fall, along with cumulative actions of instream water withdrawals and Climate change may exacerbate water temperatures. Currently there are only summer water temperature targets for the Mainstem Willamette. Water quality parameters such as TDG, Turbidity, HABs are negligible or have not been reported as a concern. Cumulative effects of RFFA's with adverse effects (section 4.2.2) to water quality may occur but it is unknown to what degree.

# 4.6 VEGETATION

## 4.6.1 Cumulative Effects Analysis Methodology for Vegetation

### *4.6.1.1 Cumulative Actions Applicable to Vegetation*

Past, present, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on vegetation include:

- WVS Dams and Reservoirs: construction and past operations and maintenance (see section 4.2.1.1) as well as ongoing operations and maintenance (see section 4.2.2)
- WRB Population Growth and Development: increased development extent and intensity within the Willamette River Basin (see section 4.2.1.2)
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development
- RFFA 2: Future agricultural development
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 4: Decarbonizing the energy sector with renewable energy sources
- RFFA 5: Federal and state wildlife and lands management
- RFFA 7: Tribal, state, and local fish and wildlife improvement
- RFFA 8: Invasive species management
- RFFA 9: Climate change
- RFFA 11: Timber and logging industry operations

Some of the other RFFAs discussed in Section 4.2.3 would not change the vegetative communities of the Willamette Basin or any changes would be negligible. These include:

- RFFA 6: Fishery management and killer whales. Because flows would not have more than a negligible effect as a result of this RFFA, vegetation would not be affected.
- RFFA 10: Mining operations. Mining operations have a negligible effect on vegetation.

Therefore, these RFFAs are dismissed from further analysis.

## 4.6.2 Cumulative Effects to Vegetation by Alternative

The WVS dams and reservoirs are currently authorized for flood control, hydropower, pollution abatement, fish and wildlife conservation, recreation, irrigation, municipal and industrial water supply, and water quality. Vegetative communities within the WRB have been changed from the natural condition by the construction and operation of the WVS dams and reservoirs, dams constructed by other entities (Section 4.1.2.1.1), urban and rural development and land use, transportation infrastructure development, logging operations within the watershed, and proliferation of invasive plant species as a result of much of this development. The cumulative effect is the conversion of complex stream reaches with a variety of habitats that support a variety of vegetative communities to inland lakes (reservoirs) and simplification of the regulated river reaches that provide less overbank flows and hydrology for streamside vegetative communities. In addition, certain invasive plants have proliferated in these hydrologic conditions such that species such as reed canarygrass now form dense monocultures in some areas, preventing a more diverse native vegetative community from establishing in these areas.

Future population growth and accompanying urban, industrial, and commercial development (RFFA 1) occurring in the WRB would continue to affect vegetation by further disturbing native vegetative communities during construction activities and would continue to introduce non-native invasive plant species that establish quickly after ground-disturbing activities. Development related to decarbonizing the energy sector with renewable energy sources (RFFA 4) such as wind and solar projects would affect vegetation similarly. There are construction standards in regard to preserving native vegetation and re-establishing vegetative communities following construction; however, this guidance and the implementation of this guidance varies by project type and the agency undertaking the project. Therefore, the cumulative actions associated with this development would create adverse, additive, and moderate effects to vegetation.

Future agricultural development (RFFA 2) occurring in historical floodplains would further limit a native diverse vegetative community in these areas. Outside of the urban growth boundaries within the WRB, this floodplain development would likely be in the form of larger ranchettes or properties that take advantage of the hydrology in soils within low-lying areas. Typically, agricultural operations that are growing crops use land that otherwise would support a native plant community and instead work to establish a monoculture of non-native plants. Some of the plants associated with these agricultural areas are also invasive and would spread into riparian and aquatic areas. In addition, agricultural development with livestock may further spread invasive plants into the watershed through the movement of the animals within riparian and floodplain areas. The cumulative actions associated with agricultural development would create adverse, additive, and minor effects to vegetation.

Water withdrawals for municipal, industrial, and agricultural uses (RFFA 3) would have the effect of either decreasing reservoir water surface elevation, decreasing instream flows, or a combination of both. Decreased water surface elevation would decrease the extent of soil saturation in proximity to reservoirs and WVS stream reaches, which would change the vegetative communities in these areas. More drought-tolerant species would become dominant and wetland and riparian vegetation that depend on greater soil saturation would become less dominant. These cumulative actions would create adverse, additive, and moderate effects to vegetation. These effects to vegetation have largely been considered in Section 3.6 as they relate to the hydrologic effects for each alternative.

Federal and state wildlife and lands management (RFFA 5) and timber and logging industry operations (RFFA 11) happen throughout the regulated and unregulated portions of the watershed and are conservation focused or expected to occur with similar actions and rates as in the recent past. National forests, wilderness areas, and wildlife refuges (listed in Section 4.2.6) management actions, including vegetation management actions, will continue as currently undertaken. Rates of herbicide application to control invasive plants, timber harvest, and tree replanting associated with logging operations would continue at rates similar to current operations. The cumulative actions would be additive and cause moderate effects to vegetation.

Tribal, state, and local fish and wildlife improvement (RFFA 7) includes river and floodplain restoration actions and potentially environmental flows to inundate floodplain areas. Environmental flows have been performed historically in the Willamette system but have been limited in magnitude to non-damaging peak flows similar to smaller regulated flood events. The floodplain restoration actions would likely include some amount of native plant preservation, invasive plant removal, and native species planting efforts. These cumulative actions would create beneficial, additive, and minor effects to vegetation within the WRB.

Invasive species management (RFFA 8) includes a range of vegetation management actions (e.g., herbicide application, mowing, controlled burns, etc.) taken by federal, state, and local agencies as well as private organizations to combat the spread of invasive plant species (see section 3.6.1.3.1 for more information). Vegetation management within the WRB would likely continue at the same rate as it currently is undertaken. These actions would create beneficial, additive, and moderate effects to vegetation within the WRB.

Climate change (RFFA 9) would change the composition of the vegetative communities within the WRB through overall drier conditions, which would affect plants in riparian areas and around the reservoirs. In addition, increased wildfires throughout the WRB would also change the composition of vegetative communities. See the climate change sections of each alternative in section 3.6 for more information. Ultimately, climate change effects would be adverse, additive, and have moderate effects to vegetation within the WRB.

In general, the RFFAs have an adverse, additive, moderate effect on vegetation throughout the WRB. Continued development throughout the basin and all the actions associated with increased population within both urban and rural areas as well as other RFFA's that cause additional stress on vegetation (e.g., water withdrawals, invasive plant proliferation, and climate change) would impact vegetative communities by changing species composition to a more drought tolerant vegetative community with less biodiversity. However, vegetative communities would continue to be improved or maintained by benefits such as restoration actions within the floodplains and management of invasive plant species. General trends described in this section apply to all subbasins within the WVS. Differences in the cumulative effects per subbasin will be described in the discussion below.

#### *4.6.2.1 No Action Alternative*

Combined with the effects of the cumulative effects listed above (particularly climate change), there would likely be additional effects to vegetation under the No Action Alternative. As discussed in section 3.6.3.1, the effects of the No Action Alternative would have both a beneficial and an adverse effect to vegetative communities in the WVS. The beneficial effect of the NAA is that water storage in the reservoirs would be maintained and would continue to support a vegetative community around the reservoirs that may not otherwise exist. The adverse effect is that streamside vegetative communities along reaches downstream of the USACE projects would continue to rely primarily on precipitation since stream flows would continue to be managed for flood control, limiting water uptake for vegetative communities across the floodplain. Therefore, combined with climate change, there would be changes in vegetative communities within the WVS due to hotter drier summers and a higher frequency of wildfires. It should be noted that the NAA will have negligible to minor effects (both beneficial and adverse) to the overall cumulative effects as it would maintain existing conditions.

#### *4.6.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Overall, cumulative effects to vegetation would be anticipated to be moderate and adverse over the period of analysis. However, Alternative 1 would not contribute substantially to the changes in the vegetative communities of the WVS. Changes to the vegetative community in terms of species composition would be affected to a greater magnitude by climate change, water withdrawals, federal and state wildlife and lands management, and invasive species management than by Alternative 1. Cumulative effect summaries for Alternative 1 by subbasin are provided below.

##### *4.6.2.2.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Santiam subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas, which would have a moderate effect to vegetation within the subbasin.

With the implementation of Alternative 1, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects thereby increasing trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.2.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail a species composition with increasing numbers of drought-tolerant and invasive plants and this would constitute a moderate effect within the Long Tom subbasin. Alternative 1 would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.6.2.2.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the McKenzie subbasin would entail a species composition dominated by drought-tolerant invasive plants along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs.

With the implementation of Alternative 1, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for vegetative communities along downstream reaches within the McKenzie subbasin. On the other hand, the drawdowns at Cougar reservoir would make vegetation around the reservoirs more susceptible to climate change effects and will push trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs. Ultimately, minor adverse effects to vegetation would be anticipated around Cougar reservoir.

#### *4.6.2.2.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Falls Creek, Hills Creek, and Lookout Point, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Middle Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas. These cumulative effects would constitute a moderate effect to vegetation within the subbasin primarily because of climate change.

With the implementation of Alternative 1, gravel augmentation downstream of the WVS dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns at Falls Creek, Hills Creek, and Lookout Point reservoirs will further exacerbate the cumulative effects thereby increasing trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs, which would be considered a moderate effect to vegetation.

##### *4.6.2.2.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants including the more resilient invasive plants that thrive in disturbed areas.

With the implementation of Alternative 1, increased storage at Cottage Grove and Dorena would offset lower reservoir elevations anticipated as a result of cumulative effects during conservation season; however, the drawdowns within Cottage Grove and Dorena will further exacerbate the cumulative effects thereby increasing trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs, an adverse moderate effect.

##### *4.6.2.2.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 1 would not have a more than negligible effect on the general trend of vegetative communities along the Mainstem Willamette River becoming more dominated by drought-tolerant and invasive plants.

#### ***4.6.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (includes structural downstream passage at Cougar Dam)***

Overall, cumulative effects to vegetation would be moderate over the period of analysis. Changes to the vegetative community in terms of species composition would be affected by climate change, water withdrawals, federal and state wildlife and lands management, and invasive species management. Alternative 2A would also have moderate effects to the vegetative communities of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below.

##### *4.6.2.3.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Santiam subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas, which would have a moderate effect to vegetation within the subbasin.

With the implementation of Alternative 2A, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to vegetation when combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.3.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail a species composition with increasing numbers of drought-tolerant and invasive plants and this would constitute a moderate effect within the Long Tom subbasin. Alternative 2A would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

##### *4.6.2.3.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the McKenzie subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 2A, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for vegetative communities along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make vegetation around the reservoirs more susceptible to climate change effects, which would constitute a minor effect, pushing trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.3.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the Middle Fork Willamette subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 2A, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for moderate effects to vegetation around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.3.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants including the more resilient invasive plants that thrive in disturbed areas.

The implementation of Alternative 2A would not have a more than negligible effect on the general trend of vegetative communities along the Coast Fork Willamette River becoming more dominated by drought-tolerant and invasive plants.

##### *4.6.2.3.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 2A would not have a more than negligible effect on the general trend of vegetative communities along the Mainstem Willamette River becoming more dominated by drought-tolerant and invasive plants.

#### ***4.6.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Overall, cumulative effects to vegetation would be moderate over the period of analysis. Changes to the vegetative community in terms of species composition would be affected by climate change, water withdrawals, federal and state wildlife and lands management, and invasive species management. Alternative 2B would also have moderate effects to the vegetative communities of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 2B (as opposed to Alternative 2A) there would be potential for major effects to vegetation around the reservoir when combined with climate change effects.

##### *4.6.2.4.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Santiam subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas, which would have a moderate effect to vegetation within the subbasin.

With the implementation of Alternative 2B, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to vegetation when combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.4.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail a species composition with increasing numbers of drought-tolerant and invasive plants and this would constitute a moderate effect within the Long Tom subbasin. Alternative 2B would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

##### *4.6.2.4.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the McKenzie subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 2B, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for vegetative communities along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make vegetation around the reservoirs more susceptible to climate change effects. Particularly at Cougar, where deep fall and spring drawdowns would be implemented, there would be potential for moderate effects to vegetation when combined with cumulative effects, particularly climate change. This would push trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.4.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the Middle Fork Willamette subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 2B, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for moderate effects to vegetation around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.4.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants including the more resilient invasive plants that thrive in disturbed areas.

The implementation of Alternative 2B would not have a more than negligible effect on the general trend of vegetative communities along the Coast Fork Willamette River becoming more dominated by drought-tolerant and invasive plants.

#### *4.6.2.4.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 2B would not have a more than negligible effect on the general trend of vegetative communities along the Mainstem Willamette River becoming more dominated by drought-tolerant and invasive plants.

### *4.6.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Overall, cumulative effects to vegetation would be moderate over the period of analysis. Changes to the vegetative community in terms of species composition would be affected by climate change, water withdrawals, federal and state wildlife and lands management, and invasive species management. Alternative 3A would also have moderate effects to the vegetative communities of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below.

#### *4.6.2.5.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Santiam subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas, which would have a moderate effect to vegetation within the subbasin.

With the implementation of Alternative 3A, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. At Detroit (fall and spring) and Green Peter (fall) drawdowns would be implemented and therefore, there would be potential for major effects to vegetation when combined with cumulative effects, particularly as a result of climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.5.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail a species composition with increasing numbers of drought-tolerant and invasive plants and this would constitute a moderate effect within the Long Tom subbasin. Alternative 3A would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.6.2.5.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the McKenzie subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 3A, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for vegetative communities along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make vegetation around the reservoirs more susceptible to climate change effects. At Cougar, a deep spring drawdown would be implemented and at Cougar and Blue River, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause moderate effects to vegetation around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.5.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the Middle Fork Willamette subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 3A, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. In addition to the drawdowns with minor vegetation effects, at Lookout Point, a deep spring drawdown would be implemented and at Lookout Point and Hills Creek, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause major effects to vegetation around the reservoirs when combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.5.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants including the more resilient invasive plants that thrive in disturbed areas.

The implementation of Alternative 3A would not have a more than negligible effect on the general trend of vegetative communities along the Coast Fork Willamette River becoming more dominated by drought-tolerant and invasive plants.

#### *4.6.2.5.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 3A would not have a more than negligible effect on the general trend of vegetative communities along the Mainstem Willamette River becoming more dominated by drought-tolerant and invasive plants.

#### 4.6.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)

Overall, cumulative effects to vegetation would be moderate over the period of analysis. Changes to the vegetative community in terms of species composition would be affected by climate change, water withdrawals, federal and state wildlife and lands management, and invasive species management. Alternative 3B would also have moderate effects to the vegetative communities of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below. Alternative 3B is very similar to 3A. The primary differences are related to locations of the drawdowns and the fact that deep drawdowns occurring at Cougar would be to the elevation of the diversion tunnel.

##### 4.6.2.6.1 Santiam Subbasin

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Santiam subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas, which would have a moderate effect to vegetation within the subbasin.

With the implementation of Alternative 3B, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. At both Detroit (fall) and Green Peter (fall and spring) deep drawdowns would be implemented and therefore, there would be potential for major effects to vegetation when combined with cumulative effects, particularly as a result of climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### 4.6.2.6.2 Long Tom Subbasin

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail a species composition with increasing numbers of drought-tolerant and invasive plants and this would constitute a moderate effect within the Long Tom subbasin. Alternative 3B would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.6.2.6.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the McKenzie subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 3B, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for vegetative communities along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make vegetation around the reservoirs more susceptible to climate change effects. At Cougar, a deep spring drawdown would be implemented and at Cougar and Blue River, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause moderate effects to vegetation around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.6.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the Middle Fork Willamette subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 3B, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. In addition to the drawdowns with minor vegetation effects, at Hills Creek, a deep spring drawdown would be implemented and at Lookout Point and Hills Creek, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause moderate effects to vegetation around the reservoirs when combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.6.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants including the more resilient invasive plants that thrive in disturbed areas.

With the implementation of Alternative 3B, the drawdowns at Cottage Grove and Dorena would make vegetation around the reservoirs more susceptible to climate change effects. These drawdowns would potentially cause moderate effects to vegetation around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.6.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 3B would not have a more than negligible effect on the general trend of vegetative communities along the Mainstem Willamette River becoming more dominated by drought-tolerant and invasive plants.

### ***4.6.2.7 Alternative 4 – Structures-Based Fish Passage Alternative***

Overall, cumulative effects to vegetation would be anticipated to be moderate over the period of analysis. However, Alternative 4 would not contribute substantially to the changes in the vegetative communities of the WVS. Changes to the vegetative community in terms of species composition would be affected to a greater magnitude by climate change, water withdrawals, federal and state wildlife and lands management, and invasive species management than by Alternative 4. Cumulative effect summaries for Alternative 4 by subbasin are provided below.

#### *4.6.2.7.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Santiam subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas, which would have a moderate effect to vegetation within the subbasin.

With the implementation of Alternative 4, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will would make vegetation around the reservoirs more susceptible to climate change effects, which would ultimately constitute a moderate effect, pushing trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.7.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail a species composition with increasing numbers of drought-tolerant and invasive plants and this would constitute a moderate effect within the Long Tom subbasin.

##### *4.6.2.7.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the McKenzie subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 4, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for vegetative communities along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make vegetation around the reservoirs more susceptible to climate change effects, which would constitute a minor effect, pushing trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.7.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the Middle Fork Willamette subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 4, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for minor effects to vegetation around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.7.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants including the more resilient invasive plants that thrive in disturbed areas.

With the implementation of Alternative 4, the drawdowns at Cottage Grove and Dorena would make vegetation around the reservoirs more susceptible to climate change effects. These drawdowns would potentially cause moderate effects to vegetation around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

##### *4.6.2.7.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 4 would not have a more than negligible effect on the general trend of vegetative communities along the Mainstem Willamette River becoming more dominated by drought-tolerant and invasive plants.

#### *4.6.2.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Overall, cumulative effects to vegetation would be moderate over the period of analysis. Changes to the vegetative community in terms of species composition would be affected by climate change, water withdrawals, federal and state wildlife and lands management, and invasive species management. Alternative 5 (as with Alternative 2B) would also have moderate effects to the vegetative communities of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 5 (as with Alternative 2B) there would be potential for major effects to vegetation around the reservoir when combined with climate change effects. The effects of Alternative 5 when combined with cumulative effects are identical to those of Alternative 2B as presented in Section 4.6.2.4. Cumulative effect summaries for Alternative 5 by subbasin are provided below.

#### *4.6.2.8.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Santiam subbasin entails a species composition dominated by drought-tolerant plants and a growing population of the more resilient invasive plants that thrive in disturbed areas, which would have a moderate effect to vegetation within the subbasin.

With the implementation of Alternative 5, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to vegetation when combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.8.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail a species composition with increasing numbers of drought-tolerant and invasive plants and this would constitute a moderate effect within the Long Tom subbasin. Alternative 5 would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.6.2.8.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the McKenzie subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 5, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for vegetative communities along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make vegetation around the reservoirs more susceptible to climate change effects. Particularly at Cougar, where deep fall and spring drawdowns would be implemented, there would be potential for moderate effects to vegetation when combined with cumulative effects, particularly climate change. This would push trends toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.8.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of vegetative communities in the Middle Fork Willamette subbasin would entail a species composition with increasing populations of drought-tolerant and invasive plants along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 5, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for moderate effects to vegetation around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward a species composition dominated by drought-tolerant and invasive plants around the reservoirs.

#### *4.6.2.8.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and

Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on vegetation around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails a species composition dominated by drought-tolerant plants including the more resilient invasive plants that thrive in disturbed areas.

The implementation of Alternative 5 would not have a more than negligible effect on the general trend of vegetative communities along the Coast Fork Willamette River becoming more dominated by drought-tolerant and invasive plants.

###### *4.6.2.8.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 5 would not have a more than negligible effect on the general trend of vegetative communities along the Mainstem Willamette River becoming more dominated by drought-tolerant and invasive plants.

## 4.7 WETLANDS

### 4.7.1 Cumulative Effects Analysis Methodology for Wetlands

#### *4.7.1.1 Cumulative Actions Applicable to Wetlands*

Past, present, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on wetlands include:

- WVS Dams and Reservoirs: construction and past operations and maintenance (see section 4.2.1.1) as well as ongoing operations and maintenance (see section 4.2.2)
- WRB Population Growth and Development: increased development extent and intensity within the Willamette River Basin (see section 4.2.1.2)
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development
- RFFA 2: Future agricultural development
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 4: Decarbonizing the energy sector with renewable energy sources
- RFFA 5: Federal and state wildlife and lands management
- RFFA 7: Tribal, state, and local fish and wildlife improvement
- RFFA 8: Invasive species management
- RFFA 9: Climate change

Some of the other RFFAs discussed in Section 4.2.3 would not change wetlands in the Willamette Basin or any changes would be negligible. These include:

- RFFA 6: Fishery management and killer whales. Because flows would not have more than a negligible effect as a result of this RFFA, wetlands would not be affected.
- RFFA 10: Mining operations. Mining operations have a negligible effect on wetlands.
- RFFA 11: Timber and logging industry operations. Timber and logging operations have a negligible effect on wetlands.

Therefore, these RFFAs are dismissed from further analysis.

### 4.7.2 Cumulative Effects to Wetlands by Alternative

The WVS dams and reservoirs are currently authorized for flood control, hydropower, pollution abatement, fish and wildlife conservation, recreation, irrigation, municipal and industrial water supply, and water quality. Wetlands within the WRB have been changed from the natural condition by the construction and operation of the WVS dams and reservoirs, dams constructed by other entities (Section 4.1.2.1.1), urban and rural development and land use, transportation infrastructure development, dredging and sediment management, and proliferation of invasive plant species as a result of much of this development. The cumulative effect is the conversion of complex stream reaches with a variety of habitats that support a variety of vegetative communities to inland lakes (reservoirs) and simplification of the regulated river reaches that provide less overbank flows and hydrology available to sustain streamside wetlands. In addition, certain invasive plants have proliferated in these hydrologic conditions which changes the character of wetlands within the WVS, limiting ecological functions.

Future population growth and accompanying urban, industrial, and commercial development (RFFA 1) occurring in the WRB would continue to affect wetlands by further impacting (excavating/filling) wetlands during construction activities. Development related to decarbonizing the energy sector with renewable energy sources (RFFA 4) such as wind and solar projects would affect wetlands similarly. There are construction standards and regulations in regard to protecting wetlands during development; however, wetlands would be impacted as permitted by regulatory agencies. Therefore, the cumulative actions associated with this development would create adverse, additive, and moderate effects to wetlands.

Future agricultural development (RFFA 2) occurring in historical floodplains would further impact wetlands and ecological function within these areas. Outside of the urban growth boundaries within the WRB, this floodplain development would likely be in the form of larger ranchettes or properties that take advantage of the hydrology in soils within low-lying areas. These areas may persist as wetlands but ecological function would be limited as they would be dominated by a monoculture of non-native crop species. Some of the plants associated with these agricultural areas are also invasive and would spread into downstream streamside wetlands. In addition, agricultural development with livestock also affects wetlands by modifying hydrology and soils during grazing and spreading non-native invasive plants. The cumulative actions associated with agricultural development would create adverse, additive, and minor effects to wetlands.

Water withdrawals for municipal, industrial, and agricultural uses (RFFA 3) would have the effect of either decreasing reservoir water surface elevation, decreasing instream flows, or a combination of both. Decreased water surface elevation would decrease the extent of soil saturation in proximity to reservoirs and WVS stream reaches, which would affect wetlands in these areas by changing wetland hydrology. By wetland hydrology being limited during a greater portion of the year and growing season, wetland areas may shrink or change in character affecting wetland function. These cumulative actions would create adverse, additive, and moderate effects to wetlands. These effects have largely been considered in Section 3.7 as they relate to the hydrologic effects for each alternative.

Federal and state wildlife and lands management (RFFA 5) happen throughout the regulated and unregulated portions of the watershed and are conservation focused or expected to occur with similar actions and rates as in the recent past. National forests, wilderness areas, and wildlife refuges (listed in Section 4.2.6) management actions, will continue as currently undertaken. The cumulative actions would be additive and cause moderate effects to wetlands.

Tribal, state, and local fish and wildlife improvement (RFFA 7) includes river and floodplain restoration actions and potentially environmental flows to inundate floodplain areas. Environmental flows have been performed historically in the Willamette system but have been limited in magnitude to non-damaging peak flows similar to smaller regulated flood events. The floodplain restoration actions usually involve existing or historical riverine wetlands within the floodplain and are thought to benefit wetlands by spreading flows out across the floodplain and reestablishing wetland hydrology. These cumulative actions would create beneficial, additive, and minor effects to wetlands within the WVS.

Invasive species management (RFFA 8) includes a range of vegetation management actions (e.g., herbicide application, mowing, controlled burns, etc.) taken by federal, state, and local agencies as well as private organizations to combat the spread of invasive plant species (see section 3.6.1.3.1 for more information). Vegetation management within the WRB would likely continue at the same rate as it currently is undertaken. Limiting the proliferation of invasive plant species benefits wetlands by helping to maintain a more diverse native plant community that improves the ecological function of wetlands. Invasive plant species management would create beneficial, additive, and moderate effects to wetlands within the WVS.

Climate change (RFFA 9) would affect wetlands primarily due to longer drier summers. Wetland hydroperiods (how long wetlands are inundated or wetland soils are saturated) would change for some wetlands which would change the wetland plant community and potentially cause wetland area to shrink. See the climate change sections of each alternative in section 3.6 for more information. Ultimately, climate change effects would be adverse, additive, and have moderate effects to wetlands within the WVS.

In general, the RFFAs have an adverse, additive, moderate effect on wetlands throughout the WRB. Continued development throughout the basin and all the actions associated with increased population within both urban and rural areas as well as other RFFA's that cause additional stress on wetlands (e.g., water withdrawals, invasive plant proliferation, and climate change) would decrease wetland acreage and impair or eliminate ecological functions of wetlands. On the other hand, wetlands and associated ecological functions would continue to be enhanced or maintained by restoration actions within the floodplains and management of invasive plant species. General trends described in this section apply to all subbasins within the WVS. Differences in the cumulative effects per subbasin will be described in the discussion below.

#### *4.7.2.1 No Action Alternative*

In addition to the cumulative effects listed above (particularly climate change), there would likely be additional effects to wetlands under the No Action Alternative. As discussed in section 3.7.2.2, the effects of the No Action Alternative would have both a beneficial and an adverse effect to vegetative communities in the WVS. The beneficial effect of the NAA is that water storage in the reservoirs would be maintained and would continue to support wetland hydrology around the reservoirs that may not otherwise exist. The adverse effect is that riverine wetlands along reaches downstream of the USACE projects would continue to rely primarily on precipitation since stream flows would continue to be managed for flood control, limiting hydrology available to wetlands across the floodplain. The NAA on its own would have negligible to minor adverse effects to wetlands, as it would maintain existing conditions. Combined with cumulative effects (primarily climate change), there would be adverse moderate effects to wetlands within the WVS in the form of changes to wetland acreage and ecological functions associated with wetlands.

#### *4.7.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Overall, cumulative effects to wetlands would be anticipated to be moderate over the period of analysis. However, Alternative 1 would not contribute substantially to the changes to wetlands of the WVS. Changes to wetland acreage and ecological functions associated with wetlands would be affected to a greater magnitude by climate change, water withdrawals, and invasive species management than by Alternative 1. Cumulative effect summaries for Alternative 1 by subbasin are provided below.

##### *4.7.2.2.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Santiam subbasin entails decreases to wetland acreage and ecological functions associated with wetlands as a result of cumulative effects which have an adverse moderate effect to wetlands within the subbasin.

With the implementation of Alternative 1, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve hydrologic conditions for wetlands along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects thereby increasing trends toward decreases to wetland acreage and ecological functions associated with wetlands. Combined with cumulative effects, an adverse moderate effect to wetlands would be anticipated.

##### *4.7.2.2.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Long Tom subbasin would entail decreases to wetland acreage and ecological functions associated with wetlands and this would constitute a moderate effect within the Long Tom subbasin. Alternative 1 would not change operations at Fern Ridge and therefore would not affect changes to wetlands within the subbasin.

#### *4.7.2.2.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the McKenzie subbasin would entail decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches due to climate change (an adverse moderate effect) but would remain largely unchanged around Cougar and Blue River reservoirs.

With the implementation of Alternative 1, gravel augmentation downstream of Cougar and Blue River dams will slightly improve hydrologic conditions for wetlands along downstream reaches within the McKenzie subbasin. On the other hand, the drawdowns at Cougar reservoir would make wetlands around the reservoirs more susceptible to climate change effects but ultimately, only minor adverse effects to wetlands would be anticipated around Cougar reservoir because of increased storage.

#### *4.7.2.2.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Falls Creek, Hills Creek, and Lookout Point, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Middle Fork Willamette subbasin entails decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches and around the reservoirs. These cumulative effects would constitute a moderate effect to wetlands within the subbasin primarily because of climate change.

With the implementation of Alternative 1, gravel augmentation downstream of the WVS dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns at Falls Creek, Hills Creek, and Lookout Point reservoirs will further exacerbate the cumulative effects thereby increasing trends toward decreases to wetland acreage and ecological functions associated with wetlands around the reservoirs, which would be considered a moderate effect.

#### *4.7.2.2.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of vegetative communities in the Coast Fork Willamette subbasin entails decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches and around the reservoirs.

With the implementation of Alternative 1, increased storage at Cottage Grove and Dorena would offset lower reservoir elevations anticipated as a result of cumulative effects during conservation season; however, the drawdowns within Cottage Grove and Dorena will further exacerbate the cumulative effects thereby increasing trends toward decreases to wetland acreage and ecological functions associated with wetlands, an adverse moderate effect.

##### *4.7.2.2.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 1 would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches.

#### ***4.7.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (includes structural downstream passage at Cougar Dam)***

Overall, cumulative effects to wetlands would be moderate over the period of analysis. Changes to wetlands in terms of wetland acreage and ecological functions would be affected by climate change, water withdrawals, and invasive species management primarily. Alternative 2A would also have moderate effects to the wetlands within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below.

##### *4.7.2.3.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would put additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Santiam subbasin entails decreases to wetland acreage and ecological functions associated with wetlands, which would have a moderate effect to wetlands within the subbasin.

With the implementation of Alternative 2A, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for wetlands along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to wetlands when combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward decreases to wetland acreage and ecological functions associated with wetlands around Green Peter.

##### *4.7.2.3.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on wetlands around the reservoir. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail decreases to wetland acreage and ecological functions associated with wetlands and this would constitute a moderate effect within the Long Tom subbasin. Alternative 2A would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

##### *4.7.2.3.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the McKenzie subbasin would entail decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 2A, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for wetlands along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wetlands around the reservoirs more susceptible to climate change effects, which would constitute a minor effect, pushing trends toward decreases to wetland acreage and ecological functions associated with wetlands around the reservoirs.

##### *4.7.2.3.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the Middle Fork Willamette subbasin would entail decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 2A, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for wetlands along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for moderate effects to wetlands around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward decreases to wetland acreage and ecological functions associated with wetlands around the reservoirs.

##### *4.7.2.3.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Coast Fork Willamette subbasin entails decreases to wetland acreage and ecological functions associated with wetlands.

The implementation of Alternative 2A would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands within the Coast Fork Willamette.

##### *4.7.2.3.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 2A would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches.

#### *4.7.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Overall, cumulative effects to wetlands would be moderate over the period of analysis. Changes to wetlands in terms of changes to wetland acreage and ecological functions would be affected by climate change, water withdrawals, and invasive species management. Alternative 2B would also have moderate effects to the wetlands of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 2B (as opposed to Alternative 2A) there would be potential for major effects to wetlands around the reservoir when combined with climate change effects.

#### *4.7.2.4.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Santiam subbasin entails decreases to wetland acreage and ecological functions, which would have a moderate effect to wetlands within the subbasin.

With the implementation of Alternative 2B, gravel augmentation downstream of Big Cliff and Foster Dams would slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit would further exacerbate the cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to wetlands when combined with cumulative effects, particularly climate change. This effect would entail decreases to wetland acreage and ecological functions of wetlands around the reservoirs.

#### *4.7.2.4.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Long Tom subbasin would entail decreases to wetland acreage and ecological functions and this would constitute a moderate effect within the Long Tom subbasin. Alternative 2B would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.7.2.4.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the McKenzie subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 2B, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for wetlands along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wetlands around the reservoirs more susceptible to climate change effects. Particularly at

Cougar, where deep fall and spring drawdowns would be implemented, there would be potential for moderate adverse effects to wetlands when combined with cumulative effects, particularly climate change. This would push trends toward decreases to wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.4.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the Middle Fork Willamette subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 2B, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for moderate effects to wetlands around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward decreases to wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.4.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Coast Fork Willamette subbasin entails decreases to wetland acreage and ecological functions.

The implementation of Alternative 2B would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands within the Coast Fork Willamette.

#### *4.7.2.4.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 2B would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches.

#### *4.7.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Overall, cumulative effects to wetlands would be moderate over the period of analysis. Changes to wetlands in terms of changes to wetland acreage and ecological functions would be affected by climate change, water withdrawals, and invasive species management. Alternative 3A would also have moderate effects to the wetlands of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below.

##### *4.7.2.5.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Santiam subbasin entails decreases to wetland acreage and ecological functions, which would have a moderate effect to wetlands within the subbasin.

With the implementation of Alternative 3A, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for wetlands along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. At Detroit (fall and spring) and Green Peter (fall) drawdowns would be implemented and therefore, there would be potential for major adverse effects to wetlands when combined with cumulative effects, particularly as a result of climate change. This effect would entail an increasing trend toward decreases to wetland acreage and ecological functions around the reservoirs.

##### *4.7.2.5.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Long Tom subbasin would entail decreases to wetland acreage and ecological functions and this would constitute a moderate effect within the Long Tom subbasin. Alternative 3A would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.7.2.5.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the McKenzie subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 3A, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for wetlands along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wetlands around the reservoirs more susceptible to climate change effects. At Cougar, a deep spring drawdown would be implemented and at Cougar and Blue River, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause moderate effects to wetlands around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases of wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.5.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the Middle Fork Willamette subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 3A, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for wetlands along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. In addition to the drawdowns with minor effects to wetlands, at Lookout Point, a deep spring drawdown would be implemented and at Lookout Point and Hills Creek, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause major effects to wetlands around the reservoirs when combined with cumulative effects, particularly climate change. This effect would entail decreases to wetland acreage and ecological functions around the reservoirs.

##### *4.7.2.5.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Coast Fork Willamette subbasin entails decreases to wetland acreage and ecological functions.

The implementation of Alternative 3A would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands within the Coast Fork Willamette.

##### *4.7.2.5.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 3A would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches.

#### ***4.7.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)***

Overall, cumulative effects to wetlands would be moderate over the period of analysis. Changes to wetlands in terms of changes to wetland acreage and ecological functions would be affected by climate change, water withdrawals, and invasive species management. Alternative 3B would also have moderate effects to the wetlands of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below. Alternative 3B is very similar to 3A. The primary differences are related to locations of the drawdowns and the fact that deep drawdowns occurring at Cougar would be to the elevation of the diversion tunnel.

##### *4.7.2.6.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Santiam subbasin entails decreases to wetland acreage and ecological functions, which would have a moderate effect to wetlands within the subbasin.

With the implementation of Alternative 3B, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for wetlands along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. At both Detroit (fall) and Green Peter (fall and spring) deep drawdowns would be implemented and therefore, there would be potential for major effects to wetlands when combined with cumulative effects, particularly as a result of climate change. This effect would entail an increasing trend toward decreases of wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.6.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetland in the Long Tom subbasin would entail decreases to wetland acreage and ecological functions and this would constitute a moderate effect within the Long Tom subbasin. Alternative 3B would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.7.2.6.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the McKenzie subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 3B, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for wetlands along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wetlands around the reservoirs more susceptible to climate change effects. At Cougar, a deep spring drawdown would be implemented and at Cougar and Blue River, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause moderate effects to wetlands around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases of wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.6.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the Middle Fork Willamette subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 3B, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for wetlands along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. In addition to the drawdowns with minor wetland effects, at Hills Creek, a deep spring drawdown would be implemented and at Lookout Point and Hills Creek, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause moderate effects to wetlands around the reservoirs when combined with cumulative effects, particularly climate change. This effect would entail decreases to wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.6.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Coast Fork Willamette subbasin entails decreases to wetland acreage and ecological functions.

With the implementation of Alternative 3B, the drawdowns at Cottage Grove and Dorena would make wetlands around the reservoirs more susceptible to climate change effects. These drawdowns would potentially cause moderate effects to wetlands around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases of wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.6.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 3B would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches.

### *4.7.2.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Overall, cumulative effects to wetlands would be anticipated to be moderate over the period of analysis. However, Alternative 4 would not contribute substantially to the changes in the wetlands of the WVS. Changes to wetlands in terms of changes to wetland acreage and ecological functions would be affected to a greater magnitude by climate change, water withdrawals, and invasive species management than by Alternative 4. Cumulative effect summaries for Alternative 4 by subbasin are provided below.

#### *4.7.2.7.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Santiam subbasin entails decreases of wetland acreage and ecological functions, which would have a moderate effect to wetlands within the subbasin.

With the implementation of Alternative 4, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for wetlands along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit will would make wetlands around the reservoirs more susceptible to climate change effects, which would ultimately constitute a moderate effect, pushing trends toward decreases of wetland acreage and ecological functions around the reservoirs.

#### *4.7.2.7.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Long Tom subbasin would entail decreases of wetland acreage and ecological functions and this would constitute a moderate effect within the Long Tom subbasin. Alternative 4 would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.7.2.7.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the McKenzie subbasin would entail decreases of wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 4, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for wetlands along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wetlands around the reservoirs more susceptible to climate change effects, which would constitute a minor effect, pushing trends toward decreases of wetland acreage and ecological functions around the reservoirs.

##### *4.7.2.7.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the Middle Fork Willamette subbasin would entail decreases of wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 4, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for wetlands along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for minor effects to wetlands around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward decreases of wetland acreage and ecological functions around the reservoirs.

##### *4.7.2.7.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Coast Fork Willamette subbasin entails decreases to wetland acreage and ecological functions.

With the implementation of Alternative 4, the drawdowns at Cottage Grove and Dorena would make wetland around the reservoirs more susceptible to climate change effects. These drawdowns would potentially cause moderate effects to wetlands around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases of wetland acreage and ecological functions around the reservoirs.

##### *4.7.2.7.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 4 would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches.

#### ***4.7.2.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Overall, cumulative effects to wetlands would be moderate over the period of analysis. Changes to wetlands in terms of changes to wetland acreage and ecological functions would be affected by climate change, water withdrawals, and invasive species management. Alternative 5 (as with Alternative 2B) would also have moderate effects to the wetlands of the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in some subbasins as discussed below. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 5 (as with Alternative 2B) there would be potential for major effects to wetlands around the reservoir when combined with climate change effects. The effects of Alternative 5 when combined with cumulative effects are identical to those of Alternative 2B as presented in Section 4.7.2.4. Cumulative effect summaries for Alternative 5 by subbasin are provided below.

##### *4.7.2.8.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Santiam subbasin entails decreases to wetland acreage and ecological functions, which would have a moderate effect to wetlands within the subbasin.

With the implementation of Alternative 5, gravel augmentation downstream of Big Cliff and Foster Dams would slightly improve conditions for vegetative communities along downstream reaches within the Santiam subbasin. On the other hand, the drawdowns within Green Peter and Detroit would further exacerbate the cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to wetlands when combined with cumulative effects, particularly climate change. This effect would entail decreases to wetland acreage and ecological functions of wetlands around the reservoirs.

##### *4.7.2.8.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Long Tom subbasin would entail decreases to wetland acreage and ecological functions and this would constitute a moderate effect within the Long Tom subbasin. Alternative 5 would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

##### *4.7.2.8.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the McKenzie subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 5, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for wetlands along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wetlands around the reservoirs more susceptible to climate change effects. Particularly at Cougar, where deep fall and spring drawdowns would be implemented, there would be potential for moderate adverse effects to wetlands when combined with cumulative effects, particularly climate change. This would push trends toward decreases to wetland acreage and ecological functions around the reservoirs.

##### *4.7.2.8.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wetlands in the Middle Fork Willamette subbasin would entail decreases to wetland acreage and ecological functions along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 5, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for vegetative communities along downstream reaches within the Middle Fork Willamette subbasin. On the other hand, the drawdowns within Hills

Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for moderate effects to wetlands around the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward decreases to wetland acreage and ecological functions around the reservoirs.

##### *4.7.2.8.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would add additional stress on wetlands around the reservoirs. Therefore, the general trend of wetlands in the Coast Fork Willamette subbasin entails decreases to wetland acreage and ecological functions.

The implementation of Alternative 5 would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands within the Coast Fork Willamette.

##### *4.7.2.8.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 5 would not have a more than negligible effect on the general trend of decreases to wetland acreage and ecological functions associated with wetlands along downstream reaches.

## 4.8 FISH AND AQUATIC HABITAT

### 4.8.1 Cumulative Effects Analysis Methodology for Fish and Aquatic Habitat

#### *4.8.1.1 Cumulative Actions Applicable to Fish and Aquatic Habitat*

Past actions include the initial authorization and implementation of the Willamette System. At this time, fish populations were in precipitous decline due to overfishing and industrialization. Several hatcheries were constructed by the state to support angling. Water quality was degraded by logging activity. Once the Willamette System was implemented, the floodplain became more channelized, water quality began to improve, urbanization increased, and migratory fish were excluded from a large proportion of spawning habitat in the upper Willamette tributaries. Downstream fish populations were affected by regulated flows. The present actions are characterized by continued decline of salmon and steelhead populations and a decrease in life history diversity due to limited juvenile outmigration opportunities for those spawned above dams. The hatchery program has had negative impacts on natural origin fish. The introduction of hatchery non-native summer steelhead has negatively impacted winter steelhead through genetic influence (introgression) and competition. The effects of the proposed actions for ESA-listed fish and aquatic species are described in Chapter 3. The following describes Reasonable Foreseeable Future Actions (RFFAs), when considered together with the Proposed Action and alternatives, would have cumulative effects on fish and aquatic habitat, that include:

- RFFA 1 - Future population growth and accompanying urban, industrial, and commercial development
- RFFA 2 - Future agricultural development
- RFFA 3 - Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 4 - Decarbonizing the energy sector with renewable energy sources
- RFFA 6 - Federal and state wildlife and lands management
- RFFA 7 - Pacific Ocean fishery management
- RFFA 8 - Tribal, state, and local fish and wildlife improvement
- RFFA 9 - Invasive species management
- RFFA 10 - Climate change

Some of the other RFFAs discussed in Section 4.2.3 would not change effects on fish and aquatic habitat in the Willamette Basin or only negligibly alter the WVS dam and reservoir operations and as such would not have a cumulative effect on fish and aquatic habitat:

RFFA 5 – Effects from emissions from the transportation sector would not be expected to have a direct impact on fish and aquatic habitat. Effects from emissions would be expected to contribute to future climate change through contribution to GHG emissions, and therefore these effects will be considered under RFFA 10.

RFFA 11 - Most future mining activities would be expected in either Clackamas or Douglas counties. Very little of the WRB occurs in Douglas County, therefore any effects from mining on WRB fish would be largely expected within the Clackamas County in the Clackamas River Sub-basin. These effects could include water quality degradation from sedimentation or release of hazardous materials into natural water bodies or those connected with natural water bodies within the Clackamas River Sub-basin.

RFFA 12 - Little timber harvest is expected to occur in the WRB since about 71% of Western Oregon forests are in Federal ownership, all of which is not available for harvest, and harvest rates are predicted to remain stable or gradually decline. Forest lands in ownership by the State of Oregon or in private ownership generally occur in the foothills of the Cascade Mountains and Coast Range portions of the WRB. Where harvest occurs on these smaller portions of the WRB, harvest can increase water run-off rates, increase sedimentation, and increase water temperatures. These effects reduce the quality and availability of aquatic habitat for native fish and aquatic organisms using forested streams until forests re-establish over the decades following harvest.

### 4.8.2 Cumulative Effects to Fish and Aquatic Habitat by Measure

RFFA 1 –

*Within the counties that comprise the WRB, human populations are continuing to increase. This growth is occurring primarily in urban metropolitan areas with smaller increases in rural areas.*

*If the relationship between the increase in population and the increase in developed land continues into the future, and mirrors the trend that existed from 1982 to 2017, developed land area of the WRB from 2020 to 2050 would be estimated to increase by 28 percent.*

*Municipal water demands may increase, which may be met by increased withdrawals from the WVS.*

*Increased urban development would decrease upland habitat and increase impervious surface in the area, changing the physical, chemical, hydrological, and ecological characteristics of stream ecosystems. In most cases, such changes are detrimental to native fish and wildlife.*

*The rate of exurban (area just beyond denser suburbs) development also appears to be increasing. Exurban development is generally associated with direct habitat conversion and loss for fish and wildlife species. Human population growth and development often leads to increased discharges of non-point source pollutants in stormwater runoff from residential, commercial, industrial, agricultural, recreational, and transportation land uses.*

*Projects to deepen channels or modify ports in Portland, OR may necessitate increasing numbers of ships and cargo tonnage on the lower Willamette and increasing rail freight and truck traffic* *on transportation corridors in the WRB that are linked to that port. Increased volumes of materials such as hazardous products and fuels that power trains, vessels, and trucks will likely move through the WRB in response to the demands of a growing population.*

*With increased movement of raw materials and manufactured goods via all three modes, more accidents and spills would be likely. Mining, logging, trade, and transportation projects also influence the hydrology, water quality, and land use in the WRB and WVS. Overall, this RFFA interacts cumulatively with all of the resources listed in Table 4.2-6.*

Future population growth and accompanying urban, industrial, and commercial development (RFFA 1) would increase local inflow in winter into river reaches downstream of the WVS dams during and increase demand for water withdrawals in consumptive uses (see RFFA 3 analysis below). The increased runoff could increase non-point source pollutants affecting fish health, behavior and survival. Increased winter flows could increase inundation of off-channel river features and the flood plain, which may provide additional habitat for rearing native fish. Increased demand for water withdrawals associated with population growth and development would increase summer water temperatures where they decrease instream flow. Fish habitat availability could increase or decrease depending on the timing and magnitude of instream flow changes, river reach affected, and the fish species life history and life stage.

RFFA 2 –

*Human population growth and related development have contributed to the decline of agricultural lands within the WRB.*

*Given the population projections shown in Table 4.2-4 that show strong growth for each of the 10 counties, land conversion and development pressures are likely to continue and the area of cropland within the WRB will likely continue to diminish. Reduced cropland acreage may reduce demands for agricultural irrigation water withdrawn from the WRB. Less cropland could also result in less soil erosion from wind and rain. Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.2-6, including but not limited to land use, soils, wetlands, listed species and critical habitat, socioeconomics, water supply, and visual resources.*

Agricultural land conversion and development pressures from population growth are projected to continue, and thus the area of cropland within the WRB will likely continue to diminish. Reduced cropland acreage may reduce demands for agricultural irrigation water withdrawn from the WRB. Decreased water demand would reduce water withdrawals for croplands from streams, and reduce exposure to agricultural pollutants from converted croplands. Negative effects from croplands on water quality and instream flow would be reduced, potentially improving habitat and survival of fish.

RFFA 3 – Future agricultural development

*Water usage within the WRB is likely to increase in the future, especially as human population growth, associated development, and climate change continue to affect water availability and scarcity in the region.*

*Water demand for irrigation usage (as seen in green) is predicted to remain relatively stable over the course of the 21$^{st}$ century; whereas water demand for municipal and residential usage (as seen in blue) would increase, likely linked to factors such as increasing human population projections and the evolving effects of climate change (WW2100, No Date).*

*By reducing the amount of water flowing through the WVS, increased withdrawals have implications for instream flow and for maintenance of riparian and aquatic habitats for fish and wildlife. New water withdrawals are typically subject to regulatory restrictions which might partially offset their negative effects. In the model's scenario, urban areas in general would be able to meet water needs with existing water rights, which would also include maintaining important water sources from outside the basin, such as the Bull Run watershed that supplies the City of Portland (WW2100, No Date). Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.2-6, including but not limited to water supply, socioeconomics, listed species and critical habitat, water quality, and hydrological processes.*

Increased water demands are expected to increase water withdrawals, particularly in the mainstem Willamette River downstream of Salem, OR (see WBR EA/BA). Increases in water withdrawals downstream from WVS dams in the 30 year period after the ROD (until ~2050) were accounted for when assessing the effects of the alternatives in the Environmental Consequences section, but not for streams in the WRB not regulated by the WVS, or beyond 2030. The effect of increased water withdrawals in these other streams, and in the WBR at large beyond 2030, would be to increase water temperatures in the WRB streams and rivers, potentially increase the concentration of toxic pollutants, and change habitat availability. The effect of increased water withdrawals on fish depends on the location, magnitude, timing and duration of the withdrawals and associated return flows. Because most of the increase in withdrawals are expected to occur during summer months downstream of Salem OR, the effect on ESA-listed fish (spring Chinook, winter steelhead and bull trout) will be limited since very few adults or juveniles are present in the mainstem during summer months. Increasing stored water releases from WVS reservoirs to meet new water withdrawals on the mainstem will increase flows in Willamette River tributaries, where both adult and juveniles are present in the summer. In these tributaries, increased flows would reduce peak summer water temperatures, however habitat availability could either increase or decrease depending on river reach, and species/lifestage.

RFFA 4 –

*Oregon's Renewable Portfolio Standard sets the requirement for how much of the state's electricity must come from renewable sources. In March 2016, this standard was set to require 50 percent of Oregon's electricity to come from renewables by 2040 (ODEQ, No Date-e).*

*Hydropower facilities typically provide more than half of the electricity generated in Oregon; natural gas fuels the second-largest share of Oregon's electricity generation, while non-hydroelectric renewable resources, including wind, biomass, solar, and geothermal power, provide almost the rest of Oregon's generation.*

*Decarbonizing the energy sector with renewable energy sources (RFFA 4) could have a number of conflicting impacts. Increasing development of wind and solar generation could reduce the demand for hydropower generation. Alternatively, the increase in solar and wind projects may increase the demand for hydropower due to its baseload and flexibility capabilities.*

If decarbonizing the energy sector with renewable energy sources reduces the demand for hydropower generation, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, including fish passage and water temperature operations. Conversely if decarbonizing the energy sector with renewable energy sources increases the demand for hydropower leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management.

RFFA 6 – Federal and state wildlife and lands management

*The WRB contains abundant public lands, especially in the headwaters and higher elevations. These lands would continue to be managed for multiple purposes, such as watershed protection, wildlife and habitat conservation, recreation, livestock grazing, resource extraction (e.g., logging, mining), and other public uses.*

*The Oregon Department of Fish and Wildlife (ODFW) and the U.S. Fish and Wildlife Service (USFWS) would continue to implement management activities at the Willamette Valley National Wildlife Refuge Complex.*

*The way that these lands are managed within the WRB can have cumulative effects when added to the actions proposed in this Draft EIS. In particular, water management, soil management, vegetation management, and fire management can have important additive effects that could be either beneficial or adverse depending on the nature of the management action. Overall, this RFFA interacts cumulatively with most of the resources listed in Table 4.2-6, including but not limited to land use, water and air quality, socioeconomics, flood risk management, water supply, recreation, listed species and critical habitat, hazardous algal blooms, tribal and cultural resources, and environmental justice.*

Baker et al. (2004) discuss alternative futures for land use in the WRB in 2050. Likely actions included those that converted agricultural to urban land use and higher prioritization on wildlife and conservation initiatives. The suite of actions analyzed under this PEIS are intended to be compatible with multiple land use approaches and conservation obligations. With the exception of future water availability, it is expected that conservation initiatives would improve the population status of endangered fish in the WRB.

It is expected that with the implementation of passage and conservation initiatives, the state's hatchery program could result in competing objectives for recreational angling and conservation. The original intent of the authorization for game fish hatcheries did not consider the recreational benefits to the State from reservoir inundation, nor the increasing budget needed to maintain services for an expanding recreational fishing industry. Retail sales for sport fishing in 2016 generated $680M in revenue and provided 11,000 jobs in the State of Oregon (Testimony of the Northwest Sportfishing Industry Association 2015 to Congress). Despite this, the State has encountered budget shortfalls as mission areas expand for conservation and ESA requirements but available spending for these programs remains the same or has declined. In 2014, ODFW expressed concerns of shrinking budgets, expanding conservation responsibilities, and increasing reliance on fishing and hunting licenses to support program missions (ODFW 2014). The popularity and revenue generation from recreational angling is particularly dependent on active stocking of game fish, Chinook salmon, and summer steelhead hatchery production. Although the Corps has continued to contribute to game fish stocking and hatchery programs to meet harvest missions, the magnitude of angling activity in Oregon has expanded beyond the stream angling experience of the late 1930's. It is expected that the hatchery program will need to be adjusted to accommodate improved habitat and passage conditions.

It is also expected that the USFWS Willamette Valley Wildlife Refuge Complex, which includes Ankeny, William L. Finley, and Baskett Slough would continue to be managed into the future.

RFFA 7- Pacific Ocean fishery management

Commercial and recreational fishing of Pacific salmon is multi-jurisdictional and multi-national. The evaluation of oceanic fishing is overseen by many agencies. However, the most robust analyses come from the Pacific Salmon Commission. The Pacific Salmon Commission relies on observers, fishermen, and information from PIT, clipped, and coded wire tagged fish to inform harvest modeling. Much of this information can be used to forecast appropriate harvest management in the future. Alternative hatchery management and production schedules could impact hatchery produced fish available to harvest. However, it is expected that improved conservation initiatives could enhance overall abundance available to ocean fisheries. Wild fish are assumed to be natural more productive than their hatchery counterparts which would naturally favor a larger wild population if hatchery fish made up a smaller component and adequate downstream passage was implemented. Alternatively, changing ocean conditions and ocean survival can outstrip the benefits of passage and reduced hatchery pressure in a given year (see Appendix E). Therefore, it is expected that fishing performance in the future would be at least as variable as it is at present.

RFFA 8- Tribal, state, and local fish and wildlife improvement

Tribal, state, and local governments work independently or collaboratively on initiatives geared toward conservation, restoration, and public access to wildlife resources. Tribal actions are related to restoration and access to wildlife resources. Initiatives to preserve cultural resources is ongoing and expected to continue.

The state has several programs focused on conservation and habitat restoration. The 2010 memorandum of understanding details a wildlife mitigation program run jointly with Bonneville Power Administration and funded by Bonneville Power Administration. The program is intended to mitigate for the effects of inundation and construction of the Willamette Valley Project by acquiring land for purposes of habitat restoration. This program is expected to continue under the terms and deadlines of that memorandum and that the effects will result in an improvement to endangered fish and aquatic wildlife. The state also operates several wildlife conservation, research, internship and public outreach programs with local and private conservation entities. These programs will directly positively impact fish and wildlife through habitat restoration and mitigation actions and indirectly positively impact fish in wildlife through public education on wildlife resource management.

RFFA 9- Invasive species management

The state of Oregon with funding from BPA manages invasive species removal. Several local agencies also surveil for invasive species and evaluate invasive species risk. Many of these local efforts are also integrated with habitat restoration. It is expected that with changes to water availability, future urbanization and withdrawals, the risk for invasive species to colonize in the Willamette in the future will be greater. Invasive species management may need to be increased to avoid detrimental effects in the future. Invasive species may have direct impacts through competition or predation, or indirect effects through reduction of critical habitat attributes.

RFFA 10- Climate change

*The RMJOC-II report (2018) found the following for the 2020 to 2049 time period:*

- Temperatures in the region have already warmed about 1.5 degrees Fahrenheit (°F) since the 1970s. Temperatures are expected to warm another 1 to 4°F by the 2030s.
- Future precipitation trends are more uncertain, but higher precipitation is likely for the rest of the 21st century, particularly in the winter months. Already-dry summers could become drier.
- The incidence of large forest fires as seen in Figure 4.2-6 has increased since the early 1980s and is projected to continue increasing through the 21st century as air surface temperatures continue to rise. Wildfire alters the land surface and can have strong influences on runoff, vegetation dynamics, erosion and sediment transport, and ecosystem processes. Strong seasonality and dependence on spring snowmelt positions the WRB to be at risk for increased fires due to the effects of climate change.
- Average winter snowpacks in the mountains surrounding the Willamette Valley are very likely to decline over time as more winter precipitation falls as rain instead of snow.
- By the 2030s, higher average fall and winter flows on WRB streams and rivers, earlier peak spring runoff, and longer periods of low summer flows are very likely.

*Overall, this RFFA interacts cumulatively with all of the resources listed in Table 4.2-6.*

Effects of climate change were accounted for when assessing the effects of the alternatives in the Environmental Consequences section to 2050. As discussed in this section, we made the following assumptions about the effects from climate change resulting in higher precipitation in winter and higher air temperatures on fish in the WRB:

**Table 4.8-1. Climate Change Assumptions**

| | Increasing winter flow, decreasing summer flow and reservoir levels | Increasing water temperatures in streams and reservoirs |
|---|---|---|
| Adult holding and spawning | Decrease in available habitat | Increase in pre-spawn mortality |
| Incubation | Mortality from redd dewatering or scouring | Earlier emergence and earlier ocean entry |
| Rearing and Emigration | Increased frequency of displacement or mortality during flooding. Decrease or elimination of summer habitat; particularly for bull trout at decreasing elevations | Decrease or elimination of summer habitat; particularly for bull trout at decreasing elevations. Earlier emigration timing and earlier ocean entry of salmon and steelhead. |

Below dams, effects of climate change on fish will vary depending on WVS dams and reservoir operations. During the conservation storage and delivery seasons (Feb 1 to Sep 31) stored water can supplement natural flows in later spring to fall downstream of WVS dams. Discharged water temperatures from each dam can influence downstream river reaches to near each tributary confluence with the mainstem Willamette River. WVS stored water releases in later spring to fall can also influence water temperatures in the mainstem Willamette River. These effects will help reduce some of the negative effects of higher temperatures (increase in adult pre-spawn mortality from higher temperatures, increase in egg or juvenile displacement from higher winter flows, decrease in rearing habitat from higher water temperatures). The extent dams and reservoirs influence below dam flows and water temperatures depends on the measures included in each WVS PEIS alternative.

Most future mining activities would be expected in either Clackamas or Douglas counties. Very little of the WRB exists in Douglas County, therefore any effects from mining on WRB fish would be largely expected within the Clackamas County in the Clackamas River Sub-basin. These effects could include water quality degradation from sedimentation or release of hazardous materials into natural water bodies or those connected with natural water bodies within the Clackamas River Sub-basin. Poor water quality could decrease fish health and survival.

**Table 4.8-2. Summation of Effects of RFFAs on Fish and Aquatic Habitat**

| RFFA # | RFFA Title | Summary effects on fish and aquatic habitat |
|---|---|---|
| RFFA 1 | Future population growth and accompanying urban, industrial, and commercial development | Increased runoff leading to non-point source pollutants affecting fish health, behavior and survival; increased winter flows leading to increased off-channel or floodplain habitat for rearing fish; increased summer water temperatures where withdrawals decrease instream flow leading to changes in fish habitat availability, particularly in the mainstem Willamette River. |
| RFFA 2 | Future agricultural development | Conversion/development of croplands will decrease water demand and water pollutants from croplands, improving aquatic habitat for fish. |
| RFFA 3 | Water withdrawals for municipal, industrial, and agricultural uses | Increased water demands, particularly below Salem, leading to increased water temperatures, pollutant concentrations, and change aquatic habitat availability. Limited negative effect on ESA-listed fish expected (spring Chinook, winter steelhead and bull trout) since very few adults or juveniles are present in the mainstem during summer months, and some positive effects may occur within tributaries from increasing stored water releases from WVS reservoirs on tributaries to meet new water withdrawals on the mainstem. |
| RFFA 4 | Decarbonizing the energy sector with renewable energy sources | If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Conversely if the demand for hydropower increases leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management. |
| RFFA 6 | Federal and state wildlife and lands management | Adjustments to fish hatchery programs to accommodate for improved fish passage conditions at dams and reduce effects on conservation of wild fish; continued operation and maintenance of the USFWS Willamette Valley Wildlife Refuge Complex |
| RFFA 7 | Pacific Ocean fishery management | Fishing performance in the future would be at least as variable as it is at present due to variability in ocean conditions and fish survival in the ocean, and changes in salmon hatchery production. |
| RFFA 8 | Tribal, state, and local fish and wildlife improvement | Positively impact on fish through habitat restoration and mitigation actions and indirectly positive impacts on fish through public education on resource management. Locations and magnitude of impacts uncertain. |
| RFFA 9 | Invasive species management | Increased negative effects (primarily competition and predation) on native fish and aquatic habitat availability from invasive species. |
| RFFA 10 | Climate change | Decrease in habitat available for spawning and rearing. Increase in adult pre-spawn mortality, change in incubation and emergence timing and decrease in summer habitat availability and quality |

#### *4.8.2.1 No Action Alternative*

Negative impacts from the RFFAs include those from increased winter runoff, increased water temperatures from water withdrawals, and non-point source pollutants from population growth and development degrading aquatic habitat conditions and reducing fish health and survival. Water withdrawals for municipal and industrial (M&I) uses will also decease flows downstream of Salem, however since very few are present in the mainstem during summer months, limited negative effects on ESA-listed fish (spring Chinook, winter steelhead and bull trout) are expected from these M&I withdrawals. Effects of decarbonizing the energy sector with renewable energy sources is difficult to predict, however if the demand for hydropower increases leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management. Increased negative effects from invasive species on native fish (primarily competition and predation) is also expected to increase, in particular due to climate change effects favoring invasive species.

Some positive effects of RFFAs on fish and aquatic habitat in the WRB can also be expected. Conversion/development of croplands will decrease water demand and water pollutants, improving aquatic habitat conditions for fish. If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Fishing performance in the future would be at least as variable as it is at present due to variability in ocean conditions and fish survival in the ocean, and changes in salmon hatchery production. Ongoing and future aquatic and riparian habitat restoration and mitigation actions would also be expected to directly and indirectly have positive impacts on fish.

RFFAs are expected to infer a net negative impact in addition to the effects accounted for in the Environmental Consequences section. Poor fish passage conditions at WVS dams will continue to significantly constrain population viability of ESA-listed salmon and steelhead, and effects of RFFAs on habitat conditions below dams will further reduce population viability. Similarly, RFFAs also will infer a net negative impact for bull trout, stemming primarily from climate change-related contraction of existing habitat occupied above WVS dams (increased winter flows, decreased summer low flows, increased water temperatures) in high elevation areas. Under the NAA, bull trout do not have effective access to below dam habitat, however stream reaches below dams will further degraded in the future and not be expected to provide any suitable spawning areas, experience a reduction and degradation in available rearing habitat, and survival rates of bull trout below dams would be expected to decline due to increases in recognized risk factors (see fish analysis appendix X, section X).

#### *4.8.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 is a storage themed alternative with the intent to store water for multiple uses across the Corps' authorizations. Under Alternative 1, at-dam structures proposed for Detroit, Green Peter, Foster and Lookout Point dams provided for fish passage and water temperature management while promoting storage, integration with hydropower, and downstream water uses nearest communities that are expected to increase in population and likely water demand downstream. Minimum flows for fish as included are designed to adjust with real-time water availability, supporting downstream fish passage measures, and habitat and water temperature needs for fish below dams.

With respect to future population growth, urbanization, industrial, and commercial development, demand for this storage would increase and specific allocation would need to be forecasted with respect to fish and wildlife needs. While there may be greater public demand for access to stored water, fish and wildlife needs would also need to be prioritized. Given the uncertainty of water availability in the future and the expected increase in wildfire frequency with ongoing climate change, the ability to store more water earlier in the year may become a very valuable resiliency strategy. It is expected that as demand for agricultural use becomes less frequent with conversion to urban uses, negative impacts from effluent and agricultural runoff will positively affect fish and wildlife resources. Increased municipal water demand would likely compete with endangered fish and aquatic species needs such that stored water would likely need to be prioritized among interests. Increased urbanization expected in the future would likely mean a greater need for decarbonization and possibly greater demand for hydropower. This could indicate a need for stored water and a greater emphasis on at dam structural fish passage that is integrated with turbine operations. Federal and state land management downstream of project may be directly impacted by water storage practices, however, conservation efforts above project where the majority of quality habitat for endangered fish is expected to be, would likely be improved under Alternative 1. Pacific Ocean harvest management is unlikely to be directly affected but may be indirectly affected by the percentage of hatchery fish that make up total catch. It is expected that water storage would most likely support above dam populations of natural origin endangered fish, which are assumed to be more productive than their hatchery counterparts. While the catchability of hatchery origin fish may decrease, the catch of natural origin fish is expected to increase. Tribal, state, and local land management may be negatively impacted downstream of project depending on the allocation and water year type experienced in any given year. However, it is expected that the opportunity for improvement, on average, would be better than the No Action Alternative. Invasive species management may become more complex under Alternative 1. However, this complexity may well be buffered by the ability to allocate stored water such that negative impacts to endangered fish and aquatic species would be mitigated through adequate planning of stored water use. With respect to climate change, water storage is likely to be a more resilient planning strategy due to the fact that precipitation patterns and snow pack are expected to be more variable (and less predictable). While water availability forecasting is relatively limited, water storage early in the year allows for a buffer against unexpected climatic events that may occur later in the year (i.e., flows needed for fish later in the year). Overall, while Alternative 1 may not perform the best over other alternatives, it does provide some resiliency for fish and wildlife given the uncertainties with respect to urbanization, land use, climate change, and water use needs predicted in the future.

#### *4.8.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Alternative 2A is an integrated water management alternative that balances practical public need with operational flexibility that may better reflect the historic hydrograph with respect to endangered fish and aquatic species. This alternative integrates a mixture of at-dam downstream passage solutions with operational solutions. At-dam structural solutions to downstream fish passage are proposed at Detroit Dam, Foster Dam, and Lookout Point Dam. Operational downstream passage is proposed at Green Peter Dam and Cougar Dam. Future population growth under this alternative will likely have lesser impact to endangered fish and aquatic species due to implementation at projects where storage is prioritized over operational passage.

Under Alternative 2A, an at-dam structure proposed for Detroit and Lookout Point dams promote storage, integration with hydropower, and downstream water uses nearest communities that are expected to increase in population and likely water demand downstream. Operational measures for downstream fish passage are proposed for Green Peter and Cougar dams. Given the uncertainty of water availability in the future and the expected increase in wildfire frequency with ongoing climate change, the ability to store more water earlier in the year may become a very valuable resiliency strategy. Minimum flow targets proposed are responsive to water storage availability in the spring. Minimum flows for fish as included are designed to adjust with real-time water availability, supporting downstream fish passage measures, and habitat and water temperature needs for fish below dams. However, the reservoir drawdown to the regulating outlet at Cougar Dam in spring proposed at Cougar Dam for downstream fish passage will eliminate much of the ability to store water in Cougar Reservoir specifically.

It is expected that agricultural demand will decrease over time as use shifts to urban expansion and municipal uses. Water withdrawals are expected to increase which will impact endangered fish and aquatic species below project negatively. Demand for hydropower may increase which will likely show positive responses for endangered fish and aquatic species where at-dam/turbine friendly solutions are prioritized, a slightly positive effect on endangered fish and aquatic species where operational downstream passage is prioritized, and a detrimental effect from decarbonization leads to increased hydropower operations where operational downstream fish passage is prioritized. Federal and state wildlife and land management would likely be less affected in terms of direct and indirect effects. Where there are opportunities for storage at large projects such as Detroit where water availability would be more variable, agencies could incorporate adaptive planning. Where operational downstream fish passage is implemented, planning would be adaptive to endangered fish and aquatic species needs without sacrificing critical habitat. Pacific Ocean harvest would likely reflect outcomes described under Alternative 1. Tribal, state, and local wildlife management would likely reflect outcomes described under Alternative 1. Invasive species management would likely be complicated by the combination of at-dam storage and operational downstream passage approaches. This could result in management plans that are more reactive given that such operations have not yet been observed and monitored.

#### *4.8.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Alternative 2B is also an integrated water management alternative. Downstream fish passage at Cougar Dam is proposed as a spring and fall reservoir drawdown to the diversion tunnel in Alternative 2B, otherwise fish passage and water quality measures are the same in Alternative 2A and 2B. Operational fish passage at Cougar Dam proposed for this Alternative is estimated to be more effective that that proposed for Alternative 2A at Cougar Dam.

Future population growth under this alternative will likely have lesser impact to endangered fish and aquatic species due to implementation at projects where storage is prioritized over operational passage. Under Alternative 2B, an at-dam structure proposed for Detroit and Lookout Point dams promote storage, integration with hydropower, and downstream water uses nearest communities that are expected to increase in population and likely water demand downstream. Operational downstream passage is proposed at Green Peter and Cougar dams where urbanization downstream is unlikely to increase and effects on the public are expected to be less impactful.

Minimum flow targets proposed are responsive to water storage availability in the spring. Minimum flows for fish as included are designed to adjust with real-time water availability, supporting downstream fish passage measures, and habitat and water temperature needs for fish below dams. However, the reservoir drawdown to the regulating outlet at Cougar Dam in spring proposed at Cougar Dam for downstream fish passage will eliminate much of the ability to store water in Cougar Reservoir specifically.

It is expected that agricultural demand will decrease over time as use shifts to urban expansion and municipal uses. Water withdrawals are expected to increase which will impact endangered fish and aquatic species below project negatively. Demand for hydropower will likely increase which will likely show positive responses for endangered fish and aquatic species where at-dam/turbine friendly solutions are prioritized, a slightly positive effect on endangered fish and aquatic species where operational downstream passage is prioritized, and a detrimental effect on decarbonization where operational downstream passage is prioritized. Federal and state wildlife and land management would likely be less affected in terms of direct and indirect effects. Where there are opportunities for storage at large projects such as Detroit where water availability would be more variable, agencies could incorporate adaptive planning. Where operational downstream fish passage is implemented, planning would be adaptive to endangered fish and aquatic species needs without sacrificing critical habitat. Pacific Ocean harvest would likely reflect outcomes described under Alternative 1. Tribal, state, and local wildlife management would likely reflect outcomes described under Alternative 1. Invasive species management would likely be complicated by the combination of at-dam storage and operational downstream passage approaches. This could result in management plans that are more reactive given that such operations have not yet been observed and monitored.

#### *4.8.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Alternative 3A is focused on operational measures at WVS dams for fish passage and water quality. Operational measures for fish passage and water quality are less resilient to changes associated with RFFAs, when compared to structural measures, since structural measures are designed to be effective at a range of reservoir pool elevations and discharge rates, whereas operational measures effectiveness varies with reservoir elevation/volume, discharge outlets available, and discharge rates.

Minimum flows for fish as included are designed to adjust with real-time water availability in spring, supporting downstream fish passage measures, and habitat and water temperature needs for fish below dams. Given the uncertainty of water availability in the future and the expected increase in wildfire frequency with ongoing climate change, the ability to store more water earlier in the year may become a very valuable resiliency strategy.

Spring reservoir drawdowns for fish significantly decrease resiliency since the availability of storage water is substantially reduced. Spring drawdowns will reduce water available for supplementing naturally low flows in summer and fall, managing summer and fall water temperatures, and reduce reservoir habitat for fish remaining above dams. Spring drawdowns to regulating outlets occur at Detroit, Lookout Point, and Cougar dams in Alternative 3A.

Lower stream flows below dams resulting for spring drawdowns of reservoirs in the North Santiam, McKenzie and Middle Fork will be further negatively impacted by population growth and development, municipal and industrial (M&I) uses which increase water temperatures from water withdrawals, and non-point source pollutants reducing fish health and survival. However, since very few adults or juveniles are present in the mainstem during summer months, limited negative effects on ESA-listed fish (spring Chinook, winter steelhead and bull trout) are expected from M&I withdrawals in particular since most are predicted to occur downstream of Salem. If the demand for hydropower increases leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management. Increased negative effects from invasive species on native fish (primarily competition and predation) is also expected to increase, in particular due to climate change effects favoring invasive species. Fishing performance in the future would be at least as variable as it is at present due to variability in ocean conditions and fish survival in the ocean, and changes in salmon hatchery production.

Some positive effects of RFFAs on fish and aquatic habitat in the WRB may counter-balance some of the negative effects. Conversion/development of croplands will decrease water demand and associated water pollutants. Adjustments to fish hatchery programs would be expected to accommodate for improved fish passage conditions at dams and reduce effects on wild fish conservation. If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Ongoing and future aquatic and riparian habitat restoration and mitigation actions would also be expected to directly and indirectly have positive impacts on fish.

#### *4.8.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Alternative 3B is also focused on operational measures at WVS dams for fish passage and water quality. As described for 3A, operational measures for fish passage and water quality are less resilient to changes associated with RFFAs, when compared to structural measures. Spring drawdowns, in particular where they occur, significantly decrease resiliency. Spring drawdowns to regulating outlets occur at Green Peter and Hills Creek, and to the diversion tunnel at Cougar Dam in Alternative 3A.

Lower stream flows below dams resulting for spring drawdowns of reservoirs in the South Santiam, McKenzie and Middle Fork will be further negatively impacted by population growth and development, municipal and industrial (M&I) uses which increase water temperatures from water withdrawals, and non-point source pollutants reducing fish health and survival. However, since very few adults or juveniles are present in the mainstem during summer months, limited negative effects on ESA-listed fish (spring Chinook, winter steelhead and bull trout) are expected from M&I withdrawals in particular since most are predicted to occur downstream of Salem. Bull trout relying on Cougar Reservoir for rearing will likely re-distribute upstream into the South Fork McKenzie watershed or below Cougar Dam, which could lead to density dependent effects from habitat and food limitations and exposure to poorer habitat conditions lower in the McKenzie Sub-basin. If the demand for hydropower increases leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management. Increased negative effects from invasive species on native fish (primarily competition and predation) is also expected to increase, in particular due to climate change effects favoring invasive species. Fishing performance in the future would be at least as variable as it is at present due to variability in ocean conditions and fish survival in the ocean, and changes in salmon hatchery production.

As for Alternative 3B, some positive effects of RFFAs on fish and aquatic habitat in the WRB may counter-balance some of the negative effects. Conversion/development of croplands will decrease water demand and associated water pollutants. Adjustments to fish hatchery programs would be expected to accommodate for improved fish passage conditions at dams and reduce effects on wild fish conservation. If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Ongoing and future aquatic and riparian habitat restoration and mitigation actions would also be expected to directly and indirectly have positive impacts on fish.

#### *4.8.2.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Alternative 4 is a structural downstream passage themed alternative with the intent to prioritize and operate with a focus on ESA-listed fish species. Proposed downstream fish passage structures are proposed for Detroit, Foster, Cougar, Hills Creek and Lookout Point dams.

Minimum flows for fish as included are designed to adjust with real-time water availability in spring, supporting downstream fish passage measures, and habitat and water temperature needs for fish below dams. Given the uncertainty of water availability in the future and the expected increase in wildfire frequency with ongoing climate change, the ability to store more water earlier in the year may become a very valuable resiliency strategy.

With respect to future population growth, urbanization, industrial, and commercial development, demand for this storage would increase and specific allocation would need to be forecasted with respect to fish and wildlife needs. While there may be greater public demand for access to stored water, fish and wildlife needs would also need to be prioritized. Given the uncertainty of water availability in the future and the expected increase in wildfire frequency with ongoing climate change, the ability to store more water earlier in the year may become a more valuable resiliency strategy. It is expected that as demand for agricultural use becomes less frequent with conversion to urban uses, negative impacts from effluent and agricultural runoff will positively affect fish and wildlife resources. Increased municipal water demand would likely compete with endangered fish and aquatic species needs such that stored water would likely need to be prioritized among interests. Increased urbanization expected in the future would likely mean a greater need for decarbonization and possibly greater demand for hydropower. This could indicate a need for stored water and a greater emphasis on at dam structural fish passage that is integrated with turbine operations. Federal and state land management downstream of project may be directly impacted by water storage practices, however, conservation efforts above project where the majority of quality habitat for endangered fish is expected to be, would likely be improved under Alternative 1. Pacific Ocean harvest management is unlikely to be directly affected but may be indirectly affected by the percentage of hatchery fish that make up total catch. It is expected that water storage would most likely support above dam populations of natural origin endangered fish, which are assumed to be more productive than their hatchery counterparts. While the catchability of hatchery origin fish may decrease, the catch of natural origin fish is expected to increase. Tribal, state, and local land management may be negatively impacted downstream of project depending on the allocation and water year type experienced in any given year. However, it is expected that the opportunity for improvement, on average, would be better than the No Action Alternative. Invasive species management success is expected to be similar or better given the implementation of biological downstream flows. With respect to climate change, water storage is likely to be a more resilient planning strategy due to the fact that precipitation patterns and snowpack are expected to be more variable (and less predictable). While water availability forecasting is relatively limited, water storage early in the year allows a for a buffer against unexpected climatic events that may occur later in the year (i.e., flows needed for fish later in the year). Alternative 4 provides some resiliency for fish and wildlife given the uncertainties with respect to urbanization, land use, climate change, and water use needs predicted in the future.

#### *4.8.2.8 Alternative 5 – Integrated Water Management Flexibility and ESA-Listed Fish with Modified Flows Alternative*

Alternative 5 is functionally similar to Alternative 2B and it is anticipated that the cumulative effects under Alternative 5 will be indistinguishable from cumulative effects under Alternative 2B. Alternative 5, similar to alternatives 2A and 2B, is integrated water management alternative with small hydrological differences noted in Chapter 4 Hydrologic Processes. Downstream minimum flows are different below Big Cliff, Foster, Cougar and Dexter dams, otherwise fish passage and water quality measures are the same in alternatives 5 and 2B. Operational fish passage at Cougar Dam proposed for this Alternative is estimated to be more effective that that proposed for Alternative 2A at Cougar Dam.

Future population growth under this alternative will likely have lesser impact to endangered fish and aquatic species due to implementation at projects where storage is prioritized over operational passage. Under Alternative 5, at-dam structures for fish passage proposed for Detroit and Lookout Point dams promote storage, integration with hydropower, and downstream water uses nearest communities that are expected to increase in population and likely water demand downstream. Minimum flow targets proposed are responsive to water storage availability in the spring. Minimum flows for fish included are designed to adjust with real-time water availability Downstream fish passage operations at Green Peter Dam will utilize surface spill, promoting storage of water in the reservoir for fish other needs during the spring and summer. The reservoir drawdown to the regulating outlet at Cougar Dam in spring proposed at Cougar Dam for downstream fish passage will eliminate much of the ability to store water in Cougar Reservoir specifically. where urbanization downstream is unlikely to increase and effects on the public are expected to be less impactful.

It is expected that agricultural demand will decrease over time as use shifts to urban expansion and municipal uses. Water withdrawals are expected to increase which will impact endangered fish and aquatic species below project negatively. Demand for hydropower will likely increase which will likely show positive responses for endangered fish and aquatic species where at-dam/turbine friendly solutions are prioritized, a slightly positive effect on endangered fish and aquatic species where operational downstream passage is prioritized, and a detrimental effect on decarbonization where operational downstream passage is prioritized. Federal and state wildlife and land management would likely be less affected in terms of direct and indirect effects. Where there are opportunities for storage at large projects such as Detroit where water availability would be more variable, agencies could incorporate adaptive planning. Where operational downstream fish passage is implemented, planning would be adaptive to endangered fish and aquatic species needs without sacrificing critical habitat. Pacific Ocean harvest would likely reflect outcomes described under Alternative 1. Tribal, state, and local wildlife management would likely reflect outcomes described under Alternative 1. Invasive species management would likely be complicated by the combination of at-dam storage and operational downstream passage approaches. This could result in management plans that are more reactive given that such operations have not yet been observed and monitored.

## 4.9 WILDLIFE, BIRDS, AND TERRESTRIAL HABITAT

### 4.9.1 Cumulative Effects Analysis Methodology for Wildlife, Birds, and Terrestrial Habitat

#### *4.9.1.1 Cumulative Actions Applicable to Wildlife, Birds, and Terrestrial Habitat*

Past, present, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on wildlife and associated habitat include:

- WVS Dams and Reservoirs: construction and past operations and maintenance (see section 4.2.1.1) as well as ongoing operations and maintenance (see section 4.2.2)
- WRB Population Growth and Development: increased development extent and intensity within the Willamette River Basin (see section 4.2.1.2)
- WVS Dams and Reservoirs: ongoing operations and maintenance (see section 4.2.2)
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development
- RFFA 2: Future agricultural development
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 4: Decarbonizing the energy sector with renewable energy sources
- RFFA 5: Federal and state wildlife and lands management
- RFFA 6: Fishery management and killer whales.
- RFFA 7: Tribal, state, and local fish and wildlife improvement
- RFFA 8: Invasive species management
- RFFA 9: Climate change
- RFFA 10: Mining operations
- RFFA 11: Timber and logging industry operations

### 4.9.2 Cumulative Effects to Wildlife, Birds, and Terrestrial Habitat by Alternative

The WVS dams and reservoirs are currently authorized for flood control, hydropower, pollution abatement, fish and wildlife conservation, recreation, irrigation, municipal and industrial water supply, and water quality. Wildlife species and wildlife habitat within the WRB has been affected by the construction and operation of the WVS dams and reservoirs, dams constructed by other entities (Section 4.1.2.1.1), urban and rural development and land use, transportation infrastructure development, dredging and sediment management and other land-altering activities. The cumulative effect is a decrease of biodiversity and changes to a variety of habitats that support a wide range of wildlife species. Simplification of the stream channels within the WVS limits habitat availability across the floodplains that support aquatic species while also extending upland habitat for terrestrial species that would not otherwise be available.

Future population growth and accompanying urban, industrial, and commercial development (RFFA 1) occurring in the WRB would continue to affect wildlife species by disturbing individuals and further fragmenting habitat during construction activities. Development related to decarbonizing the energy sector with renewable energy sources (RFFA 4) such as wind and solar projects would likely affect wildlife species and habitat similarly. There is particular guidance for federal actions involving development to protect certain ESA-listed species and critical habitat. However, some development-related impacts would be permitted and state and local actions would be less regulated. The cumulative actions associated with development would create adverse, additive, and moderate effects to wildlife and wildlife habitat.

Future agricultural development (RFFA 2) occurring in historical floodplains would further fragment wildlife habitat and passage within these areas. Outside of the urban growth boundaries within the WRB, this floodplain development would likely be in the form of larger ranchettes or properties that take advantage of the hydrology in soils within low-lying areas. These are areas that terrestrial wildlife species cross in order to access water. Fence installation, grazing livestock, and cultivating crops with machinery would affect wildlife by limiting passage through these areas. In addition, spreading invasive plant species from these areas can affect downstream riparian habitat that is important to many wildlife species. The cumulative actions associated with agricultural development would create adverse, additive, and moderate effects to wildlife and wildlife habitat.

Water withdrawals for municipal, industrial, and agricultural uses (RFFA 3) would have the effect of either decreasing reservoir water surface elevation, decreasing instream flows, or a combination of both. Decreased water surface elevation would affect aquatic species such as breeding amphibians and reptiles that depend on inundation at certain times of year for reproductive success. Many aquatic wildlife species also depend on wetland habitat that would be affected by decreasing water surface elevations. These cumulative actions would create adverse, additive, and moderate effects to wildlife species and wildlife habitat. These effects have largely been considered in Section 3.9 as they relate to the hydrologic effects of each alternative.

Federal and state wildlife and lands management (RFFA 5) happen throughout the regulated and unregulated portions of the watershed and are conservation focused or expected to occur with similar actions and rates as in the recent past. National forests, wilderness areas, and wildlife refuges (listed in Section 4.2.6) management actions, will continue as currently undertaken. Similarly, timber and logging industry operations (RFFA 11) will continue as currently undertaken throughout the watershed. The cumulations actions associated with these RFFA's would continue to affect wildlife and wildlife habitat by disturbing individuals, particularly during breeding periods, and fragmenting habitat. These cumulative actions would be additive and cause adverse moderate effects to wildlife and wildlife habitat.

Tribal, state, and local fish and wildlife improvement (RFFA 7) includes river and floodplain restoration actions and potentially environmental flows to inundate floodplain areas. Environmental flows have been performed historically in the Willamette system but have been limited in magnitude to non-damaging peak flows similar to smaller regulated flood events. These floodplain restoration actions would sometimes involve some consideration of wildlife effects and improvement of wildlife habitat. These cumulative actions would create beneficial, additive, and minor effects to wildlife and wildlife habitat within the WVS.

Invasive species management (RFFA 8) includes a range of management actions taken by federal, state, and local agencies as well as private organizations to combat the spread of invasive species, including invasive wildlife species. In addition, management of invasive plants can help by protecting wildlife habitat, like wetlands, where the ecological functions of the habitat would change with invasive plant infestation. Invasive species management within the WRB would likely continue at the same rate as it currently is undertaken. Invasive species management would create beneficial, additive, and moderate effects to wildlife and wildlife habitat within the WVS.

Climate change (RFFA 9) would affect wildlife and wildlife habitat primarily due to longer drier summers. Habitat that occurs in riparian areas, such as wetland and aquatic habitat, would shrink and the ecological functions would change and less able to support certain aquatic species. Water temperature would increase with climate change, which would affect fish and other forage species that wildlife species depend on. With increased water temperature there would be an increase in toxic algal blooms, which can adversely affect wildlife species and food chains. The seasonality of wildlife species (e.g., birds, reptiles, insects, etc.) life histories would need to adjust to the new climate patterns, which would have a number of adverse effects to species, interactions between species, and interactions with their habitats. See the climate change sections for each alternative in section 3.9 for more information. Ultimately, climate change effects would be adverse, additive, and have major effects to wetlands within the WVS.

In general, the RFFAs have an adverse, additive, major effect on wildlife and wildlife habitat throughout the WRB. Continued development throughout the basin and all the actions associated with increased population within both urban and rural areas as well as other RFFA's that cause additional stress on wildlife (e.g., water withdrawals, habitat fragmentation, and climate change) would decrease biodiversity and habitat available for wildlife species. On the other hand, conditions for wildlife and wildlife habitat would be enhanced or maintained by restoration actions within the floodplains and management of invasive species. General trends described in this section apply to all subbasins within the WVS. Differences in the cumulative effects per subbasin will be described in the discussion below.

#### *4.9.2.1 No Action Alternative*

Combined with the effects of the cumulative effects listed above (particularly climate change), there would likely be additional effects to wildlife and wildlife habitat under the No Action Alternative. As discussed in section 3.9.2.2, the effects of the No Action Alternative would have both a beneficial and an adverse effect to wildlife and wildlife habitat in the WVS. The beneficial effect of the NAA is that water storage in the reservoirs would be maintained and would continue to support hydrology in aquatic and wetland habitats at the reservoirs that may not otherwise exist. One adverse effect is that since stream flows would continue to be managed for flood control and confined to a fairly uniform channel, wildlife habitat along reaches downstream of the USACE projects would continue to be limited in diversity and amount available. In addition, without fish passage provided, forage species (including but not limited to salmonids) population size would be limited upstream of the WVS projects. The NAA on its own would have both minor beneficial and adverse effects to wildlife and wildlife habitat, maintaining existing conditions. Combined with cumulative effects (primarily climate change), there would be major adverse effects to wildlife within the WVS in the form of changes to suitable habitat acreage, water quality, and the seasonality of wildlife life histories.

#### *4.9.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Overall, cumulative effects to wildlife and wildlife habitat would be anticipated to be major over the period of analysis. However, Alternative 1 would not contribute substantially to the changes to wildlife and wildlife habitat within the WVS. Changes to biodiversity and suitable habitat availability would be affected to a greater magnitude by climate change, water withdrawals, and habitat fragmentation due to development than by Alternative 1. Cumulative effect summaries for Alternative 1 by subbasin are provided below.

##### *4.9.2.2.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers affecting stream flows and water quality. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Santiam subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories. Cumulative effects would have an adverse major effect to wildlife and wildlife habitat within the subbasin.

With the implementation of Alternative 1, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve hydrologic conditions for aquatic and wetland habitat along downstream reaches within the Santiam subbasin. In addition, providing fish passage at Green Peter, Foster, and Detroit will slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects thereby increasing trends of decreases to suitable habitat acreage. Combined with cumulative effects, an adverse major effect to wildlife and wildlife habitat would be anticipated.

#### *4.9.2.2.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would affect aquatic and wetland habitat at the reservoirs. Alternative 1 would improve foraging opportunities for wildlife slightly by providing downstream fish passage over the drop structures downstream of Fern Ridge. However, the overall trend of wildlife and wildlife habitat in the Long Tom subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories and this would constitute a major adverse effect within the Long Tom subbasin.

#### *4.9.2.2.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife in the McKenzie subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories largely due to climate change (an adverse major effect). It should be noted that aquatic and wetland habitat would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 1, gravel augmentation downstream of Cougar and Blue River dams will slightly improve hydrologic conditions for aquatic and wetland habitat along downstream reaches within the McKenzie subbasin. On the other hand, the drawdowns at Cougar reservoir would make aquatic and wetland habitat around the reservoirs more susceptible to climate change effects but ultimately, only minor adverse effects to wetlands would be anticipated around Cougar reservoir because of increased storage. Combined with the cumulative effects, a major adverse effect to wildlife and wildlife habitat is anticipated.

#### *4.9.2.2.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the Middle Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 1, gravel augmentation downstream of the WVS dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Middle Fork Willamette subbasin. Providing downstream fish passage at Lookout Point and Dexter would slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns at Falls Creek, Hills Creek, and Lookout Point reservoirs will further exacerbate the cumulative effects at the reservoirs thereby increasing trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories, which would be considered a major adverse effect overall for the subbasin.

##### *4.9.2.2.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Coast Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

With the implementation of Alternative 1, increased storage at Cottage Grove and Dorena would offset lower reservoir elevations anticipated as a result of cumulative effects during conservation season; however, the drawdowns within Cottage Grove and Dorena will further exacerbate the cumulative effects thereby increasing trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories. Ultimately, combined with cumulative effects, a major adverse effect would be anticipated.

##### *4.9.2.2.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 1 would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches.

#### *4.9.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (includes structural downstream passage at Cougar Dam)*

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 2A would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins as discussed below.

#### *4.9.2.3.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Santiam subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories, which would have a major adverse effect to wildlife and wildlife habitat within the subbasin.

With the implementation of Alternative 2A, gravel augmentation downstream of Big Cliff and Foster Dams would slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Santiam subbasin. Adding lamprey passage at Green Peter and downstream fish passage at Detroit and Foster would slightly improve foraging opportunities for wildlife species within the subbasin. Adding a WTC tower at Detroit would slightly improve water temperature for salmonids, which are important to piscivorous wildlife. On the other hand, the drawdowns within Green Peter and Detroit would further exacerbate cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to aquatic and wetland habitat when combined with cumulative effects, particularly climate change. This major adverse effect would entail an increasing trend toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.3.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would affect aquatic and wetland habitat around the reservoir. Therefore, the general trend of vegetative communities in the Long Tom subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories and this would constitute a major adverse effect within the Long Tom subbasin. Alternative 2A would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.9.2.3.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the McKenzie subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 2A, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. Adding downstream fish passage at Cougar would slightly improve foraging opportunities for wildlife species within the subbasin. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make aquatic and wetland habitat around the reservoirs more susceptible to climate change effects, which would constitute a minor adverse effect. Overall, coupled with cumulative effects, Alternative 2A would have a major adverse effect to wildlife and wildlife habitat along downstream reaches and a minor adverse effect around the reservoirs within the subbasin.

##### *4.9.2.3.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the Middle Fork Willamette subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change (a major adverse effect) but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 2A, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Middle Fork Willamette subbasin. Providing downstream passage at Lookout Point would improve foraging opportunities and nutrient cycling for wildlife. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects around reservoirs. Overall, within the subbasin there would be potential for major adverse effects to wildlife and wildlife habitat as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail an increasing trend toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

##### *4.9.2.3.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Coast Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

The implementation of Alternative 2A would not have a more than negligible effect on the general trend of decreases to decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories within the Coast Fork Willamette. Overall, a major adverse effect.

##### *4.9.2.3.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 2A would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches.

#### *4.9.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 2B would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins as discussed below. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 2B (as opposed to Alternative 2A) there would be potential for major effects to aquatic and wetland habitat around the reservoir when combined with climate change effects.

##### *4.9.2.4.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Santiam subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories, which would have a major adverse effect to wildlife and wildlife habitat within the subbasin.

With the implementation of Alternative 2B, gravel augmentation downstream of Big Cliff and Foster Dams would slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Santiam subbasin. Adding lamprey passage at Green Peter and downstream fish passage at Detroit and Foster would slightly improve foraging opportunities for wildlife species within the subbasin. Adding a WTC tower at Detroit would slightly improve water temperature for salmonids, which are important to piscivorous wildlife. On the other hand, the drawdowns within Green Peter and Detroit would further exacerbate cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to aquatic and wetland habitat when combined with cumulative effects, particularly climate change. This major adverse effect would entail an increasing trend toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

##### *4.9.2.4.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would affect wildlife and wildlife habitat at the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Long Tom subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories and this would constitute a major adverse effect within the Long Tom subbasin. Alternative 2B would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

##### *4.9.2.4.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the McKenzie subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 2B, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make aquatic and wetland habitat around the reservoirs more susceptible to climate change effects. Particularly at Cougar, where deep fall and spring drawdowns would be implemented, there would be potential for major adverse effects to wildlife and wildlife habitat when combined with cumulative effects, particularly climate change. This would push trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.4.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the Middle Fork Willamette subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change (a major adverse effect) but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 2B, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Middle Fork Willamette subbasin. Adding downstream fish passage at Lookout Point would slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects at the reservoirs. There would be potential for major adverse effects to wildlife and wildlife habitat as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.4.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would affect wildlife and wildlife habitat at the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Coast Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

The implementation of Alternative 2B would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories within the Coast Fork Willamette.

#### *4.9.2.4.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 2B would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches.

#### *4.9.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 3A would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins as discussed below.

##### *4.9.2.5.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Santiam subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories, which would have a major adverse effect to wildlife and wildlife habitat within the subbasin.

With the implementation of Alternative 3A, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Santiam subbasin. Adding downstream fish passage at Big Cliff and Green Peter and lamprey passage at Green Peter would slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. At Detroit (fall and spring) and Green Peter (fall) drawdowns would be implemented and therefore, there would be potential for major adverse effects to wildlife and wildlife habitat when combined with cumulative effects, particularly as a result of climate change. This effect would entail an increasing trend toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

##### *4.9.2.5.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would affect wildlife and wildlife habitat at the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Long Tom subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories and this would constitute a major adverse effect within the Long Tom subbasin. Alternative 3A would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.9.2.5.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the McKenzie subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 3A, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. Adding lamprey passage at Blue River would slightly improve foraging opportunities for wildlife species within the subbasin. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wildlife and wildlife habitat at the reservoirs more susceptible to climate change effects. At Cougar, a deep spring drawdown would be implemented and at Cougar and Blue River, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause major adverse effects to wildlife and wildlife habitat around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.5.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the Middle Fork Willamette subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change (a major adverse effect) but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 3A, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Middle Fork Willamette subbasin. Adding lamprey passage at Hills Creek and downstream fish passage at Dexter, Fall Creek, and Hills Creek would slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. In addition to the drawdowns with minor effects, at Lookout Point, a deep spring drawdown would be implemented and at Lookout Point and Hills Creek, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause major adverse effects to wildlife and wildlife habitat at the reservoirs when combined with cumulative effects, particularly climate change. This effect would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.5.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would affect wildlife and wildlife habitat at the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Coast Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

The implementation of Alternative 3A would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories associated with wetlands within the Coast Fork Willamette.

#### *4.9.2.5.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 3A would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches.

### ***4.9.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)***

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 3B would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins as discussed below. Alternative 3B is very similar to 3A. The primary differences are related to locations of the drawdowns and the fact that deep drawdowns occurring at Cougar would be to the elevation of the diversion tunnel.

#### *4.9.2.6.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Santiam subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories, which would have a major adverse effect to wildlife and wildlife habitat within the subbasin.

With the implementation of Alternative 3B, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Santiam subbasin. Adding lamprey passage at Green Peter and downstream fish passage at Detroit would slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns within Green Peter and Detroit will further exacerbate the cumulative effects. At both Detroit (fall) and Green Peter (fall and spring) deep drawdowns would be implemented and therefore, there would be potential for major adverse effects to wildlife and wildlife habitat when combined with cumulative effects, particularly as a result of climate change. This effect would entail an increasing trend toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

##### *4.9.2.6.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would affect wildlife and wildlife habitat at the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Long Tom subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories and this would constitute a major adverse effect within the Long Tom subbasin. Alternative 3B would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

##### *4.9.2.6.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the McKenzie subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 3B, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. Adding lamprey passage at Blue River would slightly improve foraging opportunities for wildlife species within the subbasin. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wildlife and wildlife habitat around the reservoirs more susceptible to climate change effects. At Cougar, a deep spring drawdown would be implemented and at Cougar and Blue River, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause major adverse effects to wildlife and wildlife habitat around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.6.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the Middle Fork Willamette subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change (a major adverse effect) but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 3B, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Middle Fork Willamette subbasin. Adding downstream fish passage at Dexter and Lookout Point and lamprey passage at Hills Creek would slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. In addition to the drawdowns with minor effects, at Hills Creek, a deep spring drawdown would be implemented and at Lookout Point and Hills Creek, a deep fall drawdown would be implemented. These deep drawdowns would potentially cause major adverse effects to wildlife and wildlife habitat at the reservoirs when combined with cumulative effects, particularly climate change. This effect would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.6.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would affect wildlife and wildlife habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Coast Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

With the implementation of Alternative 3B, the drawdowns at Cottage Grove and Dorena would make wildlife and wildlife habitat at the reservoirs more susceptible to climate change effects. These drawdowns would potentially cause major adverse effects to wetlands around the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.6.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 3B would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches.

### ***4.9.2.7 Alternative 4 – Structures-Based Fish Passage Alternative***

Overall, cumulative effects to wildlife and wildlife habitat would be anticipated to be major adverse over the period of analysis. However, Alternative 4 would not contribute substantially to the changes in the wildlife and wildlife habitat of the WVS. Changes to wildlife and wildlife habitat in terms of changes to biodiversity and suitable habitat availability would be affected more by climate change, water withdrawals, and habitat fragmentation due to development than by Alternative 4. Cumulative effect summaries for Alternative 4 by subbasin are provided below.

#### *4.9.2.7.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Santiam subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories, which would have a major adverse effect to wildlife and wildlife habitat within the subbasin.

With the implementation of Alternative 4, gravel augmentation downstream of Big Cliff and Foster Dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Santiam subbasin. Adding downstream fish passage at Detroit and Foster would slightly improve foraging opportunities for wildlife species within the subbasin. Adding a WTC tower at Detroit would slightly improve water temperature for salmonids, which are important to piscivorous wildlife. On the other hand, the drawdowns within Green Peter and Detroit will would make wildlife and wildlife habitat around the reservoirs more susceptible to climate change effects, which would ultimately constitute a major adverse effect, pushing trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

##### *4.9.2.7.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would affect wildlife and wildlife habitat at the reservoirs. Alternative 4 would improve foraging opportunities for wildlife slightly by providing downstream fish passage over the drop structures downstream of Fern Ridge. However, the overall trend of wildlife and wildlife habitat in the Long Tom subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories and this would constitute a major adverse effect within the Long Tom subbasin.

##### *4.9.2.7.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the McKenzie subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 4, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. Adding downstream fish passage at Cougar would slightly improve foraging opportunities for wildlife species within the subbasin. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make wildlife and wildlife habitat at the reservoirs more susceptible to climate change effects, which would constitute a minor adverse effect. With the drawdowns, trends would continue to be pushed toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories within the subbasin. Major adverse effects would be anticipated along downstream reaches but only moderate adverse effects at the reservoirs when Alternative 4 effects and cumulative effects are combined.

##### *4.9.2.7.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the Middle Fork Willamette subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change (a major adverse effect) but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 4, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Middle Fork Willamette subbasin. Adding downstream fish passage at Hills Creek and Lookout Point and lamprey passage at Hills Creek would slightly improve foraging opportunities for wildlife species within the subbasin. Adding a WTC tower at Hills Creek and Lookout Point would slightly improve water temperature for salmonids, which are important to piscivorous wildlife. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects. There would be potential for moderate adverse effects to wildlife and wildlife habitat at the reservoirs as a result of the drawdowns combined with cumulative effects, particularly climate change. These effects would push an increasing trend toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

###### *4.9.2.7.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would affect wildlife and wildlife habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Coast Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

With the implementation of Alternative 4, the drawdowns at Cottage Grove and Dorena would make wildlife and wildlife habitat at the reservoirs more susceptible to climate change effects. These drawdowns would potentially cause major adverse effects to wildlife and wildlife habitat at the reservoirs when combined with cumulative effects, particularly climate change. This would push trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories at the reservoirs.

###### *4.9.2.7.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 4 would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches.

#### *4.9.2.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 5 (as with Alternative 2B) would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins as discussed below. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 5 (as with Alternative 2B) there would be potential for major effects to aquatic and wetland habitat around the reservoir when combined with climate change effects.

The effects of Alternative 5 when combined with cumulative effects are identical to those of Alternative 2B as presented in Section 4.9.2.4. except that the refined integrated temperature and habitat flow regime (Measure #30b) would be implemented instead of Measure #30a and would yield slightly better survival of ESA-listed salmonids within all WVS tributaries, though it is unknown to what degree. This may improve foraging opportunities for piscivorous wildlife throughout the WVS; however, the improvement would most likely be negligible over what had been presented for Alternative 2B. Cumulative effect summaries for Alternative 5 by subbasin are provided below.

##### *4.9.2.8.1 Santiam Subbasin*

As a result of cumulative effects within the Santiam subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Detroit and Green Peter, which would affect aquatic and wetland habitat around the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Santiam subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories, which would have a major adverse effect to wildlife and wildlife habitat within the subbasin.

With the implementation of Alternative 5, gravel augmentation downstream of Big Cliff and Foster Dams would slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Santiam subbasin. Adding lamprey passage at Green Peter and downstream fish passage at Detroit and Foster would slightly improve foraging opportunities for wildlife species within the subbasin. Adding a WTC tower at Detroit would slightly improve water temperature for salmonids, which are important to piscivorous wildlife. On the other hand, the drawdowns within Green Peter and Detroit would further exacerbate cumulative effects. Particularly at Green Peter, where a deep fall drawdown would be implemented, there would be potential for major effects to aquatic and wetland habitat when combined with cumulative effects, particularly climate change. This major adverse effect would entail an increasing trend toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.8.2 Long Tom Subbasin*

As a result of cumulative effects within the Long Tom subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Fern Ridge dam and reservoir; however, there would be warmer drier summers. In addition, there would be decreased overall reservoir elevations at Fern Ridge, which would affect wildlife and wildlife habitat at the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Long Tom subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories and this would constitute a major adverse effect within the Long Tom subbasin. Alternative 5 would not change operations at Fern Ridge and therefore would not affect changes within the subbasin.

#### *4.9.2.8.3 McKenzie Subbasin*

As a result of cumulative effects within the McKenzie subbasin, there would be an increase in winter instream flows, both upstream and downstream of Cougar and Blue River dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the McKenzie subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change but would remain largely unchanged around Cougar and Blue River reservoirs as a result of cumulative effects.

With the implementation of Alternative 5, gravel augmentation downstream of Cougar and Blue River dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the McKenzie subbasin, which could offset some of the climate change effects in downstream reaches. At the reservoirs, on the other hand, the drawdowns at Cougar and Blue River would make aquatic and wetland habitat around the reservoirs more susceptible to climate change effects. Particularly at Cougar, where deep fall and spring drawdowns would be implemented, there would be potential for major adverse effects to wildlife and wildlife habitat when combined with cumulative effects, particularly climate change. This would push trends toward decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

#### *4.9.2.8.4 Middle Fork of the Willamette Subbasin*

As a result of cumulative effects within the Middle Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the WVS dams and reservoirs, which would lead to higher reservoir elevations during the conservation season. However, these would be offset by warmer drier summers and water withdrawals. The general trend of wildlife and wildlife habitat in the Middle Fork Willamette subbasin would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches due to climate change (a major adverse effect) but would remain largely unchanged around Hills Creek, Lookout Point, and Fall Creek reservoirs as a result of cumulative effects.

With the implementation of Alternative 5, gravel augmentation downstream of the Middle Fork dams will slightly improve conditions for aquatic and wetland habitat along downstream reaches within the Middle Fork Willamette subbasin. Adding downstream fish passage at Lookout Point would slightly improve foraging opportunities for wildlife species within the subbasin. On the other hand, the drawdowns within Hills Creek, Lookout Point, and Fall Creek will further exacerbate the cumulative effects at the reservoirs. There would be potential for major adverse effects to wildlife and wildlife habitat as a result of the drawdowns combined with cumulative effects, particularly climate change. This effect would entail decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

##### *4.9.2.8.5 Coast Fork of the Willamette Subbasin*

As a result of cumulative effects within the Coast Fork Willamette subbasin, there would be an increase in winter instream flows, both upstream and downstream of the Cottage Grove and Dorena dams and reservoirs; however, there would be warmer drier summers. In addition, there would be decreased reservoir elevations at Cottage Grove and Dorena during the conservation season, which would affect wildlife and wildlife habitat at the reservoirs. Therefore, the general trend of wildlife and wildlife habitat in the Coast Fork Willamette subbasin entails decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories.

The implementation of Alternative 5 would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories within the Coast Fork Willamette.

##### *4.9.2.8.6 Mainstem Willamette River*

The general trends as a result of the cumulative effects would see an increase in winter inflows and a decrease of instream flows within the Mainstem Willamette River during the conservation season. The implementation of Alternative 5 would not have a more than negligible effect on the general trend of decreases to suitable habitat acreage, degraded water quality, and changes to the seasonality of wildlife life histories along downstream reaches.

## 4.10 AIR QUALITY

This section discusses the cumulative effects on air quality. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect air quality. The geographic scope for air quality would be the same boundary as described in the Affected Environment in Chapter 3, which includes all USACE project locations within the WVS.

### 4.10.1 Cumulative Actions Applicable to Air Quality

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects on air quality, include:

- Operation of the WVS dams and supporting structures and facilities;
- Structural improvements to modify existing WVS structures;
- Trap-and-haul fish trucking operation;
- Transportation corridor development;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 4, decarbonizing the energy sector with renewable energy sources;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 7, Tribal, state, and local fish and wildlife improvement; and
- RFFA 9, climate change.

Some of the RFFAs discussed in Section 4.2.3 would not have a cumulative effect on air quality. These include RFFA 2, reduced agricultural production; RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; RFFA 6, fishery management and killer whales; and RFFA 8, invasive species management. These actions do not contribute to air quality; thus, these RFFAs are not discussed further in this cumulative effects analysis. Other RFFAs could have contributed to cumulative effects for air quality had they occurred at or in close proximity to the WVS dams and reservoirs. These include RFFA 10, mining operations; and RFFA 11, timber and logging industry operations. Mining operations and timber and logging operations are not located within the geographic scope of USACE project locations, and there are no planned projects or projected changes for the foreseeable future. Therefore, these RFFAs are not discussed further in this cumulative effects analysis.

### 4.10.2 Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect to air quality. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.10.2.1 Construct water temperature control (WTC) towers (#105), Construct structural downstream fish passages (#392), Construct adult fish facilities (AFFs) (#722), and Provide Pacific lamprey passage and infrastructure (#52)*

As discussed in Section 3.10.3.3.1, the magnitude of adverse effects from the construction of WTC towers (#105), structural downstream fish passages (#392), AFFs (#722), and Pacific lamprey passage and infrastructure (#52) would be negligible to minor because additional emissions from truck mileage and generators would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographic region of the WVS. O&M of USACE infrastructure, trap-and-haul fish trucking operations, transportation corridor development, population growth and associated urban landscape development, renewable energy, land management, fish and wildlife management and improvement, and climate change would have a range of similar effects on air quality as the proposed measures.

Structural improvements are already planned to occur under the interim injunction within the WVS at Dexter, Big Cliff, and Cougar Dams. These actions and others would potentially include construction upgrades at all dams and could potentially adversely affect air quality with additional construction vehicles and/or modifications to fish trucking and generator usage. O&M of USACE infrastructure and trap-and-haul fish trucking operations would continue to contribute diesel emissions into the atmosphere (as discussed in Chapter 3). Population growth and continued development would additively contribute to an increase in air emissions, as more construction activities, paved roadways, and urban sprawl would lead to more personal vehicles, vehicle miles traveled, buses, construction vehicles and equipment, and shipping trucks throughout the WRB.

Urban development would also greatly reduce natural spaces that do not contribute air emissions, and in fact reduce some criteria pollutants through plant uptake. Climate change may also adversely affect air quality through an increased future incidence of forest fires; combustion of woody matter generates criteria pollutants such as carbon monoxide, particulate matter, volatile organic compounds, and nitrogen oxides, the latter two of which are ozone precursors. Some of these adverse effects would be minimized by actions to conserve and protect natural resources in the WRB, such as wildlife refuges, preserves, national forests, and through other land management strategies, such as the use of prescribed fire to prevent the accumulation of excessive fuel loads. These actions have already been undertaken at many project sites through the creation of parks, recreational reservoirs and beaches, and wildlife trails.

Renewable energy sources, such as wind turbines, solar arrays, and geothermal power, could potentially offset or counteract these adverse effects to some extent by producing clean energy without emitting criteria pollutants into the atmosphere. Several USACE project locations feature dams that produce hydropower, another form of renewable, clean energy; however, there are no proposed renewable energy projects within the counties representing the WRB. Overall, when considered together with the proposed measures, applicable cumulative actions would create adverse, additive, negligible to minor cumulative effects to air quality.

#### *4.10.2.2 Restore upstream and downstream passage at drop structures (#639)*

As discussed in Section 3.10.3.3.2, the magnitude of beneficial effects from restoring upstream and downstream passage at drop structures (#639) would be minor because fish passage measures would allow fish to pass through the Fern Ridge Dam without being trapped or hauled, thereby reducing the amount of total fish trucking mileage and associated air emissions. Renewable energy, land management, and fish and wildlife management and improvement would have a range of similar effects on air quality as the drop structures. Renewable energy sources, such as wind turbines, solar arrays, and geothermal power, produce clean energy without emitting criteria pollutants into the air. Several USACE project locations feature dams that produce hydropower, another form of renewable, clean energy; however, there are no proposed renewable energy projects within the counties representing the WRB. Actions to conserve and protect natural areas and resources, such as wildlife refuges, preserves, national forests, and other wildlife habitats and public lands, would preserve natural trees, shrubs, and other vegetation that do not contribute to air emissions. This vegetation would actually decrease the amount of some criteria pollutants in the air through plant uptake. Overall, when considered together with the proposed measures, applicable cumulative actions would result in beneficial, additive, and negligible to minor cumulative effects to air quality, which as noted in the Air Quality Affected Environment section (3.10.2.2), is generally relatively good.

#### *4.10.2.3 Deeper fall reservoir drawdowns for fish passage (#40) and Spring reservoir drawdown for downstream fish passage (#720)*

As discussed in Section 3.10.3.3.3, the magnitude of adverse effects from deeper fall reservoir drawdowns (#40) and spring reservoir drawdowns (#720) would be negligible because atmospheric conditions would not be conducive to producing fugitive dust emissions over the relatively short time span of the drawdowns. Therefore, reservoir drawdowns would also contribute a negligible cumulative effect to air quality, and may be dismissed from further analysis.

### 4.10.3 Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to air quality.

#### *4.10.3.1 No Action Alternative*

The NAA would include an adaptive hatchery program (#719), the continued operation of AFFs, and the maintenance of existing and new fish release sites (#726). Because these activities are already occurring and would not change the total truck mileage or number of generators from current levels, their contribution to cumulative effects would be negligible. The NAA would also include the Fall Creek Reservoir drawdown which would be negligible in magnitude (as discussed in Section 3.10.3.3.3 and 3.10.3.4). None of the cumulative actions would have similar effects; as such, any contribution to cumulative effects would be negligible.

#### *4.10.3.2 Alternative 1. Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, total fish trucking mileage and the number of generators would increase, but additional associated air emissions would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographic region of the WVS. As discussed above in Sections 4.10.2.1 and 4.10.2.2, these measures would contribute beneficial and adverse, additive, negligible to minor cumulative effects. Alternative 1 would have the same general cumulative effect as all other alternatives. Any new structures under Alternative 1 would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

#### *4.10.3.3 Alternative 2A. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Under Alternative 2A, total fish trucking mileage and the number of generators would increase, but additional associated air emissions would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographic region of the WVS. As discussed above in Sections 4.10.2.1 and 4.10.2.3, these measures would contribute adverse, additive, negligible to minor cumulative effects. Alternative 2A would have the same general cumulative effect as all other alternatives. Any new structures under Alternative 2A would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

#### *4.10.3.4 Alternative 2B. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 2B, the cumulative effects to air quality would be the same as those described under Alternative 2A. As discussed above in Sections 4.10.2.1 and 4.10.2.3, these measures would contribute adverse, additive, negligible to minor cumulative effects. Alternative 2B would have the same general cumulative effect as all other alternatives. Any new structures under Alternative 2B would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

#### *4.10.3.5 Alternative 3A. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Under Alternative 3A, total fish trucking mileage and the number of generators would increase, but additional associated air emissions would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographic region of the WVS. As discussed above in Sections 4.10.2.1 and 4.10.2.3, these measures would contribute adverse, additive, negligible to minor cumulative effects. Alternative 3A would have the same general cumulative effect as all other alternatives. Any new structures under Alternative 3A would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

#### *4.10.3.6 Alternative 3B. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 3B, the cumulative effects to air quality would be the same as those described under Alternative 3A. As discussed above in Sections 4.10.2.1 and 4.10.2.3, these measures would contribute adverse, additive, negligible to minor cumulative effects. Alternative 3B would have the same general cumulative effect as all other alternatives. Any new structures under Alternative 3B would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

#### *4.10.3.7 Alternative 4. Improve Fish Passage with Structures-Based Approach*

Under Alternative 4, total fish trucking mileage and the number of generators would increase, but additional associated air emissions would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographic region of the WVS. As discussed above in Sections 4.10.2.1 and 4.10.2.2, these measures would contribute beneficial and adverse, additive, negligible to minor cumulative effects. Alternative 4 would have the same general cumulative effect as all other alternatives. Any new structures under Alternative 4 would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

#### *4.10.3.8 Alternative 5. Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 5, the cumulative effects to air quality would be the same as those described under Alternative 2B. As discussed above in Sections 4.10.2.1 and 4.10.2.3, these measures would contribute adverse, additive, negligible to minor cumulative effects. Alternative 5 would have the same general cumulative effect as all other alternatives. Any new structures under Alternative 5 would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

### 4.10.4 Summary

In summary, the cumulative effects of each of the alternatives would have similar additive, negligible to minor effects. Any cumulative effect to air quality from any alternative would represent a very small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB as a whole.

## 4.11 SOCIOECONOMIC RESOURCES

This section discusses the cumulative effects on socioeconomic resources. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect socioeconomic resources. The ROI for socioeconomic resources would be the same boundary as described in the Affected Environment in Chapter 3, or Lane, Linn, and Marion counties.

### 4.11.1 Cumulative Actions Applicable to Socioeconomic Resources

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects on socioeconomic resources, include:

- Construction of the WVS and other dams and supporting structures in the WRB;
- WRB population growth and development;
- Transportation corridor development;
- Floodplain development;
- Logging and mining within the watershed;
- Commercial and recreational fish harvesting;
- Water withdrawals for irrigation, municipal, and industrial uses;
- Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 2, reduced agricultural production;
- RFFA 3, water withdrawals for municipal, industrial, and agricultural uses;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 7, Tribal, State, and local fish and wildlife improvement;
- RFFA 8, invasive species management;
- RFFA 9, climate change;
- RFFA 10, mining operations; and
- RFFA 11, timber and logging industry operations.

Some of the other RFFAs discussed in Section 4.2.3 would not affect socioeconomic resources and therefore are not discussed further in these cumulative effects analysis. These include RFFA 4, decarbonizing the energy sector with renewable energy sources; and RFFA 6, fishery management and killer whales.

### 4.11.2 Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect to socioeconomic resources. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.11.2.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Improvements*

Construction, modification, operation and maintenance of all 13 proposed structural measures in conjunction with the past, present, and RFFAs would cumulatively affect labor and earnings; population and housing; recreational value; quality of life for local residents; low-income populations; and non-use and existence values.

##### *4.11.2.1.1 Labor and Earnings*

As discussed in Sections 3.11.2.4.1, the magnitude of beneficial effects to labor and earnings within the ROI from the construction of structural improvements would be negligible to minor depending upon the scale of the required capital expenditures which would occur within the ROI under each alternative. These revenues would likely result in the creation of a relatively small number of construction jobs in the short and medium term sourced from within the ROI. Construction workers employed on the project would also likely increase revenues at local retail stores and restaurants, resulting in induced (i.e., third-order) economic benefits. Construction materials would also be sourced from local vendors whenever possible and would likely contribute to the indirect creation of jobs within the ROI.

The results of modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would have similar beneficial effects on socioeconomic resources as the construction of structural measures. These actions would provide additional influxes of capital into the ROI, prompting direct, indirect, and induced creation of jobs. When considered cumulatively, these benefits can be considered interactive; each action introduces additional revenue streams into the ROI and synergistically increases the overall level of consumer demand, thereby stimulating further job and revenue growth. As such, the magnitude of these cumulative effects would be considered minor to moderate in the short and medium term given the third order increases in consumer demand throughout the ROI. The magnitude of the benefits would be contingent on the level of expenditures and the timing associated with each of the actions in relation with the proposed measures. In particular, effects would be greatest if large expenditures associated with the cumulative actions listed above occurred at the same time as more expensive, medium-term measures (e.g., construction of WTC tower or structural downstream passage).

#### *4.11.2.1.2 Population and Housing*

As discussed in 3.11.2.4.1, the in-migration of workers to support the construction, operation, and maintenance of structural measures would contribute negligible to minor adverse effects on housing in the short and medium term. In addition to RFFA 1, future population growth and accompanying urban, industrial, and commercial development, other cumulative actions that require specialized contractors to migrate to the ROI would have cumulative effects on population and housing. These cumulative actions include construction of the WVS and other dams, reservoirs, and supporting structures in the WRB; transportation corridor development; floodplain development; modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations. These actions would contribute additive cumulative effects and would increase demand on housing if many of the actions occurred at the same time as medium-term structural measures (e.g., construction of WTC towers). However, given the existing housing vacancies within the ROI, housing would likely continue to operate below capacity and therefore cumulative, additive effects would be minor in the short and medium term.

#### *4.11.2.1.3 Recreational Value*

As discussed in Section 3.11.2.4.1, adverse effects to recreational quality at recreational sites in the vicinity of project activities from construction-related noise, emissions, and congestion would be negligible to moderate in the short and medium term. The proposed structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the recreational quality at recreational sites in the vicinity of project activities. The cumulative effects would be additive and negligible to moderate in the short and medium term. The magnitude of the effect would depend on the proximity of the cumulative actions and proposed structural measures to the recreational site or the recreationist, as well as the timing of the projects. For example, if construction of medium-term proposed structural measures (e.g., Structural improvements to reduce TDG) occurred at the same time as modifications of existing WVS structures at Dexter, Big Cliff, and Cougar, cumulative effects would be moderate in the medium term.

The proposed structural measures would have indirect, adverse effects to the quality of recreational fishing in reservoirs and on rivers for some species due to increased turbidity from suspended sediment associated with construction measures. As discussed in Appendices F1 and F2 (Qualitative Assessment of Climate Change Impacts and Supplemental Climate Change Information, respectively), climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB. As such, climate change would have additive, minor, cumulative, indirect, adverse effects in the long term to recreational quality, and therefore recreational users' contribution to the economy of the ROI through expenditures in support of recreational activities; as well as induced effects of retail revenue streams.

The proposed structural measures would also have long-term, indirect, minor, beneficial effects on recreational fishing and visitation within the ROI. Floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and RFFA 9, climate change would have interactive, countervailing cumulative effects to recreational quality in the form of construction-related noise, congestion, turbidity, and emissions. These cumulative actions would reduce both the value of affected reservoirs as well as their visitation rates – thereby reducing expenditures within the ROI and ultimately consumer demand. Although the majority of adverse cumulative effects would likely be confined to the construction phases of each project, overlapping project timelines or vicinities could potentially extend effects over a larger period of time and compound adverse effects within smaller portions of the ROI. As such these cumulative effects would be considered interactive and countervailing; and the overall indirect, long-term beneficial effect on recreational fishing would be negligible.

#### *4.11.2.1.4 Quality of Life*

Adverse effects to quality of life of residents in the vicinity of project would be negligible to moderate in magnitude in the short and medium term. The same factors that degrade recreational quality – construction-related noise, emissions, and congestion – would similarly be nuisances to local residents and reduce the overall quality of life. The proposed structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the quality of life for nearby residents. The use of local roadways during work periods for transport of workers and materials associated with the above-listed cumulative actions would further temporarily increase traffic levels and average length of transit for nearby communities, and could reduce resident access to community resources such as places of worship, recreational facilities, and healthcare. The cumulative effects would be additive and negligible to moderate in the short and medium term. The magnitude of the effect would ultimately depend on the timing and proximity of the projects to residents – especially in the towns of Detroit, Lowell, Veneta, and Sweet Home that are on the shores of Detroit, Dexter, Fern Ridge, and Foster reservoirs, respectively. For example, if construction of medium-term proposed structural measures (e.g., Structural improvements to reduce TDG at Dexter, as is the case under Alternatives 1 and 4) occurred at the same time as modifications of existing WVS structures at Dexter, cumulative effects to the quality of life of Lowell residents would be moderate in the medium term.

#### *4.11.2.1.5 Low Income Populations*

Low-income populations in Lane, Linn, and Marion counties that are hired to work on could experience negligible to minor health benefits through economic pathways in the short and medium term. There may also be negligible to minor adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects. Negligible to minor, adverse and beneficial additive, cumulative effects to the health of low-income populations would occur in the short and medium term when the proposed structural measures are considered in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar.

As discussed in Section 3.11.2.4.1, the short- and medium-term construction projects under the proposed action and alternatives would not affect any ongoing shortages for low-income populations or the availability of general or affordable housing within the ROI. However, if the proposed structural measures occurred at the same time as some or all of the other cumulative construction actions that would create jobs and an in-migration of workers (i.e., modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10 mining operations; and RFFA 11 timber and logging industry), rent prices could increase and the availability of affordable (and general) housing could decrease. Oregon now has rent control that limits rent increases for existing tenants. Rent cannot be increased during any 12-month period above the existing rent in an amount greater than 7% plus the consumer price index from the previous calendar year (OSB 2019). There are a total of approximately 21,121 available housing units in the ROI; and about half of those are considered affordable housing (USCB 2019c; State of Oregon 2022). Although housing supplies would likely expand with new development, it is possible that stresses on the existing housing supply would increase housing prices and potentially displace low-income residents from housing and access to community resources. Depending on the timing of the proposed structural measures and the cumulative actions, cumulative, additive effects to housing availability and rent prices would be negligible to minor in the short and medium term.

#### *4.11.2.2 Alteration of Outflows and Reservoir Levels*

Measures that would alter flows and reservoir levels in conjunction with past, present, and RFFAs would cumulatively affect recreational value; agricultural irrigation and municipal and industrial (M&I) use; and the quality of life for nearby residents.

##### *4.11.2.2.1 Recreational Value*

As discussed in Section 3.11.2.4.2, reservoir drawdowns would have short- and long-term recurring adverse effects on recreational value that would range from minor to major. Reservoir drawdowns would reduce water levels and substantially decrease recreational use and the recreational value of the reservoir, indirectly affecting socioeconomic resources throughout the ROI. Reservoir drawdowns during the primary spring/summer recreational season (measure #720 and #714) would reduce recreational use of water-based activities, value, and quality at affected reservoirs, potentially reducing visitation. Recreational users contribute to the economy of the ROI through the expenditure of funds in support of their activity of choice, such as specialized sporting equipment, licensing, hiring of guides, fuel, food, and lodging; reduction of visitation would subsequently reduce this revenue stream within the ROI. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses would have similar short-term effects on recreational value. Both would reduce recreational access and quality of reservoirs, thereby reducing visitation and its associated revenues. However, it is important to note that the allocation of agricultural, municipal, and industrial water demand is much smaller than that required for fish and wildlife management and these additional drawdowns would only marginally affect reservoir levels. RFFA 9, climate change could exacerbate short-term effects from sediment transport during drawdowns, as increased wildfire ash, HABs, and upstream erosion would cause erosion in reservoirs and would further increase turbidity and decrease water quality downstream; affecting the recreational experience and visitation in both reservoirs and rivers. The overall water level could be further reduced in the long term.

In addition to RFFA 3, water withdrawals for municipal, industrial, and agricultural uses, RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and RFFA 9, climate change would also have adverse long-term effects to recreational value. RFFA 1 would likely increase visitation of recreational reservoirs, but could potentially degrade the quality of recreational visitation due to crowding and congestion. Lower recreational quality could lower the amount of revenues expected from each visitor, as well as the probability of repeat visits. Climate change would contribute to cumulative effects for socioeconomic resources through longer and more arid drought seasons and smaller snowpacks, lowering reservoir levels and reducing recreational visitation. Increased water temperatures as a result of climate change could also reduce the habitat suitability of the ROI for recreationally fished salmonids, which are major drivers of recreational visitation.

As discussed in Section 3.11.2.4.2, reservoir drawdowns would have long-term, indirect beneficial effects to socioeconomic resources with the improvement of downstream riverine habitat quality for ESA-listed fish species, recreational fisheries, and water quality throughout the ROI. (Note that reservoir visitation provides a far greater proportion of recreational revenues within the ROI than riverine visitation.) RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state and local fish and wildlife improvement; and RFFA 8, invasive species management would also improve the overall quality of fish habitat within the ROI, which could potentially offset some of the adverse effects of climate change on fishery quality and subsequent recreational visitation in the long term.

Overall, cumulative, additive adverse effects on the recreational value would be minor to major in the short and long term (recurring). RFFA 9, climate change; the timing of RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; and the timing and number of reservoir drawdowns for juvenile fish passage would be the main indicators of the magnitude of effects on recreational value under each alternative.

##### *4.11.2.2.2 Irrigation and M&I Use*

As discussed in Section 3.11.2.4.2, spring drawdowns would result in major adverse socioeconomic effects from reduced water availability for agricultural irrigation and M&I purposes. Fall drawdowns would occur during periods with minimal WVS water use and would only result in negligible to minor socioeconomic effects. As such, adverse effects attributable to water supply would range from negligible to major in the short term and would recur in the long term.

RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would exacerbate these effects. As noted above, the allocation of agricultural, municipal, and industrial water demand is much smaller than that required for fish and wildlife management and these additional drawdowns would only marginally affect reservoir levels. As such, cumulative, additive effects from RFFA 3, RFFA 9, and spring drawdowns would be major due to reduced water availability for agricultural irrigation and M&I purposes. Cumulative, additive effects from RFFA 3, RFFA 9, and fall drawdowns would be negligible to minor. Overall, cumulative, additive adverse effects attributable to water supply would range from negligible to major in the short term and would recur in the long term.

##### *4.11.2.2.3 Quality of Life*

As discussed in Section 3.11.2.4.2, the loss of surface water during reservoir drawdowns would have minor to moderate short- and long-term effects to the viewshed and therefore quality of life of nearby residents – especially in the town of Detroit, which is located on the shores of Detroit Dam and Reservoir. (The towns of Lowell, Veneta, and Sweet Home on the shores of Dexter, Fern Ridge, and Foster Dams, respectively, would not be affected because drawdowns are not proposed at these locations under any of the alternatives). RFFA 3, water withdrawals for municipal, industrial, and agricultural uses would further decrease the water level and have similar short-term effects on the viewshed. RFFA 9, climate change could exacerbate short-term effects from sediment transport during drawdowns, as increased wildfire ash, HABs, and upstream erosion would cause erosion in reservoirs and would further increase turbidity and decrease water quality downstream; affecting the aesthetics of both reservoirs and rivers. Less snowpack would decrease spring reservoir inflows, and drier, hotter summers (in terms of both air and water temperatures) would increase evaporation rates and further limit water quantity and further reduce the overall water level in the long term. As such, cumulative, additive adverse effects to the quality of life from the proposed reservoir drawdowns, RFFA 3, and RFFA 9 would be minor to moderate in the short and long term.

#### ***4.11.2.3 Non-Use and Existence Values***

As discussed in 3.11.2.4.3, implementation of all the proposed measures would help preserve the existence value (the benefit people receive from knowing that it exists, or its intrinsic value) of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society. Without these proposed measures, these species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – could cease to exist in the WRB; the resulting loss of their existence values would be major and adverse. The modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, State and local fish and wildlife improvement; and RFFA 8, invasive species management would further benefit fish habitat and populations and generally help to avoid jeopardizing the continued existence of the UWR Chinook salmon and UWR steelhead.

However, the remaining past, present, and RFFAs listed in 4.11.1 would be interactive and countervailing, working against the proposed measures. construction of the WVS and other dams, reservoirs, and supporting structures in the WRB ; WRB population growth and development; transportation corridor development; floodplain development; commercial and recreational fish harvesting; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations could affect turbidity and water quality and therefore fish habitat. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change could further affect water quantity. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative long-term benefits would be negligible.

### 4.11.3 Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to socioeconomic resources.

#### *4.11.3.1 No Action Alternative*

Under the NAA, current actions within the WVS and the conditions that would result from continued O&M and configuration of the WVS under existing management would persist. As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompting the creation of jobs and a small in-migration of specialized contractors. These cumulative effects to labor and earnings (including low-income populations) would be synergistic if they occur at the same time and thus would create minor, beneficial cumulative effects in the short and medium term. Cumulative effects to population and housing would be additive but also minor in the short and medium term.

The continued O&M structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the recreational quality at recreational sites in the vicinity of project activities as well as to the quality of life of nearby residents. The cumulative effects would be additive and negligible in the short and medium term.

The Fall Creek drawdown would occur annually under the NAA. RFFAs 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; and RFFA 9, climate change would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from the drawdowns and climate change would affect both the quality of the recreational experience as well as the quality of life of nearby residents. Lower recreational quality could lower the amount of revenues expected from each visitor, as well as the probability of repeat visits. Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state and local fish and wildlife improvement; and RFFA 8, invasive species management would also improve the overall quality of fish habitat within the ROI, which could potentially offset some of the adverse effects of climate change on fishery quality and subsequent recreational visitation in the long term. But overall, cumulative, additive effects to recreational value and quality of life would be minor and additive in the short and long term (recurring).

RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would exacerbate effects from reduced water availability to agricultural irrigation and M&I use from the Fall Creek drawdown. As noted above, the allocation of agricultural, municipal, and industrial water demand is much smaller than that required for fish and wildlife management and these additional drawdowns would only marginally affect reservoir levels. The Fall Creek drawdown occurs in the autumn or during periods with minimal WVS water use. As such, cumulative, additive effects from RFFA 3, RFFA 9, and the Fall Creek Drawdown would be negligible in the short and long-term (recurring).

As discussed in 3.11.2.4.3, without the proposed measures under the action alternatives, the evolutionarily significant units (ESUs) and distinct population segments (DPSs) of the UWR Chinook salmon and UWR steelhead could, quite literally, cease to exist in the WRB; the resulting loss of their existence values would be major and adverse. Overall, as discussed above in 4.11.2.3, most of the cumulative actions would further jeopardize the existence of these fish and therefore overall cumulative effects would be major and adverse in the long term.

#### *4.11.3.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 consists of structural improvements and alteration of reservoir outflows measures, which maximize refill volumes of spring conservation pools at WVS reservoirs in support of improved survival of ESA-listed fish species, in addition to all other authorized project purposes of the structures. Three WTC towers (#105), three downstream passage structures (#639, #52, and #392), and two AFFs (#722) would be constructed, affecting five project locations at Dexter, Detroit, Green Peter, Lookout Point, and Foster Dams. Alternative 1 would have similar effects to socioeconomic resources as Alternative 4, and would have substantially more beneficial short- and medium-term effects to labor and earnings and more adverse effects to quality of life (and less adverse short and long-term recurring effects to recreational value and M&I use and irrigation) than Alternatives 2A, 2B, 3A, 3B, and 5.

As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompt the creation of jobs and a small in-migration of specialized contractors. Construction expenditures associated with Alternative 1 are expected to total approximately $1.8B over the life of the project – the second highest of the alternatives. As such, these cumulative effects to labor and earnings (including low-income populations) would be synergistic if they occur at the same time and thus would create moderate, beneficial cumulative effects in the short and medium term. Cumulative effects to population and housing would be additive and minor in the short and medium term.

Construction of the structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the recreational quality at recreational sites in the vicinity of project activities, as well as to the quality of life of nearby residents. The magnitude of effects would depend on the proximity of the cumulative actions and proposed structural measures to the recreational site or the recreationist or the resident, as well as the timing of the projects. For example, if the construction of structural improvements to reduce TDG at Dexter (#174) under Alternative 1 occurs at the same time as modifications of existing WVS structures at Dexter, cumulative effects to the quality of life from noise, emissions, and congestion to the residents of Lowell would be more severe than if they occurred consecutively. As such, cumulative effects to recreational value and quality of life would be moderate and additive under Alternative 1 and would occur in the short and medium term.

The Fall Creek drawdown would also occur annually under Alternative 1. RFFA 1, future population growth and accompanying urban, industrial, and commercial development would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from drawdowns, RFFA 3, water withdrawals for municipal, industrial, and agricultural uses, and RFFA 9, climate change would affect both the quality of the recreational experience as well as the quality of life of nearby residents (though, there is not a city on the shores of Fall Creek). Lower recreational quality could lower the amount of revenues expected from each visitor, as well as the probability of repeat visits. Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state, and local fish and wildlife improvement; and RFFA 8, invasive species management would improve the overall quality of fish habitat within the ROI, which could potentially offset some of the adverse effects of climate change on general fishery quality and subsequent recreational visitation in the long term. But overall, cumulative, additive effects to recreational value and quality of life would be minor and additive in the short and long term (recurring).

As discussed in 3.11.2.6.2, the alteration of outflows and reservoir levels under Alternative 1 would have beneficial, moderate effects on water supply in the short and long term. One drawdown during the fall at one location (Fall Creek) would have negligible, short- and long-term recurring adverse effects to water supply. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would offset these benefits and have countervailing cumulative effects. As such, overall cumulative effects on M&I use and agricultural irrigation from the proposed measures, RFFA 3, and RFFA 9 would be beneficial and minor in the short and long term (recurring).

As discussed in 3.11.2.4.3, the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and would have long-term, minor, beneficial effects. As discussed above in 4.11.2.3, most of the past, present, and RFFAs would be interactive and countervailing, working against the proposed measures. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative, long-term benefits to the existence value of these ESA-listed fish would be negligible.

#### *4.11.3.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Under Alternative 2A, fewer construction and infrastructure improvement activities would be implemented compared to Alternative 1 and would impact fewer project locations. Alternative 2A would have similar effects to socioeconomic resources as Alternatives 2B and 5 and would have effects of substantially lower magnitude than Alternatives 1, 3A, 3B and 4.

As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompt the creation of jobs and a small in-migration of specialized contractors. Construction expenditures associated with Alternative 2A would total only approximately $1.1B, which is almost half of those which would occur under Alternative 1. As such, these cumulative effects to labor and earnings (including low-income populations) would be synergistic, minor, and beneficial in the short and medium term. Cumulative effects to population and housing due to an influx of specialized workers would be additive and minor in the short and medium term.

As described above in 4.11.2.1, construction of the structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the recreational quality at recreational sites in the vicinity of project activities as well as to the quality of life of nearby residents. Given the fewer structural measures compared to Alternative 1, cumulative effects to recreational value and quality of life would be minor and additive under Alternative 1 and would occur in the short and medium term.

Under Alternative 2A, a fall drawdown would occur annually at Fall Creek as well as Green Peter. RFFA 1, future population growth and accompanying urban, industrial, and commercial development would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from drawdowns, RFFA 3, water withdrawals for municipal, industrial, and agricultural uses, and RFFA 9, climate change would affect both the quality of the recreational experience as well as the quality of life of nearby residents (though, there are no cities directly on the shores of Fall Creek or Green Peter). Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state, and local fish and wildlife improvement; and RFFA 8, invasive species management could potentially offset some of the adverse effects of climate change on general fishery quality and subsequent recreational visitation in the long term. But overall, cumulative, additive effects to recreational value and quality of life would still be minor and additive in the short and long term (recurring).

As discussed in 3.11.2.6.2, the alteration of outflows and reservoir levels from the two drawdowns under Alternative 2A would reduce the availability of water supply for M&I and agricultural users. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would further reduce water availability. But, the allocation of agricultural, municipal, and industrial water demand is much smaller than that required for fish and wildlife management and the additional drawdown at Green Peter would only marginally affect reservoir levels. Also, both drawdowns occur in the autumn or during periods with minimal WVS water use. As such, cumulative, additive effects from RFFA 3, RFFA 9, and the Green Peter and Fall Creek drawdowns would be minor in the short and long term (recurring).

As discussed in 3.11.2.4.3, the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and would have long-term, minor, beneficial effects. As discussed above in 4.11.2.3, most of the past, present, and RFFAs would be interactive and countervailing, working against the proposed measures. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative, long-term benefits to the existence value of these ESA-listed fish would be negligible.

#### *4.11.3.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Under Alternative 2B, the cumulative effects to socioeconomic resources would be very similar as those described under Alternative 2A. Under this alternative, one fewer downstream passage structure would be built (#392), and two additional drawdowns – one in the fall (#40) and one in the spring (#720) – would occur at Cougar.

As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompt the creation of jobs and a small in-migration of specialized contractors. Alternative 2B is $52M lower in construction expenditures than Alternative 2A, but overall effects would be the same as Alternative 2A. Cumulative effects to labor and earnings (including low-income populations) would be synergistic, minor, and beneficial in the short and medium term. Cumulative effects to population and housing due to an influx of specialized workers would be additive and minor in the short and medium term.

As described above in 4.11.2.1, construction of the structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the recreational quality at recreational sites in the vicinity of project activities as well as to the quality of life of nearby residents. Despite one fewer structural downstream fish passage compared to Alternative 2A, effects to recreational value and quality of life would also be minor and additive in the short and medium term.

Under Alternative 2B, a fall drawdown would occur annually at Fall Creek, Green Peter, and Cougar; a spring drawdown would also occur at Cougar. The spring drawdowns at Cougar would reduce recreational expenditures at this reservoir throughout the life of the project due to decreased recreational quality during the spring/summer recreation season. However, Cougar is one of the least visited reservoirs of the 13 reservoirs; and visitors spend the least amount of dollars per visit at this reservoir (USACE 2019e). RFFA 1, future population growth and accompanying urban, industrial, and commercial development would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from drawdowns; RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; and RFFA 9, climate change would affect both the quality of the recreational experience as well as the quality of life of nearby residents (though, there are no cities directly on the shores of Fall Creek, Green Peter, or Cougar). Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state, and local fish and wildlife improvement; and RFFA 8, invasive species management could potentially offset some of the adverse effects of climate change on general fishery quality and subsequent recreational visitation in the long term. Overall, cumulative, additive effects to recreational value and quality of life would still be minor and additive in the short and long term (recurring).

As discussed in 3.11.2.6.2, the alteration of outflows and reservoir levels under Alternative 2B would reduce the availability of water supply for M&I and agricultural users. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would further reduce water availability. But, the allocation of agricultural, municipal, and industrial water demand is much smaller than that required for fish and wildlife management. While three drawdowns occur in the autumn or during periods with minimal WVS water use, the spring drawdown at Cougar would reduce the recharge ability of WVS system-wide and occur during periods of highest use for both agricultural irrigation and M&I purposes. As such, cumulative, additive effects from RFFA 3, RFFA 9, and the four total drawdowns would be minor to moderate in the short and long term (recurring).

As discussed in 3.11.2.4.3, the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and would have long-term, minor, beneficial effects. As discussed above in 4.11.2.3, most of the past, present, and RFFAs would be interactive and countervailing, working against the proposed measures. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative, long-term benefits to the existence value of these ESA-listed fish would be negligible.

#### *4.11.3.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Alternative 3A consists primarily of alteration of outflows and reservoir drawdowns, along with minor structural improvements and maintenance which increase stream flows and enhance fish passage in support of improved survival of ESA-listed fish species.

As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA, 10 mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompt the creation of jobs and a small in-migration of specialized contractors. Construction expenditures associated with Alternative 3A would total only approximately $330M, which is only 34 percent of those of Alternatives 2A and 2B. Construction expenditures would be lowest for this alternative, and as such would result in fewer construction and infrastructure improvement activities compared to all other alternatives. As such, cumulative effects to labor and earnings (including low-income populations) would be synergistic, negligible, and beneficial in the short and medium term. Cumulative effects to population and housing would be additive but also minor in the short and medium term.

As discussed in Section 3.11.2.8.2, alteration of outflows and a total of 10 drawdowns at seven reservoirs would likely substantially decrease the recreational expenditures within the ROI. Annual deep spring drawdowns in particular at Cougar, Detroit, and Lookout Point reservoirs would substantially reduce their recreational value during the spring/summer recreation season. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from the drawdowns and climate change would affect both the quality of the recreational experience as well as the quality of life of nearby residents, in particular for residents of the city of Detroit living along the shores of Detroit Reservoir. Lower recreational quality could lower the amount of revenues expected from each visitor, as well as the probability of repeat visits. Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state, and local fish and wildlife improvement; and RFFA 8, invasive species management would also improve the overall quality of fish habitat within the ROI, which could potentially offset some of the adverse effects of climate change on fishery quality and subsequent recreational visitation in the long term. However overall, cumulative, additive effects to recreational value and quality of life would be major and additive in the short and long term (recurring).

As discussed in Section 3.11.2.8.2, alteration of outflows and the drawdowns under Alternative 3A would also significantly reduce the availability of water supply for M&I and agricultural users. The spring drawdowns at Cougar, Detroit, and Lookout Point in particular would reduce the recharge ability of WVS system-wide and occur during periods of highest use for both agricultural irrigation and M&I purposes. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would further reduce water availability. As such, cumulative, additive effects from RFFA 3, RFFA 9, and the ten total drawdowns would be major in the short and long-term (recurring).

As discussed in 3.11.2.4.3, the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and would have long-term, minor, beneficial effects. As discussed above in 4.11.2.3, most of the past, present, and RFFAs would be interactive and countervailing, working against the proposed measures. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative, long-term benefits to the existence value of these ESA-listed fish would be negligible.

#### *4.11.3.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Under Alternative 3B, the cumulative effects to socioeconomic resources would be almost the same as those described under Alternative 3A. Under 3B, spring drawdowns would occur at Green Peter and Hills Creek instead of at Detroit and Lookout Point under Alternative 3A.

As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompt the creation of jobs and a small in-migration of specialized contractors. Construction expenditures associated with Alternative 3B would total approximately $415, or $85M in additional construction and maintenance expenditures compared to Alternative 3A. Overall cumulative effects to labor and earnings (including low-income populations) would be the same as under Alternative 3A, or synergistic, negligible, and beneficial in the short and medium term. Cumulative effects to population and housing would be additive but also minor in the short and medium term.

As discussed in Section 3.11.2.8.2, alteration of outflows and a total of 10 drawdowns at seven reservoirs would likely substantially decrease the recreational expenditures within the ROI. Annual deep spring drawdowns in particular at Hills Creek, Cougar, and Green Peter reservoirs would substantially reduce their recreational value during the spring/summer recreation season. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from the drawdowns and climate change would affect both the quality of the recreational experience as well as the quality of life of nearby residents. Lower recreational quality could lower the amount of revenues expected from each visitor, as well as the probability of repeat visits. Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state, and local fish and wildlife improvement; and RFFA 8, invasive species management would also improve the overall quality of fish habitat within the ROI, which could potentially offset some of the adverse effects of climate change on fishery quality and subsequent recreational visitation in the long term. However overall, cumulative, additive effects to recreational value and quality of life would be major and additive in the short and long term (recurring).

As discussed in Section 3.11.2.8.2, alteration of outflows and the drawdowns under Alternative 3B would also significantly reduce the availability of water supply for M&I and agricultural users. The spring drawdowns at Hills Creek, Cougar, and Green Peter in particular would reduce the recharge ability of WVS system-wide and occur during periods of highest use for both agricultural irrigation and M&I purposes. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would further reduce water availability. As such, cumulative, additive effects from RFFA 3, RFFA 9, and the ten total drawdowns would be major in the short and long-term (recurring).

As discussed in 3.11.2.4.3, the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and would have long-term, minor, beneficial effects. As discussed above in 4.11.2.3, most of the past, present, and RFFAs would be interactive and countervailing, working against the proposed measures. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative, long-term benefits to the existence value of these ESA-listed fish would be negligible.

#### *4.11.3.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Under Alternative 4, the cumulative effects to socioeconomic resources would be similar to those described under Alternative 1. Under this alternative, two additional downstream passage structures would be constructed. Alternative 4 would have the largest expenditures compared to the other alternatives, and therefore would have the greatest beneficial short- and medium-term effects to labor and earnings and most adverse effects to quality of life (and less adverse short and long-term recurring effects to recreational value and M&I use and agricultural irrigation) than Alternatives 2A, 2B, 3A, 3B, and 5.

As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompt the creation of jobs and a small in-migration of specialized contractors. Construction and maintenance expenditures associated with Alternative 4 would total approximately $2B, which is $200M greater than those of Alternative 1, and the most expensive of the alternatives. As such, cumulative effects to labor and earnings (including low-income populations) would be synergistic, moderate, and beneficial in the short and medium term. Cumulative effects to population and housing would be additive and minor in the short and medium term.

Construction of the structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the recreational quality at recreational sites in the vicinity of project activities as well as to the quality of life of nearby residents. The magnitude of effects would depend on the proximity of the cumulative actions and proposed structural measures to the recreational site or the recreationist or the resident, as well as the timing of the projects. For example, if the construction of structural improvements to reduce TDG at Dexter and Cougar occur at the same time as modifications of existing WVS structures at Dexter and Cougar, cumulative effects would be more severe than if they occurred consecutively. As such, cumulative effects to recreational value and quality of life would be moderate and additive in the short and medium term.

As under Alternative 1, the Fall Creek drawdown would also occur annually under Alternative 4. RFFA 1, future population growth and accompanying urban, industrial, and commercial development would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from drawdowns, RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would affect both the quality of the recreational experience as well as the quality of life of nearby residents (though, there is not a city on the shores of Fall Creek). Lower recreational quality could lower the amount of revenues expected from each visitor, as well as the probability of repeat visits. Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state, and local fish and wildlife improvement; and RFFA 8, invasive species management would improve the overall quality of fish habitat within the ROI, which could potentially offset some of the adverse effects of climate change on general fishery quality and subsequent recreational visitation in the long term. But overall, cumulative, additive effects to recreational value and quality of life would be minor and additive in the short and long term (recurring).

As discussed in 3.11.2.6.2, the alteration of outflows and reservoir levels under Alternative 4 would have beneficial, minor effects on water supply in the short and long term. One drawdown during the fall at one location (Fall Creek) would have negligible, short- and long-term recurring adverse effects to water supply. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would offset these benefits and have countervailing cumulative effects. As such, overall cumulative effects on M&I use and agricultural irrigation from the proposed measures, RFFA 3, and RFFA 9 would be beneficial and negligible to minor in the short and long term (recurring).

As discussed in 3.11.2.4.3, the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and would have long-term, minor, beneficial effects. As discussed above in 4.11.2.3, most of the past, present, and RFFAs would be interactive and countervailing, working against the proposed measures. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative, long-term benefits to the existence value of these ESA-listed fish would be negligible.

#### *4.11.3.8 Alternative 5 – Alternative 5 – Integrated Water Management and ESA-Listed Fish Alternative (using diversion tunnel at CGR)*

Under Alternative 5, the cumulative effects to socioeconomic resources would be identical to those described under Alternative 2B. Alternative 5 differs from Alternative 2B only in its use of a refined integrated temperature and habitat flow regime (#30b).

As described above in 4.11.2.1, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations would also provide influxes of capital into the ROI and prompt the creation of jobs and a small in-migration of specialized contractors. Cumulative effects to labor and earnings (including low-income populations) would be synergistic, minor, and beneficial in the short and medium term. Cumulative effects to population and housing due to an influx of specialized workers would be additive and minor in the short and medium term.

As described above in 4.11.2.1, construction of the structural measures in combination with floodplain development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would also add noise, emissions, and congestion and therefore have adverse effects to the recreational quality as well as to the quality of life of nearby residents. Cumulative effects to recreational value and quality of life would be minor and additive in the short and medium term.

Under Alternative 5, a fall drawdown would occur annually at Fall Creek, Green Peter, and Cougar; a spring drawdown would also occur at Cougar. The spring drawdowns at Cougar would reduce recreational expenditures during the spring/summer recreation season. However, Cougar is one of the least visited reservoirs with the least amount of dollars spent per visit of all 13 reservoirs (USACE 2019e). RFFA 1, future population growth and accompanying urban, industrial, and commercial development would further decrease the recreational quality of visits due to crowding and congestion. The visual effects from drawdowns, RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 10, climate change would affect both the quality of the recreational experience and the quality of life of nearby residents (though, there are no cities directly on the shores of Fall Creek, Green Peter, and Cougar). Benefits from RFFA 5, federal and state wildlife and lands management; RFFA 7, Tribal, state, and local fish and wildlife improvement; and RFFA 8, invasive species management could potentially offset some of the adverse effects of climate change on general fishery quality and subsequent recreational visitation in the long term. Overall, cumulative, additive effects to recreational value and quality of life would still be minor and additive in the short and long term (recurring).

As discussed in 3.11.2.6.2, the alteration of outflows and reservoir levels under Alternative 5 would reduce the availability of water supply for M&I and agricultural users. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change would further reduce water availability. The spring drawdown in particular at Cougar would reduce the recharge ability of WVS system-wide and occur during periods of highest use for both agricultural irrigation and M&I purposes. As such, cumulative, additive effects from RFFA 3, RFFA 9, and the four total drawdowns would be minor to moderate in the short and long-term (recurring).

As discussed in 3.11.2.4.3, the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and would have long-term, minor, beneficial effects. As discussed above in 4.11.2.3, most of the past, present, and RFFAs would be interactive and countervailing, working against the proposed measures. These would further jeopardize the existence of the ESA-listed fish and therefore overall cumulative, long-term benefits to the existence value of these ESA-listed fish would be negligible.

### 4.11.4 Summary

In summary, Alternatives 1 and 4 would have beneficial effects on labor and earnings than Alternatives 2a, 2b, and 5, which in turn have greater beneficial effects than Alternatives 3a and 3b. Alternatives 3a and 3b have greater adverse effects on the quality of life and recreational value, than Alternatives 1 and 4, which are in turn greater than Alternatives 2a, 2b, and 5. Similarly, Alternatives 3a and 3b would have greater adverse effects to water supply than Alternatives 2a, 2b, and 5, which in turn have greater effects than Alternatives 1 and 4. The cumulative effects on the existence value of ESA-listed fish would be **negligible** and **beneficial** for all alternatives in the **long-term.**

The cumulative effects of Alternative 1 and 4 on labor earnings would be **beneficial,** and **minor** to **moderate** in the **short**, **medium,** and **long term**. Under Alternative 2a, 2b, and 5, the cumulative effects to labor and earnings would be **minor** and **beneficial** in the **short** and **medium term**. The cumulative effects to labor and earnings under Alternative 3a and 3b would be **beneficial,** and **negligible to minor** and in the **short** and **medium term**.

Under Alternatives 1 and 4, there would be **minor** to **moderate, additive, adverse** cumulative effects to recreational value and quality of life in the **short, medium,** and **long term (recurring).** Given the fewer structural measures compared to Alternatives 1 and 4, the cumulative effects of Alternatives 2a, 2b, and 5 on recreational value and the quality of life would be **minor**, **adverse**, and **additive** in the **short, medium,** and **long term (recurring).** Under Alternatives 3a and 3b, the alteration of outflows and a total of 10 drawdowns at seven reservoirs would result in **major** and **additive** cumulative effects to recreational value and quality of life in the **short** and **long term (recurring).**

# 4.12 POWER AND TRANSMISSION

## 4.12.1 Cumulative Effects Analysis Methodology for Power and Transmission

The following sections are a qualitative assessment of anticipated trends and their cumulative impact on power and transmission. This incorporates past, present, and future actions.

### *4.12.1.1 Cumulative Actions Applicable to Power and Transmission*

Past, present, and reasonably foreseeable future actions (RFFAs) that, when considered together with the Proposed Action and alternatives, would have cumulative effects on Power and Transmission include:

- WVS Dams and Reservoirs
- WRB Population Growth and Development
- Near-Term Operations Measure
- Near-Term Structural Measure
- RFFA 1 – Future population growth and accompanying urban, industrial, and commercial development
- RFFA 4 - Decarbonizing the energy sector with renewable energy sources
- RFFA 5 – Vehicle emissions reductions
- RFFA 10 – Climate change

The other RFFAs discussed in Section 4.2.3 do not impact power generation and transmission as they do not impact operations or flow in the river system and do not impact operation of the power system or the energy market as a whole. Therefore, these RFFAs are dismissed from further analysis for Power and Transmission. The near-term operations measure impacts to hydropower generation were analyzed in section 3.13.3.2.8 of Chapter 3.

## 4.12.2 Effects to Power and Transmission by Alternative

Hydropower generation and transmission in the Willamette Valley exists as a result of construction and operation of the WVS dams and reservoirs for flood risk management. Hydropower generation from the WVS dams is integrated into the Federal Columbia River Power System, which is marketed as a system by Bonneville. WVS dams are integrated into the regional transmission system, and provide islanded service to the nearby communities Oakridge and Blue River in weather or fire incidents, as well as during system maintenance. Hydropower generation from the WVS does not specifically supply nearby communities, instead communities served by Bonneville wholesale power receive their power from the entire FCRPS. Specific releases for hydropower generation occur only after operations for other project purposes are optimized, both at the specific reservoir and in coordination among the entire

WVS. Consequently, hydropower generation should be viewed as a residual benefit after other benefits are provided for.

#### *4.12.2.1 No Action Alternative*

Cumulative effects to hydropower and transmission for the No Action Alternative are described for the WVS as a whole.

The cumulative effects of past and present actions including the near-term operations measure, RFFA 10 described above, and the No Action Alternative would be major long-term adverse impacts to power.

Under the No Action Alternative, separate from the near-term operations measure, generation for the Willamette Valley projects would be 171 aMW. This translates to roughly enough to power 136,416 household customers. The loss of load probability (LOLP) refers to the probability that a system demand will exceed capacity during a given period. The LOLP would be 6.5 percent, which is within the current range of the Pacific Northwest Power System recent reliability assessments, but above the five percent standard established by the Northwest Power and Conservation Council. This suggests a risk of blackouts approximately once every fifteen years. The Net Present Value (NPV) for the combined WVS projects would be $225 million. The estimated levelized cost of generation (LCOG)—which refers to the average cost of power generation for a given plant or system—would be $26.70/MWh.

Assuming the near-term operations measures occur under the No Action Alternative, power generation would decrease by 52 aMW, resulting in a NPV of -$196 million, and would increase the LCOG to $38.35/MWh from $26.70/MWh for WVS projects. Note that the near-term operations measure used the No Action Alternative as the baseline, and as such is a direct comparison. There are no costs associated with the near-term operations measure, so these estimated changes would be due solely to a decrease in generation. Costs of near-term structural measures being proposed by the Court-created expert panel are currently unknown but would be expected to reduce the NPV and increase the LCOG.

See Section 3.13 for the full description of the No Action Alternative and the affected environment.

Climate change could further complicate expectations for hydropower generation. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of demand is uncertain. There is a potential for a decrease in demand during the time frame analyzed due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and use of water/space heaters due to population growth), and load spikes due to temperature fluctuations from extreme weather. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

For Transmission, the cumulative effects of past and present actions including the near-term operations measure, the RFFAs described above, and the No Action Alternative would be long-term moderate impacts. The effect ratings used in this Draft PEIS for power and transmission are based on the unique definitions being used to distinguish among alternatives and are not conclusive for decision making or other studies conducted outside this Draft PEIS.

The creation of the dams and past population growth in the region led to the need to develop the transmission system. Under the No Action Alternative, the Cross Cascades South (CCS) and South of Allston (SOA) transmission paths are congested but operational. Hills Creek and Cougar are capable of islanded operations to provide some isolated communities with power during emergencies such as wildfires.

The near-term operations measure increases loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Under the near-term operations measure, Hills Creek would continue to be able to operate islanded, but Cougar may not be able to operate islanded during deep drawdowns.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

#### *4.12.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Cumulative effects to hydropower and transmission for Alternative 1 are described for the WVS as a whole.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 1—would be major long-term adverse impacts to the economic viability of power generation at Willamette Valley projects. The creation of the system and population growth in the past created the ability to generate power and a demand for that power. The near-term operations measure would decrease power generation by 52 aMW, resulting in a NPV of -$196 million, and would increase the LCOG to $38.35/MWh from $26.70/MWh for Willamette Valley projects. There are no capital costs associated with the near-term operations measure, so these changes are due solely to a decrease in generation.

The direct and indirect impacts on power associated with Alternative 1 would be primarily a result of the costs associated with implementing the alternative as there are positive impacts to generation. Generation at the projects as a whole would increase by 8 aMW under Alternative 1, an increase of 4.7%. The LOLP metric would decrease by 0.1% to 6.4% due to the increase in generation. Due to the costs of the alternative, the NPV for the Willamette Valley would decrease by $1.159 billion to -$934 million. The LCOG would increase by $27.14 to $53.84/MWh. Costs of near-term structural measures are currently unknown but would be expected to further reduce the NPV and increase the LCOG. Note that the near-term operations measure and Alternative 1 were analyzed separately, so metrics associated with each one are not necessarily additive.

See Section 3.13 for the full analysis of direct and indirect effects of Alternative 1 on power.

Climate change further complicates expectations for hydropower generation. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of power demand is uncertain. There is a potential for a decrease in demand during the time frame due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and water/space heaters), and load spikes due to temperature fluctuations from extreme weather. Decreasing flows and lower reservoir elevations expected in the spring and summer would negatively impact generation going into a high demand summer season, with demand expected to increase as temperatures increase. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

The cumulative effects of past and present actions—including the near-term operations measure, near-term structures measure, RFFA 10 described above, and Alternative 1—would be long-term moderate impacts on the transmission system.

The creation of the dams and past population growth in the region led to the need to develop the transmission system. Currently, the CCS and SOA transmission paths are congested but operational. Hills Creek and Cougar are able to operate islanded to provide Oakridge and Blue River communities, respectively, with power under temporary weather or fire related outage conditions.

The near-term operations measure would increase loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Hills Creek would continue to be able to operate islanded, but Cougar may not due to deep drawdowns under the near-term operations measure.

The direct and indirect effects of Alternative 1 would be less than 10MW of increased load on the CCS and SOA paths in all seasons. Hills Creek and Cougar would continue to be able to operate islanded under Alternative 1. However, if the near-term operations measure were implemented in conjunction with Alternative 1, Cougar would have a compromised ability to do so. Note that the near-term operations measure and Alternative 1 were analyzed separately, so metrics associated with each one are not additive and should not be combined.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

**Table 4.12-2. Summary of effects for Power and Transmission under Alternative 1 – Improve Fish Passage Through Storage-Focused Measures**

| Resource | Past Actions | Present Actions | Direct and Indirect Effects | Future Actions | Cumulative Effect |
|---|---|---|---|---|---|
| Power | The construction and operation of the WRB dams and reservoirs created the Willamette Valley hydropower system. The population growth and the economic development in the region has led to the current demand for power that exists. | The near-term operations measure has a negligible impact on power system reliability, blackouts, and LOLP, but does decrease generation by about 52 aMW. It also would have long-term major impacts on the economic viability of power generation at WVS projects, resulting in a Net Present Value of -$196 and a levelized cost of generation to $38.35/MWh (an increase of $11.65/MWh over the existing condition) for the system. | Alternative 1 would have negligible impacts on power system reliability and long-term major impacts to the economic viability of power generation in the WVS. Average annual generation would increase by 8 aMW and LOLP decreases by 0.1 percent. Alternative 1 would result in a $1.159 billion reduction of NPV to -$934 million and a $27.14 increase in the LCOG to $53.84/MWh. | Climate change may increase or decrease power demand while reducing generation capability during high demand seasons. | Overall, there would be long-term, major, adverse effects on power given cumulative effects of past, present, future actions, and Alternative 1. This alternative would create a situation where power in the Willamette Valley would no longer be cost effective at many of the dams. Other factors unrelated to Alternative 1 itself would have the potential to further adversely impact power. |

| Resource | Past Actions | Present Actions | Direct and Indirect Effects | Future Actions | Cumulative Effect |
|---|---|---|---|---|---|
| Transmission | The creation of the WVS Dams and Reservoirs for flood risk management required transmission lines to be built to service the dams. The population growth in the area also created demand for transmission in the area. | The near-term operations measure would have long-term moderate adverse effects on the transmission system. Deep fall and spring drawdowns would also compromise the ability of Cougar Dam to operate islanded and serve the community of Blue River under temporary weather or fire related outage conditions. | Alternative 1 would have long-term, minor adverse effects on the transmission system including some increased loading on already congested transmission paths. | Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system.<br><br>The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge. | Overall, there would be long-term, moderate adverse effects on transmission given cumulative effects of past, present, future actions, and Alternative 1. Other factors unrelated to Alternative 1 itself would have the potential to further adversely impact transmission. |

#### *4.12.2.3 Alternative 2a – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Cumulative effects to hydropower and transmission for Alternative 2a are described for the WVS as a whole.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 2a—would be major long-term adverse impacts to the economic viability of power generation at Willamette Valley projects. The creation of the system and population growth in the past created the ability to generate power and a demand for that power. The near-term operations measure would decrease power generation by 52 aMW, resulting in a NPV of -$196 million, and would increase the LCOG to $38.35/MWh from $26.70 for Willamette Valley projects. There are no costs associated with the near-term operations measure, so these estimated changes are due solely to a decrease in generation. Costs of near-term structural measures are currently unknown but would be expected to further reduce the NPV and increase the levelized cost of generation.

The direct and indirect impacts on power associated with Alternative 2a would primarily result in the costs associated with implementing the alternative as well as a decrease in generation. Generation at the projects would decrease by 4 aMW under Alternative 2a, a decrease of 2.3%. LOLP would not change from 6.5%. Due to the costs of the alternative, the NPV for the Willamette Valley would decrease by $863 to -$638 million. The LCOG would increase by $20.75 to $47.45/MWh. Note that the near-term operations measure and Alternative 2a were analyzed separately, so metrics associated with each one are not necessarily additive. Changes to hydropower generation resulting from the various cumulative effects would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section above.

See Section 3.13 for the full analysis of direct and indirect effects of Alternative 2a on power.

Climate change could further complicate expectations for hydropower generation. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of demand is uncertain. There is a potential for a decrease in demand during the time frame due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and water/space heaters), and load spikes due to temperature fluctuations from extreme weather. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

The cumulative effects of past and present actions including the near-term operations measure, RFFA 10 described above, and Alternative 2a would be long-term moderate impacts on the transmission system. The creation of the dams and past population growth in the region led to the need to develop the transmission system. Currently, the CCS and SOA transmission paths are congested but operational. Hills Creek and Cougar are able to operate islanded to provide Oakridge and Blue River communities, respectively, with power under temporary weather or fire related outage conditions.

The near-term operations measure would increase loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Hills Creek would continue to be able to operate islanded, but Cougar may not due to deep drawdowns under the measure.

The direct and indirect effects of Alternative 2a would be increased loading on the CCS path (18.4 MW) in the winter and on both SOA (11.8 MW) and CCS (61.3 MW) in spring.

Hills Creek and Cougar would continue to be able to operate islanded under Alternative 2a. However, if the near-term operations measure were implemented in conjunction with Alternative 2a, Cougar would have a compromised ability to do so. Note that the near-term operations measure and Alternative 2a were analyzed separately, so metrics associated with each one are not additive.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

### 4.12.2.4 Alternative 2b – Integrated Water Management Flexibility and ESA-Listed Fish Alternative

Cumulative effects to hydropower and transmission for Alternative 2b are described for the WVS as a whole.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 2b—would be major long-term adverse impacts to the economic viability of power generation at Willamette Valley projects. The creation of the system and population growth in the past created the ability to generate power and a demand for that power. The near-term operations measure would decrease power generation by 52 aMW, resulting in a NPV of -$196 million, and would increase the LCOG to $38.35/MWh from $26.70/MWh for Willamette Valley projects. There are no costs associated with the near-term operations measure, so these estimated changes are due solely to a decrease in generation. Costs of near-term structural measures are currently unknown but would be expected to further reduce the NPV and increase the levelized cost of generation.

The direct and indirect impacts on power associated with Alternative 2b would be primarily a result of the costs associated with implementing the alternative as well as a decrease in generation. Generation at the projects would decrease by 18 aMW under Alternative 2b, a decrease of 10.5%. LOLP would increase to 6.6%. Due to the costs of the alternative, the NPV for the Willamette Valley would decrease by $933 to -$708 million. The LCOG would increase by $23.96 to $50.66/MWh. Note that the near-term operations measure and Alternative 2b were analyzed separately, so metrics associated with each one are not necessarily additive. Changes to hydropower generation resulting from the various cumulative effects would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section above.

See Section 3.13 for the full analysis of direct and indirect effects of Alternative 2b on power.

Climate change further complicates expectations. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of demand is uncertain. There is a potential for a decrease in demand during the time frame due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and water/space heaters), and load spikes due to temperature fluctuations from extreme weather. Decreasing flows and lower reservoir elevations expected in the spring and summer would negatively impact generation going into a high demand summer season, with demand expected to increase as temperatures increase. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 2b—would be long-term moderate impacts on the transmission system. The creation of the dams and past population growth in the region led to the need to develop the transmission system. Currently, the CCS and SOA transmission paths are congested but operational. Hills Creek and Cougar are able to operate islanded to provide Oakridge and Blue River communities, respectively, with power under temporary weather or fire related outage conditions.

The near-term operations measure would increase loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Hills Creek would continue to be able to operate islanded, but Cougar may not due to deep drawdowns under the measure.

The direct and indirect effects of Alternative 2b would be increased loading on the CCS path (21.9 MW) in the winter and on both SOA (5.1 MW) and CCS (25.1 MW) in spring.

Hills Creek would continue to be able to operate islanded under Alternative 2b. However, the drawdowns at Cougar under both the near-term operations measure and Alternative 2b would compromise Cougar's ability to operate islanded under temporary weather or fire related outage conditions.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

#### *4.12.2.5 Alternative 3a – Operations-Focused Fish Passage Alternative*

Cumulative effects to hydropower and transmission for Alternative 3a are described for the WVS as a whole.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 3a—would be long-term, moderate adverse impacts to the economic viability of power generation at Willamette Valley projects. The creation of the system and population growth in the past created the ability to generate power and a demand for that power. The near-term operations measure would decrease power generation by 52 aMW, resulting in a NPV of -$196 million, and would increase LCOG to $38.35/MWh from $26.70 for Willamette Valley projects. There are no costs associated with the near-term operations measure, so these estimated changes are due solely to a decrease in generation. Costs of near-term structural measures are currently unknown but would be expected to reduce the NPV and increase the levelized cost of generation.

The direct and indirect impacts on power associated with Alternative 3a would primarily result in the costs associated with implementing the alternative as well as a large decrease in generation. Generation at the projects would decrease by 87 aMW under Alternative 3a, a decrease of 50.9%. LOLP would increase to seven percent. The NPV for the Willamette Valley would decrease by $853 to -$628 million. The LCOG would increase by $37.61 to $64.32/MWh. Note that the near-term operations measure and Alternative 3a were analyzed separately, so metrics associated with each one are not necessarily additive. Changes to hydropower generation resulting from the various cumulative effects would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section above.

See Section 3.13 for the full analysis of direct and indirect effects of Alternative 3a on power.

Climate change further complicates expectations. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of demand is uncertain. There is a potential for a decrease in demand during the time frame due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and water/space heaters), and load spikes due to temperature fluctuations from extreme weather. Decreasing flows and lower reservoir elevations expected in the spring and summer would negatively impact generation going into a high demand summer season, with demand expected to increase as temperatures increase. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

The cumulative effects of past and present actions—including the near-term operations measure, RFFAs described above, and Alternative 3a—would be long-term moderate impacts on the transmission system. The creation of the dams and past population growth in the region led to the need to develop the transmission system. Currently, the CCS and SOA transmission paths are congested but operational. Hills Creek and Cougar are able to operate islanded to provide Oakridge and Blue River communities, respectively, with power under temporary weather or fire related outage conditions.

The near-term operations measure would increase loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Hills Creek would continue to be able to operate islanded, but Cougar may not due to deep drawdowns under the near-term operations measure.

The direct and indirect effects of Alternative 3a would be increased loading on the CCS (37.2 MW) and SOA (13.6 MW) paths in the winter. It would also lead to increased loading on both paths in spring.

Drawdowns at Hills Creek and Cougar under Alternative 3a would compromise both plants' abilities to operate islanded under temporary weather or fire related outage conditions.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

**Table 4.12-5. Summary of effects for Power and Transmission under Alternative 3a – Operations-Focused Fish Passage Alternative**

| Resource | Past Actions | Present Actions | Direct and Indirect Effects | Future Actions | Cumulative Effect |
|---|---|---|---|---|---|
| Hydropower | The construction and operation of the WRB dams and reservoirs created the Willamette Valley hydropower system. The population growth and the economic development in the region has led to the current demand for power that exists. | The near-term operations measure has a negligible impact on power system reliability, blackouts, and LOLP, but does decrease generation by about 52 aMW. It also would have long-term major impacts on the economic viability of power generation at WVS projects, resulting in a Net Present Value of -$196 and a levelized cost of generation to $38.35/MWh (an increase of $11.65/MWh over the existing condition) for the system. | Alternative 3a would have negligible impacts on power system reliability and long-term, major effects on the economic viability of power generation. Average annual generation would decrease by 87 aMW and LOLP would increase by 0.5 percent. Alternative 3a would result in a $853 million reduction of NPV to -$628 and a $37.61 increase in the LCOG to 64.32/MWh. | Climate change may increase or decrease power demand while reducing generation capability during high demand seasons. | Overall, there would be long-term, major, adverse effects on power given cumulative effects of past, present, future actions, and Alternative 3a. This alternative would create a situation where hydropower in the Willamette Valley would no longer be cost effective at many of the dams. Other factors unrelated to Alternative 3a itself would have the potential to further adversely impact hydropower. |
| Transmission | The creation of the dams required transmission lines to be built to service the dams. #### *4.12.2.6 Alternative 3b – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Cumulative effects to hydropower and transmission for Alternative 3b are described for the WVS as a whole.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 3b—would be major long-term adverse impacts to the economic viability of power generation at Willamette Valley projects. The creation of the system and population growth in the past created the ability to generate power and a demand for that power. The near-term operations measure would decrease power generation by 52 aMW, resulting in a NPV of -$196 million, and would increase the LCOG to $38.35/MWh from $26.70 for Willamette Valley projects. There are no costs associated with the near-term operations measure, so these estimated changes are due solely to a decrease in generation. Costs of near-term structural measures are currently unknown but would be expected to reduce the NPV and increase the levelized cost of generation.

The direct and indirect impacts on power associated with Alternative 3b would be primarily a result of the costs associated with implementing the alternative as well as large decreases in generation. Generation at the projects would decrease by 79 aMW under Alternative 3a, a decrease of 46.2%. LOLP would increase to seven percent. The NPV for the Willamette Valley would decrease by $829 to -$604 million. The LCOG would increase by $32.72 to $59.42/MWh. Note that the near-term operations measure and Alternative 3b were analyzed separately, so metrics associated with each one are not necessarily additive. Changes to hydropower generation resulting from the various cumulative effects would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section above.

See Section 3.13 for the full analysis of direct and indirect effects of Alternative 3b on power.

Climate change further complicates expectations. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of demand is uncertain. There is a potential for a decrease in demand during the time frame due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and water/space heaters), and load spikes due to temperature fluctuations from extreme weather. Decreasing flows and lower reservoir elevations expected in the spring and summer would negatively impact generation going into a high demand summer season, with demand expected to increase as temperatures increase. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 3b—would be long-term moderate impacts on the transmission system. The creation of the dams and past population growth in the region led to the need to develop the transmission system. Currently, the CCS and SOA transmission paths are congested but operational. Hills Creek and Cougar are able to operate islanded to provide Oakridge and Blue River communities, respectively, with power under temporary weather or fire related outage conditions.

The near-term operations measure would increase loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Hills Creek would continue to be able to operate islanded, but Cougar may not due to deep drawdowns under the measure.

The direct and indirect effects of Alternative 3b would be increased loading on the CCS and SOA paths in all seasons.

Drawdowns at Hills Creek and Cougar under Alternative 3b would compromise both plants' abilities to operate islanded under temporary weather or fire related outage conditions.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette

Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

**Table 4.12-6. Summary of effects for Power and Transmission under Alternative 3b – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)**

The other factors unrelated to Alternative 3b itself would have the potential to further adversely impact transmission. |

#### *4.12.2.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Cumulative effects to hydropower and transmission for Alternative 4 are described for the WVS as a whole.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 4—would be major long-term adverse impacts to the economic viability of power generation at Willamette Valley projects. The creation of the system and population growth in the past created the ability to generate power and a demand for that power. The near-term operations measure would decrease power generation by 52 aMW, resulting in a NPV of -$196 million, and would increase LCOG to $38.35/MWh from $26.70 for Willamette Valley projects. There are no costs associated with the near-term operations measure, so these estimated changes are due solely to a decrease in generation. Costs of near-term structural measures are currently unknown but would be expected to reduce the NPV and increase the levelized cost of generation.

The direct and indirect impacts on power associated with Alternative 4 would be primarily a result of the costs associated with implementing the alternative as there are minor increases in generation. Generation at the projects would increase by 1 aMW under Alternative 4, an increase of 0.6%. LOLP would remain 6.5% under Alternative 4. Again, due to the costs of the alternative, the NPV for the Willamette Valley would decrease by $1.162 billion to -$937 million. The LCOG would increase by $27.84 to $54.54/MWh. Note that the near-term operations measure and Alternative 4 were analyzed separately, so metrics associated with each one are not necessarily additive. Changes to hydropower generation resulting from the various cumulative effects would further impact the expected adverse impacts to the economic viability of power that were described in the “Environmental Consequences” section above.

See Section 3.13 for the full analysis of direct and indirect effects of Alternative 4 on power.

Climate change further complicates expectations for hydropower generation. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of demand is uncertain. There is a potential for a decrease in demand during the time frame due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and water/space heaters), and load spikes due to temperature fluctuations from extreme weather. Decreasing flows and lower reservoir elevations expected in the spring and summer would negatively impact generation going into a high demand summer season, with demand expected to increase as temperatures increase. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the “Environmental Consequences” section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 4—would be long-term minor impacts on the transmission system. The creation of the dams and past population growth in the region led to the need to develop the transmission system. Currently, the CCS and SOA transmission paths are congested but operational. Hills Creek and Cougar are able to operate islanded to provide some isolated communities with power during emergencies such as wildfires.

The near-term operations measure would increase loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Hills Creek would continue to be able to operate islanded, but Cougar may not due to deep drawdowns under the measure.

The direct and indirect effects of Alternative 4 would be less than 10MW of increased load on the CCS and SOA paths in all seasons, except an increase of 15MW on the CCS path in spring. Hills Creek and Cougar would continue to be able to operate islanded under Alternative 4. However, if the near-term operations measure were implemented in conjunction with Alternative 4, Cougar would have a compromised ability to do so.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

**Table 4.12-7. Summary of effects for Power and Transmission under Alternative 4 – Structures-Based Fish Passage Alternative**

| Resource | Past Actions | Present Actions | Direct and Indirect Effects | Future Actions | Cumulative Effect |
|---|---|---|---|---|---|
| Hydropower | The construction and operation of the WRB dams and reservoirs created the Willamette Valley hydropower system. The population growth and the economic development in the region has led to the current demand for power that exists. | The near-term operations measure has a negligible impact on power system reliability, blackouts, and LOLP, but does decrease generation by about 52 aMW. It also would have long-term major impacts on the economic viability of power generation at WVS projects, resulting in a Net Present Value of -$196 and a levelized cost of generation to $38.35/MWh | Alternative 4 would have negligible impacts on power system reliability and long-term adverse effects on the economic viability of power generation. Generation would slightly increase by 1 aMW and LOLP remains the same as the No Action Alternative. However, due to the high cost associated with Alternative 4, the NPV estimate would be reduced by $1.162 billion to | Climate change would likely increase demand for power while reducing generation capability during high demand seasons. | The cumulative effects of past, present, future actions, and Alternative 4 on hydropower would be minor, long-term adverse impacts to hydropower. Choosing this alternative would create a situation where hydropower in the Willamette Valley would no longer be cost effective at many of the dams. The other factors unrelated to Alternative 4 itself would have the potential to further adversely impact hydropower. |

| Resource | Past Actions | Present Actions | Direct and Indirect Effects | Future Actions | Cumulative Effect |
|---|---|---|---|---|---|
| | | (an increase of $11.65/MWh over the existing condition) for the system. | -$937 million; and the LCOG would increase by $27.84/MWh to $54.54/MWh. | | |
| Transmission | The creation of the dams required transmission lines to be built to service the dams. Deep drawdowns would also compromise the ability of Cougar Dam to operate islanded in cases of emergency. | Alternative 4 would have long-term, minor effects on the transmission system increased loading on already congested transmission paths. Cougar and Hills Creek would remain able to operate islanded under temporary weather or fire related outage conditions. | Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system.<br><br>The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge. | The cumulative effects of past, present, future actions, and Alternative 4 on transmission would be moderate, long-term adverse impacts to transmission. The other factors unrelated to Alternative 4 itself would have the potential to further adversely impact transmission. |

#### *4.12.2.8 Alternative 5 – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Cumulative effects to hydropower and transmission for Alternative 5 are described for the WVS as a whole. It should be noted that these effects were put together using the Alt2b results. The small flow changes under Alt5 as compared to Alt2b could possibly lead to lower generation at Green Peter, Foster, and Hills Creek than is detailed below.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 5—would be major long-term adverse impacts to the economic viability of power generation at Willamette Valley projects. The creation of the system and population growth in the past created the ability to generate power and a demand for that power. The near-term operations measure would decrease power generation by 52 aMW, resulting in a NPV of -$196 million, and would increase the LCOG to $38.35/MWh from $26.70/MWh for Willamette Valley projects. There are no costs associated with the near-term operations measure, so these estimated changes are due solely to a decrease in generation. Costs of near-term structural measures are currently unknown but would be expected to further reduce the NPV and increase the levelized cost of generation.

The direct and indirect impacts on power associated with Alternative 5 would be primarily a result of the costs associated with implementing the alternative as well as a decrease in generation. Generation at the projects would decrease by 18 aMW under Alternative 5, a decrease of 10.5%. LOLP would increase to 6.6%. Due to the costs of the alternative, the NPV for the Willamette Valley would decrease by $939 to -$714 million. The LCOG would increase by $24.11 to $50.81/MWh. Note that the near-term operations measure and Alternative 5 were analyzed separately, so metrics associated with each one are not necessarily additive. Changes to hydropower generation resulting from the various cumulative effects would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section above.

See Section 3.13 for the full analysis of direct and indirect effects of Alternative 5 on power.

Climate change further complicates expectations. While stream flows are expected to increase in the Willamette basin in the winter, which may lead to increased generation, the level of demand is uncertain. There is a potential for a decrease in demand during the time frame due to increasing temperatures. However, there is also a potential for an increase in Pacific Northwest regional demand during the winter from increased electrification of various sectors (e.g., transportation and water/space heaters), and load spikes due to temperature fluctuations from extreme weather. Decreasing flows and lower reservoir elevations expected in the spring and summer would negatively impact generation going into a high demand summer season, with demand expected to increase as temperatures increase. See also the climate change section in the Power and Transmission section of Chapter 3.

Overall, cumulative effects on hydropower generation would further impact the expected adverse impacts to the economic viability of power that were described in the "Environmental Consequences" section. Unless energy prices significantly increase at the same time, producing power at Willamette Valley projects—given the other cumulative actions discussed above—would no longer be cost effective.

The cumulative effects of past and present actions—including the near-term operations measure, the RFFAs described above, and Alternative 5—would be long-term moderate impacts on the transmission system. The creation of the dams and past population growth in the region led to the need to develop the transmission system. Currently, the CCS and SOA transmission paths are congested but operational. Hills Creek and Cougar are able to operate islanded to provide Oakridge and Blue River communities, respectively, with power under temporary weather or fire related outage conditions.

The near-term operations measure would increase loading on the CCS path in both spring (47.0 MW) and winter (59.8 MW). Hills Creek would continue to be able to operate islanded, but Cougar may not due to deep drawdowns under the measure.

The direct and indirect effects of Alternative 5 would be increased loading on the CCS path (21.9 MW) in the winter and on both SOA (5.1 MW) and CCS (25.1 MW) in spring.

Hills Creek would continue to be able to operate islanded under Alternative 5. However, the drawdowns at Cougar under both the near-term operations measure and Alternative 5 would compromise Cougar's ability to operate islanded under temporary weather or fire related outage conditions.

Population growth and development, decarbonization of the energy sector, and targeted reduction in vehicle emissions could conceivably add loading on the regional transmission system. These potential changes could be quite large, but since the changes to Willamette Valley hydropower generation would be quite small in comparison, the availability of these resources would not significantly impact long-term transmission planning.

The increased potential of extreme weather events and wildfires due to climate change could also affect how frequently transmission lines may temporarily be de-energized. During these events, the diminished ability of Cougar and Hills Creek to operate islanded could affect service to the communities of Blue River and Oakridge.

## 4.13 WATER SUPPLY

### 4.13.1 Cumulative Effects Analysis Methodology for Water Supply

#### *4.13.1.1 Cumulative Actions Applicable to Water Supply*

Past actions, present actions, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on water supply, include:

- WVS Dams and Reservoirs: construction and past operations and maintenance (see section 4.1.2.1.1)
- WRB Population Growth and Development: altered land use within the Willamette River (see section 4.1.2.1.2)
- WVS Dams and Reservoirs: ongoing operations and maintenance (see section 4.1.2.2)
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development
- RFFA 2: Reduced agricultural development
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses
- RFFA 5: Federal and state wildlife and lands management
- RFFA 7: Tribal, state, and local fish and wildlife improvement
- RFFA 9: Climate change

Some of the other RFFAs discussed in Section 4.2.3 would not change the hydrology of the Willamette Basin or only negligibly alter the WVS dam and reservoir operations and as such would not have a cumulative effect on Water Supply.

- RFFA 4: Decarbonizing the energy sector with renewable energy sources. There is minimal variation in total flow due to outlet choice, such as whether to run the WVS dam's hydroelectric turbines.
- RFFA 6: Fishery management and killer whales. The flow targets in the WVS are specific to the river reaches and habitat where they occur. They are not variable based on Pacific Ocean salmon returns.
- RFFA 8: Invasive species management. Does not affect flow or regulation decisions for the WVS dams.
- RFFA 10: Mining operations. Negligible cumulative changes to total flow in the Willamette Basin from the status quo.
- RFFA 11: Timber and logging industry operations. Negligible cumulative changes to total flow in the Willamette Basin from the status quo.

Therefore, these RFFAs are dismissed from further analysis.

### 4.13.2 Cumulative Effects Analysis Methodology for Water Supply

Table 4.13-1 below describes the cumulative effect from the applicable RFFAs noted above.

**Table 4.13-1. Reasonable and Foreseeable Future Actions applicable to water supply.**

| RFFA # | RFFA Description | Cumulative Effect Description |
|---|---|---|
| RFFA 1 | Future population growth and urban, industrial, and commercial development | Increased water demand basin wide, resulting in decreased water in the streams. |
| RFFA 2 | Future agricultural development | Conversion of cropland to urban development, resulting in decreased demand for irrigation water and an increased demand for M&I water supply. |
| RFFA 3 | Water withdrawals for municipal, industrial, and agricultural uses | An increase in water withdrawals may result in decreased streamflows. |
| RFFA 5 | Federal and State Wildlife and Lands Management | Potential increased demand for M&I water supply. |
| RFFA 7 | Tribal, State, and local fish and wildlife improvement | Potential adverse effect to water supply as instream flows are protected with senior instream water rights. |
| RFFA 9 | Climate Change | A decrease in flow and water volumes in the summer may have an adverse effect on water supply as users aren’t able to withdraw water from the stream for consumptive uses. |

As noted in Sections 4.1.2.1.1 and Section 4.3.3. (hydrologic processes), the WVS dams have altered the hydrology in the mainstem Willamette River and in some of the tributaries in the WRB, most notably affecting water supply in the summer months when naturally low flows are augmented by releases of stored water from the federal dams. Low flow augmentation allows existing water right holders to withdraw water from the streams for longer period of times and in many years when natural streamflows would not be available to satisfy all water rights issued by the state.

Past WRB population growth in the WVS watershed noted in Section 4.1.2.1.2 has resulted in increased withdrawals from the rivers and streams to supply demands for both municipal and industrial water supply needs. While cropland has decreased basin wide, there is an increasing need for irrigation water supply to increase productivity on existing agricultural lands. These increased withdrawals increase the need and benefit of stored water releases from the reservoirs to support instream purposes.

Future population growth and accompanying urban, industrial, and commercial development (RFFA 1) is likely to lead to increased water withdrawals for municipal, industrial (M&I), and agricultural uses (RFFA 3). Increased demands for M&I and agricultural uses were the driving force behind the Willamette Basin Review reallocation feasibility study completed in 2019, resulting in reallocation of conservation storage space in the WVS reservoirs. These two RFFAs were considered in the Water Supply analyses in Chapter 3.

As noted in Hydrologic Processes Section 4.3.3 above, future federal and state lands management (RFFA 5) is not likely to result in noticeable differences to inflow to the reservoirs nor alter the volume of flow in the rivers downstream of the dams. Land management actions could result in increased urbanization, thus resulting in need for additional municipal and industrial water supply. This need has been forecasted in and included in the Water Supply Environmental Consequences for the No Action and Action Alternative in Chapter 3.

Tribal, state, and local fish and wildlife improvement (RFFA 7) could result in conversion of the minimum perennial streamflows (MPSFs) to instream water rights, giving instream flows protection and seniority against out of stream uses. This could result in existing users needing alternative sources of water supply, for both M&I and agricultural irrigation. This was considered as part of the Willamette Basin Review (WBR) feasibility study resulting in reallocation of the conservation storage to the authorized purposes of M&I water supply, irrigation, and fish and wildlife. Effects of this increased demand were included in the Water Supply analyses in Chapter 3.

Climate change (RFFA 9) is likely to increase the demand for M&I water supply and agricultural irrigation. These effects were considered during the WBR forecasting for future demands of stored water and included in the reallocation volumes for M&I water supply and irrigation. These effects were also addressed in the Water Supply section of Chapter 3.

### 4.13.3 Cumulative Effects to Water Supply by Alternative

The effects of the RFFAs, including climate change, were included in the Water Supply Environmental Consequences section of Chapter 3. No additional effects are expected in addition to those described in Chapter 3.

## 4.14 RECREATION

This section discusses the cumulative effects on recreation. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each alternative would cumulatively affect recreation. The geographic scope for recreation would be the same boundary as described in the Affected Environment in Chapter 3, which is the boundary of the WRB. This includes the 13 Oregon counties that intersect or lie within the boundary: Benton, Clackamas, Columbia, Douglas, Klamath, Lane, Linn, Marion, Multnomah, Polk, Tillamook, Washington, and Yamhill counties.

### 4.14.1 Cumulative Actions Applicable to Recreation

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects on recreation, include:

- Construction of the WVS dams, non-USACE dams, and supporting structures;
- Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar;
- WRB population growth and development;
- Transportation corridor development;
- Point and non-point source water pollution;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 3, water withdrawals for municipal, industrial, and agricultural uses;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 6, fishery management and killer whales;
- RFFA 7, tribal, state, and local fish and wildlife improvement;
- RFFA 8, invasive species management;
- RFFA 9, climate change; and
- RFFA 10, mining operations.

Some of the RFFAs discussed above in Section 4.2.3 would not have effects on recreation. These include RFFA 2, reduced agricultural production; RFFA 4, decarbonizing the energy sector with renewable energy sources; and RFFA 11, timber and logging industry operations. No new logging operations have been proposed in the WRB. If new logging operations began in the future, it is unlikely that operations would occur near the shores of any WVS reservoirs due to local zoning ordinances. Therefore, these RFFAs are not discussed further in this cumulative effects analysis.

### 4.14.2 Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect to recreation. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.14.2.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Restore upstream and downstream passage at drop structures (#639), Use spillway for surface spill in summer (#721), Provide Pacific lamprey passage and infrastructure (#52), Operation, Maintenance, Repair, Replacement and Rehabilitation, Structural improvements to reduce total dissolved gas (#174), Construct WTC towers (#105), Construct structural downstream fish passage (#392), Foster Fish Ladder Temperature Improvement (#479), and Construct AFF (#722)*

As discussed in Sections 3.14.2.4.1 through 3.14.2.4.3 and Section 3.14.2.4.7, adverse effects from construction activities associated with these measures would range from negligible to moderate in magnitude and occur in the short and medium term. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; and RFFA 1, future population growth and accompanying urban, industrial, and commercial development would have similar effects as construction from the proposed measures. RFFA 9, climate change and RFFA 10, mining operations would have effects similar to those of construction from the proposed measures, but would occur in the short, medium, and long term. These cumulative actions would also affect the recreational experience due to noise and air emissions, traffic from hauling material, and from generally attracting attention due to changes in the viewshed. RFFA 9, climate change (discussed in greater detail below in Section 4.14.2.3), would further exacerbate the decreased recreational experience from water pollution due to lower water levels and higher water temperatures, increasing the likelihood of HABs that could further adversely affect water quality. The quality of recreational fishing along rivers for some species could be further adversely impacted in the short, medium, and long term due to the increased turbidity from suspended sediment and other potential pollution. As with direct effects to the recreational experience discussed in Section 3.14, the magnitude of the short- and medium-term construction-related effects from the cumulative actions on the quality of recreation depends on the proximity of the construction project site to the recreational facility or the recreator.

Modifications of existing WVS structures would include upgrades to the existing Dexter AFF, a structural solution for mitigating excess TDG levels during spill operations at Big Cliff, and a structural solution to improve and/or modify Cougar Dam's ROs to ensure safer fish passage and reduced TDG levels. The type, location, and size of these cumulative actions are very similar to measures proposed in the action alternatives. RFFA 1, future population growth and accompanying urban, industrial, and commercial development would continue to occur along the I-5 corridor (closest to the cities of Corvallis, Eugene, and Portland). Effects on recreational quality would occur along the mainstem Willamette River and at any recreational facility or to any recreator near construction and development; the severity of the effect would dependent on the proximity of the recreator or the recreational facility. However, as discussed in Section 3.15.2, far less development will occur in the future than has already occurred in the past. Adverse effects on recreation from intense development are less likely to occur at WVS reservoirs due to local zoning ordinances that may prohibit commercial or industrial development near shorelines – except for residential development at Detroit, Dexter, Fern Ridge, and Foster reservoirs, which have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively.

Like the RFFAs discussed above, RFFA 10, mining operations would also affect the recreational experience due to noise and air emissions, traffic from hauling material, and from generally attracting attention due to changes in the viewshed. Mining could also contribute to water pollution, such as increased turbidity from suspended sediment, discharged mine effluent, and seepage from tailings and waste rock impoundments, which would further decrease the quality of the recreational experience. Although no new mine sites have been proposed in the WRB, many existing claims exist, and there are several claims adjacent to WVS reservoirs. If new mining operations began in the future, these operations would continue in the long term, but it is unlikely that intensive or large-scale operations would occur near the shores of any WVS reservoirs due to local zoning ordinances. Further, mining operations would be required to comply with environmental regulations (as applicable), such as Section 402 of the Clean Water Act, which would mitigate effects of water pollution and ensure adequate water quality for enjoyable recreational experiences.

Overall short-, medium-, and long-term, cumulative effects on the recreational experience of the proposed structural measures in combination with transportation and residential development, potential mining operations, climate change, and the construction or modification of WVS structures would be negligible to moderate, additive, and adverse. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure because Pacific lamprey are not fished recreationally and Operation, Maintenance, Repair, Replacement and Rehabilitation because the purpose of this measure is not specifically to benefit ESA-listed fish) would have beneficial, minor, additive, cumulative effects on recreational fishing.

#### 4.14.2.2 *Integrated temperature and habitat flow regime (#30a), Refined integrated temperature and habitat flow regime (#30b), Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166), Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), Pass water over spillway in spring for fish passage (#714), Continued Operation of Existing AFFs, and Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)*

As discussed in Section 3.14.2.4.4, the effects of these measures (except #723) would be indirect, beneficial, and minor in the long term. As discussed in Section 3.14.2.4.5, the effects of reducing minimum flows to Congressionally authorized minimum flow requirements (#723) would be moderate and beneficial at reservoirs in the long term. The results of RFFAs 6, 7, and 8 would have similar effects on recreation as the measures listed above.

RFFA 6, fishery management and killer whales would improve the management of salmon fisheries in offshore ocean waters. Although the Pacific Ocean is outside of the boundary of the WRB, salmon are anadromous, and this RFFA could eventually benefit salmon and recreational fishing in the WVS. RFFA 7, tribal, state, and local fish and wildlife improvement generally promotes habitat and ecosystem functions, as well as species-specific conservation. One recent project restored a stretch of the Willamette River and provided resting spots for salmon, wetland habitat for wildlife, and fertile floodplains for trees, shrubs, and other plants. RFFA 8, invasive species management would prevent and eradicate invasive bass that disrupt aquatic ecosystems by preying on native fish, which would improve recreational fishing. Both land- and water-based recreational experiences would benefit from improved fishery and invasive species management, fish and wildlife habitat, and riparian aesthetics in general. Therefore, when considered in tandem with RFFAs 6, 7, and 8, the proposed measures would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

#### 4.14.2.3 *Deeper fall reservoir drawdowns for fish passage (#40), Spring reservoir drawdown for downstream fish passage (#720), Fall Creek drawdown, and Suite of near-term operations*

As discussed in Section 3.14.2.4.8, the effects of reservoir drawdowns and the suite of near-term operations would be major, adverse, short-term and recur in the long term. Visitation would decrease during drawdowns; and some recreationists would continue to visit the reservoir despite drastic changes in the WSE. Drawdowns would substantially impact the recreational experience for those who continue to visit the reservoir during this time. RFFA 3, water withdrawals for municipal, industrial, and agricultural uses, and RFFA 9, climate change, would also affect both the recreational experience and opportunities.

RFFA 3, water withdrawals for municipal, industrial, and agricultural uses, is expected to decrease the amount of water flowing through the WVS due to increasing water demands. Decreased flows would be further exacerbated by RFFA 9, climate change. Climate change is expected to result in less snowpack, drier, hotter summers (in terms of both air and water temperatures), and increased evaporation. Both would limit the quantity of water available in the WVS for recreation, which could shorten the recreational season.

As water quantity decreases in the future, water quality and air quality could also decrease due to RFFA 9, climate change; and affect both the recreational experience as well as opportunities. Higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would decrease water quality from higher turbidity, elevated concentrations of contaminants such as mercury and wildfire ash, and increased occurrence of HABs which could affect the recreational experience. Increased occurrence and severity of wildfires would substantially degrade air quality during wildfire season, which would not only decrease the quality of the recreational experience due to adverse visual impacts, but could put recreationists at risk of health effects due mainly to particle pollution, a main component of wildfire smoke. During times when regional air quality from wildfire smoke is poor, the majority of recreationists are likely to forego outdoor recreation; recreational areas or part or all of the reservoir(s) may be closed.

While the effects of water withdrawals and climate change may only be slightly noticeable on the quantity and quality of recreation available, these effects would become more adverse over time as water levels fall and temperatures climb higher. When considered in tandem with RFFA 3 and RFFA 9, reservoir drawdowns and delayed refills would create adverse, additive, and major cumulative effects on the recreational experience and opportunities in both the short and long term (recurring).

RFFA 5, federal and state wildlife and lands management, involves designating and managing lands such as wildlife refuges and national forests. The recent revision to the Oregon Statewide Planning Goals and Guidelines included a goal to establish a Willamette greenway, which would provide additional recreational opportunities for bike riding, walking, and viewing wildlife. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from the Willamette greenway would have interactive, countervailing cumulative effects on recreation. However overall, the proposed drawdowns in combination with the Willamette greenway would still have major, adverse, cumulative effects on recreational opportunities.

A study of the effects of the Fall Creek drawdown has shown that it reduced abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al. 2019). Drawdowns have also been used for invasive plant control, which can benefit fisheries; but can also increase water column nutrient concentrations and temperature of shallow water layers and lead to algal blooms (MWRA 2021; Cooke 1980; Bakker and Hilt 2016). RFFA 8, invasive species management would prevent and eradicate invasive bass that disrupt aquatic ecosystems by preying on native fish, which would improve recreational fishing. Therefore, when considered together with RFFA 8, drawdowns would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

### 4.14.3 Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to recreation.

### 4.14.4 No Action Alternative

Under the NAA, the existing O&M of the WVS would continue. The NAA includes water quality, flow, and upstream and downstream fish passage operations, which includes an annual drawdown at the Fall Creek Reservoir. Operation, maintenance, repair, replacement, and rehabilitation under the NAA would continue to adversely impact the recreational experience. Effects to the recreational experience would be would be adverse and range from negligible to moderate in the short, medium, and long term for scheduled/routine maintenance and major maintenance and rehabilitation due to increases in noise, air emissions, visual intrusions, and traffic. As discussed above in Section 4.14.2.1, modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the operation, maintenance, repair, replacement, and rehabilitation under the NAA would have negligible to moderate short, medium and long term (recurring) additive cumulative effects. The severity of effects would increase proportionally with the recreational facility's or recreator's proximity to these activities.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the recurring Fall Creek Drawdown would create adverse, additive, and major cumulative effects to recreational experiences and opportunities in the short and long term (recurring). Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation. However overall, the proposed drawdowns in combination with the Willamette greenway would still have major, adverse, cumulative effects on recreational opportunities in the short and long term (recurring).

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the Fall Creek Drawdown would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

### 4.14.5 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures

Alternative 1 would combine storage-focused measures in order to improve fish passage. Augmenting gravel below dams (#384); maintaining or altering revetments (#9); maintaining existing and new fish release sites (#726); restoring upstream and downstream passage at drop structures (#639); providing Pacific lamprey passage and infrastructure (#52); operation, maintenance, repair, replacement and rehabilitation; improving structures to reduce total dissolved gas (#174); constructing WTC Towers (#105), AFFs (#722), and structural downstream fish passage (#392); and the Foster Fish Ladder Temperature Improvement (#479) would have negligible to moderate adverse effects on the recreational experience in the short and medium term due to increases in noise, air emissions, visual intrusions, and traffic. In the long term, recreational fishing could benefit indirectly. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the above-listed structural measures under Alternative 1 would have negligible to moderate cumulative and additive effects on the recreational experience in the short, medium, and long term. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure and Operation, Maintenance, Repair, Replacement and Rehabilitation) would have beneficial, minor, additive, cumulative effects on recreational fishing.

Augmenting instream flows by using the inactive pool and augmenting instream flows by using the power pool would have indirect, beneficial, and minor effects in the long term. These measures in combination with RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have minor, beneficial, additive, cumulative effects in the long term due to vegetation and habitat improvement projects and improved reservoir storage.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the recurring Fall Creek Drawdown would create adverse, additive, and major cumulative effects to recreational experiences and opportunities. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation. Alternative 1 is also the only action alternative that would result in direct benefits to recreation by promoting reservoir storage and therefore would also have interactive, countervailing cumulative effects on increased water demand and climate change and the associated effects to recreation. However, despite reducing minimum flows to the Congressionally authorized minimum flow requirements and the addition of the Willamette greenway, the proposed drawdowns would still have major, adverse, additive, cumulative effects on recreational opportunities in the short and long term (recurring).

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the Fall Creek Drawdown would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

Under Alternative 1, adverse cumulative effects would be less severe than all other action alternatives. Alternative 1 includes only one recurring drawdown at Fall Creek and does not include the suite of near-term operations.

### 4.14.6 Alternative 2a – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)

Alternative 2a would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). Augmenting gravel below dams (#384); maintaining or altering revetments (#9); maintaining existing and new fish release sites (#726); providing Pacific lamprey passage and infrastructure (#52); operation, maintenance, repair, replacement, and rehabilitation; constructing WTC Towers (#105), AFFs (#722), and structural downstream fish passage (#392); and the Foster Fish Ladder Temperature Improvement (#479) would have negligible to moderate adverse effects on the recreational experience in the short and medium term due to increases in noise, air emissions, visual intrusions, and traffic. In the long term, recreational fishing could benefit indirectly. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the above-listed structural measures under Alternative 2a would have negligible to moderate cumulative and additive effects on the recreational experience in the short, medium, and long term. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure and Operation, Maintenance, Repair, Replacement and Rehabilitation) would have beneficial, minor, additive, cumulative effects on recreational fishing.

Augmenting instream flows by using the inactive pool, augmenting instream flows by using the power pool, and the integrated habitat and flow regime would have indirect, beneficial, and minor effects in the long term. These measures in combination with RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have minor, beneficial, additive, cumulative effects in the long term due to vegetation and habitat improvement projects.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the drawdowns at Fall Creek and Green Peter and the suite of near-term operations would create adverse, additive, and major cumulative effects to recreational experiences and opportunities. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation.

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the drawdowns at Fall Creek and Green Peter would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

Under Alternative 2a, adverse cumulative effects would be more severe than Alternative 1 but less severe than Alternatives 2b, 3a, 3b, 4, and 5.

### 4.14.7 Alternative 2b – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)

Alternative 2b would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam’s DT). Augmenting gravel below dams (#384); maintaining or altering revetments (#9); maintaining existing and new fish release sites (#726); providing Pacific lamprey passage and infrastructure (#52); operation, maintenance, repair, replacement, and rehabilitation; constructing WTC Towers (#105), AFFs (#722), and structural downstream fish passage (#392); and the Foster Fish Ladder Temperature Improvement (#479) would have negligible to moderate adverse effects on the recreational experience in the short and medium term due to increases in noise, air emissions, visual intrusions, and traffic. In the long term, recreational fishing could benefit indirectly. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; and RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the above-listed structural measures under Alternative 2b would have negligible to moderate cumulative and additive effects on the recreational experience in the short, medium, and long term. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure and Operation, Maintenance, Repair, Replacement and Rehabilitation) would have beneficial, minor, additive, cumulative effects on recreational fishing.

Augmenting instream flows by using the inactive pool and the power pool and the integrated habitat and flow regime would have indirect, beneficial, and minor effects in the long term. These measures in combination with RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have minor, beneficial, additive, cumulative effects in the long term due to vegetation and habitat improvement projects.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the drawdowns at Cougar, Fall Creek, and Green Peter and the suite of near-term operations would create adverse, additive, and major cumulative effects to recreational experiences and opportunities. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation.

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the drawdowns at Cougar, Fall Creek, and Green Peter would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

Under Alternative 2b, adverse cumulative effects would be the same in severity as Alternative 5, more severe than Alternatives 1 and 2a, but less severe than Alternatives 3a, 3b, or 4.

### 4.14.8 Alternative 3a – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)

Alternative 3a would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam’s RO). Augmenting gravel below dams (#384), maintaining or altering revetments (#9), maintaining existing and new fish release sites (#726), providing Pacific lamprey passage and infrastructure (#52), operation, maintenance, repair, replacement, and rehabilitation; and constructing AFFs (#722) would have negligible to moderate adverse effects on the recreational experience in the short and medium term due to increases in noise, air emissions, visual intrusions, and traffic. In the long term, recreational fishing could benefit indirectly. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the above-listed structural measures under Alternative 3a would have negligible to moderate cumulative and additive effects on the recreational experience in the short, medium, and long term. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure and Operation, Maintenance, Repair, Replacement and Rehabilitation) would have beneficial, minor, additive, cumulative effects on recreational fishing.

Using the spillway for surface spill, augmenting instream flows by using the inactive and power pools, and integrated habitat and flow regime would have indirect, beneficial, and minor effects in the long term. These measures in combination with RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have minor, beneficial, additive, cumulative effects in the long term due to vegetation and habitat improvement projects.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the ten drawdowns across seven reservoirs as well as the suite of near-term operations under Alternative 3a would create adverse, additive, and major cumulative effects to recreational experiences and opportunities. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation.

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the ten drawdowns across seven reservoirs under Alternative 3a would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

Alternative 3a would include more recurring drawdowns than Alternatives 1, 2a, or 2b. Adverse cumulative effects would be less severe than Alternative 3b but more severe than Alternatives 1, 2a, 2b, 4, and 5.

### 4.14.9 Alternative 3b – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)

Alternative 3b would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's DT). Augmenting gravel below dams (#384); maintaining or altering revetments (#9); maintaining existing and new fish release sites (#726); providing Pacific lamprey passage and infrastructure (#52); operation, maintenance, repair, replacement, and rehabilitation; and constructing AFFs (#722) would have negligible to moderate adverse effects on the recreational experience in the short and medium term due to increases in noise, air emissions, visual intrusions, and traffic. In the long term, recreational fishing could benefit indirectly. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the above-listed structural measures under Alternative 3b would have negligible to moderate cumulative and additive effects on the recreational experience in the short, medium, and long term. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure and Operation, Maintenance, Repair, Replacement and Rehabilitation) would have beneficial, minor, additive, cumulative effects on recreational fishing.

Using the spillway for surface spill, augmenting instream flows by using the inactive pool and the power pools, and the integrated habitat and flow regime would have indirect, beneficial, and minor effects in the long term. These measures in combination with RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have minor, beneficial, additive, cumulative effects in the long term due to vegetation and habitat improvement projects.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the ten drawdowns at seven reservoirs as well as the suite of near-term operations would create adverse, additive, and major cumulative effects to recreational experiences and opportunities. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation.

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the ten drawdowns across seven reservoirs under Alternative 3b would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

Although Alternative 3b would include the same number of recurring drawdowns as Alternative 3a, it's cumulative effects would be more severe (slightly) due to the additional bridge and tower construction project required to draw-down the Cougar Reservoir to the DT. Under Alternative 3b, adverse cumulative effects would be more severe than any other action alternative due to the number of recurring drawdowns.

### 4.14.10 Alternative 4 – Improve Fish Passage with Structures-Based Approach

Alternative 4 would improve fish passage with structures-based measures. Adverse effects from augmenting gravel below dams (#384); maintaining or altering revetments (#9); maintaining existing and new fish release sites (#726); restoring upstream and downstream passage at drop structures (#639); providing Pacific lamprey passage and infrastructure (#52); operation, maintenance, repair, replacement and rehabilitation; structural improvements to reduce total dissolved gas (#174); constructing WTC Towers (#105), AFFs (#722), and structural downstream fish passage (#392); and the Foster Fish Ladder Temperature Improvement (#479) would have negligible to moderate adverse effects on the recreational experience in the short and medium term due to increases in noise, air emissions, visual intrusions, and traffic. In the long term, recreational fishing could benefit indirectly. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the above-listed structural measures under Alternative 4 would have negligible to moderate cumulative and additive effects on the recreational experience in the short, medium, and long term. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure and Operation, Maintenance, Repair, Replacement and Rehabilitation) would have beneficial, minor, additive, cumulative effects on recreational fishing.

Augmenting instream flows by using the inactive and power pools and the integrated habitat and flow regime would have indirect, beneficial, and minor effects in the long term. These measures in combination with RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have minor, beneficial, additive, cumulative effects in the long term due to vegetation and habitat improvement projects.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the recurring Fall Creek Drawdown would create adverse, additive, and major cumulative effects to recreational experiences and opportunities. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation.

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the Fall Creek and Green Peter drawdowns would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

Under Alternative 4, adverse cumulative effects would be more severe than alternatives 1, 2a, 2b, and 5 due to the number of construction projects, but less severe than alternatives 3a and 3b due to the number of recurring drawdowns.

### 4.14.11 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)

Alternative 5 would only differ from Alternative 2b by way of the refined integrated temperature management and habitat flow regime measure (#30b), which would not have noticeable effects on recreation. Therefore, the effects of Alternative 5 would be identical to those of Alternative 2b. Augmenting gravel below dams (#384); maintaining or altering revetments (#9); maintaining existing and new fish release sites (#726); providing Pacific lamprey passage and infrastructure (#52); operation, maintenance, repair, replacement, and rehabilitation; constructing WTC Towers (#105), AFFs (#722), and structural downstream fish passage (#392); and the Foster Fish Ladder Temperature Improvement (#479) would have negligible to moderate effects on the recreational experience in the short and medium term due to increases in noise, air emissions, visual intrusions, and traffic. In the long term, recreational fishing could benefit indirectly. Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 9, climate change; and RFFA 10, mining operations in combination with the structural measures under Alternative 5 would have negligible to moderate cumulative and additive effects on the recreational experience in the short, medium, and long term. In the long term, the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar (specifically) in combination with the proposed measures (except for providing Pacific lamprey passage and infrastructure and Operation, Maintenance, Repair, Replacement and Rehabilitation) would have beneficial, minor, additive, cumulative effects on recreational fishing.

Augmenting instream flows by using the inactive and power pools and the refined integrated habitat and flow regime would have indirect, beneficial, and minor effects in the long term. These measures in combination with RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have minor, beneficial, additive, cumulative effects in the long term due to vegetation and habitat improvement projects.

As discussed above in Section 4.14.2.3, when considered in tandem with RFFA 3, water withdrawals for municipal, industrial, and agricultural uses and RFFA 9, climate change, the drawdowns at Cougar, Fall Creek, and Green Peter and the suite of near-term operations would create adverse, additive, and major cumulative effects to recreational experiences and opportunities. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from RFFA 5, federal and state wildlife and lands management would have interactive, countervailing cumulative effects on recreation.

As discussed above in 4.14.2.3, drawdowns at other reservoirs have been used to control invasive plants, which can also benefit fisheries (MWRA 2021; Cooke 1980). At Fall Creek in particular, the drawdown has shown to reduce the abundance of warm-water invasive fishes in the reservoir after it refills, in addition to improving passage and connectivity for juvenile Chinook salmon (Murphy et al 2019). When considered together with RFFA 8, invasive species management, the drawdowns at Cougar, Fall Creek, and Green Peter would result in indirect, beneficial, additive, and minor cumulative effects to recreational fishing and the recreational experience in the long term.

Under Alternative 5, adverse effects would be the same as Alternative 2b, more severe than Alternatives 1, 2a, and 4, and less severe than Alternatives 3a, and 3b.

#### 4.14.12 Summary

The cumulative effects on the recreational experience would be additive, adverse, and negligible to moderate in the short, medium, and long term under all alternatives from construction projects when considered in combination with transportation and residential development, potential mining operations, climate change, and the construction or modification of WVS structures. There would also be adverse, additive, and major cumulative effects in the long term from recurring drawdowns when considered in tandem with water withdrawals for municipal, industrial, and agricultural uses and climate change. Because visitation to reservoirs would decrease during drawdowns, the provision of additional recreational opportunities from federal and state wildlife and lands management would have interactive, countervailing cumulative effects, and In the long term, all alternatives would have beneficial, minor, additive, cumulative effects on recreational fishing and the recreational experience. However, effects would still be major and adverse overall. Alternative 1 would have the least-severe adverse effects, followed by Alternatives 2a, 2b, 4, 3a, and 3b, primarily due to the number of recurring drawdowns and secondarily due to the number of short- and medium-term construction projects.

## 4.15 LAND USE

This section discusses the cumulative effects on land use. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect land use. The geographic scope for land use would be the same boundary as described in the Affected Environment in Chapter 3, which is the entire WRB including all twelve of its sub-basins, even those that do not include a USACE dam.

### 4.15.1 Cumulative Actions Applicable to Land Use

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects on land use, include:

- Construction of the WVS dams, non-USACE dams, and supporting structures;
- Transportation corridor development;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 3, water withdrawals for municipal, industrial, and agricultural uses;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 7, tribal, state, and local fish and wildlife improvement;
- RFFA 9, climate change;
- RFFA 10, mining operations;
- RFFA 11, timber and logging industry operations.

The construction of the WVS dams, non-USACE dams, and supporting structures had major impacts to land use at the time of construction because land was inundated with water and its use was changed in the long term. Past agricultural, urban, transportation, and floodplain development also had major impacts to land use as previously unaltered lands were developed for various uses. This analysis focuses on ongoing, present, and future actions, rather than past actions, to allow for a greater emphasis on future effects.

The future structural improvements at Dexter, Big Cliff, and Cougar would not have effects on land use. Other RFFAs discussed in Section 4.2.3 that would not have effects on land use include: RFFA 2, reduced agricultural production RFFA 4, decarbonizing the energy sector with renewable energy sources; RFFA 6, fishery management and killer whales; and RFFA 8, invasive species management. RFFA 4, decarbonizing the energy sector with renewable energy sources, could have an effect on land use, however, there are no proposed renewable energy projects in the WRB. RFFA 6 primarily relates to managing fisheries, subsequently, these RFFAs would not contribute to cumulative effects on land use. RFFA 8, invasive species management, could alter the type of plants contributing to land cover, but not affect the land cover type, thus it would not have cumulative effects on land use.

### *4.15.2* Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect to land use. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.15.2.1 Restore upstream and downstream passage at drop structures (#639) and Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

As discussed in Sections 3.15.4.3.1 and 3.15.4.3.2, effects from restoring upstream and downstream passage at drop structures and maintaining revetments using nature-based engineering or altering revetments for aquatic ecosystem restoration would be minor in magnitude, regional in extent, and long term in duration.

RFFA 5, federal and state wildlife and lands management, involves designating and managing lands such as wildlife refuges and national forests. Upcoming potential and ongoing federal and state wildlife and lands management activities in the WRB include improvements at the Wapato Lake National Wildlife Refuge, where the Fish and Wildlife Service would restore native plant communities, and the post-fire restoration of the Santiam State Forest (Mullan, 2021; ODF, No date). These activities would result in very noticeable improvements to land cover on a regional level, and thus, provide major cumulative effects on a regional level. Restoring upstream and downstream passage at drop structures and maintaining revetments using nature-based engineering methods would result in a minor contribution to the major cumulative effects to land cover occurring in the WRB. Therefore, when considered in tandem with applicable cumulative actions, restoring upstream and downstream passage at drop structures and maintaining revetments using nature-based engineering methods would result in additive and major cumulative effects to land cover.

#### *4.15.2.2 Construct Adult fish facilities (#722)*

As discussed in Section 3.15.4.3.3, effects from constructing AFFs would be minor in magnitude, localized in extent, and long term in duration. The results of future population growth and accompanying urban, industrial, and commercial development, climate change, mining operations, and timber and logging industry operations would have similar effects to those of constructing adult fish facilities.

Land use trends in the WRB from the 1970s to 2019 have resulted in a three percent increase in developed land and an 11 percent decrease in forest cover, while agriculture has stayed nearly the same between 21 and 22 percent (NLCD, 2019). The historic loss of forests is attributed to logging and wildfires (Oregon Wild, 2019; OFRI, 2014), but mining could have also played a minor role, especially if open pits were used. No new mine sites or logging operations have been proposed in the WRB, so these are less likely to contribute to cumulative effects to land cover and land use than other applicable RFFAs. As discussed above in Section 3.15.4.4.1, climate change is expected to exacerbate the intensity and frequency of wildfires, floods, and landslides in the future. These natural disasters would result in land use changes through expanding development (from housing relocation) and may include rerouting roads and making changes to county or local land use plans as applicable. Floodplains may also be re-mapped in order to restrict development.

As described above in Section 3.15, WRB land development has been occurring most rapidly along the I-5 corridor parallel to the mainstem Willamette River. This includes the cities of Corvallis, Eugene, and Portland, all of which will continue to develop over time. These land use trends are independent of USACE's O&M of the WVS. However, the past actions of constructing and operating dams along the Willamette River's tributaries have contributed to the development of rural land by creating desirable lakefront real estate, although lakefront development is likely of "low intensity" (i.e., less densely developed than other types of urban cover). Land development has been occurring less rapidly in rural areas, such as those surrounding WVS reservoirs. Among the thirteen WVS reservoirs, nine are less developed than the others, including: Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. The remaining reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively. The populations of these towns range from 80 to 10,000. Land surrounding these reservoirs would continue to be slowly developed.

As discussed in Section 3.15.2, developed land in the WRB is at approximately 94 percent of the limit imposed by the Oregon Statewide Planning Program's Urban Growth Boundary. Effects from future population growth and accompanying urban, industrial, and commercial development, climate change, mining operations, and timber and logging industry operations together would be highly conspicuous and have substantial consequences on a regional level by developing areas of land. Therefore, the effects would be major in magnitude. However, constructing AFFs would only develop up to three acres per facility, so it would result in a negligible contribution to the cumulative effects to land cover or use occurring in the WRB. This is because, when land would be developed for AFFs, it would be similar to and consistent with the adjacent uses at the nearby dam and reservoir. These developments would not be residential, commercial, or industrial; and thus, would not be the type of development that would have a "multiplier" effect, i.e., increase the demand for infrastructure, goods, and services such as water, power, and roads. Therefore, when considered in tandem with applicable cumulative actions, constructing AFFs would create additive, and major cumulative effects to land cover. Any land development under the action alternatives would represent a considerably small contribution to the overall cumulative effects compared to all cumulative actions within the WRB as a whole.

#### *4.15.2.3 Deeper fall reservoir drawdowns for fish passage (#40), Spring reservoir drawdown for downstream fish passage (#720), and Fall Creek drawdown*

As discussed in Section 3.15.4.3.4, the effects of drawing down reservoirs for fish passage would be moderate in magnitude, localized in extent, and long-term recurring in duration. The results of future population growth and accompanying urban, industrial, and commercial development; water withdrawals for municipal, industrial, and agricultural uses; and climate change would have similar effects on land use as drawing down the reservoirs in the fall and spring for fish passage.

Very limited aspects of RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; and RFFA 9, climate change, would have similar effects on land cover as reservoir drawdowns. These RFFAs would have similar effects on water levels water levels. As populations increase, water withdrawals for municipal, industrial, and agricultural uses would increase proportionally as more humans would require more water and water-demanding agriculture. The increase in the demand for water would strain reservoir storage and could reduce average annual water levels over time, resulting in decreased open water land coverage. Climate change is expected to exacerbate these effects by creating longer and more arid drought seasons and smaller snowpacks. Increasing air temperatures would also contribute to lower water levels by increasing evaporation rates. When considered in tandem with each other, RFFAs 1, 2, 3, and 9 would contribute to less open water land cover, and thus, would be exacerbated by reservoir drawdowns. In the short and medium terms, reservoir drawdowns would be much more noticeable than the effects of RFFAs 1, 2, 3, and 9 on open water coverage, but over time, would increasingly contribute to the decline of open water coverage. Therefore, when considered in tandem with applicable cumulative actions, reservoir drawdowns would create additive, and moderate cumulative effects on land cover.

### *4.15.3* Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to land use.

#### *4.15.3.1 No Action Alternative*

Under the NAA, the existing O&M of the WVS would continue. The Fall Creek Reservoir is annually drawn down to levels near the historic streambed to assist juvenile fish passage. As described in Section 4.3.15.2.4, when considered in tandem with applicable cumulative actions, recurring drawdowns would create additive, and moderate cumulative effects to land use.

#### *4.15.3.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 would include restoring upstream and downstream passage at drop structures, maintaining or altering revetments, constructing an AFF, and continuing the Fall Creek drawdown. As discussed above in Sections 4.15.2.1 through 4.15.2.3, effects would be minor in magnitude, regional in extent, and long-term in duration for restoring upstream and downstream passage and maintaining or altering revetments; minor in magnitude, localized in extent, and long term for constructing an AFF; and moderate in magnitude, localized in extent, and long-term recurring for drawdowns. Cumulative effects would be less than Alternatives 2a, 2b, 3a, 2b, 4, and 5.

#### *4.15.3.3 Alternative 2a –Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Alternative 2a would include maintaining or altering revetments, constructing an AFF, drawing down reservoirs in the fall for fish passage, and continuing the Fall Creek drawdown. As discussed above in Sections 4.3.15.2.1 through 4.3.15.2.3, effects would be minor in magnitude, regional in extent, and long-term in duration for restoring upstream and downstream passage and maintaining or altering revetments; minor in magnitude, localized in extent, and long term for constructing an AFF; and moderate in magnitude, localized in extent, and long-term recurring for drawdowns. Cumulative effects would be greater than Alternatives 1 and 4, but less than Alternatives 2b, 3a, 3b, and 5.

#### *4.15.3.4 Alternative 2b – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2b would include maintaining or altering revetments, constructing an AFF, drawing down reservoirs in the fall for fish passage, drawing down reservoirs in the spring for fish passage, and continuing the Fall Creek drawdown. As discussed above in Sections 4.3.15.2.1 through 4.3.15.2.3, effects would be minor in magnitude, regional in extent, and long-term in duration for restoring upstream and downstream passage and maintaining or altering revetments; minor in magnitude, localized in extent, and long term for constructing an AFF; and moderate in magnitude, localized in extent, and long-term recurring for drawdowns. Cumulative effects would be greater than Alternatives 1, 2a, and 4, the same as Alternative 5, and less than Alternatives 3a, and 3b.

#### *4.15.3.5 Alternative 3a – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Alternative 3a would include maintaining or altering revetments, constructing AFFs, drawing down reservoirs in the fall for fish passage, drawing down reservoirs in the spring for fish passage, and continuing the Fall Creek drawdown. As discussed above in Sections 4.3.15.2.1 through 4.3.15.2.3, effects would be minor in magnitude, regional in extent, and long-term in duration for restoring upstream and downstream passage and maintaining or altering revetments; minor in magnitude, localized in extent, and long term for constructing an AFF; and moderate in magnitude, localized in extent, and long-term recurring for drawdowns. Cumulative effects would be the same as Alternative 3b and greater than Alternatives 1, 2a, 2b, 4, and 5.

#### *4.15.3.6 Alternative 3b – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Alternative 3b would include maintaining or altering revetments, constructing AFFs, drawing down reservoirs in the fall for fish passage, drawing down reservoirs in the spring for fish passage, and continuing the Fall Creek drawdown. As discussed above in Sections 4.3.15.2.1 through 4.3.15.2.3, effects would be minor in magnitude, regional in extent, and long-term in duration for restoring upstream and downstream passage and maintaining or altering revetments; minor in magnitude, localized in extent, and long term for constructing an AFF; and moderate in magnitude, localized in extent, and long-term recurring for drawdowns. Cumulative effects would be the same as Alternative 3a and greater than Alternatives 1, 2a, 2b, 4, and 5.

#### *4.15.3.7 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

Alternative 4 would include restoring upstream and downstream passage at drop structures, maintaining or altering revetments, constructing an AFF, and continuing the Fall Creek drawdown. As discussed above in Sections 4.3.15.2.1 through 4.3.15.2.3, effects would be minor in magnitude, regional in extent, and long-term in duration for restoring upstream and downstream passage and maintaining or altering revetments; minor in magnitude, localized in extent, and long term for constructing an AFF; and moderate in magnitude, localized in extent, and long-term recurring for drawdowns. Cumulative effects would be greater than Alternative 1 and less than Alternatives 2a, 2b, 3a, 3b, 4, and 5.

#### *4.15.3.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 would only differ from Alternative 2b by way of the refined integrated temperature management and habitat flow regime measure (#30b), which is not a measure that would have effects on land cover. Therefore, the effects of Alternative 5 would be identical to those of Alternative 2b; and thus, would be greater than Alternatives 1, 2a, and 4, and less than Alternatives 3a, and 3b.

### *4.15.4* Summary

The cumulative effects of each of the alternatives would be additive and major from constructing AFFs when considered in tandem with land development occurring in the WRB. Cumulative effects would be adverse, additive, and moderate from recurring drawdowns, and would be additive, and major from restoring downstream passage at drop structures and maintaining or altering revetments when considered in tandem with federal and state wildlife and lands management. Alternative 1 would have the least-severe effects, followed by Alternatives 4, 2a, 2b and 5, 3a, and 3b due to the number of recurring drawdowns and AFFs constructed.

## 4.16 HAZARDOUS MATERIALS

This section discusses the cumulative effects from hazardous materials. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively contribute to the emission, discharge, or deposition of hazardous materials in soil, sediment, air, and/or water. The geographic scope for hazardous materials would be the same boundary as described in the Affected Environment in Chapter 3.

### *4.16.1* Cumulative Actions Applicable to Hazardous Materials

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects from hazardous materials, include:

- Construction of the WVS dams, non-USACE dams, and supporting structures;
- Proliferation of invasive species;
- Ongoing and present structural improvements;
- RFFA 8, invasive species management; and
- RFFA 9, climate change.

The initial construction of the WVS dams, non-USACE dams, and supporting structures occurred over 80 years ago, but created a system that requires the use of hazardous materials for activities such as construction, demolition, and maintenance (which requires the storage and use of compressed gasses, management of LBP and ACM, and other hazardous materials); O&M of fish collection and hatchery facilities; and the O&M of oil-filled equipment. Additionally, the proliferation of invasive species has required pesticides to be used basin-wide in the WVS on an as needed basis. The hazardous materials used in the O&M of the WVS are described in greater detail in Section 3.16.2.3. This analysis focuses on ongoing, present, and future actions, rather than past actions, to allow for a greater emphasis on future effects.

Some of the RFFAs discussed above in Section 4.2.3, such as RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations, may appear to contribute to effects from hazardous materials. However, these actions are occurring outside of the WVS (the system of 13 dams and reservoirs), and instead, are occurring in the larger region of the WRB. Because the area of analysis for hazardous materials has been defined as the WVS (Section 3.16), these RFFAs would not contribute to effects from hazardous materials *in the WVS* and therefore, are not discussed further in this section. Effects from *hazardous wastes* are considered in Section 3.18, Public Health and Safety – Hazardous, Toxic, and Radioactive Waste as applicable, which has a larger area of analysis than hazardous materials.

Other RFFAs would not contribute to effects from hazardous materials because they are generally not applicable, and therefore, are not discussed further. These include RFFA 2, reduced agricultural production; RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; RFFA 4, decarbonizing the energy sector with renewable energy sources; RFFA 5, federal and state wildlife and lands management; RFFA 6, fishery management and killer whales; and RFFA 7, tribal, state, and local fish and wildlife improvement.

### *4.16.2* Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect from hazardous materials. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects. The discussion of cumulative effects below does not include adapting the hatchery program because it is the only measure that would have beneficial effects, and no cumulative actions would contribute to beneficial effects from hazardous materials.

#### *4.16.2.1 Continued Operation of Existing AFFs, Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Restore upstream and downstream passage at drop structures (#639), Provide Pacific lamprey passage and infrastructure (#52), Use spillway for surface spill in summer (#721), Structural improvements to reduce total dissolved gas (#174), Foster Fish Ladder Temperature Improvement (#479), Construct AFF (#722), Construct water temperature control tower (#105), Deeper fall reservoir drawdowns for fish passage (#40), Construct structural downstream fish passage (#392), and a Suite of near-term operations*

As discussed in Section 3.16.2.4, the effects of these measures would be negligible to minor in magnitude, adverse, and local to regional in extent in the short, medium, and long term. These effects would be caused by the use of hazardous materials for construction, operation, and maintenance activities, and would be mitigated by adhering to applicable environmental laws and regulations and following BMPs. The results of ongoing and present structural improvements would have similar effects from hazardous materials because they would involve construction.

The ongoing and present structural improvement projects at Dexter, Big Cliff, and Cougar could require hazardous materials such as diesel and gasoline for fueling equipment and compressed gasses for welding, cutting, and brazing. They also may involve the management of LBP and ACM, fish collection and hatchery chemicals, and the operation of oil-filled equipment. However, as discussed above in Section 3.16.2.3, effects from hazardous materials would be mitigated by adhering to the USACE Hazard Communication Plan (which includes training and wearing PPE as applicable) and the requirements for compressed gasses and welding, cutting, and brazing in 29 CFR parts 1910.101 and 1910.253. Further, BMPs would be followed, such as maintaining a clean working environment and adhering to proper storage and fueling guidelines.

Therefore, when considered in tandem with applicable cumulative actions, these measures would create additive, negligible to minor, cumulative effects from hazardous materials.

#### *4.16.2.2 Operation, Maintenance, Repair, Replacement and Rehabilitation;*

The discussion in this subsection focuses on the *operation* and *maintenance* components of operation, maintenance, repair, replacement, and rehabilitation, with particular emphasis on pesticide use, which is the only component of hazardous materials in the WVS not discussed above in Section 3.16.2.4. As discussed above in Sections 3.19.1.7 and 3.16.2.3.1, pesticides are used basin-wide across the WVS as necessary to manage and control pest species. The results of RFFA 8, invasive species management and RFFA 9, climate change, would have similar effects from hazardous materials.

As stated in Section 3.16.2.3.1, environmental effects from pesticide use would be negligible in magnitude, adverse, and local in extent. Climate change would have no effects from hazardous materials through construction, demolition, and repair of buildings and structures, storage and use of compressed gasses, fish collection and hatchery chemicals, management of LBP and ACM, or operation of oil-filled equipment at hydroelectric dams. However, the proliferation of invasive species/invasive species management and climate change may interact additively or synergistically with hazardous materials.

Human activity has led to the spread of invasive species, particularly in water bodies, as boats can accidentally transport and spread species if boats and equipment are not thoroughly cleaned. Wetter winters and drier summers would also be expected to lead to changes in vegetation community composition and distribution over time, as drought-tolerant species become predominant and invasive plants potentially spread further into or take over communities of native species, as discussed in Section 3.06, Vegetation. Climate change would exacerbate the spread of invasive species (both plants and animals) facilitated by human activity.

If invasive species proliferate throughout the WVS over time as a result of human activity and anthropogenic climate change, the quantity of pesticides used to control them could increase proportionally. As discussed above in Section 3.16.1.1 and detailed in the Hazard Communication Plan, USACE personnel are informed of and able to identify hazardous chemicals, as well as protect themselves from hazardous chemical exposures using PPE. Further, pesticides are securely stored, many are considered non-hazardous, and the majority of applications are away from water. Therefore, when considered in tandem with applicable cumulative actions, operation, maintenance, repair, replacement, and rehabilitation would likely create additive, negligible, cumulative effects from hazardous materials.

### 4.16.3 Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to hazardous materials.

#### *4.16.3.1 No Action Alternative*

Under the NAA, the existing O&M of the WVS would continue. The O&M of the WVS includes construction, demolition, and maintenance (which requires the storage and use of compressed gasses, management of LBP and ACM, and other hazardous materials); fish collection and hatchery chemicals; pesticides; and the operation of oil-filled equipment. As discussed above in Sections 4.16.2.1 and 4.16.2.2, when considered in tandem with applicable cumulative actions, these activities would create negligible to minor in magnitude, adverse, cumulative effects from hazardous materials.

#### *4.16.3.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 would combine storage-focused measures in order to improve fish passage. As discussed above in Sections 4.16.2.1 and 4.16.2.2, when considered in tandem with applicable cumulative actions, these activities would create negligible to minor in magnitude, adverse, cumulative effects from hazardous materials.

Although not appreciable, cumulative effects would be greater than Alternatives 2a, 2b, 3a, 3b, and 5, but less than Alternative 4. All alternatives, including the NAA, include the management and use of hazardous materials. Any hazardous materials required under Alternative 1, either in the short-, medium-, or long-term, would represent a considerably small contribution to environmental effects from hazardous materials in the WVS.

#### *4.16.3.3 Alternative 2a – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Alternative 2a would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). As discussed above in Sections 4.16.2.1 and 4.16.2.2, when considered in tandem with applicable cumulative actions, these activities would create negligible to minor in magnitude, adverse, cumulative effects from hazardous materials.

Cumulative effects would be the same as Alternative 3a, greater than Alternatives 2b and 5, but less than Alternatives 1, 3b, and 4. Any hazardous materials required under Alternative 2a, either in the short-, medium-, or long-term, would represent a considerably small contribution to environmental effects from hazardous materials in the WVS.

#### *4.16.3.4 Alternative 2b – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2b would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam's DT). As discussed above in Sections 4.16.2.1 and 4.16.2.2, when considered in tandem with applicable cumulative actions, these activities would create negligible to minor in magnitude, adverse, cumulative effects from hazardous materials.

Cumulative effects would be the same as Alternative 5 and less than all other action alternatives because these alternatives include the fewest short- and medium-term construction projects. Any hazardous materials required under Alternative 2b, either in the short-, medium-, or long-term, would represent a considerably small contribution to environmental effects from hazardous materials in the WVS.

#### *4.16.3.5 Alternative 3a – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Alternative 3a would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). As discussed above in Sections 4.16.2.1 and 4.16.2.2, when considered in tandem with applicable cumulative actions, these activities would create negligible to minor in magnitude, adverse, cumulative effects from hazardous materials.

Cumulative effects would be the same as Alternative 2a, greater than Alternatives 2b and 5, and less than Alternatives 1, 3b, and 4. Any hazardous materials required under Alternative 3a, either in the short-, medium-, or long-term, would represent a considerably small contribution to environmental effects from hazardous materials in the WVS.

#### *4.16.3.6 Alternative 3b – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Alternative 3b would improve fish passage by using operations-focused measures (using a deep drawdown to Cougar Dam's DT). As discussed above in Sections 4.16.2.1 and 4.16.2.2, when considered in tandem with applicable cumulative actions, these activities would create negligible to minor in magnitude, adverse, cumulative effects from hazardous materials.

Cumulative effects would be greater than Alternatives 2a, 2b, and 5, but less than Alternatives 1 and 4. Any hazardous materials required under Alternative 3b, either in the short-, medium-, or long-term, would represent a considerably small contribution to environmental effects from hazardous materials in the WVS.

#### *4.16.3.7 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

Alternative 4 would improve fish passage with structures-based measures. As discussed above in Section 4.16.2, the effects of these measures would be negligible in magnitude, adverse, and local in extent in the short, medium, and long term.

Cumulative effects would be greater than all other action alternatives due to the number of medium-term construction projects that would occur. Any hazardous materials required under Alternative 4, either in the short-, medium-, or long-term, would represent a considerably small contribution to environmental effects from hazardous materials in the WVS; however, it would be a greater contribution than any of the other action alternatives.

#### *4.16.3.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 would only differ from Alternative 2b by way of the *refined* integrated temperature management and habitat flow regime measure (#30b), which is not a measure that would have effects from hazardous materials. Therefore, the effects of Alternative 5 would be identical to those of Alternative 2b: negligible to minor in magnitude, and less than all other action alternatives because these alternatives include the fewest short- and medium-term construction projects.

### 4.16.4 Summary

The cumulative effects under all alternatives would be adverse, additive, and negligible to minor from construction measures, especially those with long-term operational effects after initial construction, when considered in tandem with the structural improvement projects at Dexter, Big Cliff, and Cougar. Alternative 2b and 5 would have the least-severe adverse effects, followed by Alternatives 2a, 3a, 3b, 1, and 4.

## 4.17 HARMFUL ALGAL BLOOMS

This section discusses the cumulative effects of harmful algal blooms (HABs) on public health and safety. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect public health and safety as related to HABs. The geographic scope for public health and safety - HABs would be the same boundary as described in the Affected Environment in Chapter 3, which includes the 13 dams, reservoirs, and downstream reaches within the WRB.

### 4.17.1 Cumulative Actions Applicable to Public Health and Safety – HABs

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects from public health and safety - HABs, include:

- Construction of the WVS dams, supporting structures, and non-USACE dams;
- Water quality management;
- Agricultural, urban and transportation corridor development;
- Water withdrawals for irrigation, municipal, and industrial uses to support human development in the Willamette Valley;
- Floodplain development;
- Dredging and sediment management;
- Point and non-point source water pollution;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 2, reduced agricultural production;
- RFFA 3, water withdrawals for municipal, industrial, and agricultural uses;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 7, tribal, state, and local fish and wildlife improvement;
- RFFA 8, invasive species management;
- RFFA 9, climate change; and
- RFFA 10, mining operations.

Other RFFAs discussed in Section 4.1 would not have a cumulative effect on public health and safety - HABs. These include RFFA 4, decarbonizing the energy sector with renewable energy sources; RFFA 6, fishery management and killer whales; and RFFA 11; timber and logging industry operations. These actions do not contribute to land development and the subsequent water pollution in the watershed that discharges to the reservoirs cumulatively lead to HABs;

thus, these RFFAs were dismissed from further analysis. RFFA 11 was dismissed from further analysis because timber and logging operations do not occur within the WRB.

### 4.17.2 Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with relevant cumulative actions to determine the potential cumulative effects to public health and safety - HABs. The proposed measures analyzed in Section 3.17 and listed below would all contribute to the cumulative effects on public health and safety – HABs.

#### *4.17.2.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9); Continued Operation of Existing Adult Fish Facilities; Operation, Maintenance, Repair, Replacement, and Rehabilitation; Restore upstream and downstream passage at drop structures (#639); Construct adult fish facility (AFF) (#722); Provide Pacific lamprey passage and infrastructure (#52); and construct structural downstream fish passage (#392)*

As discussed under Section 3.17.5.3, the effects of these measures are adverse and/ or beneficial, negligible and/or minor in magnitude, small in extent, in the short term, medium term, and long term. These effects are caused by either construction of the proposed measure or maintenance activities which would be mitigated by erosion and sediment controls at the construction or maintenance site, and/or would be required to meet water quality requirements for construction discharges or effluent from fish facilities.

The ongoing and present construction of the WVS dams would continue to have similar effects as the proposed measures. Construction of the above listed measures would negligible as measures to prevent erosion and sedimentation would be implemented during construction. Therefore, when considered in tandem with applicable cumulative actions, these measures would create additive, negligible to minor, cumulative effects from public health and safety – HABs.

#### *4.17.2.2 Foster Fish Ladder Temperature Improvement (#479); Construct water temperature control (WTC) tower (#105); Structural improvements to reduce total dissolved gas (#174); Use spillway for surface spill in summer (#721), Pass water over spillway in spring for fish passage (#714); Augment instream flows by using the inactive pool (#718); Augment instream flows by using the power pool (#304); Reduce minimum flows to Congressionally authorized minimum flow requirements (#723); Fall Creek drawdown, Deeper fall reservoir drawdowns for fish passage (#40); Spring reservoir drawdown for downstream fish passage (#720); and Use regulating outlets (ROs) to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)*

As discussed under Section 3.17.5.3, the effects of these measures are adverse and/ or beneficial, minor in magnitude, large in extent, and long term. These measures promote the continual flow and blending of water that could inhibit HABs from forming. These measures also contribute to adverse minor, large, and long-term effects due to the release of excess nutrients downstream that could cause a HABs event downstream.

The ongoing and present construction of the WVS system and water quality management would continue to have similar effects with the proposed measures. Construction measures would be mitigated as discussed above in 4.17.2.1 and the ongoing and present water quality management measures proposed would also aid in inhibiting HABs growth.

The ongoing and present land development actions discussed could however interact additively or synergistically with public health and safety – HABs. Measures which include increased development in the watershed due to population growth, such as construction of the WVS dams and non-USACE dams; agricultural, urban and transportation corridor development; water withdrawals for irrigation, municipal, and industrial uses; development of the floodplain; and point and non-point source water pollution are all activities which can lead to stormwater pollution and excessive nutrients discharging into the environment. The nutrient laden runoff from the developed land in the watershed collects in the reservoirs which can lead to HABs formation. The cumulative effects of land development actions in the watershed would be adverse and minor to major. Excess nutrients would lead to small changes in water quality or could lead to substantial changes in water quality that could cause a HABs event and unsafe exposure.

Invasive species management (RFFA 8) in the watershed would have minor to major cumulative effects due to the use of pesticides and herbicides which could further exacerbate a HABs event.

Conversely, land management and restoration for fish and wildlife (RFFA 5 and 7), as well as water quality management in the watershed, would result in beneficial direct minor to major cumulative effects on HABs occurrence as the preservation of natural land would protect water resources and reduce water pollution.

Dredging and sediment management would have direct beneficial minor to moderate effects as the sediment in the reservoir would trap nutrients. Thus, dredging sediment from the reservoirs would reduce nutrients in the reservoir which could reduce the occurrence of HABs.

Climate change would contribute to adverse moderate to major cumulative effects due to changes in temperature, precipitation and stream baseflows as described in Section 3.17.5.

Lastly, mining operations are required to meet water quality requirements for effluent and therefore would have negligible to minor adverse cumulative effects on public health and safety - HABs.

Therefore, when considered in tandem with applicable cumulative actions, these measures would create additive, negligible to major, cumulative effects on public health and safety – HABs.

#### *4.17.2.3 Integrated temperature and habitat flow regime (#30a) and Refined integrated temperature and habitat flow regime (#30b)*

As discussed under Section 3.17.5.3, the effects of these measures are beneficial, minor in magnitude, small in extent, and long term. These measures promote the continual flow and blending of water that could inhibit HABs from forming. The beneficial effects associated with land management and restoration as well as dredging and sediment management would have additive beneficial effects for the reasons discussed in 4.17.2.2 to public health and safety – HABs.

When considered in tandem with these measures, cumulative actions would have adverse and beneficial, additive, and negligible to major cumulative effects to public health and safety - HABs in the WVS.

### 4.17.3 No Action Alternative

The NAA aggregated with the cumulative effects of past, ongoing and reasonably foreseeable future actions would cause additive adverse effects due to the land development activities in the watershed, invasive species management, climate change, and mining operations and beneficial additive effects due to land management, restoration, water quality management, and dredging as discussed under Section 4.17.2.1 and 4.17.2.2. The additive effects would result in adverse and beneficial additive, negligible to major effects on the formation of HABs and public health and safety.

### 4.17.4 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures

Under Alternative 1, fish passage would be improved through storage-focused measures by maximizing refill volumes of conservation pools, tapping into the power pool, and augmenting flow to the congressionally authorized minimum flows. This would increase the likelihood of refilling to the maximum conservation pool levels as discussed under Section 2.4.3. The effects are similar to the NAA but still appreciably greater than the NAA because the reservoirs will be maximizing storage which can lead to greater nutrient accumulation in the reservoir which could lead to a HABs occurrence. The aggregated effects on Alternative 1 would result in overall adverse additive, negligible to major cumulative effects.

### 4.17.5 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative

Under Alternative 2A, integrated temperature and habitat flow regimes would be utilized as well as using the power pool to augment flows. Structural and operational measures are proposed to address water quality as well as the Near-Term Operations Measure as discussed under Section 2.2.5. These measures would have adverse and beneficial additive, negligible to major cumulative effects similar to Alternative 1 but would be appreciably less because Alternative 1 has a focus on maximizing storage which can lead to a higher accumulation of nutrients in the reservoirs and subsequent HABs occurrences.

### 4.17.6 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative

Under Alternative 2B, the cumulative effects to public health and safety - HABs would be the same as those described under Alternative 2A. The difference is that the downstream passage measure at Cougar Dam is changed from a structural fish passage structure (#392) under 2A to changing of operations to a deeper fall (#40) and spring reservoir drawdown (#720) with the construction of a diversion tunnel under 2B. These measures would contribute nearly identical adverse and beneficial, additive, negligible to major cumulative effects as Alternative 1 and 2A, however effects would overall be less than Alternative 1.

### 4.17.7 Alternative 3A – Operations-Focused Fish Passage Alternative

Under Alternative 3A, improved fish passage is proposed through the modifying of operations instead rather than focusing on storage (Alternative 1) or structural measures (Alternative 4). This alternative also includes the Near-Term Operations Measure. As discussed above in Sections 4.17.2, these measures would have adverse and beneficial, additive, negligible to major cumulative effects. Alternative 3A would have the same cumulative effect as Alternatives 1, 2A, and 2B, however effects would be overall less than Alternative 1.

### 4.17.8 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)

Under Alternative 3B, the cumulative effects to public health and safety - HABs would be the same as those described under Alternative 3A. Alternative 3B proposes the slightly different combination of operations for the downstream passage. 3A proposes the drawdown to 10 feet over the top of the Cougar Dam RO for deep fall and spring drawdown measures and 3B includes drawdown utilizing the diversion tunnel at Cougar.

As discussed above in Sections 4.17.2, these measures would contribute adverse and beneficial additive, negligible to major cumulative effects. Alternative 3B would have the same cumulative effect as Alternative 1, 2A, 2B, and 3A, however effects would be overall less than Alternative 1.

### 4.17.9 Alternative 4 – Structures-Based Fish Passage Alternative

Under Alternative 4, a structures-based approach is proposed to improve fish passage. The cumulative effects to public health and safety - HABs would be the same as those described under Alternative 2A. Alternative 4 utilizes the integrated temperature and habitat flow regime proposed in Alternative 2A and includes Near Term Operations Measures as well as structural improvements.

As discussed above in Sections 4.17.2, these measures would contribute adverse and beneficial additive, negligible to major cumulative effects. Alternative 4 would have the same cumulative effect as Alternative 1, 2A, 2B, 3A, and 3B, however effects would be overall less than Alternative 1.

### 4.17.10 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)

Under Alternative 5 – the Preferred Alternative, fish passage would be improved through a combination of modified operations and structural improvements. Alternative 5 is exactly the same as Alternative 2B except the integrated temperature and habitat flow regime (#30a) is replaced with refined integrated temperature and habitat flow regime (#30b). As discussed above in Section 4.17.2.3., these measures would have adverse and beneficial additive, negligible to major cumulative effects. Alternative 5 would have the same cumulative effects as Alternative 1, 2A, 2B, 3A, 3B and 4, however effects would be overall less than Alternative 1.

### 4.17.11 Summary

In summary, the cumulative effects of each of the alternatives would have similar adverse and beneficial additive, negligible, minor, moderate and major effects. However, Alternative 1 has appreciably greater effects than Alternatives 2A, 2B, 3A, 3B, 4 and 5 since it maximizes conservation storage as discussed in Sections 4.17.4 and 4.17.5.

## 4.18 PUBLIC HEALTH AND SAFETY – HAZARDOUS, TOXIC, AND RADIOACTIVE WASTE

This section discusses the cumulative effects on public health and safety from HTRW. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect public health and safety from HTRW. The geographic scope for public health and safety HTRW would be the same boundary as described in the Affected Environment in Chapter 3, which is the WVS, but also includes some nearby facilities on private property within the WRB such as mines, from which contamination has migrated onto USACE property.

### 4.18.1 Cumulative Actions Applicable to Public Health and Safety – Hazardous, Toxic, and Radioactive Waste

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects on public health and safety from HTRW, include:

- Construction of the WVS dams, non-USACE dams, and supporting structures;
- Ongoing and present structural improvements;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 2, reduced agricultural production;
- RFFA 8, invasive species management;
- RFFA 9, climate change; and
- RFFA 10, mining operations.

The initial construction of the WVS dams, non-USACE dams, and supporting structures occurred over 50 years ago, but the lack of proper hazardous waste management left a legacy of contamination at eight of the WVS dams. These contamination sites pose varying risks to public health and safety and are summarized in Section 3.18.1.6. Additionally, the construction of the dams and supporting structures, specifically those that produce hydropower, created small ongoing sources of hazardous waste from the chemicals necessary for their operation, such as waste from oil used in turbines and transformers, described in further detail in Section 3.18.1.1. This analysis focuses on ongoing, present, and future actions, rather than past actions, to allow for a greater emphasis on future effects.

Some of the RFFAs discussed in Section 4.2.3 would not have an effect on public health and safety from HTRW. These include RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; RFFA 4, decarbonizing the energy sector with renewable energy sources; RFFA 5, federal and state wildlife and lands management; RFFA 6, fishery management and killer whales; RFFA 7, tribal, state, and local fish and wildlife improvement; and RFFA 11, timber and logging industry operations.

### *4.18.2* Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect on public health and safety from HTRW. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.18.2.1 Operation, Maintenance, Repair, Replacement and Rehabilitation, Use spillway for surface spill in summer (#721), Provide Pacific lamprey passage and infrastructure (#52), Foster Fish Ladder Temperature Improvement (#479), Structural improvements to reduce total dissolved gas (#174), Construct adult fish facility (#722), Construct water temperature control tower (#105), and Construct structural downstream fish passage (#392)*

As discussed in Section 3.18.2.3 the effects of these measures would primarily be negligible in magnitude, adverse, and local in extent in the short, medium, and long term. These effects would be caused by the generation of small amounts of hazardous waste from maintenance and construction activities, but would be mitigated through RCRA compliance and BMPs as discussed in Section 3.18.2.3. The results of ongoing and present structural improvements; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 8, invasive species management; and RFFA 10, mining operations, would have similar effects on public health and safety from HTRW. RFFA 2, reduced agricultural production would have countervailing beneficial effects; however, these would not be great enough to make the overall effects beneficial.

RFFAs 1, 2, 8, and 10 would also all produce hazardous waste and subsequently contribute to the risk to public health and safety. Ongoing and present structural improvements could potentially generate small amounts of hazardous waste from activities such as using compressed gasses for cutting, welding, and brazing, or could otherwise require hazardous material and generate small amounts of hazardous waste from construction activities in general. Therefore, these actions would have identical effects as described above in Section 3.18.2.3: negligible to minor in magnitude, local in extent, adverse, and short-, medium-, and/or long-term in duration.

Industrial development is a notable contributor to hazardous waste in the U.S. As populations grow, increased industrial development would result in more hazardous waste, and increase the risk to public health and safety. One indicator of facilities that produce hazardous waste is the EPA Toxics Release Inventory (TRI)[61]. Although numerous TRI-reporting-facilities exist in the WRB, there were no TRI-reporting-facilities adjacent to WVS reservoirs according to 2020 data (EPA 2020c). Invasive species management could require the management of pests with hazardous chemicals, which would generate waste when chemicals are leftover. Several WVS reservoirs have agriculture directly on their shores (primarily hay and pastureland), and pesticides are used basin-wide as necessary (NLCD 2019; USACE 2021a). The amount of

[61] TRI information is not all encompassing because facilities are only required to report when a threshold of toxic chemical use is met, typically, 10,000 pounds.

hazardous waste from leftover pesticides would decrease proportionally with reduced agricultural production, resulting in countervailing beneficial effects. However, the effects on public health and safety from this hazardous waste would be undetectable, so the overall effects would still be adverse. Mining operations also produce hazardous waste. Several production mines and active and/or closed mining claims exist near the Blue River, Detroit, Fall Creek, Foster, Green Peter, and Lookout Point reservoirs. The majority of these mines are related to gold, which is known to generate hazardous waste (The Diggings 2022; Fashola et al. 2016). Although these cumulative actions would generate hazardous waste, generators would generate and store waste in accordance with RCRA regulations, or else face steep penalties. Therefore, the risk to public health and safety would likely be near regulatory standards.

The WVS only generates small amounts of hazardous waste pursuant to CESQG generator status that would have adverse but negligible effects to public health and safety. However, when considered in tandem with applicable cumulative actions, these measures would create additive, minor to moderate cumulative effects to public health and safety from HTRW.

#### *4.18.2.2 Deeper fall reservoir drawdowns for fish passage (#40)*

Deeper fall drawdowns at the Blue River Reservoir could expose the previously inundated legacy-contaminated sediment near the saddle dam, described above in Section 3.18.2.3.5. The effects of this would be minor in magnitude, recurring in the long term, and be reduced using administrative controls as necessary. The results of RFFA 9, climate change, would have similar effects on public health and safety from HTRW. As discussed above in Section 3.18.2.4.1, climate change presents indirect risks to public health and safety from HTRW. Climate change is expected to exacerbate the frequency and severity of natural disasters such as wildfires and floods, and could increase the risk to public health by spreading or exposing contamination that had previously been inaccessible to the public. Seven superfund sites in the WRB have been found to be vulnerable to climate change, including one adjacent to the mainstem Willamette River (Hasemeyer and Olsen 2020).

Other waste sites that are not classified as superfund sites but could potentially be vulnerable to climate change are those at Big Cliff, Blue River, Cougar, Detroit, Dexter, Dorena, Fall Creek, and Green Peter, described in Section 3.18.1.6. However, deeper fall drawdowns for fish passage would only pose risks for three weeks out of the year at one location, so it would result in a minor contribution to the overall adverse cumulative effects to public health and safety from HTRW occurring in the WVS.

Therefore, when considered in tandem with applicable cumulative actions, deeper fall reservoir drawdowns for fish passage would create additive, minor, cumulative effects to public health and safety from HTRW.

### *4.18.3* Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to Public Health and Safety - HTRW.

#### *4.18.3.1 No Action Alternative*

Under the NAA, the existing O&M of the WVS would continue. The O&M of the WVS generates small amounts of hazardous waste as described in section 3.18.2.4, which would result in negligible effects to public health and safety because the management of the waste would comply with RCRA regulations. RFFAs 1, 2, 9, and 10 apply to the NAA the same way they apply to the specific measures described above in Section 4.18.2.

The effects of the NAA would be a negligible contribution to the overall adverse cumulative effects to public health and safety from HTRW occurring in the WVS from applicable cumulative actions. Therefore, when considered in tandem with applicable cumulative actions, the NAA would create adverse, additive, and negligible cumulative effects to public health and safety from HTRW.

#### *4.18.3.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 would combine storage-focused measures in order to improve fish passage. As discussed above in Section 4.18.2, the effects of these measures would be negligible in magnitude, adverse, and local in extent in the short, medium, and long term.

Cumulative effects would be greater than Alternatives 2A, 2B, 3A, 3B, and 5, but less than Alternative 4. Any hazardous waste generated under Alternative 1 would represent a very small contribution to the overall cumulative effects compared to all cumulative actions within the WVS and WRB.

#### *4.18.3.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Alternative 2A would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). As discussed above in Section 4.18.2, the effects of these measures would be negligible in magnitude, adverse, and local in extent in the short, medium, and long term.

Cumulative effects would be greater than Alternatives 2B and 5, although not appreciably, and less than Alternatives 1, 3A, 3B, and 4. Any hazardous waste generated under Alternative 2A would represent a very small contribution to the overall cumulative effects compared to all cumulative actions within the WVS and WRB.

#### *4.18.3.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2B would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam's DT). As discussed above in Section 4.18.2, the effects of these measures would be negligible in magnitude, adverse, and local in extent in the short, medium, and long term.

Cumulative effects would be the same as Alternative 5 and less than all other action alternatives due to the number of construction projects that would have medium- and long-term effects. Any hazardous waste generated under Alternative 2B would represent a small contribution to the overall cumulative effects compared to all cumulative actions within the WVS and WRB.

#### *4.18.3.5 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Alternative 3A would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). As discussed above in Section 4.18.2, the effects of these measures would primarily be negligible in magnitude, adverse, and local in extent in the short, medium, and long term. Due to the deeper fall reservoir drawdown at Blue River, there would also be minor in magnitude, local in extent, adverse, and long-term recurring effects.

Cumulative effects would be greater than Alternatives 2A, 2B, and 5, but less than Alternatives 1, 3B, and 4. Any hazardous waste generated under Alternative 3A would represent a small contribution to the overall cumulative effects compared to all cumulative actions within the WVS and WRB.

#### *4.18.3.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Alternative 3B would improve fish passage by using operations-focused measures (using a deep drawdown to Cougar Dam's DT). As discussed above in Section 4.18.2, the effects of these measures would primarily be negligible in magnitude, adverse, and local in extent in the short, medium, and long term. Due to the deeper fall reservoir drawdown at Blue River, there would also be minor in magnitude, local in extent, adverse, and long-term recurring effects.

Cumulative effects would be greater than Alternatives 2A, 2B, 3A, and 5, but less than Alternatives 1 and 4. Any hazardous waste generated under Alternative 3B would represent a small contribution to the overall cumulative effects compared to all cumulative actions within the WVS and WRB.

#### *4.18.3.7 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

Alternative 4 would improve fish passage with structures-based measures. As discussed above in Section 4.18.2, the effects of these measures would be negligible in magnitude, adverse, and local in extent in the short, medium, and long term.

Cumulative effects would be greater than Alternatives 1, 2A, 2B, 3A, 3B, and 5. Any hazardous waste generated under Alternative 4 would represent a small contribution to the overall cumulative effects compared to all cumulative actions within the WVS and WRB; however, it would be a greater contribution than any of the other action alternatives.

#### ***4.18.3.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Alternative 5 would only differ from Alternative 2B by way of the *refined* integrated temperature management and habitat flow regime measure (#30b), which is not a measure that would have effects on public health and safety from HTRW. Therefore, the effects of Alternative 5 would be identical to those of Alternative 2B: negligible in magnitude, and less than all other action alternatives because these alternatives include the fewest construction projects with medium- and long-term effects.

### 4.18.4 Summary

The cumulative effects under all alternatives would be adverse, additive, and minor to moderate from construction measures, especially those with long-term operational effects after initial construction, when considered in tandem with ongoing and present structural improvements, future population growth and accompanying urban, industrial, and commercial development, invasive species management, and mining operations. Alternatives 3A and 3B would have additional adverse, additive, and minor cumulative effects from recurring fall reservoir drawdown at Blue River when considered in tandem with climate change. Alternative 2B and 5 would have the least-severe adverse effects, followed by Alternatives 2A, 3A, 3B, 1, and 4.

## 4.19 PUBLIC HEALTH AND SAFETY - DRINKING WATER

This section discusses the cumulative effects on Public Health and Safety – Drinking Water. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect public health and safety as related to drinking water. The geographic scope for public health and safety – drinking water would be the same boundary as described in the Affected Environment in Chapter 3, which includes the 13 dams, reservoirs, and downstream reaches within the WRB.

### 4.19.1 Cumulative Actions Applicable to Public Health and Safety – Drinking Water

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects from public health and safety – drinking water, include:

- Construction of the WVS dams, supporting structures, and non-USACE dams;
- Water quality management;
- Agricultural, urban and transportation corridor development;
- Water withdrawals for irrigation, municipal, and industrial uses to support human development in the Willamette Valley;
- Floodplain development;
- Dredging and sediment management;
- Point and non-point source water pollution;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 2, reduced agricultural production;
- RFFA 3, water withdrawals for municipal, industrial, and agricultural uses;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 7, tribal, state, and local fish and wildlife improvement;
- RFFA 8, invasive species management;
- RFFA 9, climate change; and
- RFFA 10, mining operations.

Other RFFAs discussed in Section 4.1 would not have a cumulative effect on public health and safety – drinking water. These include RFFA 4, decarbonizing the energy sector with renewable energy sources; RFFA 6, fishery management and killer whales; and RFFA 11; timber and logging industry operations. These actions do not contribute to land development and the subsequent water pollution in the watershed that discharges to the reservoirs cumulatively lead to poor drinking water quality; thus, these RFFAs were dismissed from further analysis. RFFA 11 was dismissed from further analysis because timber and logging operations do not occur within the WRB.

### 4.19.2 Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with relevant cumulative actions to determine the potential cumulative effects to public health and safety - Drinking water. The proposed measures analyzed in Section 3.19 and listed below would all contribute to the cumulative effects on public health and safety – Drinking water.

#### *4.19.2.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Continued Operation of Existing Adult Fish Facilities, Operation, Maintenance, Repair, Replacement, and Rehabilitation, Restore upstream and downstream passage at drop structures (#639), Construct adult fish facility (AFF) (#722), Provide Pacific lamprey passage and infrastructure (#52), and Construct structural downstream fish passage (#392)*

As discussed under Section 3.19.6.3, the effects of these measures are adverse and/ or beneficial, negligible and/or minor in magnitude, small in extent, in the short term, medium term, and long term. These effects are caused by either construction of the proposed measure or maintenance activities which would be mitigated by erosion and sediment controls at the construction or maintenance site, and/or would be required to meet water quality requirements for construction discharges or effluent from fish facilities.

The ongoing and present construction of the WVS dams would continue to have similar effects with the proposed measures. Construction measures would be mitigated similarly to the construction measures proposed for the above listed measures. Therefore, when considered in tandem with applicable cumulative actions, these measures would create additive, negligible to minor, cumulative effects from public health and safety – Drinking water.

#### *4.19.2.2 Foster Fish Ladder Temperature Improvement (#479), Construct water temperature control (WTC) towers (#105), Structural improvements to reduce total dissolved gas (#174), Use spillway for surface spill in summer (#721), Pass water over spillway in spring for fish passage (#714), Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), Reduce minimum flows to Congressionally authorized minimum flow requirements (#723), Fall Creek drawdown, Deeper fall reservoir drawdowns for fish passage (#40), and Use regulating outlets (ROs) to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)*

As discussed under Section 3.19.6.3, the effects of these measures are adverse and/ or beneficial, minor in magnitude, large in extent, and long term. These measures allow the continual flow and blending of water that would prevent degradation of water quality that occurs when water is stagnant resulting in beneficial effects. These measures also contribute to adverse minor, large, and long-term effects due to the release of excess nutrients downstream that could cause adversely impact drinking water quality downstream.

The ongoing and present construction of the WVS system and water quality management would continue to have similar effects with the proposed measures. Construction measures would be mitigated as discussed above in 3.19.6.3.1 and the ongoing and present water quality management measures proposed would also aid in improving water quality of drinking water.

The ongoing and present land development actions discussed would interact additively or synergistically with public health and safety – drinking water. Measures which include increased development in the watershed due to population growth, such as construction of the WVS dams and non-USACE dams; agricultural, urban and transportation corridor development; water withdrawals for irrigation, municipal, and industrial uses; development of the floodplain; and point and non-point source water pollution are all activities which can lead to stormwater pollution and excessive nutrients discharging into the environment. The nutrient-laden runoff from the developed land in the watershed collects in the reservoirs reduces water quality. Excess nutrients would lead to small changes in water quality or could lead to substantial changes in water quality that could be mitigated by treatment at the drinking water facility. The cumulative effects of land development actions in the watershed would be adverse and negligible to minor.

Invasive species management (RFFA 8) in the watershed would have negligible to minor cumulative effects due to the use of pesticides and herbicides which could contaminate runoff and discharge into the reservoirs.

Conversely, land management and restoration for fish and wildlife (RFFA 5 and 7), as well as water quality management in the watershed, would result in beneficial direct minor to moderate cumulative effects on water quality as the preservation of natural land would protect water resources by filtering out nutrients in the environment and thereby reducing polluted discharge of water to the reservoirs.

Dredging and sediment management would have direct beneficial minor to moderate effects as the sediment in the reservoir would trap nutrients. Thus, dredging sediment from the reservoirs would reduce nutrients in the reservoir which could improve water quality.

Climate change would contribute to adverse moderate to major cumulative effects due to changes in temperature, precipitation and stream baseflows as analyzed in Section 3.19.

Lastly, mining operations are required to meet water quality requirements for effluent and therefore would have negligible to minor adverse cumulative effects on public health and safety – drinking water.

Therefore, when considered in tandem with applicable cumulative actions, these measures would create additive, negligible to major, cumulative effects on public health and safety – drinking water.

#### *4.19.2.3 Integrated temperature and habitat flow regime (#30a) and Refined integrated temperature and habitat flow regime (#30b)*

As discussed under Section 3.19.6.3, the effects of these measures are beneficial, minor in magnitude, small in extent, and long term. These measures promote the continual flow and blending of water that would be beneficial for water quality. The beneficial effects associated with land management and restoration as well as dredging and sediment management would have additive beneficial effects for the reasons discussed in 4.20.2.2 to public health and safety – drinking water.

When considered in tandem with these measures, cumulative actions would have adverse and beneficial, additive, and negligible to major cumulative effects to public health and safety - drinking water in the WVS.

#### *4.19.2.4 Spring reservoir drawdown for downstream fish passage (#720)*

As discussed under Section 3.19.6.3, the effects of the spring drawdown are adverse, major, and large and long term. The spring drawdown has major effects on the availability of drinking water for public health and safety because the spring drawdowns do not maintain conservation storage for M&I water usage affecting the ability to refill system-wide storage.

When considered in tandem with this measure, cumulative actions would have adverse, additive, and negligible to major cumulative effects to public health and safety - drinking water in the WVS.

### 4.19.3 Discussion of Cumulative Effects by Alternative

This section considers the relevant cumulative actions by alternative to determine the potential cumulative effects to Public Health and Safety - Drinking Water.

#### *4.19.3.1 No Action Alternative*

The NAA aggregated with the cumulative effects of past, ongoing and future actions would cause additive adverse effects due to the land development activities in the watershed, invasives management, climate change, and mining operations and beneficial additive effects due to land management, restoration, water quality management, and dredging as discussed under Section 4.20.1 and 4.20.2. The additive effects would result in adverse and beneficial additive, negligible to major effects on drinking water and public health and safety. Spring drawdown

#### *4.19.3.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, fish passage would be approved through storage-focused measures by maximizing refill volumes of conservation pools and tapping into the power pool and augmenting flow to the congressionally authorized minimum flows. This would increase the likelihood of refilling to the maximum conservation pool levels as discussed under Section 2.4.3. The effects are similar to the NAA but still appreciably greater than the NAA because the reservoirs will be maximizing storage which can lead to greater nutrient accumulation in the reservoir which could reduce water quality. The aggregated effects on Alternative 1 would result in overall adverse additive, negligible to major cumulative effects.

#### *4.19.3.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Under Alternative 2A, integrated temperature and habitat flow regimes would be utilized as well as using the power pool to augment flows. Structural and operational measures are proposed to address water quality as well as the Near-Term Operations Measure as discussed under Section 2.2.5. These measures would have adverse and beneficial additive, negligible to major cumulative effects similar to Alternative 1 but would be appreciably less than the effects of Alternative 1 because it has a focus on maximizing storage which can lead to a higher accumulation of nutrients in the reservoirs and poor water quality.

#### *4.19.3.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Under Alternative 2B, the cumulative effects to public health and safety – drinking water would be the same as those described under Alternative 2A. The difference is that the downstream passage measure at Cougar Dam is changed from a structural fish passage structure (#392) under 2A to changing of operations to a deeper fall reservoir drawdown (#40) and spring reservoir drawdown (#720) with the construction of a diversion tunnel under 2B. These measures would contribute nearly identical adverse and beneficial, additive, negligible to major cumulative effects as Alternative 1 and 2A, however effects would be appreciably greater than 1 and 2A due to the major adverse impacts resulting from the spring reservoir drawdown for downstream fish passage (#720).

#### *4.19.3.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Under Alternative 3A, improved fish passage is proposed through the modifying of operations instead rather than focusing on storage (Alternative 1) or structural measures (Alternative 4). This alternative also includes the Near-Term Operations Measure. As discussed above in Sections 4.19.2, these measures would have adverse and beneficial, additive, negligible to major cumulative effects. Alternative 3A would have the same cumulative effect as Alternatives 1, 2A, and 2B, however effects would be nearly identical to 2B and appreciably greater than 1 and 2A due to the major adverse impacts resulting from the spring reservoir drawdown for downstream fish passage (#720).

#### *4.19.3.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Under Alternative 3B, the cumulative effects to public health and safety – drinking water would be the same as those described under Alternative 3A. Alternative 3B proposes the slightly different combination of operations for the downstream passage. 3A proposes the drawdown to 10 feet over the top of the Cougar Dam RO for deep fall and spring drawdown measures and 3B includes drawdown utilizing the diversion tunnel at Cougar.

As discussed above in Sections 4.19.2, these measures would contribute adverse and beneficial additive, negligible to major cumulative effects. Alternative 3B would have the same cumulative effect as Alternative 1, 2A, 2B, and 3A, however effects would be overall less than Alternative 1. Alternative 3A would have the same cumulative effect as Alternatives 1, 2A, 2B, and 3A, however effects would be nearly identical to 2B and 3A and appreciably greater than 1 and 2A due to the major adverse impacts resulting from the spring reservoir drawdown for downstream fish passage (#720).

#### *4.19.3.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Under Alternative 4, a structures-based approach is proposed to improve fish passage. The cumulative effects to public health and safety – drinking water would be the same as those described under Alternative 2A. Alternative 4 utilizes the integrated temperature and habitat flow regime proposed in Alternative 2A and includes Near Term Operations Measures as well as structural improvements.

As discussed above in Sections 4.19.2, these measures would contribute adverse and beneficial additive, negligible to major cumulative effects. Alternative 4 would have the same cumulative effect as Alternative 1, 2A, 2B, 3A, and 3B, however effects would be overall less than Alternatives 2B, 3A, and 3B because this alternative does not include the spring reservoir drawdown for downstream fish passage (#720).

#### *4.19.3.8 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 5 – the Preferred Alternative, fish passage would be improved through a combination of modified operations and structural improvements. Alternative 5 is exactly the same as Alternative 2B except the integrated temperature and habitat flow regime (measure #30a) is replaced with refined integrated temperature and habitat flow regime (measure #30b). As discussed above in Section 4.19.2, these measures would have adverse and beneficial additive, negligible to major cumulative effects. Alternative 5 would have the same cumulative effects as Alternative 1, 2A, 2B, 3A, 3B and 4, however effects would be overall less than Alternatives 2B, 3A, and 3B because this alternative does not include the spring reservoir drawdown for downstream fish passage (#720).

### 4.19.4 Summary

In summary, the cumulative effects of each of the alternatives would have similar additive, negligible, minor, moderate and major effects. Effects would be appreciably greater for Alternatives 2B, 3A and 3B due to the effects of spring reservoir drawdown for downstream fish passage (#720) on the availability of drinking water for public health and safety because the spring drawdowns do not maintain conservation storage for M&I water usage.

## 4.20 ENVIRONMENTAL JUSTICE

This section discusses the cumulative effects on environmental justice. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect environmental justice. The geographic scope for environmental justice would be the same as described in the Affected Environment in Chapter 3, which is the following 10 counties:

- Benton County;
- Clackamas County;
- Columbia County;
- Lane County;
- Linn County;
- Marion County;
- Multnomah County;
- Polk County;
- Washington County; and
- Yamhill County.

Note that because this Draft PEIS discusses general, qualitative effects from construction at the programmatic level, the above-listed counties and specific Tribes were chosen as the ROI and the State of Oregon or the respective county as the ROC. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects and conduct the EJ analysis on a smaller scale, and use census tracts or census blocks to further identify pockets of minority, low-income, and Native American communities that could be disproportionately affected by the proposed construction measures.

### 4.20.1 Cumulative Actions Applicable to Environmental Justice

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have disproportionately high cumulative effects on environmental justice, include:

- Construction of the WVS and other dams and reservoirs in the WRB;
- Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar;
- Transportation corridor development;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;

- RFFA 3, water withdrawals for municipal, industrial, and agricultural uses;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 6, fishery management and killer whales;
- RFFA 7, tribal, state, and local fish and wildlife improvement;
- RFFA 8, invasive species management;
- RFFA 9, climate change; and
- RFFA 10, mining operations.

Some of the other RFFAs discussed in Section 4.1.2.3 would not affect environmental justice within the ROI and hence are not considered in the cumulative effects analysis. These include RFFA 2, reduced agricultural production; RFFA 4, decarbonizing the energy sector with renewable energy sources; and RFFA 11, timber and logging industry operations. These actions would not appreciably affect the physical or environmental health and socioeconomic status of minority communities and would lead to no observable changes to Tribal subsistence and ceremonial fishing activities and recreation; they would not have disproportionately high effects on communities with EJ concerns. Therefore, these RFFAs are not discussed further in this analysis.

### 4.20.2 Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect to environmental justice. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.20.2.1 Construction and/or Modification of Structural Measures*

This section discusses the potential cumulative effects to communities with EJ concerns from the construction and/or modification of the structural measures in combination with applicable cumulative actions. As discussed in Section 3.20.4.3.1, effects from construction and infrastructure modification/improvement activities would lead to short- and medium-term, negligible to minor socioeconomic benefits to minority communities due to creation of employment opportunities and the health benefits associated with employment. The long-term beneficial socioeconomic effects would be negligible.

There would also be negligible to minor adverse effects to the physical health and well-being of minority communities that are hired to work at the sites for the duration of these projects. During the post-construction lifetime of the project, noise, air emissions, and traffic from operation and maintenance activities would be minimal and therefore no long-term effects are anticipated.

Residential development on most of the shores of most of the WVS reservoirs is minimal, including at Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills

Creek, and Lookout Point reservoirs. None of these reservoirs have towns on their shorelines. Detroit, Dexter, Fern Ridge, and Foster reservoirs have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 192 to 10,000. As discussed in Section 3.20.1, the town of Detroit is in Marion County (which was identified as having minority populations with EJ concerns), but the town of Detroit does not qualify as a population with EJ concerns (USCB, 2019s; USCB, 2019t). Lowell and Veneta are in Lane County and Sweet Home is in Linn County, so discussion of disproportionately high impacts from noise disturbances, air emissions, or traffic to these towns from construction measures will be included in a tiered EA or EIS if after using census tracts or census blocks, they are identified as having populations with EJ concerns.

Short- and medium-term negligible to minor effects to Tribal subsistence fishing activities and recreation would occur due to construction-related disturbances to fish species and restricted access to the affected reservoirs; as well as to the physical health of recreators due to increased air emissions. While the implementation of the above measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, the effects would be less adverse than those currently experienced by Tribes from dwindling fish populations in the WRB. These adverse effects would range from minor to major in the long term.

Modifications of existing WVS and other, non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1, future population growth and accompanying urban, industrial, and commercial development; and RFFA 10, mining operations would have similar socioeconomic benefits and adverse health effects on minority populations hired to work on the construction of the proposed structural measures. As such, these additional projects would result in greater effects to communities with EJ concerns overall, compared to the effects described in Section 3.20.4.3.1, but not so great that the magnitude of a particular activity would increase. The cumulative effects to communities with EJ concerns from construction/modification of structural measures in combination with the above-mentioned cumulative actions are described below.

The direct and indirect cumulative socioeconomic effect on minority communities from job creation and the health benefits associated with jobs would be beneficial, additive, negligible to minor in magnitude, and occur in the short-term and medium-term. These long-term beneficial cumulative effects would be negligible in magnitude and additive. Adverse, additive, cumulative effects on the health of communities with EJ concerns hired to work at the project sites would occur in the short-term and medium-term and be negligible to minor in magnitude. Once construction of the projects is complete, no long-term adverse cumulative health effects to workers would occur. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

Modifications of existing WVS structures and other non-USACE structures at Dexter, Big Cliff, and Cougar in combination with the proposed structural measures would have adverse cumulative effects to Tribal subsistence fishing activities and recreation at and near the affected reservoirs. More restricted access to these sites, disturbances to fish species from increased turbidity and suspended sediment transport during construction, and contamination of the harvest in the event of accidental fuel and chemical spills would occur. RFFA 9, climate change, could further exacerbate effects as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. As such, the proposed structural measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar and climate change would have adverse, minor to moderate, additive, cumulative effects in the short and medium term. The implementation of the structural measures at Dexter, Big Cliff, and Cougar would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, but would generally contribute to decreasing the severity of effects of those that are currently experienced by Tribes due to dwindling fish populations in the WRB. As such, additive, cumulative effects to Tribal subsistence fishing would range from minor to moderate in the long term. These effects would be disproportionately high and adverse, but would not be significant.

#### *4.20.2.2 Implementation of Water Management Measures*

This section discusses the potential cumulative effects to communities with EJ concerns from the implementation of water management measures in combination with applicable cumulative actions.

Adverse economic effects associated with drawdowns are discussed at length throughout the socioeconomics section, beginning in Section 3.11.2.4.2 (Alteration of outflows and reservoir levels/Recreational Value), and is summarized briefly here as it applies to populations with EJ concerns. Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. These short- and long-term recurring adverse effects would range from minor to major. The magnitude of effects under each alternative would depend on the number of drawdowns per year and the number of reservoirs at which they would occur. These effects would be adverse and disproportionate to populations with EJ concerns that are located in the county where drawdowns would occur or that are economically dependent on the reservoir where the drawdowns would occur. Disproportionately high and adverse effects that are major in magnitude would be considered a significant effect.

The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are located in Yamhill, Jefferson and Wasco, Wasco, Lincoln, and Lincoln counties (respectively). Drawdowns are not proposed at any of the reservoirs located in the aforementioned counties. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns under all alternatives could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the reservoirs where drawdowns are proposed.

As discussed in 3.20.4.3.2, reservoir drawdowns would result in high rates of sediment transport from the reservoir and high turbidity levels in areas downstream; and cause minor adverse effects to Tribal subsistence fishing activities – in particular to Pacific lamprey – in the short-term and long-term recurring. While it is assumed that the majority of recreationists would forgo visiting the reservoir during drawdowns, those that continue to visit reservoirs during drawdowns would experience adverse and major effects because visually drawdowns would be very noticeable, and would substantially impact the recreational experience – including that of Tribal members. These effects would occur in the short term during the three-week drawdown and recur in the long term.

RFFA 1, future population growth and accompanying urban, industrial, and commercial development; RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; and RFFA 9, climate change would have similar types of effects as or exacerbate effects from the proposed drawdowns and could adversely affect freshwater fish species due to the decrease in water quantity, increase in temperature, and degradation of water quality in streams and rivers throughout the WRB. The human population, which is expected to grow by 37 percent by 2050, would create further developmental pressures on riparian areas and floodplains, leading to their conversion to impervious areas, and generation of greater volumes of effluents and non-point source pollution that heats water bodies and affects water quality. The changing regional and global climate is expected to affect water bodies in the WRB by resulting in changes to the water temperatures, flow regime, hydrology and ecosystem processes, increased exposure of fish to diseases and parasites, and increase in the prevalence of invasive species, thereby leading to changes in population, habitat quality, and distribution of fisheries resources harvested by subsistence communities. Higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would decrease water quality from higher turbidity and increased occurrence of HABs (which would decrease dissolved oxygen (DO) concentrations and could adversely affect fish populations). The effects from RFFA 9, climate change would (in particular) affect the hatching, growth, migration, and survival of fish species in the WVS (Hixon et al. 2010). These cumulative actions would further disrupt subsistence harvest patterns by decreasing the fish species available for harvest, disrupting the seasonality of harvest activities and locations of fishing areas, and inducing stress within or between communities by adversely affecting subsistence resource sharing activities. RFFAs 1, 3, and 9, when considered in tandem with the proposed drawdowns would have additive, adverse, minor cumulative effects on Tribal subsistence fishing in the short term and recur in the long term. These effects to Tribal subsistence fishing would be disproportionately high and adverse, but would not be significant.

RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the proposed drawdowns. RFFA 9 would cause longer and more arid drought seasons and smaller snowpacks, which affect reservoir storage capacity. If reservoir levels are already lower due to low summer flows and long-lasting droughts, RFFA 3 would exacerbate these low levels. Shoreline erosion from low reservoir levels could occur and cause sedimentation and increase turbidity, affecting water color and clarity; RFFA 1 would also contribute to sedimentation and increased turbidity with the conversion of riparian areas and floodplains to impervious surfaces (as discussed above). These cumulative actions would further affect the recreational experience of Tribal members. As such, RFFAs 1, 3, and 9, when considered in tandem with the proposed drawdowns would result in additive, adverse, major cumulative effects on all recreationists, including Tribal recreationists in the short term and recur in the long term. These disproportionately high and major, adverse effects would be considered significant.

RFFA 5, federal and state wildlife and lands management, RFFA 6, fishery management and killer whales, RFFA 7, tribal, state, and local fish and wildlife improvement, and RFFA 8, invasive species management would have benefits similar to those from the proposed water management measures and augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. For example, RFFA 6 and RFFA 7 improve habitat and ecosystem functions, as well as species-specific conservation. One recent project restored a stretch of the Willamette River and provided resting spots for salmon, wetland habitat for wildlife, and fertile floodplains for trees, shrubs, and other plants. As such, RFFAs 5, 6, 7, and 8 would offset some of the adverse effects from RFFAs 1, 3, and 9 described above. However, these RFFAs and the water management measures are not expected to lead to an increase in the availability of salmon, steelhead, or lamprey for Tribal subsistence and ceremonial purposes, but would further reduce the likelihood that the species would be in jeopardy of extinction. Overall, fishing activities would not be restored at traditional sites currently abandoned by the Tribes due to dwindling fish populations. Members of the Tribes would still need to spend as much time and money as they presently do in order to travel to distant fishing sites to secure sufficient quantities of harvest. This would not help ease conflict between competing Tribes that are forced to share specific fishing sites; however, the continued existence of these fish species in the WRB would support the preservation of their cultural practices and pass on their knowledge of traditional fishing methods and customs to their youth. RFFAs 5, 6, 7, and 8 and the implementation of water management measures would not provide adequate food reserves for meetings, celebrations, and subsistence; Tribes would continue to rely on hatchery fish from ODFW facilities. While the implementation of water management measures as well as RFFAs 5, 6, 7, and 8 would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, the effects would be less adverse than those currently experienced by Tribes due to dwindling fish populations in the WRB. As such, cumulative, adverse effects would be additive, minor to moderate in magnitude, and long-term in duration. These effects to Tribal subsistence fishing would be disproportionately high and adverse, but would not be significant.

### *4.20.3* Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to environmental justice.

#### *4.20.3.1 No Action Alternative*

Under the NAA, the current operating conditions of the WVS would continue, including major maintenance and rehabilitation projects and the annual Fall Creek reservoir drawdown. As described above in Section 4.20.2.1, when considered in tandem with cumulative actions that would create jobs (the modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; and RFFA 10, mining operations), major maintenance and rehabilitation projects would create negligible, beneficial, additive, cumulative effects to the socioeconomic conditions of minority communities in the ROI in the short, medium, and long term. The adverse, additive cumulative effects from air quality, noise levels, viewshed, and traffic and transportation conditions to the physical health and well-being of communities with EJ concerns hired to work at the project sites and communities residing in the vicinity of the project locations would be negligible to minor. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

As discussed above in 4.20.2.1, modifications of existing WVS structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, modifications of existing WVS structures at Dexter, Big, Cliff and Cougar and any major maintenance and rehabilitation projects at these locations would have minor and additive cumulative adverse effects to Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative, adverse effects to Tribal subsistence fishing would be major in the long term because measures under the NAA and the modifications of existing WVS structures would continue to not adequately benefit the fish species essential to meet the subsistence and ceremonial requirements of the Tribes in the ROI. These effects are the most adverse and severe in magnitude compared to the other action alternatives. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane County, where the Fall Creek Drawdown occurs. However, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the Fall Creek Reservoir. Given that one drawdown would occur annually in one county, the magnitude of effects would be minor and extent of the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the Fall Creek Drawdown as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. RFFAs 1, 3, and 9, when considered in tandem with the Fall Creek drawdown would have additive, adverse, minor cumulative effects on Tribal subsistence fishing in the short term and recur in the long term. RFFAs 1, 3, and 9, in combination with the Fall Creek drawdown would result in additive, adverse, major cumulative effects on all recreationists, including Tribal recreationists, because visually even lower water levels and even more turbidity would be very noticeable and would substantially impact the recreational experience. These effects would occur in the short term and recur in the long term. These disproportionately high and major, adverse effects to recreation would be considered significant.

#### *4.20.3.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 consists of structural improvements and water management measures which maximize refill volumes of conservation pools at WVS reservoirs in support of improved survival of ESA-listed fish species in addition to other authorized project purposes of the structures. As discussed above in Sections 4.20.2.1, when the proposed structural measures are considered in tandem with the other cumulative actions that would create jobs (i.e., modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10), the cumulative socioeconomic benefit on minority communities would be additive and minor in magnitude in the short and medium term and negligible in the long term. Adverse cumulative effects of construction and infrastructure improvement activities on the health of minority construction workers hired to work at the project sites and neighboring EJ communities would be additive and minor in magnitude, and would be short- to medium- term in duration. No long-term adverse cumulative health effects to workers would occur once construction is complete. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

As discussed above in 4.20.2.1, modifications of existing WVS structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, structural measures under Alternative 1 and modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would have minor to moderate and additive cumulative, adverse effects to Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative effects to Tribal subsistence fishing would be minor to moderate in the long term under Alternative 1. No long-term effects would occur to recreation. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane County, where the Fall Creek Drawdown occurs. While many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the Fall Creek Reservoir. Given that one drawdown would occur annually in one county, the magnitude of effects would be minor and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the Fall Creek Drawdown as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. As such, cumulative effects on Tribal subsistence fishing would be additive, adverse, and minor in the short term and recur in the long term. These effects would be disproportionately high and adverse, but would not be significant.

When the Fall Creek drawdown is considered in tandem with RFFAs 1, 3, and 9, cumulative effects to recreation would be major, adverse, additive, and would occur in the short term and recur in the long term. These disproportionately high and major, adverse effects would be considered significant.

As described above, while the implementation of the proposed measures and the cumulative actions would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be moderate in magnitude and would be additive. These impacts would be disproportionately high and adverse but would not be considered significant.

#### *4.20.3.3 Alternative 2a – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Alternative 2a aims to improve fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to manage water management flexibility and meet ESA-listed fish obligations. As discussed above in Section 4.20.2.1, when the proposed structural measures are considered in tandem with cumulative actions with construction phases that would create jobs (i.e., modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10), the cumulative socioeconomic effects of Alternative 2a on minority communities would be beneficial, additive, and minor in magnitude in the short and medium term and negligible and beneficial in the long term. Adverse cumulative effects of construction and infrastructure improvement activities on the health of minority construction workers hired to work at the project sites and neighboring communities with EJ concerns would be additive and minor in magnitude, and would be short- to medium- term in duration. No long-term adverse cumulative health effects to workers would occur once construction is complete. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

As discussed above in 4.20.2.1, modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, structural measures under Alternative 2a and modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would have minor to moderate and additive, cumulative adverse effects to Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative effects to Tribal subsistence fishing would be minor to moderate in the long term under Alternative 2a. No long-term effects would occur to recreation. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane and Linn counties, where the Fall Creek and Green Peter reservoirs (respectively) are located; and where annual drawdowns are proposed. While many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022) and may be impacted by annual drawdowns at Fall Creek and Green Peter reservoirs. As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the Fall Creek and Green Peter reservoirs. Given that two annual drawdowns would occur at two reservoirs, the magnitude of effects would be minor and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the Fall Creek and Green Peter drawdowns as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. When the Green Peter and Fall Creek drawdowns are considered in tandem with RFFAs 1, 3, and 9, cumulative, additive, and adverse effects would be major on Tribal recreation and minor on Tribal subsistence fishing activities; and would occur in the short term and recur in the long term. Overall impacts to Tribes would be disproportionately high and adverse. Impacts to subsistence fishing would not be considered significant but impacts to recreation would be significant.

As described above, while the implementation of the proposed measures and the cumulative actions would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be moderate in magnitude and would be additive. These impacts would be disproportionately high and adverse but would not be considered significant.

#### *4.20.3.4 Alternative 2b – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2b is similar to Alternative 2a but proposes a slightly different combination of measures at Cougar Dam that are lower in construction expenditures than Alternative 2a. Given their overall similarity, the EJ effects of the measures under Alternative 2b are very similar to Alternative 2a and are affected by the same mechanisms discussed in Section 3.20.4.6.

As discussed above in Section 4.20.2.1, when the proposed structural measures are considered in tandem with the other cumulative actions that would create jobs (i.e., modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10), the cumulative socioeconomic benefits of Alternative 2b on minority communities would be additive and minor in magnitude in the short and medium term and negligible in the long term. Adverse cumulative effects of construction and infrastructure improvement activities on the health of minority construction workers hired to work at the project sites and neighboring communities with EJ concerns would be additive and minor in magnitude, and would be short- to medium- term in duration. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, structural measures under Alternative 2b and modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would have minor to moderate and additive, cumulative adverse effects to Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative effects to Tribal subsistence fishing would be minor to moderate in the long term under Alternative 2b. No long-term effects would occur to recreation. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane and Linn counties, where the Fall Creek, Green Peter, and Cougar reservoirs are located – and where annual drawdowns are proposed. While many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022) and may be impacted by annual drawdowns at Fall Creek, Green Peter, and Cougar reservoirs. As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the Fall Creek, Green Peter, and Cougar reservoirs. Given that three annual drawdowns would occur at three reservoirs, the magnitude of effects would be moderate and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the Fall Creek, Cougar, and Green Peter drawdowns as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. Drawdown-related impacts would be slightly greater for Alternative 2b compared to Alternative 2a due to an additional drawdown at Cougar, but overall cumulative effects would be the same. When the Cougar, Green Peter, and Fall Creek drawdowns are considered in tandem with RFFAs 1, 3, and 9, cumulative, additive, and adverse effects would be major on Tribal recreation and minor on Tribal subsistence fishing activities; and would occur in the short term and recur in the long term. Overall impacts to Tribes would be disproportionately high and adverse. Impacts to subsistence fishing would not be considered significant but impacts to recreation would be significant.

As described above, while the implementation of the proposed measures and the cumulative actions would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be moderate in magnitude and would be additive. These impacts would be disproportionately high and adverse but would not be considered significant.

#### *4.20.3.5 Alternative 3a – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Alternative 3a focuses on modifying operations rather than storage or structural measures to improve the survival of ESA-listed fish species. As discussed above in Sections 4.20.2.1, when the proposed structural measures (comparatively fewer, especially when compared to Alternatives 1 and 4) are considered in tandem with the other cumulative actions that would create jobs (i.e., modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10, mining operations), the cumulative socioeconomic benefits of Alternative 3a on minority communities would be additive and negligible in the short, medium, and long term. Adverse cumulative effects of construction and infrastructure improvement activities on the health of neighboring communities with EJ concerns would be additive and negligible in magnitude. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

As discussed in 4.20.2.1, modifications of existing WVS structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, structural measures under Alternative 3a and modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would have minor and additive effects on Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative effects to Tribal subsistence fishing would be minor in the long term under Alternative 3a. No long-term effects would occur to recreation. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. Minority populations with EJ concerns in Marion County could experience disproportionate and adverse effects associated with the fall and spring drawdowns at Detroit Reservoir. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are located in Yamhill, Jefferson and Wasco, Wasco, Lincoln, and Lincoln counties (respectively). Drawdowns are not proposed at any of the reservoirs located in the aforementioned counties. While many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the seven reservoirs where drawdowns are proposed, though drawdowns would not occur at any of the reservoirs located in counties encompassing Tribal reservations. Given that a total of ten drawdowns would occur at seven reservoirs, the magnitude of effects would be major and the extent would likely be large under this alternative, occurring in all the counties in the WVS. These disproportionately high and major, adverse effects would be considered significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from drawdowns as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. Drawdown-related impacts would be greatest under Alternative 3a (and 3b, discussed below) compared to the other alternatives due to the ten drawdowns across seven reservoirs. When the ten drawdowns are considered in tandem with RFFAs 1, 3, and 9, cumulative, additive, and adverse effects would be major on Tribal recreation and minor on Tribal subsistence fishing activities; and short-term and long-term recurring. Overall impacts to

Tribes would be disproportionately high and adverse. Impacts to subsistence fishing would not be considered significant but impacts to recreation would be significant.

As described above, while the implementation of the proposed measures and the cumulative actions would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Adverse, cumulative effects under Alternative 3a (and Alternative 3b, discussed below) would be the least severe in the long term due to the number of drawdowns and the associated benefits to ESA-listed fish. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be minor in magnitude and would be additive. These effects would be disproportionately high and adverse, but would not be significant.

#### *4.20.3.6 Alternative 3b – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Alternative 3b is similar to Alternative 3a but differs primarily in the downstream passage measures. Given their overall similarity, the EJ impacts of the measures under Alternative 3b are very similar to Alternative 3a and are affected by the same mechanisms discussed in Section 3.20.2.3.

As discussed above in Sections 4.20.2.1, when the proposed structural measures (similar to 3a but comparatively fewer, especially when compared to Alternatives 1 and 4) are considered in tandem with the other cumulative actions that would create jobs (i.e., modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10, the cumulative socioeconomic benefits on minority communities would be additive and negligible in the short, medium, and long term. Adverse cumulative effects of construction and infrastructure improvement activities on the health of neighboring communities with EJ concerns would be additive and negligible in magnitude. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

As discussed in 4.20.2.1, modifications of existing WVS structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, structural measures under Alternative 3b and modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would have minor and additive effects on Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative effects to Tribal subsistence fishing would be minor in the long term under Alternative 3b. No long-term effects would occur to recreation. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. Minority populations with EJ concerns in Marion County could experience disproportionate and adverse effects associated with the fall and spring drawdowns at Detroit Reservoir. Drawdowns are not proposed at any of the reservoirs located in the counties where Tribal reservations occur (Yamhill, Jefferson, Wasco, and Lincoln counties); however, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the seven reservoirs where drawdowns are proposed. Given that a total of ten drawdowns would occur at seven reservoirs, the magnitude of effects would be major and the extent would likely be large under this alternative, occurring in all the counties in the WVS. These disproportionately high and major, adverse effects would be considered significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from drawdowns as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. Drawdown-related impacts would be greatest under Alternative 3b (and 3a, discussed above) compared to the other alternatives due to the ten drawdowns across seven reservoirs. When the ten drawdowns are considered in tandem with RFFAs 1, 3, and 9, cumulative, additive, and adverse effects would be major on Tribal recreation and minor on Tribal subsistence fishing activities; and short-term and long-term recurring. Overall impacts to Tribes would be disproportionately high and adverse. Impacts to subsistence fishing would not be considered significant but impacts to recreation would be significant.

As described above, while the implementation of the proposed measures and the cumulative actions would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Adverse, cumulative effects under Alternative 3b (and Alternative 3a, discussed above) would be the least severe in the long term due to the number of drawdowns and the associated benefits to ESA-listed fish. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be minor in magnitude and would be additive. These effects would be disproportionately high and adverse, but would not be significant.

#### *4.20.3.7 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

Alternative 4 consists almost entirely of structural improvements which increase stream flows and enhance fish passage in support of improved survival of ESA-listed fish species, and is very similar to Alternative 1. As discussed above in Sections 4.20.2.1, when the proposed structural measures are considered in tandem with the other cumulative actions that would create jobs (i.e., modifications of existing WVS structures and non-USACE structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10), the cumulative socioeconomic benefit of Alternative 4 on minority communities would be additive and minor in magnitude in the short and medium term and negligible in the long term. Adverse cumulative effects of construction and infrastructure improvement activities on the health of minority construction workers hired to work at the project sites and neighboring communities with EJ concerns would be additive and minor in magnitude, and would be short- and medium-term in duration. No long-term adverse cumulative health effects to workers would occur once construction is complete. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

As discussed above in 4.20.2.1, modifications of existing WVS structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, structural measures under Alternative 4 and modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would have minor to moderate and additive cumulative, adverse effects to Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative effects to Tribal subsistence fishing would be minor to moderate in the long term under Alternative 1. No long-term effects would occur to recreation. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane County, where the Fall Creek Drawdown occurs. While many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the Fall Creek Reservoir. Given that one drawdown would occur annually in one county, the magnitude of effects would be minor and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the Fall Creek Drawdown as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. As such, cumulative effects on Tribal subsistence fishing would be additive, adverse, and minor in the short term and recur in the long term. When the Fall Creek drawdown is considered in tandem with RFFAs 1, 3, and 9, cumulative effects to recreation would be major, adverse, additive, and would occur in the short term and recur in the long term. Overall impacts to Tribes would be disproportionately high and adverse. Impacts to subsistence fishing would not be considered significant but impacts to recreation would be significant.

As described above, while the implementation of the proposed measures and cumulative actions would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be moderate in magnitude and would be additive. These effects would be disproportionately high and adverse, but would not be significant.

#### *4.20.3.8 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 would only differ from Alternative 2b by way of the refined integrated temperature management and habitat flow regime measure (#30b), which is not a measure that would have effects on environmental justice. Therefore, the effects of Alternative 5 would be identical to those of Alternative 2b.

As discussed above in Sections 4.20.2.1, when the proposed structural measures are considered in tandem with the other cumulative actions that would create jobs (i.e., modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10), the cumulative socioeconomic benefits of Alternative 5 on minority communities would be additive and minor in magnitude in the short and medium term and negligible in the long term. Adverse cumulative effects of construction and infrastructure improvement activities on the health of minority construction workers hired to work at the project sites and neighboring communities with EJ concerns would be additive and minor in magnitude, and would be short- to medium- term in duration. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns would be disproportionately high, but would not be significant.

As discussed in 4.20.2.1, modifications of existing WVS structures at Dexter, Big Cliff, and Cougar could further restrict access to subsistence fishing and recreation activities, disturb fish species from increased turbidity and suspended sediment transport during construction, and contaminate the harvest if accidental fuel and chemical spills occur. As such, structural measures under Alternative 5 and modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would have minor to moderate and additive, cumulative adverse effects to Tribal subsistence fishing and recreation in the short and medium term. Additive, cumulative effects to Tribal subsistence fishing would be minor to moderate in the long term under Alternative 5. No long-term effects would occur to recreation. These effects would be disproportionately high and adverse, but would not be significant.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane and Linn counties, where the Fall Creek, Green Peter, and Cougar reservoirs are located – and where annual drawdowns are proposed. As such, drawdowns could adversely and disproportionately affect Tribal members throughout the WVS that are economically dependent on the Fall Creek, Green Peter, and Cougar reservoirs. Given that three annual drawdowns would occur at three reservoirs, the magnitude of effects would be moderate and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

As discussed above in 4.20.2.2, RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the Fall Creek, Cougar, and Green Peter drawdowns as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. When the Cougar, Green Peter, and Fall Creek drawdowns are considered in tandem with RFFAs 1, 3, and 9, cumulative, additive, and adverse effects would be major on Tribal recreation and minor on Tribal subsistence fishing activities; and would occur in the short term and recur in the long term. Overall impacts to Tribes would be disproportionately high and adverse. Impacts to subsistence fishing would not be considered significant but impacts to recreation would be significant.

As described above, while the implementation of the proposed measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be moderate in magnitude and would be additive. These effects would be disproportionately high and adverse, but would not be significant.

### *4.20.4* Summary

The cumulative actions that would create jobs during construction phases (i.e., modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; transportation corridor development; RFFA 1; and RFFA 10) would have similar adverse and beneficial socioeconomic and health effects on communities with EJ concerns, including Tribes as the proposed structural measures. Cumulative effects would range from negligible to minor in the short and medium-term and be most severe for Alternatives 1 and 4, and least severe for Alternatives 3a and 3b since the greatest number of construction/structural measures would be implemented under Alternatives 1 and 4. Beneficial socioeconomic effects and adverse health effects on communities with EJ concerns, including Tribes, would be disproportionately high, but would not be significant.

RFFAs 1, 3, and 9 would have similar types of visual effects as or exacerbate effects from the drawdowns as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. Cumulative effects from the implementation of water management measures, in particular reservoir drawdowns, in combination with RFFAs 1, 3, and 9 would be most severe for Alternatives 3a and 3b, followed by Alternative 2a, 2b, and5, and least severe for Alternatives 1 and 4. Major and adverse cumulative effects to Tribal recreation would occur under all alternatives in the short-term and recur in the long-term because visually lower water levels and increased turbidity would be very noticeable, and would substantially impact the recreational experience.

Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. As such, drawdowns could adversely and disproportionately affect minority communities and Tribal members throughout the WVS that are economically dependent on the impacted reservoirs. Ten annual drawdowns would occur at seven reservoirs for alternatives 3a and 3b and as such, the magnitude of effects would be major and the extent would likely be large these two alternatives, occurring in all the counties in the WVS. These effects would be disproportionately high and adverse, and would be considered significant for these two alternatives. For all other alternatives, impacts from drawdowns would be less pronounced and would not be considered significant.

While the implementation of the proposed measures under any of the alternatives and the cumulative actions would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Though beneficial effects from the effective implementation of RFFAs 5, 6, 7, and 8 could offset some of the adverse effects from RFFAs 1, 3, and 9, these are not expected to change the severity of adverse effects. Overall, long-term adverse cumulative effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude; and be the least adverse under Alternatives 3a and 3b. These effects would be disproportionately high and adverse, but would not be significant.

## 4.21 CULTURAL RESOURCES

### 4.21.1 Cumulative Effects Analysis Methodology for Cultural Resources

#### *4.21.1.1 Cumulative Actions Applicable to Cultural Resources*

Past, present, and RFFAs that, when considered together with the Proposed Action and alternatives, would have cumulative effects on Cultural Resources, include:

- WVS Dams and Reservoirs: construction and past operations and maintenance (see section 4.2.1.1).
- WVS Dams and Reservoirs: ongoing operations and maintenance (see section 4.2.2).
- RFFA 1: Future population growth and accompanying urban, industrial, and commercial development.
- RFFA 5: Federal and state wildlife and lands management.
- RFFA 7: Tribal, state, and local fish and wildlife improvement.
- RFFA 9: Climate change.
- RFFA 10: Mining operations.
- RFFA 11: Timber and logging industry operations.

See Tables 4.21-1 and 4.21-2 for description of the cumulative impacts to Cultural Resources.

**Table 4.21-1. Summary of Past and Present Actions Relevant to Cultural Resources**

| Action | Description | Cumulative Impact Description |
|---|---|---|
| Past | WVS Dams and Reservoirs: construction and past operations and maintenance | Activities related to construction and the 50-80 years of fill and drawdown cycle of the reservoir resulted in additive, major, and adverse effects to archaeological sites through disturbance, erosion, and exposure, and traditional cultural properties through reduced and restricted access to tribal members and actions that have impacted habitat and water quality as well as destruction of archaeological sites that are part of traditional cultural properties.<br><br>It also resulted in the construction of the WVS which is composed of 13 historic districts. Management and operations have been mostly beneficial through retainment of historic fabric of the 13 historic districts. Some modification or removal of some contributing resources in the past have had minor adverse cumulative effects. |

| Action | Description | Cumulative Impact Description |
|---|---|---|
| Present | WVS Dams and Reservoirs: ongoing operations and maintenance | Continued draft and fill cycle is an irreversible, additive and incremental adverse cumulative effect to archaeological sites due to active erosion and exposure.<br><br>Actions that support improved habitat and water quality would have beneficial impacts to traditional cultural properties. The continued existence of the WVS restricts and reduces tribal access to traditional cultural properties which is a major adverse cumulative impact that is potentially reversible.<br><br>Current operations to not include additions or modifications to the historic built environment, which is a beneficial cumulative effect. |

**Table 4.21-2. Summary of Reasonably Foreseeable Future Actions (RFFA) Relevant to Cultural Resources**

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| RFFA 1 | Future population growth and urban, industrial, and commercial development | Adverse effect to archaeological sites due to increased looting, traditional cultural properties through competition for access and resources important to Indian tribes and built resources that experience degradation due to increased visitor use. |
| RFFA 5 | Federal and State Wildlife and Lands Management | Varies, could be beneficial or adverse depending on management action. |
| RFFA 7 | Tribal, State, and local fish and wildlife improvement | Varies, could be beneficial or adverse depending on improvement action. |
| RFFA 9 | Climate change | Adverse effect due to increased winter precipitation that erodes archaeological sites, reduced water levels in the summer that expose archaeological sites, both would increase looting and vandalism to archaeological sites. Adverse effect to traditional cultural properties through reduced/degraded water quality and habitat of species important to Indian tribes. Wildfire would negatively affect all types of cultural resources. |
| RFFA 10 | Mining operations | Localized to mining operation, direct adverse effects to archaeological sites (erosion) and traditional cultural properties downstream habitat and water quality degradation), but unlikely to affect built resources. |
| RFFA 11 | Timber and logging industry operations | Direct effects localized to logging unit, where ground disturbance can negatively affect archaeological sites, but indirect effects could negatively affect viewshed of 13 historic districts (built resources) and traditional cultural properties on decadal scale. Indirect effects would be temporary. |

Some of the other RFFAs discussed in section 4.2.3 would not occur at or in close proximity to the WVS dams and reservoirs and as such would not have a cumulative effect on Cultural Resources located in the WVS. (Had they occurred at or in close proximity to the WVS dams and reservoirs, they would have contributed to cumulative effects for Cultural Resources).

- RFFA 2: Future agricultural development.
- RFFA 3: Water withdrawals for municipal, industrial, and agricultural uses.
- RFFA 4: Decarbonizing the energy sector with renewable energy sources.
- RFFA 6: Fishery management and Killer Whales.
- RFFA 8: Invasive species management.

Therefore, these RFFAs are dismissed from further analysis.

### 4.21.2 Cumulative Effects to Cultural Resources by Alternative

Construction of the Willamette Valley dams and reservoirs has had major adverse irreversible effects to cultural resources in the WVS. The clearing of large swaths of timbered land directly impacted archaeological sites through logging practices that caused major ground disturbance and damaged the physical integrity of the archaeological sites. The rerouting of historic infrastructure (roads and railways) and the building of new linear infrastructure also disturbed archaeological sites through major ground disturbance. These actions impacted historic buildings, roads, trails, etc., that were present prior to construction of the WVS. The building of the dams and reservoirs displaced several historic communities (such as Old Detroit, Hebron, Lowell, Dorena, and Winberry) and rural homesteads spread throughout the six subbasins. In general, construction of the WVS directly and adversely impacted archaeological sites through major ground disturbance on a massive scale (thousands of acres per each of the 13 WVS projects), and greatly changed the historic nature of the pastoral or timbered landscape of rural Oregon. These historic communities and homesteads, many of which were Donation Land Claims, were deeply connected to the development of the State of Oregon. The eventual filling and use of the 13 reservoirs further directly adversely affected cultural resources through submersion and disruption of the recently disturbed sediments (from timber clearing, road building, etc.). Tribal individuals and communities lost access to portions of their usual and accustomed areas and the landscape that existed prior to construction of the WVS that today would be identified as a landscape of traditional cultural properties.

The construction of the WVS ultimately created another series of cultural resources – the built environment of the 13 historic districts that comprise the WVS. The past operations have retained much of the historic fabric of the WVS dams and reservoirs, constructed between 1940 and 1969, and Corps management of this aspect of the WVS infrastructure has been immensely beneficial. Other historic infrastructure has been neglected, such as old engineering offices, or removed, such as non-functioning gantry cranes, and these are minor to moderate adverse effects to elements that contribute to the aesthetic of the historic districts.

The past annual cycles of drawdown and fill of the reservoirs, occurring over 50 to 80 years depending on the Project, has had major direct adverse effects to cultural resources that are located within or overlap with the reservoir as discussed in section 3.21. This action has created an annual cycle of erosion that incrementally destroys the physical integrity of sites and exposure that increases each site's vulnerability to illicit collection and other forms of human-caused destruction. The annual cycles of erosion and exposure have caused incremental impacts that have had major cumulative impacts over the last five to eight decades and these impacts are irreversible and additive. Archaeological sites cannot be remade, refurbished, or reconstructed once any part of the physical makeup is disturbed. Current operations include annual drawdown and fill of the reservoirs, which continues to have major direct adverse effects to archaeological sites in and around the reservoirs. As discussed in section 3.21.3.3.1, several near-term operations would have direct adverse effects from deep drawdowns at several of the reservoirs and operations that would result in reservoir elevation change, both that will increase erosion and exposure of archaeological sites. The built environment would also be directly adversely affected by structural modifications and additions that change the historic fabric of the 13 historic districts of the WVS.

Future population growth, urban, industrial, and commercial development (RFFA 1) may cause direct adverse effects due to an increase in the number of people who recreate at the 13 reservoirs. This would result in an uptick of illicit collection when archaeological sites are exposed during low water levels and damage from other human impacts such as unauthorized vehicle use in the reservoirs. The continued illicit removal of artifacts from archaeological sites is irreversible and additive. Increased population would also result in more resource extraction in the WVS that could lead to direct effects from actions such as mineral extraction, logging operations, floodplain development, and dredging and sediment management. Increased use of the WVS could also adversely affect traditional cultural properties by creating competition for access to locations and resources important to Indian tribes. Built resources, particularly those at recreation sites, may experience heavier use and related degradation that would directly and adversely impact the aspects that qualify them as contributing to the 13 historic districts.

Federal and State Wildlife and Land Management (RFFA 5) may have adverse or beneficial direct and indirect effects to Cultural Resources in the WVS. This is dependent on how resources and lands are managed. If the result is to stabilize landscapes through encouraging native vegetation, this would be directly beneficial to archaeological sites that would have reduced exposure and visibility to people who may illegally collect artifacts. It would also have the indirect result of improving the aesthetics and viewshed of places that are important to Indian tribes. If the result is to return a waterway to pre-dam conditions and required the removal of historic built environment or ground disturbance that impacts archeological sites, this could have direct adverse effects to cultural resources. Management actions that improve tribal access to usual and accustomed areas as well as habitat and environment, this would have beneficial effects on traditional cultural properties (even if built resources and archaeological sites are adversely impacted).

Tribal, state, and local fish and wildlife improvement (RFFA 7) may be beneficial to some cultural resources for the same reasons discussed for RFFA 5. Management strategies that prioritize habitat improvement and water quality benefit tribal communities and places identified as traditional cultural properties. However, these actions have the potential to negatively affect the built environment and archaeological sites that may be removed or damaged by ground-disturbing aspects of conservation and restoration efforts.

Climate Change (RFFA 9) would have negative direct effects to cultural resources, as discussed in section 3.21. Notable impacts would include more winter rains that would increase erosion of exposed reservoir beds and cause instability to archaeological components. This would also expose more artifacts to illicit collection. Less water in the summer would cause similar issues for sites by leaving more reservoir bed exposed when people are flocking to shoreline recreation sites and would have easy access to exposed non-vegetated reservoir beds. Increased wildfires are a major negative direct impact to WVS cultural resources. Fires destabilize soils and denude forests which cause erosion at archaeological sites. Reduced vegetation also increases visibility of archaeological sites and leaves them vulnerable to illicit collection. Changes to landscape also could lead to greater high-water events that weaken soils and increase erosion and channel incision both negatively directly affecting cultural resources. Unchecked wildfire (as opposed to controlled burns) destroys habitat and creates unsafe wilderness that reduces tribal access to traditional cultural properties.

Mining operations (RFFA 10) have the potential to directly and indirectly adversely affect cultural resources when they occur within the WVS. Operations that disturb soils along the banks cut into existing archaeological sites as well as create unstable banks that are more likely to erode and would indirectly affect archaeological sites downstream from the mining operations.

Timber and logging industry operations (RFFA 11) are declining in western Oregon and low in the Willamette Valley when compared to other western Oregon physiographic provinces. However, many of the WVS dams and reservoirs are located in timber country and surrounded by private timber company inholdings and the Willamette National Forest, and the agency actively manages the forests for timber products and fire reduction. Timber operations that occur near or in the WVS have the potential to directly and indirectly negatively affect archaeological sites through ground disturbance, soil instability, and water runoff in newly unvegetated areas. They can also create indirect effects through modification of the forested viewshed (as can mining operations). While the WVS is a human constructed entity, the 13 Projects are nestled into pastoral or timbered landscapes, and they are places where people go to recreate and enjoy the natural setting. This aesthetic is important to the appeal of the 13 historic districts. The impacts to the viewshed, however, are temporary, though they may last several decades. Noise from these operations would be another potential indirect effect that could adversely affect the aesthetic of the historic environment.

The following considers the effects of the proposed alternatives and cumulative actions outlined in Chapter 4 on Cultural Resources. The discussion is organized by resource type: archaeological sites, traditional cultural properties, and built resources.

#### *4.21.2.1 No Action Alternative*

The No Action Alternative (NAA) maintains an annual draft and fill cycle that has major direct irreversible adverse effects to 80% of archaeological sites documented in the WVS, as discussed in section 3.21. This draft and fill erodes archaeological sites that overlap with the reservoirs and exposes these sites to illicit collection and other human-caused damage. RFFA 1 and 9 would have additive, major, and adverse effects to archaeological sites. Archaeological sites in the WVS have already experienced major irreversible impacts from the construction of the WVS dams and reservoirs and have experienced five to eight decades of draft and fill cycles. Increased recreation at the WVS will further exacerbate looting and illicit collection that degrades the integrity of archaeological sites. Climate change that results in increased erosion of reservoir beds in the winter and increased exposure of reservoir beds in the spring and summer will have similar impacts. The deep drawdowns at Fall Creek continue to increase the erosion and exposure of archaeological sites present at this reservoir.

Traditional cultural properties are not well documented in the WVS, but it is assumed that they are present given the lengthy habitation of the Willamette Valley by indigenous communities as discussed in section 3.21. The construction and continued operation of the WVS has had major direct adverse effects to traditional cultural properties including archaeological sites, habitat, and water quality as well as reduced and restricted access to the lands that now comprise the WVS. The cumulative effects of past and present actions and RRFAs 1 and 10 are major and adverse. There is potential to reverse some of these negative effect through management actions that improve habitat, water quality, and access to them by tribal communities. Potentially, RFFAs 5 and 7 would have beneficial effects to traditional cultural properties, but with RFFA 1 and 10 tribal communities may be forced to compete for access and resources as more people move into the Willamette Valley. The archaeological components of traditional cultural properties cannot be rehabilitated, but increased access by tribal members would provide a beneficial cumulative effect. RFFA 10 and 11, which would adversely impact the viewsheds of traditional cultural properties, have the potential to cause minor to moderate cumulative impacts. The existence of the WVS has already significantly directly and indirectly impacted traditional cultural properties in the six sub-basins, so continued resource extraction would not greatly increase the negative effects.

No new construction or modification to the 13 historic districts is considered under the NAA, but increased visitor use and resource extraction (RFFA 10 and 11) have the potential to directly and indirectly impact historic recreation sites that are present in the WVS. Over time, this could result in minor to moderate adverse cumulative effects, but these could be minimized or reversed through maintenance plans and recreation management plans that prioritize maintaining the historic aesthetic and viewshed of the WVS.

#### *4.21.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 and the NAA both follow a rule curve that includes an annual draft and fill cycle of WVS reservoirs and a deep drawdown at Fall Creek. Alternative 1 combined with past, present, and reasonably foreseeable actions would have similar direct, indirect, and cumulative effects to archaeological sites and traditional cultural properties as the NAA. For archaeological sites, the cumulative effects are major, additive, irreversible, and adverse. For traditional cultural properties, the cumulative effects vary from beneficial to adverse, but most are potentially reversible with the exception of the destruction of archaeological sites that may be part of traditional cultural properties, as described for the NAA (preceding section).

Alternative 1 deviates from the NAA in the management of built resources, which includes structural modifications to seven of the historic districts including Fern Ridge, Dexter, Lookout Point, Cougar, Foster, Green Peter, and Detroit and would have moderate to major direct effects. Overall, the cumulative effects do not increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

#### *4.21.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Like the NAA and Alterative 1, Alternative 2A follows a rule curve that results in one major cycle of draft and fill per water year, which has major direct irreversible adverse effects to archaeological resources. Alternative 2A proposes a deep fall drawdown at Green Peter (780 feet) and Fall Creek as opposed to just Fall Creek (with the NAA and Alternative 1). This would increase negative erosion and exposure of archaeological sites that will occur at two reservoirs. Similar to the NAA and Alternative 1, the cumulative effects of past, present, and reasonably foreseeable actions combined with Alternative 2A will be additive, major, and adverse to archaeological sites.

Traditional cultural properties would have similar and varying cumulative impacts as described in the NAA and Alternative 1 sections. Built resource cumulative impacts would be similar to those described for Alternative 1 but occur at six projects (rather than seven as in Alternative 1) including Dexter, Lookout Point, Cougar, Foster, Green Peter, and Detroit.

#### *4.21.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Like the NAA and Alterative 1, Alternative 2A follows a rule curve that results in one major cycle of draft and fill per water year, which has major direct irreversible adverse effects to archaeological resources. Alternative 2A proposes a deep fall drawdown at Green Peter (780 feet) and Fall Creek as opposed to just Fall Creek (with the NAA and Alternative 1). This is an increase in negative erosion and exposure of archaeological sites that will occur at two reservoirs. Similar to the NAA and Alternative 1, the cumulative effects of past, present, and reasonably foreseeable actions combined with Alternative 2A will be additive, major, and adverse to archaeological sites.

Traditional cultural properties will be similarly cumulatively impacted as described in the NAA and Alternative 1 sections. Built resource cumulative impacts would be similar to those described for Alternative 1 and occur at the same six reservoirs listed in Alternative 2A.

#### *4.21.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

The NAA, Alternative 1, Alternative 2A, Alternative 2B, and Alternative 3A have an annual cycle of draft and fill of the reservoirs, which have direct, irreversible, adverse effects to archaeological sites. Alternative 3 would strongly accelerate major direct adverse effects to archaeological sites with proposed deep drawdowns at six reservoirs including Blue River, Hills Creek, Green Peter, Detroit, Lookout Point, and Cougar. Alternative 3 combined with past, present, and reasonably foreseeable actions would have the greatest adverse additive impacts to archaeological sites.

Traditional cultural properties would likely have adverse cumulative effects that are greater than those described in the NAA, Alternative 1, Alternative 2A, and Alternative 2B, but this resource type is not well documented in the WVS and cannot be fully discussed other than to note that there are tradeoffs to measures that negatively affect archaeological sites that are part of traditional cultural properties but would benefit habitat and water quality.

Alternative 3A would have less adverse cumulative effects to built resources than Alternative 1, Alternative 2A, and Alternative 2B, but more than the NAA. Modifications would occur at four of the historic districts including Hills Creek, Cougar, Blue River, and Green Peter.

#### *4.21.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Alterative 3B shares similarities with 3A, but is quite different from the NAA, Alternative 1, Alternative 2A, and Alternative 2B. Fall deep drawdowns are proposed for the same six reservoirs including Blue River, Hills Creek, Green Peter, Detroit, Lookout Point, and Cougar. Spring deep drawdowns, however, are proposed at Hills Creek, Cougar, and Green Peter. In both of these alternatives, Cougar will have a spring and fall deep drawdown. In Alternative 3B, the fall deep drawdown will pass through the diversion tunnel. Like Alternative 3A, these actions will have major irreversible direct adverse effects to archaeological sites, more so than the NAA, Alternative 1, Alternative 2A, and Alternative 2B. Severe additive and adverse cumulative impacts to archaeological sites would occur with Alternatives 3A and 3B.

There would likely be greater adverse cumulative effects to traditional cultural properties (TCPs) than those described in the NAA, Alternative 1, Alternative 2A, and Alternative 2B, and similar to those that would occur with Alternative 3A. However, this resource type is not well documented in the WVS and cannot be fully discussed other than to note that there are tradeoffs to measures that negatively affect archaeological sites that are part of traditional cultural properties but would benefit habitat and water quality.

Alternative 3B would have less adverse cumulative effects to built resources than Alternative 1, Alternative 2A, and Alternative 2B, more than the NAA, and similar to Alternative 3A. Modifications would occur at the same four of the historic districts including Hills Creek, Cougar, Blue River, and Green Peter.

#### *4.21.2.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Alternative 4 follows a rule curve that results in one major cycle of draft and fill per water year and is similar to Alternative 1 in regard to impacts to archaeological resources. The impacts are also similar to the NAA. Alternative 4, however, does not propose any deep drawdowns or spring spills over the spillway, which differs greatly from Alternative 2A, Alternative 2B, Alternative 3A, and Alternative 3B. Rather this alternative focuses heavily on structure-based measures to accomplish downstream fish passage. As with the NAA, the WVS cycle of draft and fill will continue to greatly, directly, irreversibly, and adversely affect 369 (80%) of the archaeological sites present in the WVS.

Cumulative impacts to traditional cultural properties are anticipated to be similar to those described in the NAA and Alternative 1, and less impactful than Alternatives 2A, 2B, 3A, and 3B that would have greatly increased adverse effects to archaeological sites.

Alternative 4 would cause the most direct adverse effects to built resources including seven historic districts: Dexter, Lookout Point, Hills Creek, Cougar, Foster, Big Cliff, and Detroit with the exception of Alternative 1. All of the other alternatives would have some adverse impact to built resources except the NAA which does not propose any modifications to the built environment.

#### *4.21.2.8 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar Drawdown to Diversion Tunnel)*

Alternative 5 and all of the other alternatives follow a rule curve that results in one major cycle of draft and fill per water year, which has major direct irreversible adverse effects to archaeological resources. Alternative 5 proposes a deep fall drawdown at Green Peter (780 feet) and Fall Creek as opposed to just Fall Creek (with the NAA and Alternative 1). This is an increase in negative erosion and exposure of archaeological sites that will occur at two reservoirs. Similar to the NAA and Alternative 1, the cumulative effects of past, present, and reasonably foreseeable actions combined with Alternative 2A will be additive, major, and adverse to archaeological sites.

Traditional cultural properties would have cumulative impacts similar to those described in the NAA and Alternative 1 sections. Built resource cumulative impacts would be similar to those described for Alternative 1 and occur at the same six reservoirs listed in Alternative 2A.

## 4.22 VISUAL RESOURCES

This section discusses the cumulative effects on visual resources. This includes a discussion of the effects of proposed measures considered alongside applicable cumulative actions, and how each project alternative would cumulatively affect visual resources. The geographic scope for visual resources would be the same boundary as described in the Affected Environment in Chapter 3, which includes the nine project locations of Lookout Point, Detroit, Green Peter, Hills Creek, Dexter, Cougar, Blue River, Foster, and Fall Creek Dams within the WRB.

### 4.22.1 Cumulative Actions Applicable to Visual Resources

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects on visual resources, include:

- Construction of the WVS dams and supporting structures;
- Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar;
- Water quality management;
- Transportation corridor development;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 3, water withdrawals for municipal, industrial, and agricultural uses;
- RFFA 4, decarbonizing the energy sector with renewable energy sources;
- RFFA 5, federal and state wildlife and lands management;
- RFFA 7, tribal, state, and local fish and wildlife improvement; and
- RFFA 9, climate change.

Some of the other RFFAs discussed in Section 4.2.3 would not have a cumulative effect on visual resources. These include RFFA 6, fishery management and killer whales; and RFFA 8, invasive species management. These actions do not contribute to visual resources; thus, these RFFAs are not discussed further in this cumulative effects analysis. Other RFFAs could have contributed to cumulative effects for visual resources had they occurred at or in closer proximity to the WVS dams and reservoirs. These include RFFA 2, reduced agricultural production; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations. Agricultural lands, mining operations, and timber and logging operations are not visible within the viewshed of project locations, and there are no planned projects or projected changes for the foreseeable future. Therefore, these RFFAs are not discussed further in this cumulative effects analysis. Renewable energy structures only include hydropower from the existing dams and supporting structures as described in Chapter 3; there are no proposed renewable energy projects within the counties representing the WRB.

### 4.22.2 Discussion of Cumulative Effects by Measure(s)

This section considers the proposed measures with applicable cumulative actions to determine the potential cumulative effect to visual resources. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.22.2.1 Construct water temperature control (WTC) towers (#105), Construct structural downstream fish passage (#392), and Construct adult fish facilities (AFFs) (#722)*

As discussed in Section 3.22.4.3.1, the magnitude of adverse effects from the construction of WTC towers (#105), structural downstream fish passages (#392), and AFFs (#722) would be minor in the short, medium, and long term, as these structures would be seen but would not attract attention and would not dominate the landscape.

Land management (e.g., chemical and mechanical treatments to vegetation, tree-trimming activities), fish and wildlife management (e.g., removing a series of gravel pits and barriers acting as levees and allowed the river to return to its natural, free-flowing state), and water quality management (e.g., monitoring water quality, water levels, and water uses) would have the same short-term, adverse effects as the construction of structural downstream fish passages and adult fish facilities. Work vehicles, machinery, and building materials similar to those used for the proposed measures would likely be used for the cumulative actions, and would be visible during the duration of the construction phase. As such, short- and medium-term, cumulative effects would be minor, additive and adverse. In the long term, these activities would generally align with the class management objectives and contribute to retaining or partially retaining the existing character of the landscape. Long-term, cumulative effects would be minor, countervailing and beneficial.

Modifications of existing WVS structures at Dexter, Big Cliff, and Cougar and the erection of buildings or infrastructure due to population growth and associated urban landscape development, and transportation corridor development would have similar short, medium, and long- term, minor adverse effects on visual resources as the construction of WTC towers, structural downstream fish passages, and AFFs. Modifications of existing WVS structures would include upgrades to the existing Dexter AFF, a structural solution for mitigating excess TDG levels during spill operations at Big Cliff, and a structural solution to improve and/or modify Cougar Dam's ROs to ensure safer fish passage and reduced TDG levels. The type, location, and size of these actions are very similar to measures proposed in the action alternatives. Work vehicles, machinery, and building materials similar to those used for the proposed measures would likely be used for all the aforementioned cumulative actions, and would be visible during the duration of the construction phase. As such, short- and medium-term, cumulative effects of the proposed structural measures in combination with cumulative actions that include development and the construction or modification of structures would be minor, additive and adverse. Ultimately these structures would be seen but would not attract attention and would not dominate the landscape. These cumulative actions – in particular the modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would alter the landscape towards a more urban and industrial character because they would at the project locations. Most project locations already include USACE infrastructure in the forms of dams and supporting structures that have been in place for several decades. As described in 3.22.4, construction of all structural measures would be consistent with Class II, III, or IV management activities; modifications of existing WVS structures at Dexter, Big Cliff, and Cougar would be no different. Many of the project locations already feature two-lane highways, small paved parking lots at viewpoints, and other small buildings that contribute urban features to the landscape. The City of Lowell is within the viewshed of Dexter and Lookout Point Dams and Reservoirs; the City of Detroit is located on the northeastern shores of the Detroit Reservoir; and the City of Sweet Home has sprawled all the way to the shores of Foster Reservoir. As such, long-term cumulative effects of proposed structural measures in combination with cumulative actions that include development and the construction or modification of structures would be minor, additive and adverse.

Indirect effects from development would include nonpoint source pollution or stormwater runoff, which affects the quality and aesthetics of the receiving waterbodies, such as the tributaries and reservoirs within the viewshed. Climate change would also adversely affect visual resources through increased forest fires, longer and more arid drought seasons, and smaller winter snowpacks – all of which would noticeably alter the landscape with lower riverine flows and more arid conditions, or drastically alter the landscape through destructive natural disasters. Warmer temperatures from climate change could also provide favorable conditions for the propagation of harmful algal blooms (HABs), which can discolor, cloud, or cover the water's surface and affect visual resources. Wildfire intensity and frequency associated with climate change would drastically alter the basic design elements of a forested, natural landscape by substantially changing the color, form, and texture due to the burnt, darkened, and decimated landscapes that follow wildfires. Wildfire ash can also land in reservoirs, streams, and rivers, increasing turbidity and affecting the visual resources of those water bodies. Some of these effects would continue to be minimized by actions to conserve and protect the natural features of the landscape in wildlife refuges, preserves, national forests, and through other land management strategies. These actions have already been undertaken at many project sites through the creation of parks, recreational reservoirs and beaches, and wildlife trails. Short- and medium-term cumulative effects of the proposed structural measures in combination with non-point source pollution, stormwater runoff, and climate change would have minor, additive and adverse effects due to increased turbidity and the effect on the quality and aesthetics of the reservoirs.

Continuing with the visual contrast rating system used to determine potential effects by VRM Class Management Objectives in Section 3.22.4, it is generally assumed that the natural landscape is valued and the more dominant the change, the more adverse the effect. Overall, the characteristic landscape at project locations already includes a mixture of natural and urban features due to the longevity of existing USACE infrastructure that is set within the backdrop of a natural landscape. Therefore, when considered in tandem with the construction of WTC towers, structural downstream fish passages, and AFFs, applicable cumulative actions would create adverse, additive, and minor cumulative effects to visual resources in the short, medium, and long term. In the long term, land management, fish and wildlife management, and water quality management activities in combination with the proposed structural measures would have cumulative effects that are minor, countervailing and beneficial.

#### *4.22.2.2 Fall Creek drawdown, Deeper fall reservoir drawdowns for fish passage (#40), and Spring reservoir drawdown for downstream fish passage (#720)*

As discussed in Section 3.22.4.3.2, the magnitude of adverse effects from deeper fall reservoir drawdowns (#40) and spring reservoir drawdowns (#720) would be moderate in the short term and major in the long term, as these drawdowns would demand attention, cannot be overlooked, and would dominate the landscapes. O&M of USACE infrastructure (e.g., reservoir drawdowns), water withdrawals, and climate change would have the same types of effects on visual resources as reservoir drawdowns and would demand attention, cannot be overlooked, and would dominate the landscape. Most project locations already include decades-old USACE infrastructure in the forms of dams and reservoirs, whose water levels change based on project location, reservoir purpose, and seasonality. Reservoir storage is typically at its peak during the summer months, lowest during the winter months, and in a transition period during the fall and spring seasons. Detroit and Foster Reservoirs have high recreational demand within the WVS, and reservoirs levels are maintained high until early September to accommodate recreational users. Water withdrawals of stored water include projected allocations over the next fifty years for fish and wildlife (F&W), municipal and industrial (M&I) water supply, and agricultural irrigation (AI), with F&W demanding the large majority of water usage (1,102,600 acre-ft) and AI and M&I water demands making up much smaller allocations (327,650 and 159,750 acre-feet, respectively).

Climate change would contribute to cumulative effects for visual resources through longer, more arid drought seasons and smaller snowpacks, which affect reservoir storage capacity. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color and clarity. This would have a noticeable effect on the basic design elements of color, texture, and form. Color would change slightly to a darker color with the introduction of darker clays, silts, and sediments; texture would change slightly with the introduction of grainy sediment particles and other larger suspended particulate materials; and form would change slightly with the introduction of a variety of irregular shapes, sizes, and masses from the suspended solids.

When considered together with reservoir drawdowns, O&M of USACE infrastructure, water withdrawals, and climate change would have adverse, additive, and moderate short-term and major long-term cumulative effects to visual resources.

### 4.22.3 Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to visual resources.

#### *4.22.3.1 No Action Alternative*

The NAA would include basin-wide measures along the Willamette River including maintaining revetments using nature-based engineering or altering revetments for aquatic ecosystem restoration (#9). Revetments were not considered key elements to visual resources as they do not occur at the 13 USACE dams and reservoirs and the locations of revetments cannot be seen from project locations. Similarly, cumulative actions along the Willamette River that cannot be seen from project locations would have negligible effects on visual resources.

The NAA would also include Fall Creek reservoir drawdowns annually to its lowest outlet for a few weeks in late fall and have moderate, short-term effects and major long-term and recurring effects. Water withdrawals of stored water for fish and wildlife (F&W), municipal and industrial (M&I) water supply, and agricultural irrigation (AI) would further exacerbate these effects. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

#### *4.22.3.2 Alternative 1. Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, three WTC towers, three structural downstream fish passages, and one AFF would be constructed, affecting four project locations – Detroit, Green Peter, Lookout Point, and Foster Dams. As discussed above in Section 4.22.2.1 and 4.22.2.2, these measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; the erection of buildings or infrastructure due to population growth and associated urban landscape development; and transportation corridor development would have adverse, additive, minor cumulative effects in the short, medium, and long term. Cumulative effects would be more severe at Foster Dam and Reservoir (Class II area) due to the visibility of the City of Sweet Home within its viewshed and the reservoir's high recreational demand; and Detroit Dam and Reservoir (Class III area) due to the reservoir's high recreational demand. Alternative 1 would have the same cumulative effect as Alternative 4, but would be less severe compared to Alternative 2A, 2B, 3A, 3B, and 5. Any new structures under Alternative 1 would represent a considerably small contribution to overall cumulative effects on visual resources when compared to all past, present, and reasonably foreseeable actions and within the WRB landscape as a whole.

As described in Section 4.22.2.2 and the NAA, water withdrawals of stored water for F&W, M&I water supply, and AI would further exacerbate the moderate, short-term and major, long-term, recurring effects from the Fall Creek Drawdown. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

#### *4.22.3.3 Alternative 2A. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Under Alternative 2A, one WTC tower, four structural downstream fish passages, and one AFF would be permanently built, and one reservoir would be drawn down annually, affecting five project locations at Detroit, Green Peter, Lookout Point, Foster, and Cougar Dams. As discussed above in Sections 4.22.2.1 and 4.22.2.2, these measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; the erection of buildings or infrastructure due to population growth and associated urban landscape development; and transportation corridor development would have adverse, additive, minor to major cumulative effects in the short, medium, and long term. Cumulative effects would be more severe at Foster Dam and Reservoir (Class II area) due to the visibility of the City of Sweet Home within its viewshed and the reservoir's high recreational demand; and Detroit Dam and Reservoir (Class III area) due to the reservoir's high recreational demand. Alternative 2A would have the same cumulative effect as Alternative 2B, 3A, 3B, and 5, but would be more severe compared to Alternatives 1 and 4 due to the reservoir drawdown. However, any new structures or drawdowns under Alternative 2A would represent a small contribution to overall cumulative effects on visual resources when compared to all past, present, and reasonably foreseeable actions and within the WRB landscape as a whole.

As described in Section 4.22.2.2 and the NAA, water withdrawals of stored water for F&W, M&I water supply, and AI would further exacerbate the moderate, short-term and major, long-term, recurring effects from the Fall Creek Drawdown and other drawdowns occurring under Alternative 2A. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown and other drawdowns in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

#### *4.22.3.4 Alternative 2B. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 2B, the cumulative effects to visual resources would be the same as those described under Alternative 2A. Under this alternative, one fewer downstream passage structure would be built, and fall and spring reservoir drawdowns would occur at Cougar in addition to fall reservoir drawdowns occurring at Green Peter. As discussed above in Section 4.22.2.1 and 4.22.2.2, these measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; the erection of buildings or infrastructure due to population growth and associated urban landscape development; and transportation corridor development would contribute adverse, additive, minor to major cumulative effects in the short, medium, and long term. Alternative 2B would have the same cumulative effect as Alternative 2A, 3A, 3B, and 5, but would be more severe compared to Alternatives 1 and 4. However, any new structures or drawdowns under Alternative 2B would represent a small contribution to overall cumulative effects on visual resources when compared to all past, present, and reasonably foreseeable actions and within the WRB landscape as a whole.

As described in Section 4.22.2.2 and the NAA, water withdrawals of stored water for F&W, M&I water supply, and AI would further exacerbate the moderate, short-term and major, long-term, recurring effects from the Fall Creek Drawdown and other drawdowns occurring under Alternative 2B. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown and other drawdowns in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

#### *4.22.3.5 Alternative 3A. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Under Alternative 3A, three AFFs would be constructed, three reservoirs would be drawn down semiannually, and three reservoirs would be drawn down annually, affecting six project locations at Detroit, Green Peter, Lookout Point, Cougar, Blue River, and Hills Creek Dams. As discussed above in Sections 4.22.2.1 and 4.22.2.2, these measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; the erection of buildings or infrastructure due to population growth and associated urban landscape development; and transportation corridor development would have adverse, additive, minor to major cumulative effects in the short, medium, and long term. Cumulative effects would be more severe at Detroit Dam and Reservoir (Class III area) due to the reservoir's high recreational demand. Alternative 3A would have the same cumulative effect as Alternative 2A, 2B, 3B, and 5, but would be more severe compared to Alternative 1 and 4. Alternative 3A (and 3B, discussed below) would have the most severe adverse cumulative effects to visual resources compared to other alternatives. Reservoir drawdowns would be a main component of these two alternatives, with a total of 10 drawdowns across seven reservoirs per year (including Fall Creek). However, any new structures or drawdowns under Alternative 3A would represent a small contribution to overall cumulative effects on visual resources when compared to all past, present, and reasonably foreseeable actions and within the WRB landscape as a whole.

As described in Section 4.22.2.2 and the NAA, water withdrawals of stored water for F&W, M&I water supply, and AI would further exacerbate the moderate, short-term and major, long-term, recurring effects from the Fall Creek Drawdown and other drawdowns occurring under Alternative 3A. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown and other drawdowns in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

#### *4.22.3.6 Alternative 3B. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 3B, the cumulative effects to visual resources would be the same as those described under Alternative 3A. Under this alternative, spring reservoir drawdowns would occur at Green Peter and Hills Creek instead of Detroit and Lookout Point. As discussed above in Sections 4.22.2.1 and 4.22.2.2, these measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; the erection of buildings or infrastructure due to population growth and associated urban landscape development; and transportation corridor development would contribute adverse, additive, minor to major cumulative effects in the short, medium, and long term. Alternative 3B would have the same cumulative effect as Alternative 2A, 2B, 3A, and 5, but would be more severe compared to Alternatives 1 and 4. Alternative 3B (and 3A, discussed above) would have the most severe adverse effects to visual resources compared to other alternatives. Reservoir drawdowns would be a main component of these two alternatives, with a total of 10 drawdowns across seven reservoirs per year (including Fall Creek). However, any new structures or drawdowns under Alternative 3B would represent a small contribution to overall cumulative effects on visual resources when compared to all past, present, and reasonably foreseeable actions and within the WRB landscape as a whole.

As described in Section 4.22.2.2 and the NAA, water withdrawals of stored water for F&W, M&I water supply, and AI would further exacerbate the moderate, short-term and major, long-term, recurring effects from the Fall Creek Drawdown and other drawdowns occurring under Alternative 3B. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown and other drawdowns in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

#### *4.22.3.7 Alternative 4. Improve Fish Passage with Structures-Based Approach*

Under Alternative 4, the cumulative effects to visual resources would be the same as those described under Alternative 1. Under this alternative, one additional downstream passage structure would be constructed, affecting a total of five project locations with the additions of Cougar and Hills Creek Dams to Alternative 1 dams (except for Green Peter Dam since it is not included in this alternative). As discussed above in Sections 4.22.2.1 and 4.22.2.2, these measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; the erection of buildings or infrastructure due to population growth and associated urban landscape development; and transportation corridor development would contribute adverse, additive, minor cumulative effects in the short, medium, and long term. Alternative 4 would have the same cumulative effect as Alternative 1, but would be less severe compared to Alternatives 2A, 2B, 3A, 3B, and 5. However, any new structures under Alternative 4 would represent a small contribution to overall cumulative effects on visual resources when compared to all past, present, and reasonably foreseeable actions and within the WRB landscape as a whole.

As described in Section 4.22.2.2 and the NAA, water withdrawals of stored water for F&W, M&I water supply, and AI would further exacerbate the moderate, short-term and major, long-term, recurring effects from the Fall Creek Drawdown. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

#### *4.22.3.8 Alternative 5. Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 5, the cumulative effects to visual resources would be the same as those described under Alternative 2B. As discussed above in Section 4.22.2.1 and 4.22.2.2, these measures in combination with modifications of existing WVS structures at Dexter, Big Cliff, and Cougar; the erection of buildings or infrastructure due to population growth and associated urban landscape development; and transportation corridor development would contribute adverse, additive, minor to major cumulative effects in the short, medium, and long term. Alternative 5 would have the same cumulative effect as Alternative 2A, 3A, and 3B, but would be more severe compared to Alternatives 1 and 4. However, any new structures or drawdowns under Alternative 5 would represent a small contribution to overall cumulative effects on visual resources when compared to all past, present, and reasonably foreseeable actions and within the WRB landscape as a whole.

As described in Section 4.22.2.2 and the NAA, water withdrawals of stored water for F&W, M&I water supply, and AI would further exacerbate the moderate, short-term and major, long-term, recurring effects from the Fall Creek Drawdown and other drawdowns occurring under Alternative 5. And as described above, climate change could further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color, clarity, and texture. Therefore, cumulative short- and long-term effects from the Fall Creek Drawdown and other drawdowns in combination with F&W, M&I, and AI water withdrawals and climate change would be major and adverse.

### 4.22.4 Summary

In summary, the cumulative effects of Alternatives 2A, 2B, 3A, 3B, and 5 would be more severe compared to Alternative 1 and Alternative 4. Effects from alternatives 2A, 2B, 3A, 3B, and 5 would be adverse, additive, and minor to major in the short, medium, and long term. Alternatives 1 and 4 would have adverse, additive, minor cumulative effects in the short, medium, and long term. Cumulative short- and long-term effects from the Fall Creek drawdown would be major and adverse for all alternatives. Alternatives 3A and 3B would have the most severe cumulative effect to visual resources because reservoir drawdowns would be a main component of these two alternatives, with a total of 10 drawdowns across seven reservoirs per year (including Fall Creek).

## 4.23 NOISE

This section discusses the cumulative effects from noise. This includes a discussion of the effects of proposed measures considered with applicable cumulative actions, and how each project alternative would be cumulatively affected by noise. The geographic scope for noise would be the same boundary as described in the Affected Environment in Chapter 3, which includes the eight project locations of Lookout Point, Detroit, Green Peter, Hills Creek, Dexter, Cougar, Blue River, and Foster Dams within the WVS.

### 4.23.1 Cumulative Actions Applicable to Noise

Past, present, and reasonably foreseeable future actions that, when considered together with the Proposed Action and alternatives, would have cumulative effects from noise, include:

- Construction of the WVS dams and supporting structures;
- Transportation corridor development;
- RFFA 1, future population growth and accompanying urban, industrial, and commercial development;
- RFFA 4, decarbonizing the energy sector with renewable energy sources;
- Court-ordered expedited design and construction at Dexter, Big Cliff, and Cougar for the management and operation of the WVS and its effects on ESA-listed salmonids.

Some of the other RFFAs discussed in Section 4.2 would not occur at or in close proximity to the WVS dams and reservoirs, or would not be a meaningful source of additive noise, and as such would not have a cumulative effect on noise. These include RFFA 2, reduced agricultural production; RFFA 3, water withdrawals for municipal, industrial, and agricultural uses; RFFA 5, federal and state wildlife and lands management; RFFA 6, fishery management and killer whales; RFFA 7, tribal, state, and local fish and wildlife improvement; RFFA 8, Invasive species management; RFFA 9, climate change; RFFA 10, mining operations; and RFFA 11, timber and logging industry operations. Agricultural lands, mining operations, and timber and logging operations are not found in close proximity to project locations, and there are no planned projects or projected changes for the foreseeable future. Therefore, these RFFAs are dismissed from further analysis.

### 4.23.2 Discussion of Cumulative Effects by Measure(s)

This section considers the interaction of proposed measures with applicable cumulative actions to determine the potential cumulative effects from noise. Where possible, the discussion of cumulative effects is grouped by measures that would have similar effects.

#### *4.23.2.1 Construct water temperature control towers (#105), Construct structural downstream fish passages (#392), Provide Pacific Lamprey passage and infrastructure (#52), and Construct adult fish facility (#722)*

As discussed in Section 3.23.2.4, the magnitude of adverse effects from the construction of WTC towers, downstream passage structures, Pacific lamprey structures, and AFFs would be moderate, and the noise from constructing these structures would be limited to areas immediately surrounding the construction site. The results of population growth and associated urban landscape development (converting rural lands to developed or urban lands), transportation corridor development, and constructing renewable energy structures would have similar effects on increasing noise generation as the construction of WTC towers, downstream passage structures, Pacific lamprey structures and AFFs. Ambient sound levels would remain at background levels and be additive only in areas immediately surrounding construction sites. The project locations already include USACE infrastructure in the forms of dams and supporting structures that have been in place for many decades (over 50 years). Many of the project locations also feature two-lane highways, small paved parking lots, and other small buildings that contribute additive background levels of noise.

Renewable energy structures only include hydropower from the existing dams and supporting structures as described in Chapter 3; there are no proposed renewable energy projects within the counties representing the WRB. These future actions would contribute only background noise levels if such actions were to occur within an audible range of the project locations.

Overall, the noise environment at project locations already includes a mixture of natural and urban sound and noise sources, due to the longevity of existing USACE infrastructure. Therefore, when considered jointly with the construction of WTC towers, downstream passage structures, Pacific lamprey structures, and AFFs, applicable cumulative actions would create adverse, additive, and moderate cumulative effects from noise.

#### *4.23.2.2 Court-Ordered Design and Construction at Three Project Sites*

As discussed in Section 4.2.2, a court-ordered interim injunction has been issued that may lead to design and construction actions at the Dexter, Big Cliff, and Cougar project sites. The specific actions that could contribute to cumulative noise effects include upgrades to the existing Dexter adult fish facility (AFF), a potential structural solution at Big Cliff for mitigating excess TDG levels during spill operations, and potential structural improvements/modifications made to Cougar Dam's ROs to ensure safer fish passage and reduce TDG levels.

Overall, the noise environment at project locations already includes a mixture of natural and urban sound and noise sources, due to the longevity of existing USACE infrastructure. Although the effects from the court-ordered construction at the three project sites is being separately assessed under NEPA, these construction activities would likely produce similar moderate effects as those from previously assessed construction activities at AFFs, TDG mitigation, and fish passages. Therefore, when considered jointly with the construction of court-ordered measures at three project sites, applicable cumulative actions would create adverse, additive, and moderate cumulative effects from noise.

### 4.23.3 Discussion of Cumulative Effects by Alternative

This section analyzes the relevant cumulative actions by alternative to determine the potential cumulative effects to noise.

#### *4.23.3.1 No Action Alternative*

The NAA would include basin-wide measures to update and maintain revetments at 88 locations along the Willamette River and its tributaries. Activities related to revetment updates and maintenance would be minor. None of the cumulative actions would have effects similar to those from updating and maintaining revetments. As such, any contribution to cumulative effects would be negligible.

#### *4.23.3.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, three WTC towers, seven total dissolved gas improvements, one upstream or downstream passage restoration, four downstream passage structures, two Pacific lamprey passages, and two AFFs would be constructed, affecting eight project locations at Fern Ridge, Dexter, Detroit, Green Peter, Cougar, Lookout Point, Big Cliff, and Foster Dams.

As discussed above in Sections 4.23.2.1 and 4.23.2.2, these measures would have adverse, additive, and moderate cumulative effects. Any new structures under Alternative 1 would represent a relatively small contribution to the overall cumulative effects compared to all cumulative actions and within the WVS area as a whole.

#### *4.23.3.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Under Alternative 2A, one WTC tower, four downstream passage structures, three Pacific lamprey structures, and one AFF would be permanently built, affecting six project locations at Dexter, Detroit, Green Peter, Lookout Point, Foster, and Cougar Dams.

As discussed above in Sections 4.23.2.1 and 4.23.2.2, these measures would have adverse, additive, and moderate cumulative effects. However, any new structures under Alternative 2A would represent a small contribution to overall cumulative effects from noise when compared to all past, present, and reasonably foreseeable actions and within the WVS area as a whole.

#### *4.23.3.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Under Alternative 2B, the cumulative effects from noise would be the same as those described under Alternative 2A. Under this alternative, one fewer downstream passage structure would be built. As discussed above in Sections 4.23.2.1 and 4.23.2.2, these measures would contribute adverse, additive, and moderate cumulative effects. However, as with Alternative 2A, any new structures under Alternative 2B would represent a small contribution to overall cumulative effects from noise when compared to all past, present, and reasonably foreseeable actions and within the WRB area as a whole.

#### *4.23.3.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Under Alternative 3A, three AFFs and four Pacific lamprey passages would be constructed, affecting five project locations at Detroit, Green Peter, Cougar, Hills Creek, and Blue River Dams. As discussed above in Sections 4.23.2.1 and 4.23.2.2, these measures would have adverse, additive, and moderate cumulative effects. However, as with Alternative 2A and 2B, any new structures under Alternative 3A would represent a small contribution to overall cumulative effects from noise when compared to all past, present, and reasonably foreseeable actions and within the WRB area as a whole.

#### *4.23.3.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Under Alternative 3B, the cumulative effects from noise would be the same as those described under Alternative 3A. As discussed above in Sections 4.23.2.1 and 4.23.2.2, these measures would contribute adverse, additive, and moderate cumulative effects. However, as with Alternative 2A, 2B, and 3A, any new structures under Alternative 3B would represent a small contribution to overall cumulative effects from noise when compared to all past, present, and reasonably foreseeable actions and within the WRB area as a whole.

#### *4.23.3.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Under Alternative 4, the cumulative effects from noise would be the same as those described under Alternative 1. Under this alternative, one additional downstream passage structure and one additional Pacific lamprey passage structure would be constructed, affecting a total of eight projects. As discussed above in Sections 4.23.2.1 and 4.23.2.2, these measures would contribute adverse, additive, and moderate cumulative effects. As with Alternative 1, any new structures under Alternative 4 would represent a small contribution to the overall cumulative effects compared to all cumulative actions and within the WRB area as a whole.

#### *4.23.3.8 Alternative 5 - Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 5, the cumulative effects from noise would be about the same as those described under Alternatives 2A and 2B. Under this alternative, one fewer downstream passage structure would be built. As discussed above in Sections 4.23.2.1 and 4.23.2.2, these measures would contribute adverse, additive, and moderate cumulative effects. However, as with Alternatives 2A and 2B, any new structures under Alternative 5 would represent a small contribution to overall cumulative effects from noise when compared to all past, present, and reasonably foreseeable actions and within the WRB area as a whole.

### 4.23.4 Summary

In summary, the cumulative effects of each of the alternatives would have similar adverse, additive, and moderate effects. However, Alternative 4 has greater additive effects than Alternatives 1, 2A, 2B, 3A, 3B, and 5 because of the relatively greater number of noise-generating structural measures.

## 4.24 TRIBAL RESOURCES

### 4.24.1 Cumulative Effects Analysis Methodology for Tribal Resources

This section briefly summarizes results from the cumulative effects sections for Water Quality (Section 4.5), Fish, Aquatic Invertebrates, and Habitat (Section 4.8), Wildlife, Birds, and Terrestrial Habitat (Section 4.9), and Cultural Resources (Section 4.21). These sections were selected to reflect the primary interests and concerns outlined by local tribes as discussed in Tribal Resources (Section 3.24). Refer to the cumulative effects sections in Chapter 4 for full consideration of impacts to these four resource types and to all resources considered in this PEIS.

#### *4.24.1.1 Cumulative Actions Applicable to Tribal Resources*

Table 4.24-1 lists by resource type all past, present, and Reasonably Foreseeable Future Actions (RFFAs) that, when considered together with the Proposed Action and alternatives, would have cumulative effects on Tribal Resources.

**Table 4.24-4.24-1. List of Past Actions, Present Actions, and RFFAs Relevant to Tribal Resources**

| Action | Water Quality | Fish, Aquatic Invertebrates and Habitat | Wildlife, Birds, and Terrestrial Habitat | Cultural Resources |
|---|---|---|---|---|
| Construction and past operations of WVS dams and reservoirs | X | X | X | X |
| Ongoing operations of WVS dams and reservoirs | X | X | X | X |
| RFFA 1: Future population growth and accompanying urban, industrial, and commercial development | X | X | X | X |
| RFFA 2 - Future agricultural development | X | X | X | |
| RFFA 3 - Water withdrawals for municipal, industrial, and agricultural uses | X | X | X | |
| RFFA 4 - Decarbonizing the energy sector with renewable energy sources | X | X | X | |
| RFFA 5: Federal and state wildlife and lands management. | X | X | X | X |

| Action | Water Quality | Fish, Aquatic Invertebrates and Habitat | Wildlife, Birds, and Terrestrial Habitat | Cultural Resources |
|---|---|---|---|---|
| RFFA 6 – Fisheries management and killer whales | | X | X | |
| RFFA 7: Tribal, state, and local fish and wildlife improvement | X | X | X | X |
| RFFA 8 – Invasive species management | X | X | X | |
| RFFA 9: Climate change. | X | X | X | X |
| RFFA 10: Mining operations. | X | | X | X |
| RFFA 11: Timber and logging industry operations. | | | X | X |

The actions that are not marked with an "X" in Table 4.24-1 would not change effects on the various resources and as such would not have a cumulative effect on them. For water quality, this includes RFFAs 6 (fisheries management and killer whales) and 11 (timber and logging industry operations). For fisheries this includes RFFAs 10 (mining operations) and 11 (timber and logging industry operations). For cultural resources, this includes RFFAs 2 (future agricultural development), 3 (water withdrawals), 6 (fisheries management and killer whales), and 8 (invasive species management). These RFFAs would not affect water quality and cultural resources because they are actions that tend to occur away from the WVS. For fisheries, these actions would occur on a localized and small-scale level and affect a very small area of the WRB. As a result, the RFFAs would not directly or greatly impact fisheries of the WVS and WRB. All of the RFFAs, however, are anticipated to have cumulative effects to WRB wildlife, birds, and terrestrial habitat.

### 4.24.2 Cumulative Effects to Tribal Resources by Alternative

Construction of the Willamette Valley dams and reservoirs has greatly changed and adversely affected tribal resources in the WVS including water quality, fisheries, wildlife, birds, and terrestrial habitat, and cultural resources. On-going operations of the WVS continues to adversely affect these resources. For cultural resources these changes are irreversible. See Table 4.24-2 for a description of past and present actions that have cumulative impact to Tribal Resources.

**Table 4.2424-2. Summary of Past and Present Actions Relevant to Tribal Resources**

| Action | Description | Cumulative Impact Description |
|---|---|---|
| Past | WVS Dams and Reservoirs: construction and past operations and maintenance | Water Quality – Changed downstream water temperatures to be unnaturally cool in the summer and warm in the winter. As water is released over the spillway this creates Total Dissolved Gas (TDG) which can be detrimental to aquatic species. Increased turbidity levels typically occur due to drawdown operations of the reservoir or high flow events due to precipitation. During construction of the WVS, contaminants may have been introduced which may require removal.<br><br>Fisheries - Once the Willamette System was implemented, the floodplain became more channelized, water quality began to improve, urbanization increased, and migratory fish were excluded from a large proportion of spawning habitat in the upper Willamette tributaries. Downstream fish populations were affected by regulated flows.<br><br>Wildlife, Birds, and Terrestrial Habitat - Wildlife species and wildlife habitat within the WRB has been affected by the construction and operation of the WVS dams and reservoirs, dams constructed by other entities (Section 4.1.2.1.1), urban and rural development and land use, transportation infrastructure development, dredging and sediment management and other land-altering activities. The cumulative effect is a decrease of biodiversity and changes to a variety of habitats that support a wide range of wildlife species. Simplification of the stream channels within the WVS limits habitat availability across the floodplains that support aquatic species while also extending upland habitat for terrestrial species that would not otherwise be available.<br><br>Cultural Resources - Activities related to construction and the 50-80 years of fill and drawdown cycle of the reservoir resulted in additive, major, and adverse effects to archaeological sites through disturbance, erosion, and exposure, and traditional cultural properties through reduced and restricted access to tribal members and actions that have impacted habitat and water quality as well as destruction of archaeological sites that are part of traditional cultural properties. It also resulted in the construction of the WVS which is composed of 13 historic districts. Management and operations have been mostly beneficial through retainment of historic fabric of the 13 historic districts. Some modification or removal of some contributing resources in the past have had minor adverse cumulative effects. |

| Action | Description | Cumulative Impact Description |
|---|---|---|
| Present | WVS Dams and Reservoirs: ongoing operations and maintenance | Water Quality – see Past Action, above.<br><br>Fisheries – The present actions are characterized by continued decline of salmon and steelhead populations and a decrease in life history diversity due to limited juvenile outmigration opportunities for those spawned above dams. The hatchery program has had negative impacts on natural origin fish. The introduction of hatchery non-native summer steelhead has negatively impacted winter steelhead through genetic influence and competition.<br><br>Wildlife, Birds, and Terrestrial Habitat – see Past Action, above.<br><br>Cultural Resources - Continued draft and fill cycle is an irreversible, additive, and incremental adverse cumulative effect to archaeological sites due to active erosion and exposure. Actions that support improved habitat and water quality would have beneficial impacts to traditional cultural properties. The continued existence of the WVS restricts and reduces tribal access to traditional cultural properties which is a major adverse cumulative impact that is potentially reversible. Current operations to not include additions or modifications to the historic built environment, which is a beneficial cumulative effect. |

For water quality, fisheries, and birds and other wildlife, population growth (RFFA 1) and water withdrawals (RFFA 3), would have adverse effects through increased water temperature and pollutants introduced into the watershed. These impacts would change and reduce prime aquatic habitat that fish, birds, and other wildlife require to maintain thriving populations. While increased agricultural development (RFFA 2) could do the same, review of human use trends in the Willamette Valley suggest that cropland development will continue to decrease, which would benefit water quality due to a decrease in water demand and pollutants, which would in turn benefit fish habitat. Wildlife and birds would still be adversely affected by this generalized activity and by the continued fragmented habitat and passage that occurs due to developed land bases (whether agricultural or other). Decarbonizing the energy sector for renewable energy sources (RFFA 4), could improve or harm water quality through changes in TDG levels which would directly affect fish habitat, but other wildlife and birds would still face adverse disruption due to fragmented habitat and passage as renewable energy projects occur throughout the WRB. Population growth and general development in the Willamette Valley (RFFA 1) would have adverse effects to cultural resources due to increased visitor access to the WVS reservoirs and associated recreation areas. This access would increase looting of archaeological sites and increase degradation of historic structures that are part of recreation sites. The increase in visitors will also increase competition for access and resources that are important to tribal communities including those associated with traditional cultural properties.

State, tribal, and federal management strategies that are conservation or restoration-focused as well as management of invasive species (RFFAs 5, 7, and 8) are likely to provide benefits to improved water quality, fisheries, and other wildlife and birds. These efforts would focus on habitat restoration and the reduction of oxygen-depleting invasive plants. However, some management actions could be detrimental if they are focused on resource development or extraction, which would continue to fragment and degrade animal habitat and passage. These actions could similarly benefit cultural resources if the actions are focused on restoring resources and access to traditional cultural landscapes, but they could also prove to be detrimental if the actions are meant to draw visitors to locations where vulnerable archaeological sites are present.

Climate change (RFFA 9) is anticipated to adversely affect all tribal resources including water quality, fisheries, wildlife, birds, and terrestrial habitat, and cultural resources due to extreme changes in environmental conditions that reduce water, increase water temperatures, increase exposure of reservoir beds and associated archaeological sites, modify and fragment prime habitat for fish wildlife, and birds, cut off access to lands and resources important to tribal communities, etc.

Mining operations (RFFA 10) and timber and logging industry operations (RFFA 11) have the potential to negatively affect water quality through the introduction of contaminants into the Willamette Valley watershed, but these actions are localized and increasingly uncommon in the Willamette Valley. Cultural resources are directly affected at these locations by ground disturbance and later erosion of surrounding landforms. Birds and other wildlife are impacted by fragmented habitat and passage, as well as noise and human interaction during breeding periods that reduce species productiveness and ability to nurse young into adulthood.

Potential effects to tribal resources are listed by RFFA in Table 4.24-3.

**Table 4.2424-3. Summary of Reasonably Foreseeable Future Actions (RFFA) Relevant to Tribal Resources**

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| RFFA 1 | Future population growth and urban, industrial, and commercial development | Water Quality - There may be adverse effects from increased water demand which cause an increase of instream water temperatures and pollution due to increased stormwater runoff from these sectors.<br><br>Fisheries - Increased runoff leading to non-point source pollutants affecting fish health, behavior and survival; increased winter flows leading to increased off-channel or floodplain habitat for rearing fish; increased summer water temperatures where withdrawals decrease instream flow leading to changes in fish habitat availability, particularly in the mainstem Willamette River. |

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| | | Wildlife, Birds, and Terrestrial Habitat – Continue to affect wildlife species by disturbing individuals and further fragmenting habitat during construction activities.<br><br>Cultural Resources - Adverse effect to archaeological sites due to increased looting, traditional cultural properties through competition for access and resources important to Indian tribes and built resources that experience degradation due to increased visitor use. |
| RFFA 2 | Future agricultural development | Water Quality - Potential beneficial effect to water quality due to decrease in cropland and water demand.<br><br>Fisheries - Conversion/development of croplands will decrease water demand and water pollutants from croplands, improving aquatic habitat for fish.<br><br>Wildlife, Birds, and Terrestrial Habitat - Would further fragment wildlife habitat and passage within these areas. Fence installation, grazing livestock, and cultivating crops with machinery would affect wildlife by limiting passage through these areas. Spreading invasive plant species from these areas can affect downstream riparian habitat. |
| RFFA 3 | Water withdrawals for municipal, industrial, and agricultural uses | Water Quality - An increase in water withdrawals may cause adverse effects for instream water temperatures.<br><br>Fisheries - Increased water demands, particularly below Salem, leading to increased water temperatures, pollutant concentrations, and change aquatic habitat availability. Limited negative effect on ESA-listed fish expected (spring Chinook, winter steelhead and bull trout) since very few adults or juveniles are present in the mainstem during summer months, and some positive effects may occur within tributaries from increasing stored water releases from WVS reservoirs on tributaries to meet new water withdrawals on the mainstem.<br><br>Wildlife, Birds, and Terrestrial Habitat - Would have the effect of either decreasing reservoir water surface elevation, decreasing instream flows, or a combination of both. Decreased water surface elevation would affect aquatic species such as breeding amphibians and reptiles that depend on inundation at certain times of year for reproductive success. Many aquatic wildlife species also depend on wetland habitat that would be affected by decreasing water surface elevations. |
| RFFA 4 | Decarbonizing the energy sector with | Water Quality – Possible adverse effects due to potential increase in lack-of-market/lack-of-turbine capacity spill, which |

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| | renewable energy sources | may lead to higher TDG levels. Decarbonizing and utilizing electrical transportation may reduce involuntary spill from lack-of-market spill<br><br>Fisheries - If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Conversely if the demand for hydropower increases leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management.<br><br>Wildlife, Birds, and Terrestrial Habitat - Continue to affect wildlife species by disturbing individuals and further fragmenting habitat during construction activities. |
| RFFA 5 | Federal and State Wildlife and Lands Management | Water Quality - Potential beneficial effect to water quality due to habitat restoration and land use management.<br><br>Wildlife, Birds, and Terrestrial Habitat – Would continue to affect wildlife and wildlife habitat by disturbing individuals, particularly during breeding periods, and fragmenting habitat.<br><br>Cultural Resources - Varies, could be beneficial or adverse depending on management action. |
| RFFA 6 | Fisheries Management and Killer Whales | Fisheries - If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Conversely if the demand for hydropower increases leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management.<br><br>Wildlife, Birds, and Terrestrial Habitat - Would continue to affect wildlife and wildlife habitat by disturbing individuals, particularly during breeding periods, and fragmenting habitat. |
| RFFA 7 | Tribal, State, and local fish and wildlife improvement | Water Quality - Potential beneficial effect to water quality due to habitat restoration and land use management.<br><br>Wildlife, Birds, and Terrestrial Habitat – Includes river and floodplain restoration actions and potentially environmental flows to inundate floodplain areas. These floodplain |

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| | | restoration actions would sometimes involve some consideration of wildlife effects and improvement of wildlife habitat.<br><br>Cultural Resources - Varies, could be beneficial or adverse depending on improvement action. |
| RFFA 8 | Invasives Species Management | Water Quality - Potential benefit in removal of oxygen depleting plant species. An adverse effect if chemicals are utilized for removal management.<br><br>Wildlife, Birds, and Terrestrial Habitat - Range of management actions taken by federal, state, and local agencies as well as private organizations to combat the spread of invasive species, including invasive wildlife species. In addition, management of invasive plants can help by protecting wildlife habitat, like wetlands, where the ecological functions of the habitat would change with invasive plant infestation. |
| RFFA 9 | Climate change | Water Quality - Potential adverse effects from increased air temperature may result in increased water temperatures. There is potential for higher winter water volumes and lower summer water volumes. Potential increased water volumes may necessitate increase spill causing elevated TDG levels. A decrease in flow and water volumes in the summer may cause elevated instream water temperatures.<br><br>Wildlife, Birds, and Terrestrial Habitat - Would affect wildlife and wildlife habitat primarily due to longer drier summers. Habitat that occurs in riparian areas, such as wetland and aquatic habitat, would shrink and the ecological functions would change and less able to support certain aquatic species. Water temperature would increase with climate change, which would affect fish and other forage species that wildlife species depend on. With increased water temperature there would be an increase in toxic algal blooms, which can adversely affect wildlife species and food chains. The seasonality of wildlife species (e.g., birds, reptiles, insects, etc.) life histories would need to adjust to the new climate patterns, which would have a number of adverse effects to species, interactions between species, and interactions with their habitats.<br><br>Cultural Resources - Adverse effect due to increased winter precipitation that erodes archaeological sites, reduced water levels in the summer that expose archaeological sites, both would increase looting and vandalism to archaeological sites. Adverse effect to traditional cultural properties through reduced/degraded water quality and habitat of species |

| RFFA # | RFFA Description | Cumulative Impact Description |
|---|---|---|
| | | important to Indian tribes. Wildfire would negatively affect all types of cultural resources. |
| RFFA 10 | Mining operations | Water Quality - Potential adverse effects due to contaminants entering waters via runoff.<br>Wildlife, Birds, and Terrestrial Habitat - Would continue to affect wildlife and wildlife habitat by disturbing individuals, particularly during breeding periods, and fragmenting habitat.<br><br>Cultural Resources - Localized to mining operation, direct adverse effects to archaeological sites (erosion) and traditional cultural properties downstream habitat and water quality degradation), but unlikely to affect built resources. |
| RFFA 11 | Timber and logging industry operations | Wildlife, Birds, and Terrestrial Habitat – Would continue to affect wildlife and wildlife habitat by disturbing individuals, particularly during breeding periods, and fragmenting habitat.<br><br>Cultural Resources - Direct effects localized to logging unit, where ground disturbance can negatively affect archaeological sites, but indirect effects could negatively affect viewshed of 13 historic districts (built resources) and traditional cultural properties on decadal scale. Indirect effects would be temporary. |

General trends in this section apply to water quality, fisheries, birds and other wildlife, and cultural resources across alternatives. The following sections briefly summarize the broad aspects of cumulative effects to tribal resources by the four resource types for each alternative (water quality, fisheries, birds and other wildlife, and cultural resources). Please refer to sections 4.5 (water quality), 4.8 (fisheries, aquatic invertebrates, and habitat), 4.9 (wildlife, bird, and terrestrial habitat), and 4.21 (cultural resources) for discussion of detailed resource specific cumulative impacts.

#### *4.24.2.1 No Action Alternative*

Within the WVS quality parameters include water temperature, TDG, Turbidity, HABs, and Mercury (Coast Fork Willamette). Under the NAA, the RFFA including climate change has the greatest potential to alter these water quality parameters. Population growth along with municipal and industrial has the potential to increase instream water demand and stormwater run-off pollution. An increase of TDG exceedances may occur with decarbonizing the energy sector and lack of turbine capacity spill for hydropower generation. Non-point and point source pollution occurrence may increase due to mining operations and population growth.

Negative impacts to fisheries from the RFFAs include those from increased winter runoff, increased water temperatures from water withdrawals, and non-point source pollutants from population growth and development degrading aquatic habitat conditions and reducing fish health and survival. Water withdrawals for municipal and industrial (M&I) uses will also decease flows downstream of Salem, however since very few are present in the mainstem during summer months, limited negative effects on ESA-listed fish (spring Chinook, winter steelhead and bull trout) are expected from these M&I withdrawals. Effects of decarbonizing the energy sector with renewable energy sources is difficult to predict, however if the demand for hydropower increases leading to increased power peaking operations or use of turbines at WVS dams, then these changes could decrease fish passage rates or survival and could affect water temperature management. Increased negative effects from invasive species on native fish (primarily competition and predation) is also expected to increase, in particular due to climate change effects favoring invasive species.

Some positive effects of RFFAs on fish and aquatic habitat in the WRB can also be expected. Conversion/development of croplands will decrease water demand and water pollutants, improving aquatic habitat conditions for fish. If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Fishing performance in the future would be at least as variable as it is at present due to variability in ocean conditions and fish survival in the ocean, and changes in salmon hatchery production. Ongoing and future aquatic and riparian habitat restoration and mitigation actions would also be expected to directly and indirectly have positive impacts on fish.

RFFAs are expected to infer a net negative impact in addition to the effects accounted for in the fisheries environmental consequences section. Poor fish passage conditions at WVS dams will continue to significantly constrain population viability of ESA-listed salmon and steelhead, and effects of RFFAs on habitat conditions below dams will further reduce population viability. Similarly, RFFAs also will infer a net negative impact for bull trout, stemming primarily from climate change-related contraction of existing habitat occupied above WVS dams (increased winter flows, decreased summer low flows, increased water temperatures) in high elevation areas. Under the NAA, bull trout do not have effective access to below dam habitat, however stream reaches below dams will further degraded in the future and not be expected to provide any suitable spawning areas, experience a reduction and degradation in available rearing habitat, and survival rates of bull trout below dams would be expected to decline due to increases in recognized risk factors

Combined with the cumulative effects listed above (particularly climate change), there would likely be additional impacts to wildlife and wildlife habitat under the NAA. As discussed in section 3.9.2.2, the effects of the No Action Alternative would have both a beneficial and an adverse effect to wildlife and wildlife habitat in the WVS. The beneficial effect of the NAA is that water storage in the reservoirs would be maintained and would continue to support hydrology in aquatic and wetland habitats at the reservoirs that may not otherwise exist. One adverse effect is that since stream flows would continue to be managed for flood control and confined to a fairly uniform channel, wildlife habitat along reaches downstream of the USACE projects would continue to be limited in diversity and amount available. In addition, without fish passage provided, forage species (including but not limited to salmonids) population size would be limited upstream of the WVS projects. The NAA on its own would have both minor beneficial and adverse effects to wildlife and wildlife habitat, maintaining existing conditions. Combined with cumulative effects (primarily climate change), there would be major adverse effects to wildlife within the WVS in the form of changes to suitable habitat acreage, water quality, and the seasonality of wildlife life histories.

The NAA maintains an annual draft and fill cycle that has major direct irreversible adverse effects to 80% of archaeological sites documented in the WVS, as discussed in section 3.21. This draft and fill erodes archaeological sites that overlap with the reservoirs and exposes these sites to illicit collection and other human-caused damage. Population growth and climate change would have additive, major, and adverse effects to archaeological sites. Archaeological sites in the WVS have already experienced major irreversible impacts from the construction of the WVS dams and reservoirs and have experienced five to eight decades of draft and fill cycles. Increased recreation at the WVS will further exacerbate looting and illicit collection that degrades the integrity of archaeological sites. Climate change that results in increased erosion of reservoir beds in the winter and increased exposure of reservoir beds in the spring and summer will have similar impacts. The deep drawdowns at Fall Creek continue to increase the erosion and exposure of archaeological sites present at this reservoir.

Traditional cultural properties are not well documented in the WVS, but it is assumed that they are present given the lengthy habitation of the Willamette Valley by indigenous communities as discussed in section 3.21. The construction and continued operation of the WVS has had major direct adverse effects to traditional cultural properties including archaeological sites, habitat, and water quality as well as reduced and restricted access to the lands that now comprise the WVS. The cumulative effects of past and present actions and population growth are major and adverse. There is potential to reverse some of these negative effect through management actions that improve habitat, water quality, and access to them by tribal communities. Potentially, RFFAs 5 and 7 (management by various entities) would have beneficial effects to traditional cultural properties, but with population growth and climate change tribal communities may be forced to compete for access and resources as more people move into the Willamette Valley. The archaeological components of traditional cultural properties cannot be rehabilitated, but increased access by tribal members would provide a beneficial cumulative effect. RFFA 10 (mining operations) and 11 (timber and logging industry operations), which would adversely impact the viewsheds of traditional cultural properties, have the potential to cause minor to moderate cumulative impacts. The existence of the WVS has already significantly directly and indirectly impacted traditional cultural properties in the six sub-basins, so continued resource extraction would not greatly increase the negative effects.

No new construction or modification to the 13 historic districts is considered under the NAA, but increased visitor use, and resource extraction (RFFA 10 and 11) have the potential to directly and indirectly impact historic recreation sites that are present in the WVS. Over time, this could result in minor to moderate adverse cumulative effects, but these could be minimized or reversed through maintenance plans and recreation management plans that prioritize maintaining the historic aesthetic and viewshed of the WVS.

#### *4.24.2.2 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Compared to the NAA, Alternative 1 would result in minor to major beneficial water temperature effects in the Middle Fork Willamette, South Santiam, and North Santiam basins due to the proposed temperature control structures at Lookout Point, Green Peter, Detroit Dams. Minor to major beneficial TDG effects are expected in the North Santiam and South Fork McKenzie basins based on the reduced number of spill days and proposed TDG abatement structures in Alternative 1. Cumulative effects from the RFFAs have the potential to modify water temperature, turbidity, HABs, and mercury in some of the WVS watersheds. In general, the cumulative effects from the RFFAs would result in negligible adverse effects or may increase negative effects to an unknown degree.

Alternative 1 implementation is predicted to have major impacts on Chinook salmon and minor adverse impacts on winter steelhead in the North and South Santiam. Lifecycle models predict a high risk of extinction in the McKenzie and Middle Fork. The downstream passage structure at Lookout Point is dependent on the dam operations and predicted to perform poorly likely due to the storage theme of Alternative 1. Scores and risks for bull trout would be ranked similar to the No Action Alternative, with minor effects predicted. Habitat scoring for bull trout is only marginally better than in the No Action Alternative with rearing/forage habitat increases for North Santiam bull trout below Detroit. Increased municipal water demand would likely compete with endangered fish and aquatic species needs such that stored water would likely need to be prioritized among interests. Federal and state land management downstream of project may be directly impacted by water storage practices, however, conservation efforts above project where the majority of quality habitat for endangered fish is expected to be, would likely be improved under Alternative 1. With respect to climate change, water storage is likely to be a more resilient planning strategy due to the fact that precipitation patterns and snow pack are expected to be more variable and less predictable. Overall, while Alternative 1 may not perform the best over other alternatives, with regard to fisheries. However, it does provide some resiliency for fish and wildlife given the uncertainties with respect to urbanization, land use, climate change, and water use needs predicted in the future.

Overall, cumulative effects to wildlife and wildlife habitat would be anticipated to be major over the period of analysis. However, Alternative 1 would not contribute substantially to the changes to wildlife and wildlife habitat within the WVS. Changes to biodiversity and suitable habitat availability would be affected to a greater magnitude by climate change, water withdrawals, and habitat fragmentation due to development than by Alternative 1.

Alternative 1 combined with past, present, and reasonably foreseeable actions would have similar direct, indirect, and cumulative effects to archaeological sites and traditional cultural properties as the NAA. For archaeological sites, the cumulative effects are major, additive, irreversible, and adverse. For traditional cultural properties, the cumulative effects vary from beneficial to adverse, but most are potentially reversible with the exception of the destruction of archaeological sites that may be part of traditional cultural properties. Alternative 1 deviates from the NAA in the management of built resources, which includes structural modifications to seven of the historic districts and would have moderate to major direct effects. Overall, the cumulative effects do not greatly increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

#### *4.24.2.3 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Compared to the NAA, Alternative 2A resulted in minor to major beneficial water temperature effects in the North and South Santiam sub-basins due to the proposed temperature control structure at Detroit dam and the Green Peter deep autumn drawdown. Minor to moderate beneficial TDG effects are expected in the North Santiam due to the proposed temperature control structure at Detroit that removes the need for operational temperature control with non-turbine outlets. Moderate to major adverse TDG effects are expected in the South Santiam due to the Green Peter deep autumn drawdown that relies on more spill flow in in Alternative 2A. Cumulative effects from the RFFAs have the potential to modify water temperature, turbidity, HABs, and mercury in some of the WVS watersheds. In general, the cumulative effects from the RFFAs would result in negligible adverse effects or may increase negative effects to an unknown degree.

Alternative 2A would have moderate adverse effects on Chinook salmon, predicted to produce the most viable populations compared to other alternatives and retains the McKenzie core legacy population. For Chinook and steelhead, there was agreement in most cases found from assessing population performance with lifecycle models, except for the South Santiam. Alternative 2A produces the most optimistic outcomes for Chinook salmon in the Middle Fork among the alternatives, accomplished with a downstream passage structure at Lookout Point exclusive of passage at Hills Creek. Alternative 2A would have minor adverse impacts to Santiam winter steelhead populations. Bull trout habitat scores and risks are comparable to Alternative 1, with a fish passage addition providing access to habitat below Cougar Dam. Alternative 2A would have minor adverse impacts for bull trout. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, and Middle Fork sub-basins. Given the uncertainty of water availability in the future and the expected increase in wildfire frequency with ongoing climate change, the ability to store more water earlier in the year may become a very valuable resiliency strategy. However, the reservoir drawdown to the regulating outlet at Cougar Dam in spring proposed at Cougar Dam for downstream fish passage will eliminate much of the ability to store water in Cougar Reservoir specifically.

Agricultural demand will likely decrease over time as use shifts to urban expansion and municipal uses. Water withdrawals are expected to increase which will impact endangered fish and aquatic species below project negatively. Demand for hydropower may increase which will likely show positive responses for endangered fish and aquatic species where at-dam/turbine friendly solutions are prioritized, a slightly positive effect on endangered fish and aquatic species where operational downstream passage is prioritized, and a detrimental effect from decarbonization leads to increased hydropower operations where operational downstream fish passage is prioritized. Federal and state wildlife and land management would likely be less affected in terms of direct and indirect effects. Where there are opportunities for storage at large projects such as Detroit where water availability would be more variable, agencies could incorporate adaptive planning. Tribal, state, and local wildlife management would likely reflect outcomes described under Alternative 1. Invasive species management would likely be complicated by the combination of at-dam storage and operational downstream passage approaches. This could result in management plans that are more reactive given that such operations have not yet been observed and monitored.

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 2A would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins.

Like the NAA and Alterative 1, Alternative 2A has major direct irreversible adverse effects to archaeological resources. Alternative 2A proposes a deep fall drawdown at Green Peter and Fall Creek as opposed to just Fall Creek (with the NAA and Alternative 1). This would increase negative erosion and exposure of archaeological sites that will occur at two reservoirs. Similar to the NAA and Alternative 1, the cumulative effects of past, present, and reasonably foreseeable actions combined with Alternative 2A will be additive, major, and adverse to archaeological sites. Traditional cultural properties would have similar and varying cumulative impacts as described in the NAA and Alternative 1 sections. Built resource cumulative impacts would be similar to those described for Alternative 1 but occur at six projects (rather than seven as in Alternative 1). Overall, the cumulative effects do not greatly increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

#### *4.24.2.4 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Compared to NAA, Alternative 2B resulted in minor to major beneficial water temperature effects in the North Santiam, South Santiam, and South Fork McKenzie sub-basins due to the proposed temperature control structure at Detroit dam, Green Peter deep autumn drawdown with operational temperature control, and a deep drawdown at Cougar. Minor to moderate beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins due to a reduced number of days with spill (at Detroit, the proposed temperature control structure removed the need for operational temperature control with non-turbine outlets). Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 2B due to the deep drawdown at Cougar that involves use of the diversion tunnel, which is expected to have lower TDG than the regulating outlet. Moderate to major adverse TDG effects are expected in the South Santiam due to the Green Peter deep autumn drawdown that relies on more spill flow in Alternative 2A. Cumulative effects from the RFFAs have the potential to modify water temperature, turbidity, HABs, and mercury in some of the WVS watersheds. In general, the cumulative effects from the RFFAs would result in negligible adverse effects or may increase negative effects to an unknown degree.

The only difference between Alternative 2A and Alternative 2B is that 2B has an operational downstream fish passage measure at Cougar Dam (deep drawdown to near the diversion tunnel in spring and fall) instead of a structural measure. Operational fish passage at Cougar Dam proposed for this Alternative is estimated to be more effective that that proposed for Alternative 2A at Cougar Dam. Future population growth under this alternative will likely have lesser impact to endangered fish and aquatic species due to implementation at projects where storage is prioritized over operational passage. Under Alternative 2B, an at-dam structure proposed for Detroit and Lookout Point dams promote storage, integration with hydropower, and downstream water uses nearest communities that are expected to increase in population and likely water demand downstream. Operational downstream passage is proposed at Green Peter and Cougar dams where urbanization downstream is unlikely to increase and effects on the public are expected to be less impactful. Minimum flow targets proposed are responsive to water storage availability in the spring. Minimum flows for fish as included are designed to adjust with real-time water availability, supporting downstream fish passage measures, and habitat and water temperature needs for fish below dams. However, the reservoir drawdown to the regulating outlet at Cougar Dam in spring proposed at Cougar Dam for downstream fish passage will eliminate much of the ability to store water in Cougar Reservoir specifically.

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 2B would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 2B (as opposed to Alternative 2A) there would be potential for major effects to aquatic and wetland habitat around the reservoir when combined with climate change effects.

Like the NAA and Alterative 1, Alternative 2A follows a rule curve that results in one major cycle of draft and fill per water year, which has major direct irreversible adverse effects to archaeological resources. Alternative 2A proposes a deep fall drawdown at Green Peter (780 feet) and Fall Creek as opposed to just Fall Creek (with the NAA and Alternative 1). This is an increase in negative erosion and exposure of archaeological sites that will occur at two reservoirs. Similar to the NAA and Alternative 1, the cumulative effects of past, present, and reasonably foreseeable actions combined with Alternative 2A will be additive, major, and adverse to archaeological sites. Traditional cultural properties will be similarly cumulatively impacted as described in the NAA and Alternative 1 sections. Built resource cumulative impacts would be similar to those described for Alternative 1 and occur at the same six reservoirs listed in Alternative 2A. Overall, the cumulative effects do not greatly increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

#### *4.24.2.5 Alternative 3A – Operations-Focused Fish Passage Alternative*

Compared to NAA, Alternative 3A resulted in minor to major beneficial water temperature effects in the Middle Fork Willamette (between Hills Creek dam and Lookout Point Dam) and South Santiam sub-basins due to the proposed deep drawdowns at Hills Creek and Green Peter dams. In the North Santiam sub-basin, minor beneficial effects to water temperature are expected during the autumn while moderate adverse effects are expected during the spring-summer due to deep drawdown at Detroit Dam in Alternative 3A. In the South Fork McKenzie sub-basin, minor adverse effects to water temperature are expected during the fall due to a partial drawdown at Cougar Dam in Alternative 3A. Minor to major adverse TDG effects are expected in the North Santiam, South Santiam, and Middle Fork Willamette due to the deep drawdowns at Detroit, Green Peter (autumn) and Lookout Point that rely on higher outflows and/or spill flow in Alternative 3A. Cumulative effects from the RFFAs have the potential to modify water temperature, turbidity, HABs, and mercury in some of the WVS watersheds. In general, the cumulative effects from the RFFAs would result in negligible adverse effects or may increase negative effects to an unknown degree.

Alternative 3A is focused on operational measures at WVS dams for fish passage and water quality. Operational measures for fish passage and water quality are less resilient to changes associated with RFFAs, when compared to structural measures, since structural measures are designed to be effective at a range of reservoir pool elevations and discharge rates, whereas operational measures effectiveness varies with reservoir elevation/volume, discharge outlets available, and discharge rates. Some positive effects of RFFAs on fish and aquatic habitat in the WRB may counter-balance some of the negative effects. Conversion/development of croplands will decrease water demand and associated water pollutants. If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Ongoing and future aquatic and riparian habitat restoration and mitigation actions would also be expected to directly and indirectly have positive impacts on fish.

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 3A would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins as discussed below.

The NAA, Alternative 1, Alternative 2A, Alternative 2B, and Alternative 3A have an annual cycle of draft and fill of the reservoirs, which have direct, irreversible, adverse effects to archaeological sites. Alternative 3 would strongly accelerate major direct adverse effects to archaeological sites with proposed deep drawdowns at six reservoirs including Blue River, Hills

Creek, Green Peter, Detroit, Lookout Point, and Cougar. Alternative 3 combined with past, present, and reasonably foreseeable actions would have the greatest adverse additive impacts to archaeological sites. Traditional cultural properties would likely have adverse cumulative effects that are greater than those described in the NAA, Alternative 1, Alternative 2A, and Alternative 2B, but this resource type is not well documented in the WVS and cannot be fully discussed other than to note that there are tradeoffs to measures that negatively affect archaeological sites that are part of traditional cultural properties but would benefit habitat and water quality. Alternative 3A would have less adverse cumulative effects to built resources than Alternative 1, Alternative 2A, and Alternative 2B, but more than the NAA. Modifications would occur at four of the historic districts. Overall, the cumulative effects do not greatly increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

#### *4.24.2.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Compared to NAA, Alternative 3B resulted in minor to moderate beneficial water temperature effects in the Middle Fork Willamette, McKenzie, and South Santiam sub-basins due to the proposed drawdowns at Hills Creek, Lookout Point, Cougar, and Green Peter dams. Minor to major adverse TDG effects are expected in the North Santiam, South Santiam, and Middle Fork Willamette (below Dexter Dam) due to the deep drawdowns at Detroit (autumn), Green Peter, and Lookout Point (autumn) that rely on high outflows, thereby increasing the number of days with spill in Alternative 3B. Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 3B due to the deep drawdown at Cougar that involves use of the diversion tunnel, which is expected to have lower TDG than the regulating outlet. Cumulative effects from the RFFAs have the potential to modify water temperature, turbidity, HABs, and mercury in some of the WVS watersheds. In general, the cumulative effects from the RFFAs would result in negligible adverse effects or may increase negative effects to an unknown degree.

Alternative 3B is also focused on operational measures at WVS dams for fish passage and water quality. As described for 3A, operational measures for fish passage and water quality are less resilient to changes associated with RFFAs, when compared to structural measures. Spring drawdowns, in particular where they occur, significantly decrease resiliency. Spring drawdowns to regulating outlets occur at Green Peter and Hills Creek, and to the diversion tunnel at Cougar Dam in Alternative 3A. Alternative 3B is very similar to 3A. The primary differences are related to locations of the drawdowns and the fact that deep drawdowns occurring at Cougar would be to the elevation of the diversion tunnel. As for Alternative 3B, some positive effects of RFFAs on fish and aquatic habitat in the WRB may counter-balance some of the negative effects. Conversion or development of croplands will decrease water demand and associated water pollutants. If the demand for hydropower generation decreases, this could benefit fish and aquatic habitat downstream by increasing operational flexibility of WVS dams and reservoirs to meet non-hydropower missions, included those for fish passage and water temperature. Ongoing and future aquatic and riparian habitat restoration and mitigation actions would also be expected to directly and indirectly have positive impacts on fish.

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 3B would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins as discussed below.

Alterative 3B shares similarities with 3A, but is quite different from the NAA, Alternative 1, Alternative 2A, and Alternative 2B. Fall deep drawdowns are proposed for the same six reservoirs including Blue River, Hills Creek, Green Peter, Detroit, Lookout Point, and Cougar. Spring deep drawdowns, however, are proposed at Hills Creek, Cougar, and Green Peter. In both of these alternatives, Cougar will have a spring and fall deep drawdown. In Alternative 3B, the fall deep drawdown will pass through the diversion tunnel. Like Alternative 3A, these actions will have major irreversible direct adverse effects to archaeological sites, more so than the NAA, Alternative 1, Alternative 2A, and Alternative 2B. Severe additive and adverse cumulative impacts to archaeological sites would occur with Alternatives 3A and 3B.

There would likely be greater adverse cumulative effects to traditional cultural properties (TCPs) than those described in the NAA, Alternative 1, Alternative 2A, and Alternative 2B, and similar to those that would occur with Alternative 3A. However, this resource type is not well documented in the WVS and cannot be fully discussed other than to note that there are tradeoffs to measures that negatively affect archaeological sites that are part of traditional cultural properties but would benefit habitat and water quality. Alternative 3B would have less adverse cumulative effects to built resources than Alternative 1, Alternative 2A, and Alternative 2B, more than the NAA, and similar to Alternative 3A. Modifications would occur at the same four of the historic districts including Hills Creek, Cougar, Blue River, and Green Peter. Overall, the cumulative effects do not greatly increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

#### *4.24.2.7 Alternative 4 – Structures-Based Fish Passage Alternative*

Compared to NAA, Alternative 4 resulted in minor to major beneficial water temperature effects in the Middle Fork Willamette (between Hills Creek Dam and Lookout Point Dam), South Santiam, and North Santiam basins due to the proposed temperature control structures at Hills Creek, Lookout Point, and Detroit Dams as well as operational temperature control at Green Peter Dam. Minor to Major beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins based on the proposed TDG abatement structures below Detroit and Big Cliff Dams and the reduced number of spill days at Cougar Dam in Alternative 4. Cumulative effects from the RFFAs have the potential to modify water temperature, turbidity, HABs, and mercury in some of the WVS watersheds. In general, the cumulative effects from the RFFAs would result in negligible adverse effects or may increase negative effects to an unknown degree.

Alternative 4 is a structural downstream passage themed alternative with the intent to prioritize and operate with a focus on ESA-listed fish species. Proposed downstream fish passage structures are proposed for Detroit, Foster, Cougar, Hills Creek, and Lookout Point dams. It is expected that as demand for agricultural use becomes less frequent with conversion to urban uses, negative impacts from effluent and agricultural runoff will positively affect fish and wildlife resources. Increased municipal water demand would likely compete with endangered fish and aquatic species needs. Increased urbanization expected in the future would likely mean a greater need for decarbonization and possibly greater demand for hydropower. Federal and state land management downstream of project may be directly impacted by water storage practices, however, conservation efforts above project where the majority of quality habitat for endangered fish is expected to be, would likely be improved under Alternative 4. Pacific Ocean harvest management is unlikely to be directly affected but may be indirectly affected by the percentage of hatchery fish that make up total catch. Tribal, state, and local land management may be negatively impacted downstream of project depending on the allocation and water year type experienced in any given year. With respect to climate change, water storage is likely to be a more resilient planning strategy due to the fact that precipitation patterns and snowpack are expected to be more variable (and less predictable). Alternative 4 provides some resiliency for fish and wildlife given the uncertainties with respect to urbanization, land use, climate change, and water use needs predicted in the future.

Overall, cumulative effects to wildlife and wildlife habitat would be anticipated to be major adverse over the period of analysis. However, Alternative 4 would not contribute substantially to the changes in the wildlife and wildlife habitat of the WVS. Changes to wildlife and wildlife habitat in terms of changes to biodiversity and suitable habitat availability would be affected more by climate change, water withdrawals, and habitat fragmentation due to development than by Alternative 4.

Alternative 4 proposes a WVS-wide cycle of draft and fill that would continue to directly, irreversibly, and adversely affect 369 (80%) of the archaeological sites present in the WVS. Alternative 4, however, does not propose any deep drawdowns or spring spills over the spillway, which differs greatly from Alternatives 2A, 2B, 3A, and 3B. Cumulative impacts to traditional cultural properties are anticipated to be similar to those described in the NAA and Alternative 1, and less impactful than Alternatives 2A, 2B, 3A, and 3B. Alternative 4 and Alternative 1 would cause the most direct adverse effects to built resources including seven historic districts. Overall, the cumulative effects do not greatly increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

#### *4.24.2.8 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar Drawdown to Diversion Tunnel)*

Compared to NAA, Alternative 5 would likely result in minor to major beneficial water temperature effects in the North Santiam, South Santiam, and South Fork McKenzie sub-basins due to the proposed temperature control structure at Detroit dam, Green Peter deep autumn drawdown with operational temperature control, and a deep drawdown at Cougar. Minor to moderate beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins due to a reduced number of days with spill (at Detroit, the proposed temperature control structure removed the need for operational temperature control with non-turbine outlets). Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 5 due to the deep drawdown at Cougar that involves use of the diversion tunnel, which is expected to have lower TDG than the regulating outlet. Moderate adverse TDG effects are expected below Green Peter Dam (above Foster Lake) due to the Green Peter deep autumn drawdown that relies on more spill flow in Alternative 5. Cumulative effects from the RFFAs have the potential to modify water temperature, turbidity, HABs, and mercury in some of the WVS watersheds. In general, the cumulative effects from the RFFAs would result in negligible adverse effects or may increase negative effects to an unknown degree.

For fisheries, Alternative 5 is functionally similar to Alternative 2B and it is anticipated that the cumulative effects under Alternative 5 will be indistinguishable from cumulative effects under Alternative 2B. Alternative 5, similar to alternatives 2A and 2B, is integrated water management alternative with small hydrological differences. Downstream minimum flows are different below Big Cliff, Foster, Cougar, and Dexter dams, otherwise fish passage and water quality measures are the same in alternatives 5 and 2B. Operational fish passage at Cougar Dam proposed for this Alternative is estimated to be more effective that that proposed for Alternative 2A at Cougar Dam.

Overall, cumulative effects to wildlife and wildlife habitat would be major over the period of analysis. Changes to wildlife and wildlife habitat in terms of biodiversity and suitable habitat availability would be affected by climate change, water withdrawals, and habitat fragmentation due to development. Alternative 5 (as with Alternative 2B) would also have moderate effects to wildlife and wildlife habitat within the WVS primarily due to drawdowns in the reservoirs. These effects would be interactive and would be major in most subbasins. Most notably at Cougar reservoir, because deep fall and spring drawdowns would be included as a part of Alternative 5 (as with Alternative 2B) there would be potential for major effects to aquatic and wetland habitat around the reservoir when combined with climate change effects.

For cultural resources, cumulative effects associated with Alternative 5 are anticipated to be the same as Alternative 2B. This alternative, like the other alternatives, follows a rule curve that results in one major cycle of draft and fill per water year, which has major direct irreversible adverse effects to archaeological resources. The cumulative effects of past, present, and reasonably foreseeable actions would be additive, major, and adverse to archaeological sites. For traditional cultural properties, the cumulative effects vary from beneficial to adverse, but most are potentially reversible with the exception of the destruction of archaeological sites that may be part of traditional cultural properties. Built resource cumulative impacts would be the same as those described in Alternative 2B, and moderate to major direct effects would occur at seven of the historic districts. Overall, the cumulative effects do not greatly increase adverse effects or create beneficial effects beyond what is discussed in section 3.21.

# CHAPTER 5 - PREFERRED ALTERNATIVE SELECTION AND IMPLEMENTATION

## 5.1 INTRODUCTION

This chapter focuses on how the Preferred Alternative was selected by USACE for the Draft PEIS. CEQ's NEPA regulations require an agency to disclose the Preferred Alternative in the draft EIS if one has been identified, 40 CFR 1502.14(e). Selection of the Preferred Alternative in no way precludes the agency from selecting a different alternative once it has had the benefit of public review and comment in the Final EIS and ROD. Identification of the Preferred Alternative and discussion of the rationale for selecting that alternative as the preferred does not predetermine the agency's final decision based on completion of the FEIS, rather it provides the public with the opportunity to understand the agency's current reasoning so that they may provide meaningful comments.

Given the complexity of this project and its implementation, this chapter also summarizes a timeline for implementation of the preferred alternative, the framework for adaptive management of a selected alternative, and the governance framework or structure for working with WATER to implement the selected alternative. Implementation plan and Adaptive Management Plan (AMP) in Chapter 5 and Appendix N is discussed solely for the purpose of providing the public with a sense of how USACE would structure these plans as applied to the alternative that is ultimately selected and documented in the ROD.

The Preferred Alternative is provided in the PEIS to provide important context and to comply with NEPA requirements to identify a Preferred Alternative. The AMP and governance structure described in this chapter and in more detail in Appendix N would apply broadly to any alternative selected in the ROD, though specific components of the AMP (like metrics) may need to be refined for a particular measure in an alternative. A unique implementation plan would need to be developed for whatever alternative is ultimately selected because construction timing and sequencing for large structural changes cannot be as easily adjusted or translated across different alterntives.

Chapter 5 is organized as follows:

**5.2 Comparison of Alternatives** – Summarizes the evaluation criteria and process for comparing the alternatives and selecting the Preferred Alternative; also evaluates the differences between the alternatives.

**5.3 Summary of the Preferred Alternative** – Summarizes the Preferred Alternative. Section 5.3.1 in the Final PEIS will also explain components of the Preferred Alternative that were further refined during ESA consultation with NMFS and USFWS and in response to public comments on the Draft PEIS. Section 5.3.1 in the Final PEIS will also describe the effects associated with refined components.

**5.4 Implementation Plan** – Summarizes how USACE would execute the Preferred Alternative under the Implementation Plan.

**5.5 Adaptive Management Plan** – Summarizes the framework for implementing actions for the Preferred Alternative under an adaptive management plan, this is be updated for the selected alternative in the FEIS. This includes assessment of actions taken, assessing hypotheses and outcomes, and introducing new actions, should they become necessary. It also describes the process including the potential for additional NEPA and ESA consultation to implement different actions.

This section also summarizes the Governance Program used to make decisions based on recommendations from the Willamette Action Team for Ecosystem Restoration (WATER) resulting from adaptive management assessments.

## 5.2 COMPARISON OF ALTERNATIVES

The potential effects associated with each of the alternatives have been assessed and the analyses are discussed in detail in Chapter 3 and further described in the associated appendices. This section provides an overview of how the alternatives were evaluated and compared for the selection of the Preferred Alternative.

USACE developed multiple criteria to evaluate how effectively each alternative met the Proposed Action objectives described in Section 2.1 with consideration of cost and the economic, environmental, and social effects and then performed a tradeoff analysis using these criteria to compare the alternatives. To develop criteria, USACE considered the benefits and environmental and social consequences as reflected in Chapters 3 and 4 and then assessed the tradeoffs presented under each alternative within and outside of current authorities.

There was little differentiation among the levels of environmental and social impacts across alternatives. Therefore, the effects to environmental and social resources were not deemed an applicable criterion to evaluate how effectively an alternative met the Proposed Action objectives.

In contrast, the cost to design, construct, and operate and maintain the WVS under each alternative in combination with impacts to recreation, hydropower production, water supply, and ESA-listed fish did provide clear tradeoffs for comparing alternatives. To develop criteria to capture this combination of costs and impacts, one or more metrics were developed to measure how effectively an alternative would meet each of the primary objectives outlined in Section 2.1 except for Objectives 2 and 7.

Objective 2, to increase opportunities for the creation of nature-based structures during maintenance of USACE-owned revetments, and Objective 7, to reduce spawning and rearing habitat competition caused by hatchery fish, would be effectively met by including the revetment and hatchery measures, respectively, under each action alternative. As all action alternatives include revetment and hatchery measures, there is no measurable difference in how well they meet these objectives.

In addition to metrics evaluating how effective an alternative is at meeting the Proposed Action objectives, metrics for cost and the economic effects resulting from impacts to recreation were also assessed. The metrics for the remaining objectives, the economic metrics for impacts to recreation, and the metrics for costs are described below.

### 5.2.1 Objective 1- Effectiveness Criteria Metrics

Two metrics were used to measure how effectively each alternative met Objective 1 to allow greater flexibility in water management:

- conservation storage
- impacts to downstream flows

Conservation storage identifies the total peak volume of water in acre-feet the WVS can store in the conservation season. Basically, the more water the WVS can store in the spring, fall, and summer the more responsive USACE can be to operate the system to support all the competing uses, including flows for water supply, hydropower production, water quality, and fish and wildlife as well as the maintenance of reservoir elevations for recreational use. Conservation storage was assessed for each alternative using ResSim as described in Section 3.2. The difference between the total conservation storage under the NAA and each action alternative is provided in Table 5.2-1.

The impact to flows at downstream control points is a qualitative assessment of the difference in flows at Salem between the NAA and each action alternative. Flows at Salem were assessed under each alternative using ResSim as described in Section 3.2. The difference between flows at Salem under the NAA and each action alternative is provided in Table 5.2-1.

Details on this analysis can be found in Section 3.2.2 and 3.13.2 and Appendices B and J.

### 5.2.2 Objective 3 - Effectiveness Criteria Metric

Net Present Value (NPV) is the metric USACE used to measure how effectively each alternative meets Objective 3 to allow greater flexibility in hydropower production when compared to the no action alternative. An alternative's NPV assesses the long-term economic viability of the hydropower plants, given implementation of the alternative.

As discussed in Section 3.12, NPV measures the impact to the economic viability of hydropower at WVS hydropower dams by comparing the expected revenue produced at the hydropower facility across the WVS to the expected future costs at the facilities, including the cost to implement the alternative. This metric helps assess the changes in hydropower generation, including any potential resulting effects on the regional energy environment, and the impact the cost to implement each alternative has on hydropower revenues.

Details on this analysis can be found in Section 3.12.2 and Appendix G.

### 5.2.3 Objectives 4 through 6 Effectiveness Criteria Metrics

Objectives 4 through 6 all pertain to meeting the needs of ESA-listed fish species and include:

- Objective 4. Increase anadromous ESA-listed fish passage survival.
- Objective 5. Improve water management during the conservation season to benefit anadromous ESA-listed species.
- Objective 6. Reduce pollutant levels to restore impaired water quality to benefit anadromous ESA-listed species.

As described in Section 3.8.2, this draft PEIS evaluates effects on ESA-listed fish species and aquatic habitat using a quantitative (ESA-listed salmon and steelhead and critical habitat) and qualitative (bull trout and habitat) framework. The quantitative framework relies on output from a suite of models developed for ESA-listed salmon and steelhead including the Ecological Diagnosis Treatment (EDT) model, the Integrated Passage Asses (IPA) model, and the National Oceanic and Atmospheric Administration Life Cycle Model (LCM).

The fish models account for effects at a population scale of the measures under the alternatives cumulatively with the other major factors occurring in the watershed as described in Chapter 4. As all major factors outside the alternative measures are the same across alternatives, the model outputs inform the level of effects each alternative would have on the species at a population level.

These models incorporate inputs for passage survival (Objective 4), appropriate flows for habitat conditions supportive of the different life stages within the river system during the conservation season (Objective 5), and improved water quality (Objective 6). Therefore, metrics derived from the outputs of these population models demonstrate the effectiveness of an alternative for all three ESA-specific objectives identified in Section 2.1.

For example, to illustrate how the models measure improved water quality per Objective 6, provides an influence diagram that shows how the water quality parameters important for ESA species survival (Total Dissolved Gas [TDG] and temperature) are intrinsic to the life cycle models used to evaluate the alternatives' effects on the listed salmonid species. This demonstrates how the quantitative framework integrates water quality parameters and, therefore, addresses Objective 6 specifically.

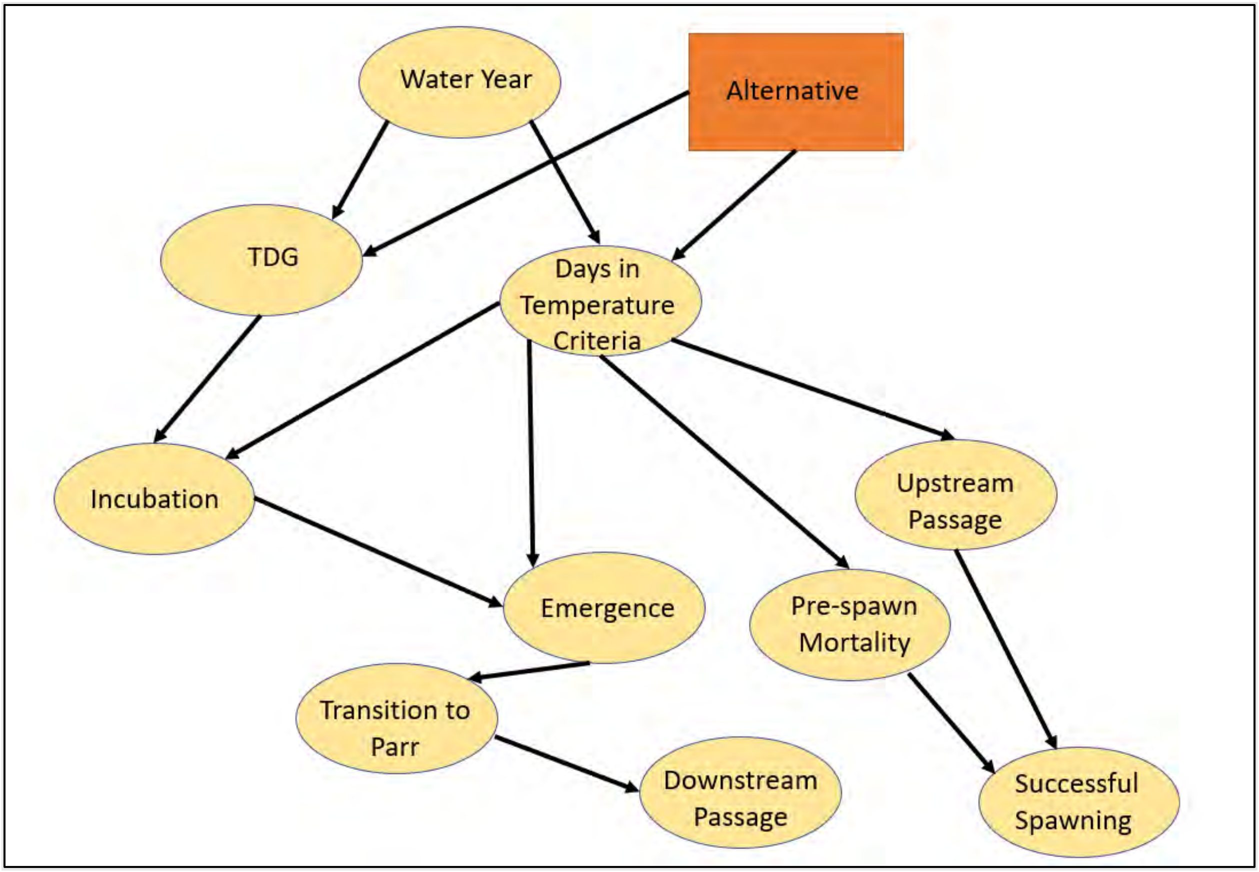

**Figure 5.2-1. Water quality influence diagram for WVS ESA listed Salmonids**

Five metrics were developed based on the outputs from these models to assess how effectively each alternative meets Objectives 4, 5, and 6. At the time the alternatives comparison and selection process occurred, only the UWR spring Chinook salmon modeling results were available; therefore, metrics specific to UWR steelhead are not included. However, USACE did review the UWR steelhead results; the UWR steelhead information does not change the rankings of the alternatives.

The five metrics used for evaluating and comparing how effectively the alternatives meet Objectives 4, 5, and 6 include:

- **Number of populations where maximum recruits/spawner (R/S) is greater than (>) 1:** The number of UWR spring Chinook salmon populations (a total of four are affected by the WVS) modeled to achieve spawner replacement on average over a 30-year timeframe. A high number is preferred. Spawner replacement occurs when offspring return to spawn in numbers equal to or greater than the number of parental spawners they were produced from. When the population replacement rate is less than 1, on average the population declines.
- **Number of populations with high persistence:** The number of UWR spring Chinook salmon populations modeled to exceed a minimum adult abundance threshold. A higher number is

preferred. The minimum adult abundance thresholds for each UWR spring Chinook salmon population were identified by the Technical Recovery Team.

- **Legacy population risk of extinction:** Indicates McKenzie Core Legacy spring Chinook salmon population risk of extinction.
- **Downstream survival relative rank**: Relative rankings of model results of UWR spring Chinook salmon and UWR steelhead survival below dams as affected by flow and water temperatures. A higher number is preferred. See appendix A for details on the ranking process.
- **Number of bull trout populations with habitat gains:** Number of bull trout populations with habitat gains from fish passage improvements allowing access downstream of WVS dams. A higher number is preferred. This assessment assumes bull trout are reintroduced above Detroit Dam. Bull trout currently reside above Cougar and Hills Creek Dams among WVS dams.

  Risk level refers to the assessment score for bull trout under each alternative, primarily relating to accessing habitat below dams. Biological risk is generally assumed to increase with downstream passage improvements.

Details on this analysis can be found in Section 3.8.2 and Appendix E. There are no metrics for UWR steelhead populations because this model output was not available at the time of the alternatives evaluation and comparison phase for identifying the Preferred Alternative. However, when UWR steelhead results became available, USACE determined the results would not change the decision.

### 5.2.4 Cost Criteria and Metrics

The cost of an alternatives was evaluated using the annual costs over the 50-year period of analysis in 2021 dollars. The annual cost includes annualized first costs for design and construction as well as the annual cost for Operations, Maintenance, Repair, Replacement and Rehabilitation as described in Section 1.8.7. Costs were estimated based on existing studies for similar projects. Costs were then scaled to site-specific needs. Cost estimate details for each alternative can be found in Appendix M.

### 5.2.5 Economic Metrics for Effects to Recreation

During public scoping, effects to recreation and the associated economic effects were identified as important to stakeholders as described in Appendix Q. For this reason, these effects were considered in evaluating and comparing the alternatives. The following economic metrics were used to assess effects to recreation:

**Average annual recreation benefits (total for all reservoirs):** This metric measures changes in availability of reservoir boat ramps and the changes in visitation across various recreation activities that are estimated to occur when boat ramps are available versus when they are not available across the Willamette Valley Basin (WVB) from the NAA. The measure of changes is in the dollar value of reservoir recreational visitations during the recreation season (April 15 through Sept 15). The dollar value of visitations is derived from Unit Day Value data provided by the Institute for Water Resources (USACE 2021). The higher the value, the greater the economic benefits as compared to the NAA.

**Regional economic impact from recreation effects:** This is a qualitative assessment considering the full-time jobs created/lost by the changes in water levels resulting from the measures under each alternative, making conditions more/less conducive to water-based recreation and the regional (sub-basin) output. The regional output is equal to the sum of employee compensation, plus proprietor income, plus other property type income, and plus indirect business taxes.

This analysis was predicated on the potential effects to localized jobs associated with dollars gained or lost as a function of water level fluctuation at a particular project's county. The higher the impact the greater the projected number for jobs lost and reduction in regional output. An assessment of a low impact means there would be negligible impact to the numbers of jobs lost and little to no reduction in regional output. The analysis does not reflect the transfer of recreation utility from one site to another within the collective basin.

An assessment of a medium impact means there would be greater than one job lost in any basin and a reduction in regional output less than $150,000 in multiple basins. An assessment of a high impact means greater numbers projected for jobs lost and a corresponding reduction in regional output greater than $150,000 in multiple counties or basins.

Details on this analysis can be found in Section 3.14.2 and Appendices K and I.

### 5.2.6 Summary of Alternatives Comparison

Although absolute values provide important context, it is more relevant for decision-makers to consider the estimated differences between each of the action alternatives and the NAA. Table 5.2-1 shows the differences in the performance that would occur under Alternatives 1 through 5 in relation to the NAA.

The methodology and analysis for each metric is provided in the associated analyses of environmental consequences in Chapter 3, and the associated appendices. Table 5.2-1 summarizes and compares the results of the evaluation criteria for each alternative as compared to the NAA.

**Table 5.2-1. Alternatives Criteria Comparison to NAA[1]**

| Criteria | Metric | No Action Alternative | Alt 1 | Alt 2A | Alt 2B | Alt 3A | Alt 3B | Alt 4 | Alt 5 |
|---|---|---|---|---|---|---|---|---|---|
| Effectiveness meeting Objective 1 | Change in Conservation Storage from NAA (acre-feet) | 1,329,000 | +168,000 | +122,000 | -64,000 | -590,000 | -669,000 | +122,000 | -98,536 |
| Effectiveness meeting Objective 1 | Impact to flows compared to NAA | – | Low | Low | Medium | High | High | Low | Medium |
| Effectiveness meeting Objective 3 | Change in NPV from NAA ($ millions) | $225 | -$1,159 | -$863 | -$933 | -$853 | -$829 | -$1,162 | -$939 |
| Effectiveness meeting Objectives 4-6 | UWR spring Chinook salmon populations reaching replacement | 2 of 4 UWR spring Chinook salmon populations reach replacement | +1 population | +2 populations | +2 populations | +2 populations | +2 populations | +1 population | +2 populations |
| Effectiveness meeting Objectives 4-6 | UWR spring Chinook salmon population persistence | 1 of 4 UWR spring Chinook salmon populations with high persistence | +1 population | +2 population | +1 population | +0 populations | +1 population | +1 population | +1 population |
| Effectiveness meeting Objectives 4-6 | McKenzie Core Legacy spring Chinook | McKenzie Core Legacy spring Chinook | No change in risk | Risk reduced | Risk reduced | No change in risk | No change in risk | Risk reduced | Risk reduced |

| Criteria | Metric | No Action Alternative | Alt 1 | Alt 2A | Alt 2B | Alt 3A | Alt 3B | Alt 4 | Alt 5 |
|---|---|---|---|---|---|---|---|---|---|
| | salmon population risk | salmon population is at risk | | | | | | | |
| Effectiveness meeting Objectives 4-6 | Downstream survival relative rank: 1=best, 7=worst | 7 | 1 | 2 | 4 | 5 | 6 | 3 | 4 |
| Effectiveness meeting Objectives 4-6 | Bull trout habitat gains | No habitat gains for bull trout | Least habitat gains for bull trout | Habitat gains for bull trout | Habitat gains for bull trout | Habitat gains for bull trout | No habitat gains for bull trout | Habitat gains for bull trout | Habitat gains for bull trout |
| Estimated Total Annual Cost | Millions of US $ | $9 | +$95 | +$58 | +$53 | +$17 | +$21 | +$104 | +$53 |
| Economic impact to recreation | Change in Average Annual NED Recreation Benefits (total for all reservoirs in millions of dollars) from NAA | $20.45 | +$0.31 | +$0.17 | +$0.02 | -$0.76 | -$1.27 | +$0.17 | +$0.02 |
| **Acceptability Criteria:** Economic | Impact to RED from Recreation Effects | – | Low | Medium | Medium | High | High | Medium | Medium |

[1]No color indicates no, negligible, or minor effects
Green indicates a positive/beneficial effect
Yellow indicates a moderate negative/adverse effect
Orange indicates a high negative/adverse effect

### 5.2.7 Discussion of Consequences

This section summarizes the differences between alternatives, including relative costs and hydrologic differences as well as some of the implications of these differences for hydropower, water supply, recreation, and endangered species in terms of relative benefits and adverse effects compared with the NAA. As all alternatives have similar outcomes for the environmental and social effects metrics, these effects will not be discussed further. This section also provides a brief summary of the USACE evaluation, including key risks and uncertainty, that influenced the decision-making process in identifying the Preferred Alternative.

#### *5.2.7.1 No Action Alternative*

The NAA is a continuation of the operation of the WVS and management actions being used to comply with the 2008 BiOp (NMFS 2008) as operated at the start of this effort in the spring of 2019. Per CEQ 40 Most Asked Questions regarding NEPA, no action means no change from current management direction or level of management intensity. This PEIS defines no action similarly - no change in direction from existing O&M of the WVS as of 2019. The NAA is designed to continue the management practices and operation of the WVS, with the addition of increased releases for municipal and industrial (M&I) water storage agreements. The NAA serves as a benchmark to compare effects across action alternatives.

##### *5.2.2.1.1 Tradeoffs*

The NAA is predicted to have major adverse effects on UWR spring Chinook salmon and UWR winter steelhead. High extinction risk in all sub-basins is predicted for both species. The NAA would be insufficient in meeting the Proposed Action ESA Objectives (objectives 4-6). Of the four Chinook salmon populations, two populations would decline and only one population would have high persistence (e.g., have low extinction risk). Additionally, under the NAA the McKenzie Core Legacy spring Chinook salmon population would be at risk and, there would be major adverse effects to the UWR winter steelhead resulting in a high risk of extinction.

The NAA would not result in habitat gains for bull trout, and it is the lowest ranked (7) of all alternatives for downstream survival. Adverse effects on bull trout are predicted to be minor. Bull trout above Cougar have been stable for several years and have been increasing above Hills Creek. Habitat scores for bull trout are reasonable, with 100 percent of the available spawning habitat available, and 70 percent of the rearing habitat available. Passage conditions at dams limit bull trout access to below dam rearing habitat.

Climate change is predicted to further degrade habitat below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature objectives below dams. See Appendix F for details on climate change effects on the WVB.

The NAA is the only alternative to utilize the BiOp flows targets established in 2008 as described in Section 2.4.1.1. Under the NAA the 75 percent exceedance level of system-wide stored water is estimated to be 1,331,864 acre-feet, and there would be no to negligible effect on hydrologic processes or flows downstream. However, this means that, under the NAA, there would not be flexibility in water management related to refill, drawdown timing, and other water management measures. For example, under the NAA operations that use the power pool or inactive pool (Sections 2.2.1.3 and 2.2.1.4 respectively) when needed to augment flows for biological purposes would not be available. Instead under the NAA only the conservation pool may be used to meet flow targets late in the fall, reducing operational flexibility for meeting flow targets. Since the WVS would be operated as designed and there would be no new structural modifications that would increase complexity, there would be a low mechanical and operational risk associated with the NAA.

Under the NAA, power generation for combined WVS projects would continue to be marginally economically viable. The median NPV for the combined WVS is about $225 million. Conservation storage would result in enough stored water to meet the M&I and agricultural irrigation (AI) demands in almost all years. Water would be released from the reservoirs to satisfy projected demands of stored water for M&I uses at the 2050 demand level and existing, as of April 2019, AI water service contracts. Additionally, the recreational experience would not change compared to current conditions, meaning there would be no effects to average annual visits or average annual benefits, and no changes to full-time jobs or the regional output.

The estimated total annual cost estimate for the NAA is $9,279 million (see Appendix M for details). The NAA provides a baseline for understanding the costs associated with operating and maintaining the WVS. The NAA also provides a starting point for determining how costs will change as various structural or operational changes or both are made under action alternatives. Under the NAA, agencies will continue to maintain system infrastructure, while routine O&M costs would occur for hydropower, cultural resources, recreation, fish and wildlife, and other routine costs. The NAA includes some proposed funding increases in routine O&M activities at Detroit/Big Cliff, Foster, Cougar, Lookout Point/Dexter, and Fall Creek reservoirs.

Overall, the NAA would perform the best for hydropower and recreational interests with marginal benefits to storage compared to some the action alternatives. Although there would be a low mechanical and operational risk under the NAA, power generation would only be marginally viable. This alternative would also have the greatest adverse effects on listed fish species. Given that USACE must comply with the ESA to continue to operate and maintain the WVS, and an appropriate level of action is necessary, the NAA is not a selectable alternative. The primary purpose of the NAA is to serve as a benchmark against which to compare the relative benefits and adverse effects of the action alternatives.

#### *5.2.7.2 Alternative 1. Improve Fish Passage Through Storage-focused Measures*

The purpose of Alternative 1, also referred to as the Project Storage Alternative, is to maximize the refill volumes of conservation pools at WVS reservoirs to meet authorized purposes that depend on full reservoirs, including M&I and AI water supply, recreation, and water quality as well as to improve fish passage through the WVS dams to increase the survival of ESA-listed fish species. Alternative 1 is designed to increase the probability of refilling the WVS reservoirs and use a greater portion of the total reservoir volume for conservation storage, including the inactive and power pools than under the NAA. One goal of alternative 1 is to fill the reservoirs as often as possible and to supply water from storage as late into the conservation season as possible through changes in operations.

The main operational features under Alternative 1 are to reduce minimum flows to congressionally authorized minimum flow requirements from the NAA 2008 BiOp flows, as well as, to augment instream flows by using the power and inactive pools which is not done under the NAA. Alternative 1 also proposes only structural measures for fish passage and water quality as shown in Table 5.2-2.

**Table 5.2-2. Water Quality and Passage Measures Under Alternative 1**

| Dam | Temperature Control | TDG Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Dexter | – | Structural* | – | – |
| Lookout Point | Structural* | – | Structural* | – |
| Hills Creek | – | – | – | – |
| Fall Creek | – | – | – | Structural* |
| Cougar | – | Structural* | – | – |
| Blue River | – | – | – | – |
| Foster | Structural | Structural* | Structural | – |
| Green Peter | Structural* | Structural* | Structural* | Structural* |
| Big Cliff | – | – | – | – |
| Detroit | Structural | – | Structural | – |

*Distinctive feature of this alternative.

Alternative 1 is like Alternative 4, which focuses on structural measures to accomplish downstream passage and water quality management. For instance, Alternatives 1 and 4 are also the only alternatives to propose restoring upstream and downstream passage at drop structures and structures to abate TDG which adds to their total costs. However, there would be several differences in the total number and the locations of these structures.

The difference between Alternative 1 and Alternative 4 with respect to structures is that they propose temperature control and downstream passage structures at different dams, and Alternative 4 proposes an additional downstream passage structure compared to Alternative 1. These differences allow for the comparison of the relative costs and benefits associated with the different combinations of structural measures across the action alternatives. There are no structures proposed under the NAA.

Table 5.2-3 shows this comparison of structural measures between Alternative 1 and 4.

**Table 5.2-3. Alternatives 1 and 4 structural measure comparison**

| Dam | Alternative 1 water temperature structure | Alternative 4 water temperature structure | Alternative 1 structural downstream passage | Alternative 4 structural downstream passage |
|---|---|---|---|---|
| Detroit | X | X | X | X |
| Foster | X | X | X | X |
| Green Peter | X | – | X | – |
| Cougar | – | – | – | X |
| Hills Creek | – | X | – | X |
| Lookout Point | X | X | – | X |

*5.2.2.2.1 Tradeoffs*

Under Alternative 1, large floating fish passage structures would be implemented in the North, South Santiam, and the Middle Fork Rivers. These structures do not require an increased release of conservation storage to facilitate passage or their use when compared to the NAA. A fall[62] deep drawdown at Fall Creek would also continue from the NAA. Flow targets from HD 531 support capturing increased amounts of water in reservoirs during spring as compared to all other alternatives including the NAA.

Despite the spending on structural measures, Alternative 1 would only marginally meet the Proposed Action ESA objectives (objectives 4-6). Although Alternative 1 did rank the highest out of all alternatives for downstream survival and three out of four Chinook salmon populations would reach replacement, only two out of four Chinook salmon populations would have high persistence (e.g., low risk of extinction). Additionally, the McKenzie Core Legacy spring Chinook salmon population would be at risk of extinction. Under Alternative 1, there would also be the least habitat gains for bull trout compared to the NAA due to lack of effective downstream passage at Cougar Dam. Alternative 1 implementation is predicted to have major effects on Chinook salmon and minor adverse effects on winter steelhead populations in the North and South Santiam sub-basins. Scores and risks for bull trout would be like the NAA, with minor effects predicted. Habitat scoring for bull trout would be only marginally better than under the NAA with rearing habitat increases for North Santiam bull trout below Detroit.

Unlike the NAA, structural improvements for fish passage and water temperature would provide resilience to adverse climate change impacts by increasing operational flexibility in the North Santiam, South Santiam, McKenzie, and Middle Fork sub-basins. See Appendix F for details on climate change effects on the WVB.

Compared to the NAA, Alternative 1 would result in minor to major beneficial water temperature effects in the Middle Fork Willamette, South Santiam, and North Santiam sub-basins due to the proposed temperature control structures at Lookout Point, Green Peter,

[62] The terms “fall” and “autumn” are synonymous in this chapter in reference to seasonal drawdown periods.

Detroit Dams. Minor to major beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins based on the reduced number of spill days and proposed TDG abatement structures under Alternative 1.

Because of many of the structural measures, reservoirs would not be drawn down for temperature management and downstream fish passage operations under Alternative 1. This, coupled with the proposed operation to reduce minimum flows to congressionally authorized minimum flow requirements, would result in the greatest increase in total water stored by mid-May of all alternatives, at an estimated increase in peak water stored system-wide under the NAA by 168,000 acre-feet in the driest year. This would result in a moderate beneficial effect to M&I water supply and AI users of the conservation storage space under Alternative 1.

The increase in total water stored and flow measures under Alternative 1 would result in the same or higher downstream flows in the summer as compared to the NAA. Flows in the mainstem Willamette River at Salem would be lower than under the NAA from mid-May through June, but flows would remain high and above 6,000 cfs. As modeled, flows at Salem during the summer would be higher than under the NAA, rarely dropping below 6,000 cfs. This would result in a minor beneficial effect to existing M&I water supply and AI users from increased summer flows in the driest years. However, as discussed in Section 3.13, in the driest years, the actual impact to M&I and irrigation is currently unquantifiable because the 2019 Willamette Basin Review (WBR) BiOp sets forth a theoretical plan to reduce contracted water availability to protect ESA-listed species that has not yet been formalized.

The additional stored water under Alternative 1 as compared to the NAA would contribute to an overall increase in average annual hydropower generation of 8 aMW (roughly enough to power 6,371 households annually; see Section 3.12.3.2 for details). However, the high capital and O&M cost of Alternative 1 would result in the greatest decrease in NPV from that provided under the NAA.

Under Alternative 1, there would be a $1.159 billion reduction in median NPV to -$934 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. There would, however, be negligible risk to local hydropower generation as Hills Creek and Cougar Dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due primarily to weather events or fires like the NAA.

Under Alternative 1, the increased stored water and reduction in minimum flows as compared to the NAA would mean that reservoir levels stay higher for more of the conservation season resulting in minor to moderate benefits to reservoir recreation. This would translate into slight increases in annual visitations, resulting in an approximate increase of $300,000 in annual economic benefits (a 1.5% increase) compared to the NAA.

The regional economic impact from recreation effects would be low under Alternative 1. The regional economic effects would be associated with the negligible effects to employment and regional output.

Alternative 1 would be the second costliest alternative to implement (surpassed only by Alternative 4) primarily driven by the cost to design, construct, operate, and maintain structural measures for temperature control, fish passage, and TDG abatement. The estimated total annual cost for Alternative 1 is $104,396 million, $95 million greater than the NAA (see Appendix M for details).

Alternative 1 would increase the probability of refilling the WVS reservoirs and the amount of water available for conservation purposes later in the season. This alternative would result in the greatest increase in total water stored by mid-May of all alternatives. Further, there would be an overall increase in average annual hydropower generation and minor to moderate benefits to reservoir recreation under Alternative 1.

However, due to the scale of actions required under Alternative 1, this is the second most expensive alternative. The high cost makes it unlikely this alternative would be acceptable to many stakeholders, agencies, and the public. Although there would be some benefits to fish species such as resilience to adverse climate change impacts from structural modifications, this Alternative 1 would result in fewer benefits to ESA species overall than several less costly alternatives, including Alternatives 2A, 2B, and 5. Therefore, Alternative 1 was not identified as the preferred alternative.

#### *5.2.7.3 Alternative 2A. Integrated Water Management Flexibility and ESA-listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Alternative 2A, also referred to as the Hybrid Alternative with Cougar Floating Screen Structure (FSS), was developed to improve fish passage through the WVS dams, as compared to the NAA, utilizing a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and to meet requirements for ESA-listed fish. Under Alternative 2A, the “Integrated Temperature and Habitat Flow Regime” operation replaces the 2008 BiOp flows under the NAA. This would shift the release of stored water from the spring to the summer and fall, most notably in dry years. Flows would be reduced within a range down to minimums needed for fish survival when reservoirs are under 90% of rule curve elevation as compared to NAA. While these minimums would be less than the BiOp targets, they would be adaptive within a water year and could return to levels that are higher than the BiOp flows under the NAA if reservoir levels are high. Alternatives 2B, 3A, 3B, and 4 also include this flow measure.

The other main operational features of Alternative 2A that differ from the operations in the NAA is the augmentation of instream flows by using the power and inactive pools and a spring spill and deep draw down for fish passage at Green Peter. Alternative 2A also proposes a combination of structural measures for fish passage and temperature control which are not in the NAA, as shown in Table 5.2-4. As under Alternative 1, and in contrast to the NAA, structural improvements for fish passage and water temperature would provide resilience to adverse climate change impacts on fish species by increasing operational flexibility.

As under the NAA, Alternative 2A does not include the structural improvements for TDG abatement included in Alternatives 1 and 4 or the fish passage and temperature structures at Hills Creek Dam under Alternative 4. In contrast to Alternative 1 but like all other action alternatives, Alternative 2A proposes operational measures utilizing the spillway and regulating outlets (ROs) for temperature management at Green Peter Dam. Alternative 2A also includes a deep fall drawdown and spring spillway operations for fish passage at Green Peter Dam, unlike Alternatives 1, 4, and the NAA .

The only difference between Alternative 2A and 2B is in their downstream passage measure at Cougar Dam. Alternative 2A proposes structural downstream fish passage at Cougar Dam whereas Alternative 2B proposes operational fish passage at Cougar Dam. The NAA does not provide operational or structural fish passage at Cougar Dam. Alternative 5 also proposes operational fish passage instead of structural fish passage as well as proposing a refined flow operation that slightly differs from the “Integrated Temperature and Habitat Flow Regime” operation under Alternatives 2A through 4 and the 2008 BiOp flow targets in the NAA.

**Table 5.2-4. Water Quality and Passage Measures Under Alternative 2A.**

| Dam | Temperature Control | TDG structural Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Dexter | – | – | – | – |
| Lookout Point | – | – | Structural | – |
| Hills Creek | – | – | – | – |
| Fall Creek | – | – | – | – |
| Cougar | – | – | Structural * | – |
| Blue River | – | – | – | – |
| Foster | Structural | – | Structural | – |
| Green Peter | Operational* | – | Operational* | Structural* |
| Big Cliff | – | – | – | – |
| Detroit | Structural | – | Structural | – |

*Distinctive feature of this alternative.

### *5.2.2.3.1 Tradeoffs*

Alternative 2A has an integrated management strategy theme. This alternative includes structural downstream passage at Detroit, Foster, Cougar and Lookout Point Dams, and operational passage at Green Peter Dam. A fall deep reservoir drawdown at Fall Creek Dam that is in the NAA would continue.

Alternative 2A would most effectively meet the Proposed Action ESA objectives (objectives 4-6) for most dams compared with all other alternatives. Alternative 2A ranks second for downstream survival, with all four Chinook salmon populations reaching replacement, and three out of four Chinook salmon populations with high persistence (e.g., low risk of extinction). Alternative 2A would also reduce risk to the McKenzie Core Legacy spring Chinook salmon population and provides more habitat gains for bull trout compared to the NAA due to the inclusion of effective downstream passage at Cougar. In addition, fish passage at Detroit Dam as part of Alternative 2A would provide access to more habitat for bull trout once they are introduced above that dam as compared the NAA. Alternative 2A would have moderate adverse effects on Chinook salmon, predicted to produce the most viable populations compared to the NAA and the other alternatives and would retain the McKenzie Core Legacy spring Chinook salmon population.

Alternative 2A would also produce the most optimistic outcomes for Chinook salmon in the Middle Fork sub-basin among the alternatives, including the NAA, accomplished with a downstream passage structure at Lookout Point exclusive of passage at Hills Creek. Alternative 2A would have minor adverse effects to Santiam winter steelhead populations. Alternative 2A would have minor adverse effects for bull trout. Bull trout habitat scores and risks are comparable to Alternative 1, with a fish passage addition providing access to habitat below Cougar Dam. Habitat scores are higher as compared to the NAA.

Alternative 2A is almost identical to Alternatives 2B and 5. The primary difference in measures between Alternative 2A and Alternatives 2B and 5 is the downstream fish passage measure proposed at Cougar Dam. Alternative 2A proposes an FSS, and Alternatives 2B and 5 propose a deep drawdown to pass fish through the Diversion Tunnel (DT). In contrast to Alternative 2A, Alternatives 2B and 5 would result in high persistence for only three of the four Chinook salmon populations though all three perform better than the NAA. The difference in the anticipated number of populations with high persistence is because the ESA models assume more optimistic downstream fish passage performance with a structure at Cougar Dam. It is assumed that more extreme operations, like a deep drawdown, may have adverse effects on viable populations downstream.

Structural improvements for fish passage and water temperature would provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, Middle Fork sub-basins, as compared to the NAA. See Appendix F for details on climate change effects on the WVB.

Compared to NAA, Alternative 2A would result in minor to major beneficial water temperature effects in the North and South Santiam sub-basins due to the proposed temperature control structure at Detroit Dam and the Green Peter Dam fall deep drawdown. A temperature control structure at these two locations would not occur under the NAA. Minor to moderate beneficial TDG effects are expected in the North Santiam sub-basin when compared to the NAA due to the proposed temperature control structure at Detroit that removes the need for operational temperature control with non-turbine outlets. Moderate to major adverse TDG effects are expected in the South Santiam sub-basin due to the Green Peter fall deep drawdown that relies on more spill flow under Alternative 2A than under the NAA.

As modeled, Alternative 2A would result in an estimated increase in the 75% exceedance level of total water stored system-wide by mid-May of 122,000 acre-feet from the NAA. The Integrated Flow Regime has lower spring mainstem requirements compared to the 2008 BiOp flows under the NAA. Additionally, because of many of the structural measures proposed under Alternative 2A, no reservoirs except Green Peter would be drawn down for temperature management and downstream fish passage during the conservation season. The combination of lower spring flow targets and minimal drawdowns during the conservation season would result in an increase from the NAA in water stored in the driest years.

Alternatives 2A and 4 are similar in this respect, tying for the second largest increase in mid-May stored water volumes when compared to the other alternatives. The increased stored water would result in a moderate beneficial effect to M&I water supply and AI users of the conservation storage space. However, as discussed in Section 3.13, in the driest years the actual impact to M&I and irrigation is currently unquantifiable because the 2019 WBR BiOp sets forth a theoretical plan to reduce contracted water availability in dry years to protect ESA-listed species that has not yet been formalized.

The anticipated increase in total system-wide stored water and flow measures would result in the same or higher downstream flows in the summer as compared to the NAA. The Integrated Flow Regime would require additional flow based on the air temperature, compared to the 2008 BiOp flows proposed under the NAA. Therefore, flows later in the summer and fall would be higher than the NAA due to the additional accumulated stored water.

Under Alternative 2A, flow in the mainstem at Salem would be lower than under the NAA from April through June about 25% of the time, but flows would remain high, usually above 10,000 cfs. During the summer, flows at Salem would be higher than under the NAA, rarely dropping below 6,000 cfs.

In most years, Alternative 2A would have a negligible effect to existing water rights for M&I water supply and AI in the spring and would have a minor beneficial effect in the summer by increasing summer flows in the driest years as modeled when compared to the NAA. However, as discussed in Section 3.13, in the driest years the actual impact to M&I and irrigation is currently unquantifiable.

The additional storage under Alternative 2A as compared to the NAA would contribute to an overall increase in average annual hydropower generation by 4 aMW (roughly enough to power 3,185 households annually) (see Section 3.12.3.3 for details). However, the high capital and O&M cost of Alternative 2A results in a reduction in NPV from that provided under the NAA.

Under Alternative 2A, there would be a $863 million reduction in median NPV to -$638 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation as compared to effects under the NAA. However, there would be negligible risk to local hydropower generation as Hills Creek and Cougar dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due primarily to weather events or fires.

Under Alternative 2A, the additional water stored system-wide as compared to the NAA would also mean reservoir levels stay higher for more of the conservation season resulting in minor to moderate benefits to reservoir recreation except for at Green Peter Reservoir. Despite the fall drawn down at Green Peter Reservoir, Alternative 2A would translate into slight increases in annual visitations across the WRB, resulting in an approximate increase of $169,000 in annual economic benefits (a 0.83% increase) compared to the NAA.

The regional economic impact from recreation effects would be medium. The regional economic effects would be associated with the potential loss of 1.7 jobs in the South Santiam sub-basin due to the drawdown at Green Peter and a moderate reduction in regional output.

Alternative 2A would be the third costliest alternative to implement (surpassed by Alternative 1 and 4) due to the incorporation of numerous structural measures. The estimated total annual cost for Alternative 2A is $67,561 million, $58 million greater than the NAA (see Appendix M for details).

During the tradeoffs analysis it was difficult to discriminate the differences in effects to ESA species among the alternatives. However, Alternative 2A would have a higher risk of not meeting the Proposed Action ESA objectives at Cougar compared to Alternatives 2B and 5. This is due to a higher uncertainty recognized for the performance of the proposed FSS at Cougar Dam when compared downstream fish passage rates of a deep reservoir drawdown using the DT. However, if the structure is as successful as assumed in the modeling it would out preform the DT fish passage rates.

The topography of Cougar Reservoir presents some unique challenges for designing an FSS. Deep reservoir drawdowns have proven very effective at Fall Creek Dam for downstream passage of juvenile Chinook salmon (NMFS 2014) and would not be impacted by the layout of Cougar Reservoir. In comparison, the range of performance among the few examples of floating fish collectors in operation varies widely, and there is only one example of an FSS operating with similar attributes to WVS dams (large temperature stratified forebay with significant reservoir fluctuation) where juvenile Chinook salmon are present (SWIFT Dam and Reservoir on the Lewis River, Washington). This floating collector has a poor rate of juvenile Chinook salmon collection (Kock et al. 2019).

Finally, if collection rates proved to be low with an FSS at Cougar there are minimal post-operation mitigation options with current technology for improving collection into the FSS. The uncertainty that an FSS would effectively collect fish at Cougar Dam coupled with the cost to design, construct, and operate the facility eliminated Alternative 2A from consideration for the Preferred Alternative.

#### *5.2.7.4 Alternative 2B. Integrated Water Management Flexibility and ESA-listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2B, also referred to as the Hybrid Alternative with Cougar Diversion Tunnel Modification, was developed to improve fish passage through the WVS dams as compared to the NAA utilizing a combination of modified operations and structural improvements, along with other measures to balance water management flexibility and meet ESA-listed fish obligations. Alternative 2B is almost exactly like Alternative 2A and 5. The difference between Alternatives 2A and 2B is the fish passage measure at Cougar Dam.

Alternative 2A would incorporate a structure that operates with existing reservoir fluctuations to pass fish downstream, whereas Alternative 2B includes an operation where the reservoir is drawn down to elevation 1330' to use the DT to pass fish. Alternative 5 also includes this measure but proposes a refined flow operation that slightly differs from the "Integrated Temperature and Habitat Flow Regime" operation under Alternatives 2A through 4.

**Table 5.2-5** shows the major operational and structural features under Alternative 2B.

**Table 5.2-5. Water Quality and Passage Measures under Alternative 2B.**

| Dam | Temperature Control | TDG structural Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Dexter | – | – | – | – |
| Lookout Point | – | – | Structural | – |
| Hills Creek | – | – | – | – |
| Fall Creek | – | – | – | – |
| Cougar | – | – | Operational * | – |
| Blue River | – | – | – | – |
| Foster | Structural | – | Structural | – |
| Green Peter | Operational* | – | Operational* | Structural* |
| Big Cliff | – | – | – | – |
| Detroit | Structural | – | Structural | – |

*Distinctive feature of this alternative.

##### *5.2.2.4.1 Tradeoffs*

Alternative 2B also has an integrated management strategy theme. The only difference with Alternative 2A is that 2B has an operational downstream fish passage measure at Cougar Dam (deep drawdown to near the DT in spring and fall) instead of a structural measure.

This deep drawdown operation is expected to result in most juvenile Chinook salmon migrating downstream of Cougar Dam in spring, along with many resident bull trout. The deep draft in spring would also negatively affect the ability to store water in the conservation pool, resulting in lower summer stream flows and changes in water temperatures below Cougar Dam. These differences would affect fish rearing patterns both above and below Cougar Dam.

Compared to Alternative 2A, 2B would result in increased adverse effects to UWR spring Chinook salmon (moderate) and bull trout (moderate) in the McKenzie sub-basin. Otherwise, effects on listed fish species are predicted to be the same as under Alternative 2A.

Alternative 2B is more likely to effectively meet the Proposed Action ESA objectives (objectives 4-6), surpassed only by Alternative 2A. Alternative 2B ranks fourth for downstream survival with all Chinook salmon populations anticipated to reach replacement. Alternative 2B would also reduce risk to the McKenzie Core Legacy spring Chinook salmon population and would provide more habitat gains for bull trout compared to the NAA due to the inclusion of effective downstream passage at Cougar Dam.

In contrast to Alternative 2A, Alternative 2B would result in only two of the four Chinook salmon populations with high persistence. This is the primary difference in how Alternative 2B would perform for the Proposed Action ESA objectives compared to Alternative 2A This difference is a result of the downstream fish passage measure proposed at Cougar Dam. Alternative 2A proposes a FSS and Alternative 2B propose a deep drawdown to pass fish through the DT. The difference in the number of populations anticipated with high persistence is because the PEIS ESA models assume more optimistic downstream survival with a structure at Cougar Dam. It is assumed that more extreme operations, like a deep drawdown, may have adverse effects on viable populations downstream.

Alternative 2B is identical to Alternative 5 except for refinements to the “Integrated Temperature and Habitat Flow Regime” measure proposed under Alternative 5. These minor refinements to the flow operation have not undergone the ESA modeling performed on the other alternatives because the minor changes could be qualitatively described. After considering available hydrologic modeling results for Alternative 5, the different outcomes for ESA species between Alternatives 2B and 5 are considered negligible.

Structural improvements for fish passage and water temperature would provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, and Middle Fork sub-basins when compared the NAA with no structural improvements. See Appendix F for details on climate change effects on the WVB.

Compared to NAA, Alternative 2B would result in minor to major beneficial water temperature effects in the North Santiam, South Santiam, and South Fork McKenzie sub-basins due to the proposed temperature control structure at Detroit Dam, Green Peter Dam autumn deep drawdown with operational temperature control, and a deep drawdown at Cougar Dam.

Minor to moderate beneficial TDG effects is expected in the North Santiam and South Fork McKenzie sub-basins due to a reduced number of days with spill (at Detroit Dam, the proposed temperature control structure removed the need for operational temperature control with non-turbine outlets). Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 2B due to the deep drawdown at Cougar Dam that involves use of the DT, which is expected to have lower TDG than the RO. Moderate to major adverse TDG effects, when compared to the NAA, are expected in the South Santiam sub-basin due to the Green Peter Dam autumn deep drawdown that relies on more spill flow under Alternative 2B.

Under Alternative 2B, there would be an estimated decrease in total water stored by mid-May at the 75% exceedance level of 64,000 acre-feet from the NAA (1,328,542 acre-feet) primarily due to the fish passage operation at Cougar Dam. The small decrease in stored water would have a minor adverse effect to M&I water supply and AI users of the conservation storage space as compared to the NAA.

Under Alternative 2B, flow targets in the summer and fall would be met more frequently due to the additional accumulated stored water at WVS reservoirs other than Cougar and Green Peter. However, compared to the NAA, the spring and early summer flows would be similar or somewhat lower across the WVS. This would be a result of the spring drawdown at Cougar Dam that occurs during the NAA refill period.

The reduced storage at Cougar Dam would mean that other WVS reservoirs, notably in the Middle Fork of the Willamette River sub-basin, would be required to release additional water to meet mainstem Willamette River flow targets. The drawdown of the Cougar Reservoir would effectively eliminate the conservation pool for use for water supply from Cougar. However, the Blue River Reservoir would fill more than under the NAA, partially offsetting the lost storage from Cougar Reservoir.

Cougar Dam is also situated on the South Fork of the McKenzie River, and its flow is a small portion of the overall McKenzie River flow. The flow on the McKenzie River would be only slightly less as compared to the NAA due to additional flow from Blue River. Therefore, Alternative 2B would have a negligible effect to live flow water rights in the McKenzie sub-basin. Due to the expected limited level of demand for stored water on the McKenzie River, Alternative 2B would be expected to have only a minor adverse effect to M&I water supply and AI users in the McKenzie sub-basin as compared to the NAA.

The decrease in stored water would contribute to an overall decrease in average annual hydropower generation by 18 aMW (roughly enough to power 14,334 households annually see Section 3.12.3.2 for details). This, coupled with the high cost of Alternative 2B, would result in a $933 million reduction in median NPV to -$708 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation under Alternative 2B as compared to the NAA.

Additionally, the fish passage operation at Cougar Dam would result in infrequent, temporary moderate adverse effects on transmission services to Blue River as compared to the NAA. Deep fall and spring drawdowns at Cougar Dam would compromise the ability to provide power to Oakridge and serve this islanded (isolated) community under temporary weather or fire related outage conditions. Generation at Hills Creek Dam would remain able to operate islanded (isolated), providing transmission services to Oakridge, like the NAA.

Alternative would 2B results in the smallest increases in annual visitations, resulting in an approximate increase of $12,000 in annual economic benefits (a 0.06% increase) compared to the NAA. Although this would be a negligible adverse effect on recreation across the WVS, the near loss of the conservation pool at Cougar Reservoir would result in major adverse effects to reservoir recreation at this location. However, the regional economic effects would similar to those under Alternative 2A because there are no jobs associated with recreation at Cougar Reservoir.

The regional economic effects would be associated with the potential loss of 1.7 jobs in the South Santiam sub-basin due to the drawdown at Green Peter Dam and a moderate reduction in regional output as compared to the NAA.

Alternative 2B would be the fourth costliest alternative to implement (surpassed by Alternatives 1, 2A, and 4) due to the incorporation of numerous structural measures. The estimated total annual cost for Alternative 2B is $62,291 million, $53 million greater than the NAA (see Appendix M for details).

The higher design costs compared to Alternative 2A is because the modification of the DT required to perform the fish passage operation at Cougar Dam under Alternative 2B would require new construction. The Cougar Dam FSS proposed under Alternative 2A has already undergone detailed design and would require limited additional design effort compared to Alternative 2B. Conversely, the annual O&M cost for Alternative 2B would be lower than under Alternative 2A because the FSS would require substantially more O&M than operation of the DT once it is constructed.

Although Alternative 2B would be beneficial for meeting the Proposed Action ESA objectives, during the tradeoffs analyses with input from USFWS and NMFS, USACE deemed Alternatives 2A, 2B, and 5 too similar to effectively differentiate between their effects on ESA-listed species. Additionally, Alternative 2A would have higher uncertainty in meeting Proposed Action ESA objectives at Cougar Dam as compared to Alternatives 2B and 5. In contrast, there is high confidence that when reservoirs are drafted very low, juvenile Chinook salmon would successfully pass downstream under Alternative 2B (NMFS, 2014).

In addition to the assumption that more extreme operations, like a deep drawdown, may have adverse effects on viable populations downstream, the main risk associated with Alternative 2B relates to modifications required to operate the DT. The DT was originally constructed to be used temporarily during dam construction and was not designed to be operated on a regular basis. Without detailed investigation and designs, the dam safety and operational feasibility of drawing down to the DT annually for fish passage is uncertain. However, unlike the FSS, which would have limited mitigation actions available for addressing the fish collection risks with current technology, there are clear engineering pathways for managing risk associated with dam safety and operational feasibility of a dam outlet.

In sum, Alternative 2B would effectively meet the Proposed Action ESA objectives at lower risk and substantially lower costs than under Alternative 2A. However, Alternative 2B was not chosen as the Preferred Alternative because discussions with cooperators revealed refinements to the "Integrated Temperature and Habitat Flow Regime" operation that could result in increased comparative beneficial effects on listed fish species. Subsequently, these refinements were included under Alternative 5, the Preferred Alternative and are not included under the NAA. Alternative 2B is identical to Alternative 5 but for these refinements to the "Integrated Temperature and Habitat Flow Regime" measure.

#### *5.2.7.5 Alternative 3A. Improve Fish Passage Through Operations-focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Alternatives 3A, also referred to as the Operations-focused Fish Passage Alternative, would primarily utilize WVS dam operations for water quality and fish passage. As under the NAA, Alternative 3A would not include structural measures for temperature control, TDG abatement, or downstream fish passage like Alternatives 1 and 4 and much of Alternatives 2A, 2B, and 5.

An important part of the operational focus under Alternative 3A, and a distinction from the NAA, would be the increased use of different flow outlets from the dams to control temperature, with the spillway supplying warmer water from the upper reservoir and the deeper outlets – ROs and turbines – supplying cooler water. Alternative 3A would also implement spring and fall drawdowns at some WVS reservoirs for volitional downstream fish passage, which would not occur under the NAA. Additionally, where Alternative 1, 2A, 2B, 4, and 5 only proposed a new adult fish facility for upstream fish passage at Green Peter Dam, Alternative 3A proposes new adult fish facilities at Hills Creek and Blue River Dams as well. No new fish facilities are proposed under the NAA.

Table 5.2-6 shows the major operational and structural features of Alternative 3A.

**Table 5.2-6. Water Quality and Passage Measures Under Alternative 3A.**

| Dam | Temperature Control | TDG structural Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Dexter | – | – | Operational – use spillway* | – |
| Lookout Point | Operational – spillway and RO releases* | – | Operational – spring and fall drawdown* | – |
| Hills Creek | Operational – spillway releases* | – | Operational – use spillway and fall drawdown* | Structural* |
| Fall Creek | – | – | Operational – use spillway* | – |
| Cougar | – | – | Operational – spring and fall | – |

| Dam | Temperature Control | TDG structural Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| | | | drawdown (RO)* | |
| Blue River | Operational – spillway releases* | – | Operational –fall drawdown* | Structural* |
| Foster | Operational – spillway releases* | – | – | – |
| Green Peter | Operational – spillway and RO releases* | – | Operational – use spillway and fall drawdown* | Structural |
| Big Cliff | – | – | Operational – use spillway* | – |
| Detroit | Operational – spillway and RO releases* | – | Operational – spring and fall drawdown* | – |

*Distinctive feature of this alternative.

Alternative 3A is very similar to Alternative 3B, with proposed differences in downstream fish passage operations in spring as shown in Table 5.2-7. Alternatives 3A and 3B also differ in the proposed drawdowns for fish passage operations at Cougar Dam.

Under Alternative 3A, the spring and fall drawdowns would target the Cougar Dam RO, whereas the Alternative 3B drawdowns would target the much lower DT (like Alternatives 2B and 5). By making these distinctions between Alternatives 3A and 3B, the unique effects associated with each of these operations for downstream passage to be identified at Cougar Dam and the tradeoffs between them can be assessed and compared.

**Table 5.2-7. Differences in Spring Downstream Fish Passage Operations between Alternatives 3A and 3B.**

| Dam | Spring Drawdown | Spring Spill |
|---|---|---|
| DEX | – | 3A & 3B |
| LOP | 3A | 3B |
| HCR | 3B | 3A |
| FCR | – | 3A |
| CGR | 3A- RO, 3B DT | – |
| BLU | – | – |
| FOS | – | – |
| GPR | 3B | 3A |
| BCL | – | 3A & 3B |
| DET | 3A | 3B |

Under Alternative 3A and Alternatives 2B, 3A, 3B, and 4, the "Integrated Temperature and Habitat Flow Regime" operation replaces the 2008 BiOp flows under the NAA. Alternative 3A would also augment instream flows by using the power and inactive pools and allows reservoirs to draft below the NAA rule curves to meet minimum flow requirements. This would usually occur during the fall of drier years at reservoirs that do not have a fall drawdown operation.

###### *5.2.2.5.1 Tradeoffs*

Alternative 3A has an operational theme (i.e., fish passage, water quality and other missions are accomplished by operation of existing structures). Unlike operations under the NAA, deep reservoir drawdowns would occur in spring and fall at Detroit, Cougar (to RO), and Lookout Dams. Spring surface spill and fall deep drawdowns would occur at Green Peter and Hills Creek Dams. A fall deep drawdown at Fall Creek would continue as under the NAA.

Alternative 3A would have major adverse effects for UWR spring Chinook salmon and UWR steelhead. Predicted performance for these species is very similar to those under the NAA, with some improvement in North Santiam Chinook salmon and South Santiam steelhead populations. Similarly, Alternative 3A would have major adverse effects for bull trout. Reservoir rearing area would be substantially reduced in both Detroit and Cougar Reservoirs. Consequently, bull trout would be expected to increase movement into more degraded rearing habitat below Detroit and Hills Creek Dams where spawning habitat does not exist, and human disturbance is high.

Alternative 3A would not effectively meet all the Proposed Action ESA objectives. Although all four Chinook salmon populations would reach replacement under Alternative 3A, only one out of four Chinook salmon populations would have high persistence (e.g., low risk of extinction), which would not be an improvement as compared to the NAA. Additionally, Alternative 3A ranks fifth for downstream survival, and the McKenzie Core Legacy spring Chinook salmon population is at risk of extinction. However, there would be habitat gains for bull trout as compared to the NAA.

Climate change is predicted to further degrade habitat for bull trout below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature targets below dams for UWR spring Chinook salmon and UWR steelhead. See Appendix F for details on climate change effects on the WVB.

Compared to the NAA, Alternative 3A would result in minor to major beneficial water temperature effects in the Middle Fork Willamette (between Hills Creek Dam and Lookout Point Dam) and South Santiam sub-basins due to the proposed deep drawdowns at Hills Creek and Green Peter Dams. In the North Santiam sub-basin, minor beneficial effects to water temperature are expected during the autumn while moderate adverse effects are expected during the spring-summer due to deep drawdown at Detroit Dam under Alternative 3A. In the South Fork McKenzie sub-basin, minor adverse effects to water temperature are expected during the fall due to a partial drawdown at Cougar Dam under Alternative 3A. Minor to major adverse TDG effects are expected in the North Santiam, South Santiam, and Middle Fork

Willamette sub-basins due to the deep drawdowns at Detroit, Green Peter (autumn) and Lookout Point Dams that rely on high outflows and/or spill flow under Alternative 3A.

By combining spring spill and drawdowns with fall drawdowns at 6 of the 11 storage projects, Alternative 3A would substantially affect the ability to refill the system-wide conservation storage. These operations would result in a 56% reduction of system-wide stored water compared to the NAA, or 590,000 acre-feet. Depending on how and when the Fish and Wildlife conservation storage allocation is takes priority over other consumptives uses it would leave very little conservation storage available for M&I water supply or AI. Therefore, Alternative 3A would have a major adverse effect to M&I water supply and irrigation.

Additionally, under Alternative 3A, flows during dry years would be lower than under the NAA starting in April, dropping below 5,000 cfs in August at Salem. This would likely cause water users in the system to be shut off more than under current conditions, resulting in a moderate adverse effect to M&I water supply and AI as compared to the NAA.

The decrease in stored water would contribute to an overall decrease in average annual hydropower generation by 87 aMW (roughly enough to power 69,283 households annually; see Section 3.12.3.2 for details). Coupled with the cost of Alternative 3A, there would be a $853 million reduction in median NPV to -$628 million. Therefore, long-term, major, adverse effects on the economic viability of WVS power generation would occur under Alternative 3A as compared to the NAA.

Additionally, the fish passage operations at Hills Creek and Cougar Dams would result in infrequent, temporary moderate adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise abilities to serve these communities from Hills Creek and Cougar Dams under temporary storm or fire related outage conditions which would not occur under the NAA where power generation would not be impacted.

Alternative 3A is one of two alternatives that would result in decreases in annual visitations as compared to the NAA. This would be a major, long-term adverse effect to recreation in the WVS, resulting in an approximate decrease of $769,000 in annual economic benefits (a 3.76% decrease) compared to the NAA.

The effects to recreation would also have a high regional economic impact with close to a 50% reduction in recreation-related jobs in the North Santiam (14 jobs lost) and Middle Fork Willamette (13.7 jobs lost) sub-basins and a reduction in regional output greater than $150,000 in multiple basins.

Alternative 3A would be the least costly alternative to implement because it incorporates the fewest structural measures. Alternative 3A would be approximately $86 million less annually than the costliest alternative, Alternative 4. The estimated total annual cost for Alternative 3A is $26,442 million, $17 million greater than the NAA (see Appendix M for details).

Although one of the least costly alternatives, Alternative 3A would perform poorly for Proposed Action ESA objectives while substantially decreasing water stored in the conservation pools with adverse effects to hydropower, water supply, and recreation. Additionally, the autumn deep and spring drawdowns would compromise the abilities to serve nearby communities from Hills Creek and Cougar Dams under temporary storm or fire related outage conditions. These adverse effects without appreciable benefits for ESA-listed species makes it unlikely this alternative would be acceptable to stakeholders, agencies, and the public. Therefore, Alternative 3A was not identified as the Preferred Alternative.

#### *5.2.7.6 Alternative 3B. Improve Fish Passage Through Operations-focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternatives 3B, also referred to as the Operations-focused Fish Passage Alternative using Diversion Tunnel at Cougar, would primarily utilize WVS dam operations for water quality and fish passage. Table 5.2-8 shows the major operational and structural features of Alternative 3B.

Alternative 3B is very similar to Alternative 3A, with differences in downstream fish passage operations in spring as shown in Table 5.2-7. Alternatives 3A and 3B also differ in the drawdowns for fish passage operations at Cougar Dam. Under Alternative 3B, the spring and fall drawdowns would target the DT (like Alternatives 2B and 5), resulting in a much lower drawdown than Alternative 3A, which proposes drawing down only to the RO. By making these distinctions between Alternatives 3A and 3B, the unique effects associated with each of these operations for downstream passage to be identified at Cougar Dam and the tradeoffs between them can be assessed and compared.

**Table 5.2-8. Water Quality and Passage Measures Under Alternative 3B.**

| Dam | Temperature Control | TDG structural Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Dexter | – | – | Operational – use spillway* | – |
| Lookout Point | Operational – spillway and RO releases* | – | Operational – use spillway and fall drawdown* | – |
| Hills Creek | Operational – spillway releases* | – | Operational – spring and fall drawdown* | Structural* |
| Fall Creek | – | – | – | – |
| Cougar | – | – | Operational – spring and fall drawdown (DT)* | – |
| Blue River | Operational – spillway releases* | – | Operational – fall drawdown* | Structural* |

| Dam | Temperature Control | TDG structural Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Foster | Operational – spillway releases* | – | – | – |
| Green Peter | Operational – spillway and RO releases* | – | Operational – spring and fall drawdown* | Structural |
| Big Cliff | – | – | Operational – use spillway* | – |
| Detroit | Operational – spillway and RO releases | – | Operational – use spillway and fall drawdown | – |

*Distinctive feature of this alternative.

##### *5.2.2.6.1 Tradeoffs*

Alternative 3B also has an operational theme, with a different combination of fish passage measures than 3A or the NAA. Deep reservoir drawdowns would occur in spring and fall at Green Peter, Cougar (to DT), and Hills Creek Dams. Spring surface spill and fall deep drawdowns would occur at Detroit and Lookout Point Dams. A fall deep drawdown at Fall Creek Dam would continue as under the NAA.

Alternative 3B would have moderate to major adverse effects on UWR spring Chinook salmon and UWR steelhead. Alternative 3B would have moderate to major adverse effects for bull trout. Reservoir rearing area is substantially reduced in Cougar Reservoir, and passage would result in increased movement into more degraded rearing habitat below Detroit and Hills Creek Dams where spawning habitat does not exist, and human disturbance is high.

Alternative 3B would not effectively meet all the Proposed Action ESA objectives (objective 4-6). Under Alternative 3B, all four Chinook salmon populations would reach replacement and two out of four Chinook salmon populations would have high persistence (e.g., low risk of extinction). However, Alternative 3B ranks sixth for downstream survival (the lowest ranking of the action alternatives) though it is still an improvement over the NAA. Additionally, the McKenzie Core Legacy spring Chinook salmon population is at risk of extinction, and there would be no habitat gains for bull trout as compared to the NAA.

As under the NAA, climate change is predicted to further degrade habitat for bull trout below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature targets below dams for Chinook salmon and steelhead. See Appendix F for details on climate change effects on the WVB.

Compared to NAA, Alternative 3B would result in minor to moderate beneficial water temperature effects in the Middle Fork Willamette, McKenzie, and South Santiam sub-basins due to the proposed drawdowns at Hills Creek, Lookout Point, Cougar, and Green Peter Dams.

Minor to major adverse TDG effects would be expected in the North Santiam, South Santiam, and Middle Fork Willamette sub-basins (below Dexter Dam) due to the deep drawdowns at Detroit (autumn), Green Peter, and Lookout Point Dams (autumn) that rely on high outflows, thereby increasing the number of days with spill under Alternative 3b as compared to the NAA or action alternatives with structural improvements for TDG like alternatives 1 and 4. Minor beneficial TDG effects are expected in the South Fork McKenzie sub-basin under Alternative 3B due to the deep drawdown at Cougar Dam that would involve use of the DT, which is expected to have lower TDG than the RO.

By combining spring spill and drawdowns with fall drawdowns at 6 of the 11 storage projects, Alternative 3B would substantially affect the ability to store water system-wide. These operations would result in a 50% reduction of water stored system-wide compared to the NAA, or 669,000 acre-feet. Depending on how and when the Fish and Wildlife conservation storage allocation is takes priority over other consumptives uses it would leave very little conservation storage available for M&I water supply or AI. Therefore, Alternative 3B would have a major adverse effect to M&I water supply and irrigation.

Unlike Alternative 3A, the goal under Alternative 3B is to fill Detroit Reservoir for a spring spill fish passage operation; hence flows at Salem in Alternative 3B would rarely drop below 5,000 cfs in the summer, though they would be lower than under the NAA in dry years. Alternative 3B includes a spring drawdown at Hills Creek Dam instead of Lookout Point Dam, so water flowing through Hills Creek Dam can be stored in Lookout Point Dam, which would preserve a larger amount of water than under Alternative 3A.

The decrease in stored water would contribute to an overall decrease in average annual hydropower generation by 79 aMW (roughly enough to power 62,912 households annually; see Section 3.12.3.2 for details). This, coupled with the cost of Alternative 3B, would result in a $829 million reduction in median NPV to -$604 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation under Alternative 3B as compared to the NAA.

Additionally, the fish passage operations at Hills Creek and Cougar Dams would result in infrequent, temporary moderate adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise abilities of Hills Creek and Cougar Dams to operate islanded and to serve these communities under temporary storm or fire related outage conditions, which would not occur under the NAA.

Alternative 3B would result in the largest decreases in annual visitations. This would be a major, long-term adverse effect to recreation in the WVS, resulting in an approximate decrease of $1,274,000 in annual economic benefits (a 6.23% decrease) compared to the NAA. The effects to recreation would also have a high regional economic impact with a 50% reduction in recreation related jobs in the South Santiam sub-basin and a reduction in regional output greater than $150,000 in multiple basins.

Alternative 3B would be the second least costly alternative to implement due to incorporation of few structural measures. Alternative 3A would be the only less costly alternative in comparison. This is because Alternative 3B includes a lower drawdown operation at Cougar Dam that requires additional costs to modify the DT, as discussed under the Alternative 2B tradeoffs which also has a fish passage measure utilizing the DT at Cougar. The estimated total annual cost for Alternative 3B is $30,652 million, $21 million greater than the NAA (see Appendix M for details).

Although one of the least costly alternatives, Alternative 3B would perform poorly for Proposed Action ESA objectives while substantially decreasing water store system-wide with adverse effects to hydropower, water supply, and recreation. Additionally, the deep fall and spring drawdowns would compromise abilities of Hills Creek and Cougar Dams to serve nearby communities under temporary storm or fire related outage conditions. These adverse effects without appreciable benefits for ESA-listed species makes it unlikely this alternative would be acceptable to stakeholders, agencies, and the public. Therefore, Alternative 3B was not identified as the Preferred Alternative.

#### *5.2.7.7 Alternative 4. Improve Fish Passage with Structures-based Approach*

Alternative 4 takes a structures-based approach to improve fish passage through the WVS dams to increase the survival of ESA-listed fish. In contrast to the NAA but as under Alternative 1, Alternative 4 proposes only structures for water quality and downstream fish passage, shifting the release of stored water from the spring into the summer and fall and augmenting instream flows by using the power and inactive pools.

Also, in contrast to the NAA and Alternative 1, Alternative 4 proposes the “Integrated Temperature and Habitat Flow Regime” operation, the targets of which are generally higher and more variable than those in the congressionally authorized minimum flow requirements proposed under Alternative 1. Alternative 4 also proposes the most structural measures for fish passage and water quality of any alternative as shown in Table 5.2-90.

**Table 5.2-9. Key measures under Alternative 4.**

| Dam | Temperature Control | TDG Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Dexter | – | Structural* | – | – |
| Lookout Point | Structural | – | Structural | – |
| Hills Creek | Structural* | – | Structural* | Structural* |
| Fall Creek | – | – | – | – |
| Cougar | – | Structural* | Structural* | – |
| Blue River | – | – | – | – |
| Foster | Structural | Structural* | Structural | – |
| Green Peter | Operational* | Structural* | – | – |
| Big Cliff | – | – | – | – |

| Dam | Temperature Control | TDG Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Detroit | Structural | – | Structural | – |

*Distinctive feature of this alternative.

In contrast to the NAA and Alternative 1, Alternative 4 would include a fish passage structure and WTC tower at Hills Creek Dam and a fish passage structure at Cougar Dam. Alternative 4 also replaces the WTC tower at Green Peter Dam proposed under Alternative 1 with using operational measures utilizing the spillway and ROs for temperature management. In contrast to the NAA and Alternatives 1, 2A, 2B, and 5, Alternative 4 proposes an upstream passage structure at Hills Creek Dam and not at Green Peter Dam. These differences allow for the comparison of the relative costs and benefits associated with the different combinations of structural measures.

*5.2.2.7.1 Tradeoffs*

Alternative 4 is a structural focused alternative and includes large floating fish passage structures coupled to temperature structures in the North, McKenzie and the Middle Fork sub-basins. Smaller structures are included at Foster Dam in the South Santiam. A fall deep drawdown at Fall Creek would continue as under the NAA.

Under Alternative 4, adverse effects are predicted to be moderate for UWR spring Chinook salmon, minor for UWR winter steelhead, and moderate for bull trout. Habitat scoring for bull trout would be improved in all three sub-basins due to passage actions as compared to the NAA. However, access to below-dam habitat would increase demographic risks especially below Hills Creek Dam and below Detroit Dam where human disturbance is higher. By increasing the number of bull trout passing downstream and becoming exposed to these disturbances compared to the NAA, there is an increase in demographic risk.

Despite the greatest spending on structural measures for ESA-listed species needs, Alternative 4 would not perform the best for meeting Proposed Action ESA objectives (objectives 4-6). Like Alternative 1, although Alternative 4 ranks moderately well for downstream survival (third), and three out of four Chinook salmon populations would reach replacement; only two out of four Chinook salmon populations would have high persistence (e.g., low risk of extinction). In contrast to Alternative 1, Alternative 4 would reduce risk to the McKenzie Core Legacy spring Chinook salmon population and would provide more habitat gains for bull trout compared to the NAA due to the inclusion of effective downstream passage at Cougar Dam. Alternative 2A would perform better than Alternative 4 for the replacement, persistence, and downstream survival metrics and Alternatives 2B and 5 for the replacement metrics.

Structural improvements for fish passage and water temperature would provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, Middle Fork sub-basins, as compared to the NAA. See Appendix F for details on climate change effects on the WVB.

Compared to NAA, Alternative 4 would result in minor to major beneficial water temperature effects in the Middle Fork Willamette sub-basin (between Hills Creek Dam and Lookout Point Dam), South Santiam, and North Santiam sub-basins due to the proposed temperature control structures at Hills Creek, Lookout Point, and Detroit Dams as well as operational temperature control at Green Peter Dam. Minor to major beneficial TDG effects are expected in the North Santiam and South Fork McKenzie sub-basins based on the proposed TDG abatement structures below Detroit and Big Cliff Dams and the reduced number of spill days at Cougar Dam under Alternative 4.

Under Alternative 4, as under Alternative 2A, there would be an estimated increase in water stored system-wide at the 75% exceedance level of 122,000 acre-feet from the NAA. The combination of lower spring flow targets and no reservoir drawdowns during the conservation season would allow for the increase from the NAA in stored water. The increased stored water would likely result in a moderate beneficial effect to municipal and industrial water supply and AI users of the conservation storage space.

The Integrated Flow Regime would include additional flow based on the air temperature, compared to the 2008 BiOp flows implemented under the NAA. Therefore, flows later in the summer and fall would be higher than the NAA due to the additional accumulated stored water.

The additional stored water would contribute to an overall slight increase in average annual hydropower generation by 1 aMW (roughly enough to power 796 households annually; see Section 3.12.3.7 for details). However, the high capital and O&M cost of Alternative 4 would result in the second greatest decrease in NPV from that provided by the NAA.

Under Alternative 4, there would be a $1.162 billion reduction in median NPV to -$937 million. Therefore, there would be long-term, major, adverse effects on economic viability of WVS power generation. There would also be negligible risk to local hydropower generation as Hills Creek and Cougar Dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due primarily to weather events or fires.

Under Alternative 4, the additional stored water would mean the reservoirs stay higher for more of the conservation season as compared to the NAA, resulting in minor to moderate benefits to reservoir recreation. This would translate into slight increases in annual visitations, resulting in an approximate increase of $167,000 in annual economic benefits (a 0.82% increase) compared to the NAA.

The regional economic impact from recreation effects would be medium. The regional economic effects would be associated with a moderate reduction in regional output and the potential loss of 1.7 jobs in the South Santiam and McKenzie sub-basins due to the drawdown at Green Peter and operations at Blue River Dam.

Alternative 4 would be the costliest alternative to implement, primarily driven by the cost to design, construct, operate, and maintain the structural measures for temperature control, fish passage, and TDG abatement. Alternative 4 proposes the most structural measures of any alternative. The estimated total annual cost for Alternative 4 is $113,001 million, $104 million greater than the NAA (see Appendix M for details).

Due to the scale of the measures under Alternative 4, which are largely structural this would be the most expensive alternative. The high cost makes it unlikely this alternative would be acceptable to many stakeholders, agencies, and the public. This is compounded by the fact that Alternative 4 would result in fewer benefits to ESA species than several less costly alternatives, including Alternatives 2A, 2B, and 5. Therefore, Alternative 4 was not identified as the Preferred Alternative.

#### *5.2.7.8 Alternative 5. Refined Integrated Water Management Flexibility and ESA-listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel) - Preferred Alternative*

Alternative 5, also referred to as the Refined Hybrid Alternative with Cougar Diversion Tunnel Modification, is the same as Alternative 2B except for the proposed flow regime. Alternative 5 was ultimately selected by the Corps as the preferred alternative. This alternative was the most successful at finding a balance between cost and meeting the proposed action ESA objectives.

The flow operation proposed under Alternative 5 is a modified version of the "Integrated Temperature and Habitat Flow Regime" proposed under all action alternatives except for Alternative 1 and the NAA.

Following discussions with cooperators on how the "Integrated Temperature and Habitat Flow Regime" could be improved to better meet the species needs during the lowest low flows, USACE refined the flow operation, which is incorporated into Alternative 5. As shown in Section 3.2.2.10, the key difference of the refined flow operation would be higher flows at Foster, Detroit, and Cougar Dams as compared to the NAA and the other action alternatives.

The refinement for Cougar Dam flows would be much smaller, however, because the drawdown operation to the DT for fish passage results in much less storage compared to Foster and Detroit Dams to supplement flow. Additionally, the mainstem Willamette River flows would have different flow levels reflective of a basin-wide hydrology forecast.

Table 5.2-10 shows the major operational and structural features of Alternative 5.

**Table 5.2-10 . Water Quality and Passage Measures Under Alternative under Alternative 5.**

| Dam | Temperature Control | TDG structural Improvements | Downstream Fish Passage | Upstream Fish Passage |
|---|---|---|---|---|
| Dexter | – | – | – | – |
| Lookout Point | – | – | Structural | – |
| Hills Creek | – | – | – | – |
| Fall Creek | – | – | – | – |
| Cougar | – | – | Operational * | – |
| Blue River | – | – | – | – |
| Foster | Structural | – | Structural | – |
| Green Peter | Operational* | – | Operational* | Structural* |
| Big Cliff | – | – | – | – |
| Detroit | Structural | – | Structural | – |

*Distinctive feature of this alternative.

*5.2.2.8.1 Tradeoffs*

The tradeoffs under Alternative 5 are the same as those discussed under Alternative 2B except that Alternative 5 would have a greater reduction by $6 million in NPV compared to Alternative 2B. Under Alternative 5, there would be a $939 million reduction in median NPV to -$714 million as compared to the NAA. The effects to UWR spring Chinook salmon, UWR steelhead, and bull trout would be the same under Alternative 5 as under Alternative 2B.

As discussed, Alternative 5 is identical to Alternative 2B except for refinements to the "Integrated Temperature and Habitat Flow Regime" measure. Despite refinements to the "Integrated Temperature and Habitat Flow Regime" measure, little to no difference between Alternative 2B and 5 is predicted regarding reservoir volumes or flows below dams, since reservoir drafting during the conservation season and early flood seasons would result in stream flows remaining above minimums. Therefore, these refinements to the flow operation have no to negligible change to the outcomes as described under Alternative 2B for hydropower, water supply, and recreation.

Alternative 5 has been identified as the Preferred Alternative by USACE. Like Alternative 2B, Alternative 5 would meet the Proposed Action ESA objectives. During the tradeoffs analyses, with input from cooperators, USACE deemed the effects on ESA listed species under Alternatives 2A, 2B, and 5 to be so similar that it was difficult to differentiate between them on that basis, however they are all an improvement for ESA species given the fish passage, flow, and water quality measures as compared to the NAA.

As discussed in the evaluation of Alternatives 2A and 2B, Alternative 5 would effectively meet the Proposed Action ESA objectives (objectives 4-6) at lower risk and substantially lower costs than Alternative 2A,1, or 4. Alternative 5 was chosen as the Preferred Alternative due to the flow operation refinements and subsequent beneficial effects that resulted from engagement with cooperators.

## 5.3 SUMMARY OF THE PREFERRED ALTERNATIVE

The Preferred Alternative is Alternative 5 as described in Section 2.4.9 of the PEIS. The Preferred Alternative contains a variety of structural and operational measures to meet the Proposed Action objectives developed for the PEIS. The measures are intended to improve conditions for ESA-listed fish while providing more flexible ways for USACE to meet demands for fish and wildlife, FRM, water supply for M&I, water quality, water supply, irrigation, hydropower generation, and recreation in the Willamette River Basin (WRB). This alternative was the most successful at finding a balance costs, impacts and the Proposed Action's ESA objectives.

The Preferred Alternative includes the measures that USACE would implement over the 30-year implementation period as well as monitoring and evaluation as described in the Adaptive Management Plan (AMP). Sections 5.4 and 5.5 summarize how the Preferred Alternative would be executed under the Implementation Plan and AMP, respectively. Appendix N provides a more detailed description of implementation and adaptive management of the Preferred Alternative.

Additionally, as described in Section 2.2.5, USACE is proposing to continue a suite of near-term operations until structural measures in the preferred alternative are operational. When all the measures in the Preferred Alternative are implemented, any remaining near-term operations will cease. How and when an operation at a location is superseded or replaced by measure in the Preferred Alternative is described in the Implementation Plan. If the Preferred Alternative is refined or changes as a result of the ongoing ESA consultation or as a result of comments from the public on the draft PEIS a new implementation plan would be developed for that alternative.

## 5.4 IMPLEMENTATION PLAN

The Implementation Plan (provided in Appendix N) is a companion document to the WVS EIS. It describes the implementation sequencing of the measures in the Preferred Alternative. This plan links immediate operations to improve fish passage and water quality (e.g., Near-term Operations measure) to the longer-term structural measures, such as the downstream fish passage construction projects, and identifies check-ins, or points along the implementation timeline where course correction (i.e., "on-ramps/off-ramps") may be necessary based on research, monitoring, and evaluation (RM&E). Any change would be evaluated for any additional NEPA or environmental compliance that would be necessary.

The Implementation Plan is considered a roadmap or high level, tentative schedule that lays out a strategy and plan for implementation of the measures developed through the PEIS process. Considerations such as basin-wide priorities, risk and uncertainty, research and development, and research, monitoring, and evaluation of data gaps and other factors have been used to shape this plan and to develop a schedule that is both reasonable and implementable given the information available to USACE at present.

### 5.4.1 Preferred Alternative Implementation and Replacement of the Near-term Operations Timeline

Figure 5.4-1 provides the proposed implementation timeline of the operations and construction of the structural measures in the Preferred Alternative. This implementation timeline is highly dependent on the timing of design and construction funding (i.e., when this funding becomes available).

In Figure 5.4-1, the check-in stars indicate when USACE will evaluate the effectiveness of the measure and determine if changes should be made based on the framework for addressing such changes in the AMP. For instance, there is currently uncertainty that the FSS structural downstream passage measures proposed at some dams would be effective. The check-ins will provide opportunities to refine future designs based on information and lessons learned from other recently constructed similar structures.

The PEIS environmental consequences analyses assumed all operations in the Near-term Operations Measure would be in place for the duration of the 30-year PEIS period of analysis to capture the full the effects of these operations, given the difficulty and uncertainty in implementing these large-scale construction projects. While uncertain, Table 5.4-1 summarizes what measure under the Preferred Alternative would replace each operation at a specific location in the Near-term Operations Measure and provides the best-case scenario date for when each would be replaced, which is based on USACE’s experience in constructing these large scale projects.

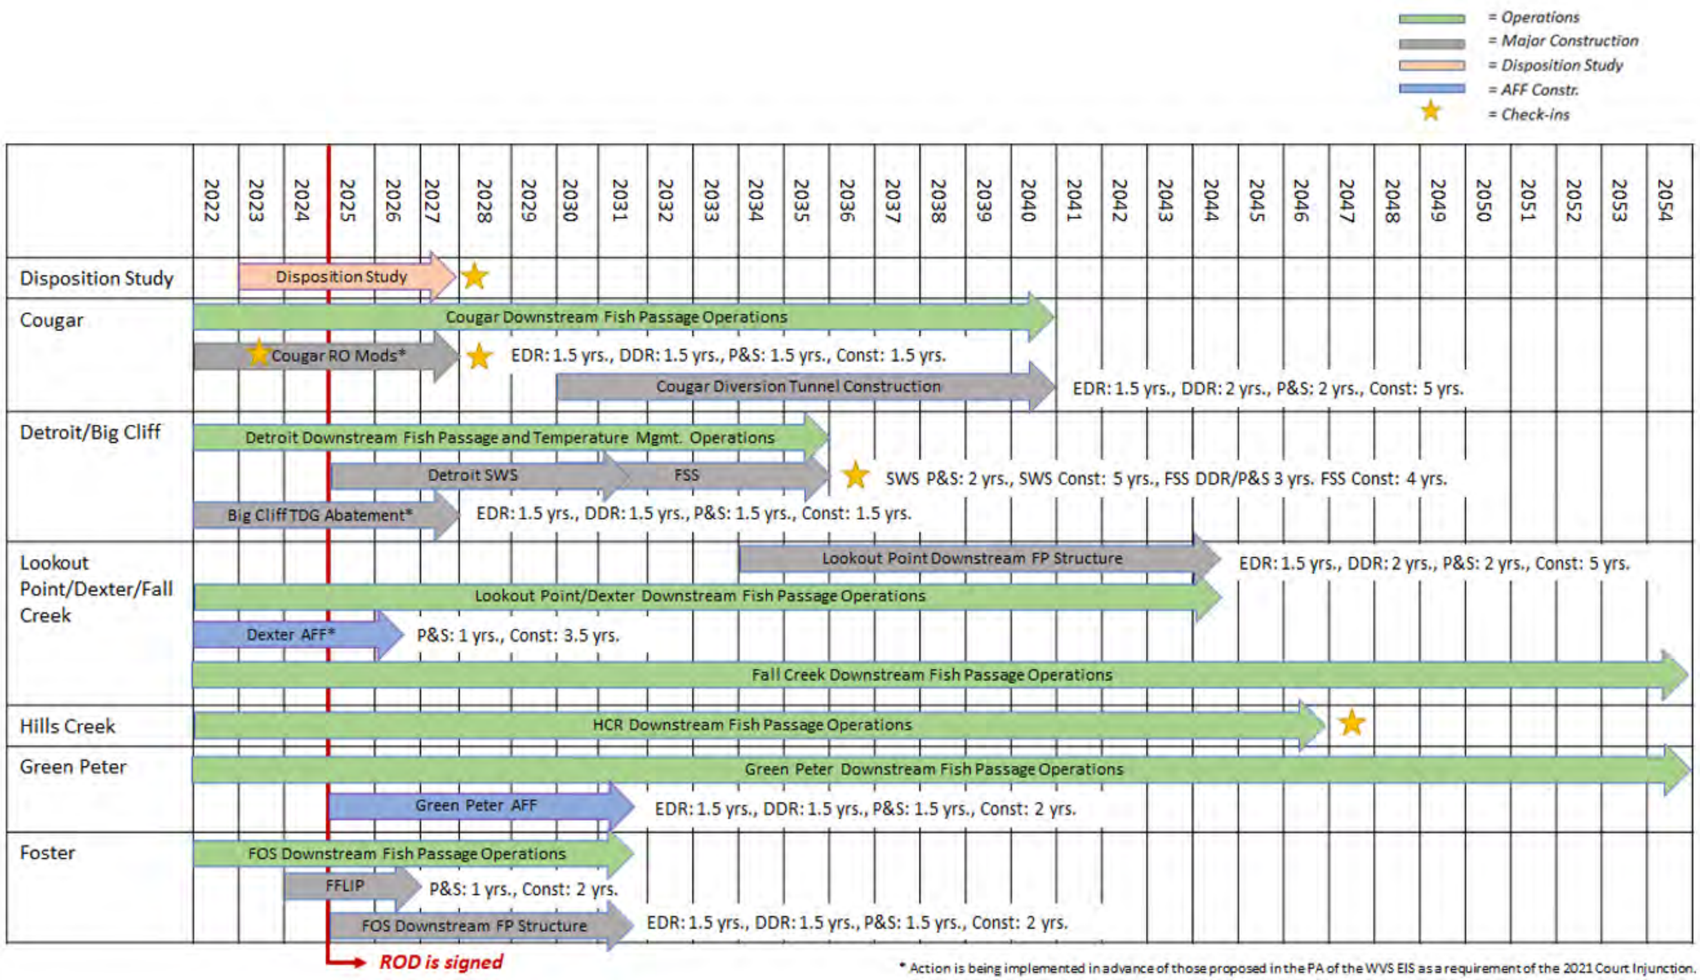

**Figure 5.4-1. Best-Case Scenario for the Preferred Alternative Implementation Timeline (funding-dependent)**

**Table 5.4-1. Base-case scenario timeline for replacing the Preferred Alternative Measures to replace Near-term Operation**

| Dam | Near-term Operation | Preferred Alternative Measure(s) to Replace Near-term Operation | Approximate Replacement Year |
|---|---|---|---|
| Detroit | Spring downstream fish passage and operational downstream temperature management | 105. Construct water temperature control tower<br><br>392. Construct structural downstream fish passage | 2031<br><br>2035 |
| Detroit | Nighttime RO prioritization for improved downstream fish passage | 392. Construct structural downstream fish passage | 2035 |
| Big Cliff | Spread spill across spillbays to reduce downstream TDG exceedances | This operation would continue until the TDG structural solution is constructed as required by the injunction. | 2027 |
| Green Peter | Outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam | 722. Construct adult fish facility | 2031 |
| Green Peter | Utilize spillway for improved downstream fish passage in the spring; perform spill operation until 01 May or for 30 days, whichever is longer | 721. Use spillway for surface spill in summer | 2025 |
| Green Peter | Deep drawdown and RO prioritization for improved downstream fish passage | 40. Deeper fall reservoir drawdowns for downstream fish passage | 2025 |
| Foster | Delay refill and utilize spillway in the spring for improved downstream fish passage.<br><br>Use the fish weir in the summer for improved downstream temperature management and upstream fish migration/passage | 392. Construct structural downstream fish passage<br><br>479. Foster Fish Ladder Temperature Improvement | 2031<br><br>2027 |
| Foster | Utilize the spillway for improved downstream fish passage in the fall | 392. Construct structural downstream fish passage | 2031 |
| Cougar | Deep drawdown and RO prioritization for improved downstream fish passage | 40. Deeper fall reservoir drawdown to the DT for downstream fish passage | 2041 |
| Cougar | Delayed reservoir refill and RO prioritization for improved downstream fish passage | 40. Deeper fall reservoir drawdown to the DT for downstream fish passage | 2041 |

| Dam | Near-term Operation | Preferred Alternative Measure(s) to Replace Near-term Operation | Approximate Replacement Year |
|---|---|---|---|
| Hills Creek | Nighttime RO prioritization for improved downstream fish passage | This operation would continue until the check-in. At which point USACE would evaluate if changes should be made per the AMP. | 2047–Check-in |
| Lookout Point | Utilize spillway for improved downstream fish passage in the spring; RO use in the fall for downstream temperature management | 392. Construct structural downstream fish passage | 2044 |
| Lookout Point | Deep drawdown and RO prioritization for improved downstream fish passage | 392. Construct structural downstream fish passage | 2044 |
| Fall Creek | Deep drawdown and RO prioritization for improved downstream fish passage | This operation would continue for the duration of the 30-year period of analysis. | 2054 |
| Fall Creek | Delayed reservoir refill and RO prioritization for improved downstream fish passage | This operation would continue for the duration of the 30-year period of analysis. | 2054 |

## 5.5 ADAPTIVE MANAGEMENT PLAN

The Adaptive Management Plan (AMP) is also a companion document to the WVS PEIS (Appendix N). The AMP outlines the governance[63] framework to be used for adaptive decision-making, the annual adaptive management process for engaging with stakeholders, and the process to incorporate new learning into management priorities. The AMP also outlines the decision criteria relevant to monitoring and evaluating the success of management measures at achieving stated objectives.

USACE's adaptive management technical guide defines adaptive management (AM) as a formal, science-based, risk management strategy that permits implementation of actions despite uncertainties (USACE, 2019r). Knowledge gained from monitoring and evaluating results will be used to adjust and direct future decisions. Simply stated, AM is learning while doing in the face of uncertain outcomes. These AM concepts are consistent with those presented in the U.S. Department of Interior's AM technical guide (Williams et al., 2009). Figure 5.4-2 illustrates the steps in an AM cycle compatible with USACE projects.

[63] Governance is the framework for how USACE will continue to work with the WATER forum to implement the preferred alternative. It describes the entities involved, the various forums set up to advise on different subject matter, and how information from those forums will be considered by USACE in implementing the preferred alternative.

The use of decision criteria plays a key role in the evaluation of management measures and in the adaptive decision-making process. As described in Appendix N, decision criteria include performance metrics, targets, and decision triggers and are defined as follows:

- Performance Metric – A specific metric or quantitative indicator that is monitored and can be used to estimate and report consequences of management alternatives with respect to a particular objective.
- Target – A specific value or range of performance metric that defines success. Targets can be quantitative values or overall trends (directional or trajectory).
- Decision Trigger - A pre-defined commitment (population or habitat metric for a specific objective) that triggers a change in a management action. Decision triggers are addressed in the Evaluate step (Step 4 of the AM process shown in Figure 5.4-2) and specify the metrics and actions that will be taken if monitoring indicates performance metrics are or are not reaching target values. In some cases, a decision trigger may be learning a new piece of information that triggers the Continue/Adjust/Complete step (Step 5 of the AM process shown in Figure 5.4-2).

The process described in the AMP is consistent with the NEPA purpose of informed decision-making and takes the process further in addressing uncertainties and data gaps that may be revealed during implementation of the selected alternative (40 CFR 1500.1(c)). This allows decision makers to adjust based on new information while observing project performance, thereby enabling transition from the planning and designing efforts associated with this WVS PEIS to implementation of the selected management actions using AM. The AMP is a living document that will be updated as new information is learned from monitoring of actual performance of the selected alternative and processed through a governance structure.

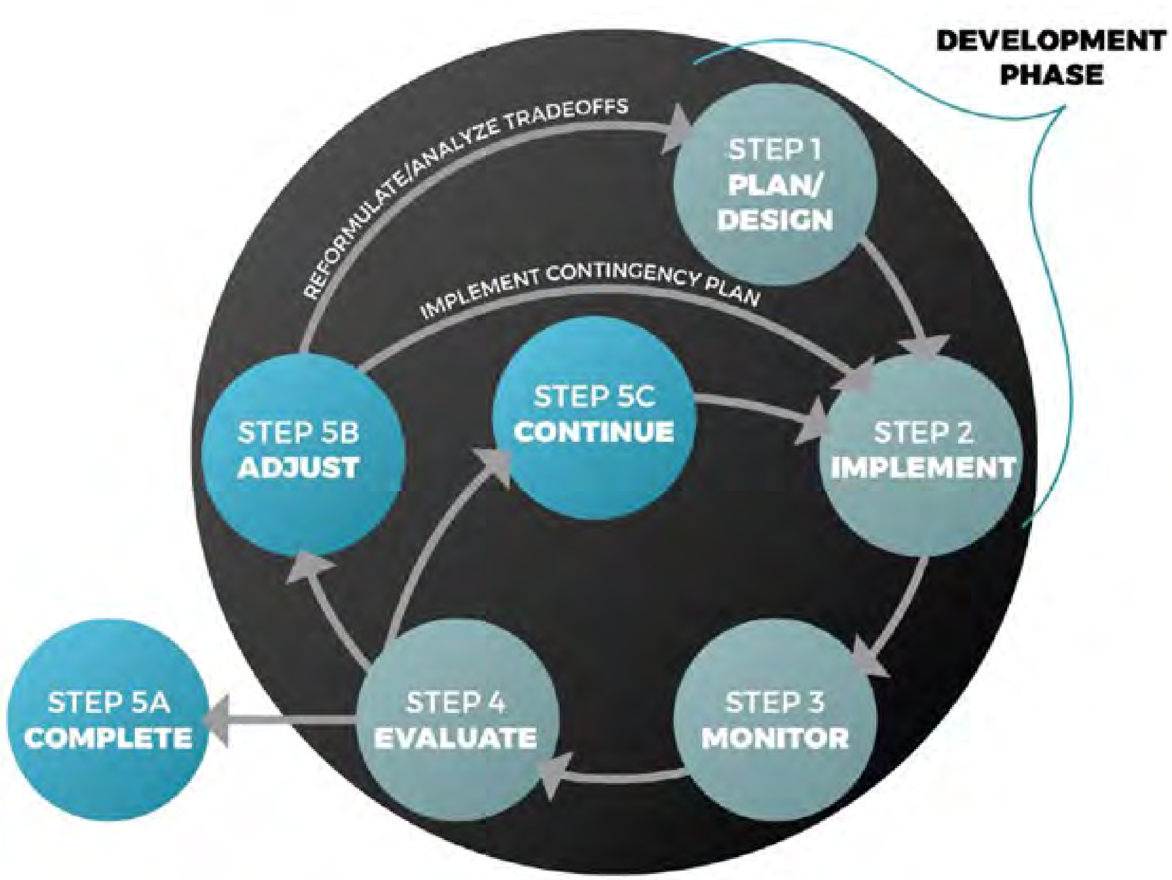

**Figure 5.5-2. USACE Adaptive Management Cycle**

# CHAPTER 6 - PUBLIC INVOLVEMENT

NEPA requires lead agencies to invite public involvement prior to decision-making on proposed actions that may affect the environment. Public involvement often starts with "scoping," which is the process of soliciting input from stakeholders such as tribes, the public (both private citizens and non-governmental organizations or "NGOs"), and other agencies. Scoping gives the lead agency perspectives from various stakeholders and helps to develop aspects of the purpose and need for the proposed action and the development of preliminary alternatives to the proposed action. Scoping also helps identify the key issues for consideration in an EIS.

## 6.1 PUBLIC SCOPING OUTREACH

USACE began public outreach for the project early in the planning process with press releases, a newspaper article in the Eugene, Oregon newspaper the *Register Guard*, and a public-facing project website. Flyers and handouts were posted at USACE properties and distributed at local Willamette Valley events, and stakeholders were notified of project developments via email. USACE also organized a presentation for the North Santiam, McKenzie, Middle Fork, and Coast Fork Watershed Councils and the Association of Oregon Counties.

### 6.1.1 Notification of Public Scoping Meetings

Scoping for the PEIS formally began on April 1, 2019 with the publication of a Notice of Intent (NOI) in the *Federal Register* (Vol. 84, No. 62, pp. 12,237 – 12,238). The NOI described USACE's intent to prepare this PEIS to address the continued O&M of the WVS in accordance with authorized project purposes while meeting ESA obligations to avoid jeopardizing the continued existence of ESA-listed species.

Public comments were accepted until June 28, 2019. The NOI also notified the public of the scoping meetings from June 4 to 13, 2019. In addition to the NOI, the meetings were advertised in 15 newspapers and with press releases, flyers, the project website, email, and social media.

### 6.1.2 Public Scoping Meetings

Five scoping meetings were held at various locations throughout the Willamette Valley to provide an opportunity for interested stakeholders from different communities to attend. In addition to a presentation, an open house format was used to encourage discussion and information sharing and to ensure that the public had opportunities to speak with representatives of USACE.

Informational posters, a public comment brochure, a public scoping meeting handout providing instructions on use of the public comment portal, and a scoping informational brochure were also available at the public scoping meetings. Meeting participants included private citizens; utility board/councils; watershed councils; farm associations; NGOs; city, state, and federal representatives; and elected officials. An average of 16 people attended each scoping meeting.

### 6.1.3 Scoping Comments

A total of 92 correspondence documents were received via email, mail, comment brochures that were distributed and then collected at meetings, and the public comment portal. Many of the correspondence documents contained multiple comments on different topics.

A total of 384 comments were received from private citizens, NGOs, government agencies, and tribes. To ensure that all comments were identified and properly reviewed, the comments were first assigned a comment identification number and documented in a database. The comments were then organized, analyzed, and categorized according to six topics (alternatives, authority, PEIS general, environmental effects, mitigation, not a comment about the PEIS). Table 6.1-1 shows the number of comments received by topic.

**Table 6.1-1. Public Scoping Comments Received by Topic**

| Topic | Number of Comments Received |
|---|---|
| Alternatives | 183 |
| Authority | 10 |
| PEIS General | 86 |
| Environmental Effects | 90 |
| Mitigation | 5 |
| Not a Comment about the PEIS | 10 |
| **Total** | **384** |

The comments were further categorized by sub-topics (e.g., ESA-listed species and/or compliance, FRM, NEPA process, water storage and allocation) to allow USACE to better understand the input received from the public. The comments were used to inform the scope of analysis, alternatives development, and effects to resources in the Draft PEIS.

The Willamette Valley System Operation and Maintenance Programmatic Environmental Impact Statement Public Scoping Report includes more details on the scoping process and comments, a database of comments received, and all scoping materials (Appendix P – Public Scoping Report).

## 6.2 KEY ISSUES AND RESOURCE CONCERNS

The NEPA public scoping process resulted in the identification of issues important to WVS stakeholders. The following list of key issues and resource concerns associated with the proposed alternatives is not all-inclusive.

### 6.2.1 Endangered Species Act

The largest number of comments received for any single issue or resource concern (136 comments of 384 total) involved ESA-listed species and compliance with the ESA, mainly with regard to UWR spring Chinook salmon, UWR steelhead, and bull trout. Concerns were raised about how dams would affect anadromous fish including fish migration patterns, water conditions affecting fish passage and fish populations, and general ecosystem effects.

### 6.2.2 Flood Risk Management

There were 48 comments pertaining to flood risk management. The scoping process identified concerns and suggestions related to retaining or improving the current WVS to assist with flood risk. Concerns in this area related to both preserving economic activities and human resources within the WVS and balancing flood risk mitigation with the need to ensure the availability of appropriate fish and wildlife habitat.

### 6.2.3 NEPA Process

There were 49 comments pertaining to the NEPA Process. Commenters focused on the scope of the PEIS, the review process, and how the PEIS may affect other ongoing USACE NEPA analyses within the WVS. Cumulative effects to natural resources and ecosystems resulting from O&M of the WVS were identified as a concern. Commenters identified elements that should potentially be included in the scope of the PEIS, such as recent research on fish habitats, water allocation and storage, and streamflow as it relates to boating, maintenance of hydropower infrastructure, and water quality.

### 6.2.4 Water Storage and Allocation

There were 48 comments pertaining to water storage and allocation. Comments were received advocating for and against adjustments to water storage capacity and allocation. Commenters suggested that water allocation and storage should be designed to meet increasing irrigation demands. Concerns were voiced about potential adverse effects to the local community should water storage allocation be decreased. Some commenters raised concerns that water storage and allocation changes could negatively affect fish populations and habitat.

### 6.2.5 Water Quality

There were 25 comments pertaining to water quality. Comments were received concerning the potential effect of O&M activities on the transformation or migration of contaminants found within the WVS. Comments called for an assessment of water quality issues and presentation of data associated with likely effects to water quality from proposed alternatives. Some commenters requested water quality sampling to ensure public safety in regard to drinking water. Overall, comments called for consideration of water quality issues, both physical and chemical, within the WVS.

### 6.2.6 Recreation

There were 24 comments pertaining to recreation. Comments were received advocating for recreational opportunities such as through recreational releases for boating and whitewater paddling as well as for sailing. Commenters also identified concerns with the recreational effects of algal blooms and pointed out that any proposed changes to reservoir levels could affect recreational use of the WVS and jobs associated with those recreational opportunities. The comments included discussion of the local and regional economies tied to recreational opportunities in the WVS. Commenters also suggested USACE consider and evaluate the recreational effects of fishing on ESA-listed species.

## 6.3 INTERAGENCY COORDINATION

Following scoping, USACE held monthly meetings with the Cooperating Agencies to provide regular updates to the PEIS status and to solicit feedback. Additionally, in April of 2020, USACE held workshop meetings with Cooperating Agencies to present information about the project and to solicit their feedback (see Appendix L for a description of Cooperating Agencies). These meetings are summarized below:

- On April 9, 2020, a webinar was held with USACE, Confederated Tribes of Grand Ronde Community of Oregon, NMFS, BoR, BPA, EPA, ODFW, ODEQ, and ODA to discuss the results of developing BiOp measures into preliminary alternatives.
- On April 15, 2020, a webinar was held with USACE, Confederated Tribes of Grand Ronde Community of Oregon, NMFS, BoR, BPA, EPA, ODFW, ODEQ, ODA, and OWRD in which USACE presented the background of the project, purpose and need, review of the alternatives' development process, and a status and overview of the preliminary alternatives.
- On April 24, 2020, a webinar was held with USACE, Confederated Tribes of Grand Ronde Community of Oregon, NMFS, BoR, BPA, EPA, ODFW, ODEQ, ODA, and OWRD in which USACE provided information regarding the NAA.

## 6.4 TRIBAL CONSULTATION

Executive Order 13175, Consultation and Coordination with Indian Tribal Governments, calls for regular and meaningful consultation and collaboration with tribal officials in the development of federal policies that have tribal implications and for strengthening government-to-government relationships between the United States and tribal governments. USACE committed from the outset to consult with federally recognized tribes throughout the PEIS development process.

Tribal consultation for this project began in 2018. USACE sent project initiation letters to Confederated Tribes of Coos, Lower Umpqua and Siuslaw Indians, Cow Creek Band of Umpqua Indians, the Confederated Tribes of Grand Ronde Community of Oregon, the Confederated Tribes of Siletz Indians, and the Confederated Tribes of Warm Springs.

On January 18, 2021, USACE mailed a letter to invite to the Confederated Tribes of Coos, Lower Umpqua and Siuslaw Indians, Cow Creek Band of Umpqua Indians, Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Siletz Indians, and Confederated Tribes of Warm Springs to be Cooperating Agencies. The Confederated Tribes of Grand Ronde

Community of Oregon accepted and signed a Memorandum of Understanding with USACE dated February 28, 2020, which can be found in Appendix O -Tribal Coordination & Perspectives. The tribe has been active in cooperator meetings.

The Confederated Tribes of Siletz Indians expressed interest in person and by email but did not sign a Memorandum of Understanding. The tribe has participated in cooperator meetings. USACE sent a letter dated September 13, 2019, reinviting the Confederated Tribes of Warm Springs to be a Cooperating Agency. This was based on further phone calls and in person meetings with the Confederated Tribes of Warm Springs personnel. The Confederated Tribes of Warm Springs staff have attended some cooperator meetings, but a Memorandum of Understanding between USACE and the Confederated Tribes of Warm Springs has not been signed.

Two tribal entities, the Columbia River Inter-Tribal Fish Commission and the Confederated Tribes of Grand Ronde Community of Oregon, responded to 2019 PEIS scoping outreach. These comments can be found in Appendix P- Public Scoping, and the key issues are summarized in Section 6.2.

USACE sent a letter dated September 30, 2021, inquiring on the tribes' interest to engage in PEIS development. The letter was sent to the Coquille Indian Tribe, Confederated Tribes of Coos, Lower Umpqua and Siuslaw Indians, Cow Creek Band of Umpqua Indians, Confederated Tribes of Siletz Indians, Confederated Tribes of Warm Springs, Klamath Tribes, Nez Perce Tribe, Confederated Tribes of the Umatilla Indian Reservation, and the Yakama Nation of Indians. The letter was not sent to the Confederated Tribes of Grand Ronde Community of Oregon as they were an active Cooperating Agency. The Cow Creek Band of Umpqua Indians and Nez Perce Tribe did not respond. The Confederated Tribes of Coos, Lower Umpqua and Siuslaw Indians, Coquille Indian Tribe, and Klamath Tribes deferred to other tribes and requested to not be consulted further. The Confederated Tribes of the Umatilla Indian Reservation and the Yakama Nation of Indians provided points of contact and requested further engagement.

USACE requested PEIS input by email correspondence on June 6, 2022 to the Confederated Tribes of the Umatilla Indian Reservation, Yakama Nation of Indians, Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Siletz Indians, Confederated Tribes of Warm Springs, the Nez Perce Tribe, and Cow Creek Band of Umpqua Indians.

## 6.5 ADDITIONAL PUBLIC OUTREACH

In 2021, USACE released a publicly accessible Virtual Room, an interactive website organized like a three-dimensional public meeting room with clickable "boards" that provided information summarizing the status of the PEIS. The information provided included an overview of the WVS PEIS background and process, including the alternatives formulation process. The Virtual Room also included an interactive map that provided descriptions of actions proposed under each alternative and allowed the visitor to explore where actions were proposed under each alternative.

Following release of the Virtual Room, USACE held an informational public meeting during which USACE subject matter experts presented the alternatives and the alternatives formulation process current at the time The presentation also provided an overview of each alternative, including the actions that make up the alternative and their proposed locations.

Over 25 members of the public attended the virtual meeting. USACE fielded questions from attendees during the meeting, but no formal comments were recorded as this was intended only as an informational meeting to update the public on the status of the PEIS.

## 6.6 DRAFT PEIS PUBLIC OUTREACH

As of November 25, 2022, the Draft PEIS is being issued for a 55-day public review period. The Draft PEIS is available for review on the Portland District's website. USACE is requesting review comments from tribes and federal and state agencies, as well as various interested parties, and the public.

In anticipation of the release of the Draft PEIS for public review, USACE plans to hold several public meetings to provide an overview of the PEIS and to inform participants on how they can access the draft PEIS for their review and how they can provide their comments.

USACE will consider all received correspondence and comments. The Corps has sent out the Public Notice of Availability for the release of the Draft PEIS for public review to tribes, interested persons, agencies, and groups.

# CHAPTER 7 - COMPLIANCE WITH ENVIRONMENTAL LAWS, REGULATIONS, AND EXECUTIVE AND SECRETARIAL ORDERS

Chapter 7 considers compliance of the Willamette Valley System (WVS) operation and maintenance (O&M) Programmatic Environmental Impact Statement (PEIS) within the context of the complex suite of federal environmental statutes, regulations, and Executive and Secretarial Orders that collectively govern the U.S. Army Corps of Engineers' (USACE's) planning activities and O&M of the WVS.

## 7.1 ENVIRONMENTAL OPERATING PRINCIPLES

The USACE) has reaffirmed its commitment to the environment by formalizing a set of "Environmental Operating Principles" applicable to all of its decision-making programs. These principles foster unity of purpose on environmental issues, reflect a new tone and direction for dialog on environmental matters, and ensure that employees consider conservation, environmental preservation, and restoration in all USACE activities. The principles are described in Engineer Circular 1105-2-404 "Planning Civil Work Projects under the Environmental Operating Principles," 1 May 2003.

This WVS Programmatic Environmental Impact Statement (PEIS) addresses USACE Environmental Operating Principles as described below.:

1. Foster sustainability as a way of life throughout the organization.

Environmental sustainability, when applied to a water resource project, must be designed to balance three major elements: environmental health, economic prosperity, and social well-being.

Several objectives of the Proposed Action are intended to support environmental health. They include:

- Increase anadromous Endangered Species Act (ESA)-listed fish passage survival at WVS dams.
- Improve water management during the conservation season to benefit anadromous ESA-listed fish and other authorized project purposes.
- Reduce pollutant levels to restore impaired water quality associated with the WVS dams to benefit anadromous ESA-listed species.
- Reduce spawning and rearing habitat competition caused by hatchery fish.

The preferred alternative will also contribute to future economic prosperity by creating jobs during construction and social well-being by continuing to reduce flood risks for the community.

2. Proactively consider environmental consequences of all USACE activities and act accordingly.

USACE has proactively considered environmental consequences of the Proposed Action. Potential consequences to environmental resources have been analyzed for the alternatives. Measures to avoid and reduce impacts on resources have been developed and will be implemented. For example, the PEIS considers the implications of the Proposed Action (and all other alternatives) for existing reservoir recreational uses and hydroelectricity generation.

3. Create mutually supporting economically and environmentally sustainable solutions.

The project will provide national and regional economic development benefits. Construction of the project is anticipated to support additional jobs and provide income for workers.

The proposed project reduces risk of flooding while balancing environmental impacts against levels of residual risk.

4. Continue meeting USACE's corporate responsibility objectives and maintain accountability under the law when carrying out actions that may impact human and natural environments.

The values of environmental sustainability are incorporated into the Nation's laws and mandates to governmental and private actors. The statute that provides a basis for evaluation of environmental impacts is the National Environmental Policy Act (NEPA). The applicable Principles, Requirements and Guidelines (PR&G) found in the Principles, Requirements and Guidelines for Water and Land Related Resources Implementation Studies (2014) provides a guide for seeking sustainable solutions in Civil Works projects.

The Proposed Action incorporates a coordinated approach to meet the purpose and need of the plan while complying with environmental laws such as NEPA, the Clean Water Act, the Clean Air Act, the Fish and Wildlife Coordination Act, and the Endangered Species Act, among others. All applicable requirements will be met.

5. Consider the environment in employing a risk management and systems approach throughout life cycles of projects and programs.

The environment was considered in employing a risk management and systems approach. USACE will continue to communicate impacts and residual risk to stakeholders and the public throughout the life cycle of the proposed project.

6. Leverage scientific, economic, and social knowledge to understand the environmental context and effects of USACE actions in a collaborative manner.

USACE must effectively utilize sources of expertise among other professional organizations, and other Federal, state, and local entities to address problems of regional and national significance. USACE has utilized the scientific expertise within the agency and the expertise of federal and state resource agencies. USACE also engaged tribes, NGOs, multiple levels of government, and the public, each of whom brings specialized knowledge and perspectives to the table.

7. Employ an open, transparent process that respects views of individuals and groups interested in USACE activities.

USACE has sought the views of individuals and groups on the WVS PEIS via the EIS scoping process and other mechanisms. USACE will continue to provide information to keep the public informed on the WVS PEIS. USACE will continue to actively listen and respond to and incorporate public concerns.

## 7.2 TRIBAL TREATIES AND TRUST RESPONSABILTIES

Since time immemorial, Native American tribes have inhabited the Willamette River Basin (WRB). These tribes successfully subsisted on the abundant natural resources of the area and built thriving communities that relied on the lands to sustain their way of life. Through treaties, executive orders, judicial decisions, and legislation, tribes ceded most of their aboriginal territory to the United States. Tribes retained smaller portions of land for their reservations on the outer edges or outside of the Willamette Valley. Many tribes, through treaties, retained the right to hunt, fish, and gather in their usual and accustomed locations, including areas outside of their reservations.

USACE has a unique legal and political relationship with tribal governments as sovereigns. This Federal trust responsibility is established through, and confirmed by, the U.S. Constitution, treaties, statutes, executive orders, and judicial decisions. Table 7.2-1 lists the federally recognized tribes affected by the proposed action and the Willamette River Basin relevant treaties.

**Table 7.2-1. Affected Indian Tribes and WRB-Relevant Treaties**

| Federally-Recognized Tribes | Treaties |
|---|---|
| Confederated Tribes of Grand Ronde Community of Oregon | Rogue River Treaty, September 10, 1853<br><br>Treaty with Cow Creek Band of Umpqua, September 19, 1853<br><br>Rogue River Treaty, November 15, 1854<br><br>Treaty with the Chasta, Scoton, and Umpqua, November 18, 1854<br><br>Treaty with the Umpqua and Kalapuya, November 29, 1854<br><br>Willamette Valley Treaty, January 22, 1855<br><br>Treaty with the Molalla, December 21, 1855 |

| Federally-Recognized Tribes | Treaties |
|---|---|
| Cow Creek Band of Umpqua Tribe of Indians | Cow Creek Band of Umpqua Treaty, September 19, 1853 |
| Confederated Tribes and Bands of the Yakama Nation | Yakama Treaty, June 9, 1855 |
| Nez Perce Tribe | Nez Perce Treaty, June 11, 1855 |
| Confederated Tribes of the Umatilla Indian Reservation | Walla Walla Treaty, June 9, 1855 |
| Confederated Tribes of Warm Springs | Treaty of 1855 (also Treaty with the Tribes of Middle Oregon, June 25, 1855) |
| Confederated Tribes of Siletz Indians | Rogue River Treaty, September 10, 1853 |

### 7.2.1 Executive Order 13175, Consultation and Coordination with Indian Tribal Governments

This order directs federal agencies to formulate and establish "regular and meaningful consultation and collaboration with tribal officials in the development of federal policies that have tribal implications, to strengthen the United States government-to-government relationships with Indian tribes, and to reduce the imposition of unfunded mandates upon Indian tribes." This consultation is meant to work toward a mutual consensus and is intended to begin at the earliest planning stages, before decisions are made and actions are taken. Consistent with this executive order, USACE initiated tribal consultation for this project in 2018. Section 6.4 describes tribal consultation efforts in detail. Additionally, each tribe was informed of the opportunity to request government-to-government consultation with USACE leadership anytime they believed it was necessary.

### 7.2.2 Secretarial Order 3175, U.S. Department of The Interior Responsibilities For Indian Trust Assets

Secretarial Order 3175 requires U.S. Department of the Interior bureaus and offices to consult with the recognized tribal government with jurisdiction over the trust property that a proposal may affect and ensure that any anticipated effects are explicitly addressed in planning, decision, and operational documents including EISs. In compliance with Secretarial Order 3175, this EIS has analyzed potential effects to Indian Trust Assets in Sections 3.24 and 4.24.

## 7.3 NATIONAL ENVIRONMENTAL POLICY ACT (NEPA) OF 1969 (42 UNITED STATES CODE [U.S.C.] §§ 4321–4347)

NEPA was established to ensure that the federal government appropriately considers the potential effects on the human environment of major federal actions. prior to implementing those actions. USACE is proposing updates to its operation and maintenance (O&M) of the WVS and has prepared this PEIS in accordance with the NEPA, the Council on Environmental

Quality's [CEQ] NEPA-implementing regulations (40 Code of Federal Regulations [CFR] Part 1500-1508), and the USACE NEPA-implementing regulations (33 CFR Part 230)[64].

### 7.2.3 Programmatic NEPA Review

The NEPA compliance process can be conducted for a specific project or for an entire program. As established in Section 1.1, a programmatic approach makes the most sense for operation and maintenance of the WVS, which consists of multiple projects, components, and activities within a shared geography (Oregon's Willamette River Basin) that are managed individually and in concert to achieve the authorized purposes of the projects and to lessen impacts on ESA-listed species. In accordance with 40 CFR Part 1500-1508 as amended and "Final Guidance for Effective Use of Programmatic NEPA Review" (CEQ 2014), USACE has prepared this PEIS for the WVS to disclose broad effects within the WVS consistent with 40 CFR 1502.4(b) and provide the framework for future decisions associated with the WVS.

These broad effects of the Proposed Action serve as a starting point for further site-specific evaluation of direct, indirect, and cumulative effects – effectively laying the groundwork for subsequent tiered analyses. Tiering means taking general, preliminary analyses from a programmatic document and adding to it in a subsequent EA or EIS when more detail and specifics about the project are known.

As directed in "Final Guidance for Effective Use of Programmatic NEPA Review" (CEQ 2014), this PEIS presents the agency's anticipated timing and sequence of actions covered under the programmatic document and actions that would be deferred to a later time; and discloses the timeframe or triggers of tiered NEPA review (CEQ 2014). The sequence of future action implementation and associated tentative NEPA review paths are further discussed in Appendix N1 – Implementation Plan. Subsequent actions triggered in accordance with the adaptive management, monitoring, and mitigation protocols may also require further NEPA review. These potential actions are discussed in Appendix N2 – Adaptive Management Plan and Appendix N3 – Monitoring and Mitigation.

### 7.2.4 Evaluation to Tier to the WVS PEIS

The WVS PEIS allows for the tiering of subsequent site-specific actions or measures, as needed. Any subsequent tiered documents will need to review briefly what level of analysis has been considered in the PEIS and whether it is still contemporary.

The PEIS fully assesses the effects of most operational measures that do not require detailed design and construction to implement immediately. This PEIS has analyzed the measures fully, and further NEPA evaluation will not be necessary. These measures are discussed further below in 7.2.2.1.

[64] The PEIS complies with the 1978 CEQ NEPA implementing regulations as amended.

Some operational measures may eventually require dam modifications to address operational and dam safety concerns; and may need further analysis. If USACE determines that this PEIS has not sufficiently evaluated the potential environmental effects of an action, then tiered NEPA analysis will be required. Dam safety modifications would likely only evaluate resource topics that are relevant to dam safety modification alternatives considered at the site-specific level, and may not include analysis of the same resource topics discussed in this PEIS. Operational measures are discussed further below in 7.2.2.2.

For measures that would require site-specific construction, USACE would perform a subsequent NEPA phase tiered to this PEIS. During this subsequent NEPA phase, the effects analysis would be informed by the site-specific designs performed at that time for measures requiring construction. Subsequent analysis would include appurtenant or ancillary implementation features or activities, such as use of construction equipment, site preparation, access, staging, and material storage and transfer facilities. Typical descriptions of several activities that may potentially occur during implementation of the measures are summarized in Section 3.1.1.2 and further described in Appendix A. These measures are discussed further in below in 7.2.2.3.

#### *7.2.2.1 Operational measures with no further NEPA analysis required*

The operational measures included in the Proposed Action listed by project location in Table 3.1-2 do not require further analysis and are considered fully evaluated through the programmatic analysis of the WVS PEIS.

**Table 3-1. Operational measures in the Proposed Action with no further site- or project-specific NEPA analysis required**

| Measures | Locations[1] |
|---|---|
| **Flow Measures** | – |
| 30b. Refined Integrated temperature and habitat flow regime | FRN, CTG, DOR, DEX, LOP, FCR, HCR, CGR, BLU, FOS, GPR, BCL, DET |
| 304. Augment instream flows by using the power pool | LOP, HCR, GPR, DET |
| 718. Augment instream flows by using inactive pool | FCR, BLU |
| **Water Quality Measures** | – |
| 166. Use Regulating Outlets for Temperature Management | GPR |
| 721. Use spillway for surface spill in summer | GPR |
| **Downstream Passage Measures** | – |
| 40. Deeper fall reservoir drawdowns for downstream fish passage | GPR |
| 714. Pass water over spillway in spring for downstream fish passage | GPR |

| Measures | Locations[1] |
|---|---|
| **Measures Common to All Alternatives** | – |
| 719. Adapt Hatchery Program | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins |
| Fall Creek Drawdown | FCR |
| Continued Operation of Existing Adult Fish Facilities | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins |
| Scheduled/Routine Maintenance of WVS Facilities | Basin-wide |
| Near-Term Operations | LOP, HCR, FCR, CGR, FOS, GPR, DET |

[1]Dam Abbreviations: BCL – Big Cliff; BLU – Blue River; CGR – Cougar; CTG – Cottage Grove ; DET – Detroit; DEX – Dexter; DOR – Dorena; FCR – Fall Creek; FOS – Foster; FRN – Fern Ridge; GPR – Green Peter; HCR – Hills Creek; LOP – Lookout Point

#### *7.2.2.2 Operational measures with limited subsequent tiered NEPA analysis*

Operational measures listed in Table 3-2 by project location would eventually require dam modifications (i.e., structural changes) to address operational and dam safety concerns. In these cases, the effects analysis would be limited to the construction activities needed to address operational and dam safety concerns. Effects for some resources (e.g., visual resources) may be fully evaluated under this PEIS; the subsequent tiered analysis would not include any additional analysis for these resources. Prior to implementation, USACE would determine whether each resource discussed in Chapters 3 and 4 has been adequately addressed at the programmatic level or whether additional analysis would be necessary during a subsequent tiered analysis. Tiered analyses for relevant resources will summarize the issues already discussed in the WVS PEIS; incorporate discussion from the WVS PEIS by reference; and concentrate on the effects that would be specific to the site or project.

**Table 3-2. Operational measures in the Proposed Action that would require site- or project-specific NEPA analysis**

| Measures | Locations |
|---|---|
| **Downstream Passage Measures** | – |
| 40. Deeper fall reservoir drawdowns for downstream fish passage for the drawdown operation to the DT | CGR |
| 720. Spring reservoir drawdown for downstream fish passage for the drawdown operation to the DT | CGR |
| **Measures Common to All Alternatives** | – |

| Measures | Locations |
|---|---|
| 726. Maintenance of existing and new fish release sites above dams | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins |
| Major Maintenance and Rehabilitation of WVS Facilities | Basin-wide |

#### *7.2.2.3 Structural measures with subsequent tiered NEPA analysis*

The structural measures listed in Table 3-3 by project location would be evaluated during subsequent tiered analyses. There are limitations in available information and uncertainty regarding the timing and location for these measures; as such, this PEIS provides the initial, general effects analysis of these structural measures. The subsequent effects analysis would be informed by the site-specific designs performed at that time for measures requiring construction. Subsequent analysis would include appurtenant or ancillary implementation features or activities, such as use of construction equipment, site preparation, access, staging, and material storage and transfer facilities.

**Table 3-3. Structural measures in the Proposed Action that would require site- or project-specific NEPA analysis**

| Measures | Locations |
|---|---|
| **Water Quality Measures** | – |
| 105. Construct water temperature control tower | DET |
| 479. Foster Fish Ladder Temperature Improvement | FOS |
| **Downstream Passage Measures** | – |
| 392. Construct structural downstream fish passage | LOP, FOS, DET |
| **Upstream Passage Measures** | – |
| 52. Provide Pacific lamprey passage and infrastructure | GPR |
| 722. Construct adult fish facility | GPR |
| **Measures Common to All Alternatives** | – |
| 384. Gravel Augmentation | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River dams |
| 9. Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration | Basin-wide |

### 7.2.5 Evaluation of new information that could require a supplemental analysis

A supplemental analysis is required when there is significant new information relevant to the Proposed Action or its impacts (CEQ 2014). Introduction of a new and viable alternative, fundamental changes to existing plans (including connected actions), or a change in purpose and scope could necessitate a supplemental analysis. In addition, if new information prompts the need to analyze effects to a new resource that has not been analyzed in the PEIS; a supplemental analysis could also be required.

Alternatively, if a new tiered NEPA analysis can include consideration of the programmatic issues, then the tiered analysis can also serve as the vehicle for supplementing the PEA or PEIS. When the new information's effects are limited to potential impacts or alternatives associated with the project- or site-specific decision, then the tiered analysis can address the new information without having to supplement the PEIS (CEQ 2014).

Programmatic NEPA reviews allow two options to complete supplementation. One option is to supplement the original PEIS, and another option is to tier NEPA evaluation of programmatic actions. The determination to evaluate new information during a tiered NEPA review relies on whether the effects of new information are limited to sequential phases of activities, or project- or site-specific activities (CEQ 2014). Following completion of the WVS PEIS, USACE would evaluate new information and determine how to analyze its effects. If supplementation is required, then the Corps would determine whether to accomplish supplementation through preparation of a tiered NEPA document or a supplemental NEPA document.

### 7.2.6 Agency and public involvement during the programmatic or subsequent tiered review

In the sections above, USACE has prepared a list of measures where effects are addressed at the programmatic level of NEPA analysis and where effects would be further analyzed during subsequent tiered NEPA analysis. This information is intended to clarify to interested parties when to provide comment; that is, whether to raise issues during the programmatic analysis, or to raise them in any subsequent tiered analyses. Participation during the broad NEPA programmatic review will ensure that stakeholder concerns are raised early on the broad effects instead of at the subsequent tiered level where site- or project- specific effects would be the focus of review and involvement. Additional information on the public involvement process for the WVS PEIS is provided in Chapter 6.

## 7.4 ENDANGERED SPECIES ACT, AS AMENDED (16 U.S.C. §§ 1531–1544)

In order to comply with obligations under CFR 50 CFR 402.16, the USACE and NMFS reinitiated consultation of the 2008 NMFS Biological Opinion to address changes to the action due to lack of available funding for key Reasonable and Prudent Alternative (RPA) elements. USACE notified NMFS of that decision on behalf of the Action Agencies in a letter dated April 9, 2018. Though USACE and USFWS have yet to formally re-initiate consultation the current USFWS biological opinion is set to expire in 2024. Since the USFWS determination of non-jeopardy was based on the completion of the NMFS 2008 RPA actions, the USFWS consultation will also need to be reconsulted on. Formal consultation on the revised proposed action, which is also the preferred alternative of this PEIS, is scheduled to begin late in 2022, with final the biological opinions to be issued by NMFS and USFWS in late 2023. Prior to the initiation of formal consultation there have been extensive pre-consultation coordination on both the PEIS and proposed action to date, which is ongoing.

## 7.5 FISH AND WILDLIFE COORDINATION ACT (FWCA) (16 U.S.C. §661 ET SEQ.)

USACE formally requested coordination under the FWCA (16 U.S.C. 661-667e as amended) with USFWS and NMFS in letters dated August 10th, 2021. The USACE and USFWS entered into an agreement for FWCA coordination in an intragovernmental reimbursable activity agreement dated September 1, 2021. Development of the USFWS scope of analysis was a collaborative effort between the NMFS, USFWS, and USACE, including the fish and wildlife resources to be analyzed (see Table 7.5-1 below). As part of the deliverables under this scope USFWS has submitted a draft Fish and Wildlife Conservation Act Report (CAR) on the 24th of May 2022.

**Table 7.5-1 Fish and wildlife resources evaluated under the draft CAR for USFWS.**

| Habitat Types | Evaluation Species |
|---|---|
| Upland | Monarch Butterfly (*Danaus plexippus*)<br>Wayside Aster (*Eucephalus vialis*)<br>Black Cottonwood[a]<br>Bradshaw's Lomatium[b] |
| Prairie | Dusky Canada Goose (*Branta canadensis occidentalis*)<br>Thin-leaved Peavine (*Lathyrus holochlorus*)<br>Bradshaw's Lomatium[b] |
| Wetland/ Off-Channel | Northern Red-Legged Frog (*Rana aurora*)<br>Pacific Lamprey (*Entosphenus tridentatus*)<br>American Beaver[a]<br>Black Cottonwood[a]<br>Oregon Chub[b] |
| Riparian | Foothill Yellow-Legged Frog (*Rana boylii*)<br>Western Pond Turtle (*Actinemys marmorata*)<br>American Beaver[a]<br>Black Cottonwood[a] |
| Riverine | Coastal Cutthroat Trout (*Oncorhynchus clarki clarki*)<br>Western Ridged Mussel (*Gonidea angulata*)<br>American Beaver[a]<br>Oregon Chub[b] |

[A] Keystone Species

[B] Delisted Species

As part of its efforts USFWS coordinated closely with resource experts from the State of Oregon Department of Fish and Wildlife, detailed in an email to USACE staff on November 17th, 2021. The USFWS has provided a suite of conservation measures based on species and habitat types which is currently being evaluated by the USACE. A final CAR will be issued and integrated into the FEIS in the summer of 2023.

A draft CAR from NMFS will not be issued at the time of publication of the Draft EIS. A Draft CAR is anticipated to be issued by NMFS in January 2023. A final CAR from NMFS will be issued in the FEIS and integrated into the FEIS at the time of its publication.

## 7.6 NATIONAL HISTORIC PRESERVATION ACT (54 U.S.C. 300101 ET SEQ.)

The National Historic Preservation Act of 1966, as amended, requires that federal agencies evaluate the effects of federal undertakings[1] on historical, archeological, and cultural resources. The Act also requires the Advisory Council on Historic Preservation have the opportunity to comment on the proposed undertaking. USACE, in coordination with the Oregon State Historic Preservation Office (SHPO) and Native American tribes, is identifying cultural resources and sites in the analysis area for inclusion on the National Register.

USACE has consulted with the State of Oregon under Section 106 of the National Historic Preservation Act and executed a Programmatic Agreement with the SHPO. Currently, USACE is in consultation with the Grand Ronde, Warm Springs, and Siletz Tribes.

## 7.7 EXECUTIVE ORDER 11988, FLOODPLAIN MANAGEMENT, AND EXECUTIVE ORDER 13960, ESTABLISHING A FEDERAL FLOOD RISK MANAGEMENT STANDARD AND A PROCESS FOR FURTHER SOLICITING AND CONSIDERING STAKEHOLDER INPUT

Executive Order (EO) 11988, Floodplain Management, signed 24 May 1977 requires Federal agencies to avoid to the extent possible the long and short-term adverse impacts associated with the occupancy and modification of natural flood plains and to avoid direct and indirect support of floodplain development wherever there is a practicable alternative. In accomplishing this objective, "*each agency shall provide leadership and shall take action to reduce the risk of flood loss, to minimize the impact of floods on human safety, health, and welfare, and to restore and preserve the natural and beneficial values served by flood plains in carrying out its responsibilities*."

To comply with EO 11988, projects are formulated and recommended that, to the extent possible, avoid, minimize, and/or mitigate adverse effects associated with use of the floodplain, and avoid inducing incompatible development in the floodplain unless there is no practicable alternative. Under the Order, USACE is required to provide leadership and take action to:

- Avoid development in the base floodplain unless it is the only practicable alternative;
- ➢ Reduce the hazard and risk associated with floods;

[1] "Federal undertakings" have not been specifically identified as synonymous with "major federal actions" under the NHPA or NEPA. However, it is common practice to consider major federal actions to trigger NHPA review and consultations.

- Minimize the impact of floods on human safety, health and welfare; and
- Restore and preserve the natural and beneficial values of the base floodplain.

The Water Resources Council Floodplain Management Guidelines for implementation of EO 11988, 10 Feb 1978 (43 FR 6030), as referenced in the Engineering Regulation (ER) 1165-2-26, 30 Mar 1984, require an eight-step process that agencies should carry out as part of their decision-making process on projects that have potential impacts to or within the base floodplain. The eight steps reflect the decision-making process required in Section 2(a) of the Order.

Executive Order 13960, Establishing a Federal Flood Risk Management Standard and a Process for Further Soliciting and Considering Stakeholder Input, dated January 30, 2015, establishes the Federal Flood Risk Management Standard (Standard), a flexible framework to increase resilience against flooding and help preserve the natural values of floodplains, and sets forth a process for further solicitation and consideration of stakeholder input prior to implementation.

The evaluation and decision making process described below are consistent with the EOs and associated federal policies.

1. Determine if the Proposed Action would be in the base (1 percent [Annual Chance Exceedance] ACE or 1/100-year) floodplain.

Measures of the Proposed Action would be located within the base floodplain; however, implementation of the Proposed Action would avoid, to the extent practicable, long- and short-term adverse impacts to the floodplain. Site-specific designs will be developed prior to construction to ensure that with EOs 11988 and 13960 through technical analysis and coordination with local floodplain management authorities during future site-specific NEPA evaluations described structural in Section 7.2.

2. If the Proposed Action would be in the base floodplain, identify and evaluate practicable alternatives to the action or to locating the action in the base floodplain.

There are no practicable alternatives to locating measures of the Preferred Alternative outside of the base floodplain. However, the purpose and need of the WVS EIS requires that alternatives not alter flood risk.

3. If the action must be in the floodplain, advise the general public in the affected area and obtain their views and comments.

Interested parties may provide comment on floodplain concerns in the affected area through the public comment process of the DPEIS.

4. Identify beneficial and adverse impacts due to the action and any expected losses of natural and beneficial floodplain values. Where actions proposed to be located outside the base

floodplain will affect the base floodplain, impacts resulting from these actions should also be identified.

No beneficial or adverse effects would occur to floodplain values from actions in the base floodplain. No increase in flood risk is expected due to future operations. Implementation of the Proposed Action will avoid, to the extent possible, long- and short-term adverse impacts to the floodplain. It will also avoid direct and indirect support of development or growth (construction of structure/or facilities, habitable or otherwise) in the base floodplain. Site-specific designs will be developed to ensure that the project complies with EOs 11988 and 13690 through technical analysis and coordination with local floodplain management authorities.

5. If the action is likely to induce development in the base floodplain, determine if a practicable non-floodplain alternative for the development exists.

The action is not likely to induce further development in the base floodplain.

6. As part of the planning process under the P&G, determine viable methods to minimize any adverse impacts of the action including any likely induced development for which there is no practicable alternative and methods to restore and preserve the natural and beneficial floodplain values. This should include reevaluation of the “no action” alternative.

Viable methods to minimize impacts of the array of alternatives were integrated as part of the purpose and need of the Proposed Action through requiring that all alternatives not alter flood risk.

7. If the final determination is made that no practicable alternative exists to locating the action in the floodplain, advise the general public in the affected area of the findings.

Interested parties are advised of that no practicable alternative exists to locating the action in the floodplain through the Notice of Availability of the DPEIS.

8. Recommend the Proposed Action most consistent with the requirements of the Executive Order 11988.

All of the alternatives, including the no action alternative, would have negligible effects to floodplain values. Thus, there is no specific alternative that is of greater consistency with EOs 11988 and 13690.

## 7.8 STATUS OF COMPLIANCE WITH OTHER ENVIRONMENTAL LAWS, REGULATIONS, AND EXECUTIVE ORDERS

In accordance with 40 CFR 1502.25 and 33 CFR 230.25(a), reviews and consultation requirements, analyses, and status of coordination associated with applicable laws, executive orders and memoranda will be summarized in the Draft PEIS.

Table 7.8-1 provides a summary of applicable reviews and consultation requirements, analyses, and status of coordination associated with applicable environmental and cultural resources laws, executive orders, and memoranda. Results of the coordination completed or underway pursuant to these authorities will be summarized in the final WVS PEIS.

**Table 7.8-1 Compliance with Applicable Environmental and Cultural Resources Regulations**

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| American Indian Religious Freedom Act of 1978, 42 U.S.C. § 1996 | Requires Federal agencies to ensure that religious rights of Native Americans are accommodated during project planning, construction, and operation. | – | Should USACE be notified of any Tribal concerns regarding access to locations of religious or spiritual importance in the WVS PEIS Area of Analysis, it will consult with Tribal representatives to address these concerns. Compliance determination to be made after completion of WVS PEIS Process, public involvement process, SHPO and Tribal consultations and final construction implementation. | During subsequent site-specific evaluation as required |
| Antiquities Act of 1906, 16 U.S.C. §§ 431-433 | The first Congressional act to protect archaeological resources on Federal lands, it has largely been superseded by the Archaeological Resources Protection Act (ARPA). Some Federal agencies will issue Antiquities Act permits rather than ARPA permits for activities on Federal lands managed by that agency. | – | No lands administered by agencies that issue Antiquities Act permits are known within the WVS PEIS project area. Should such lands be identified in the future, the appropriate agency would address Antiquities Act requirements. | During subsequent site-specific evaluation as required |
| Archaeological Resources Protection Act of 1979 (ARPA), 16 U.S.C. §§ 470aa-470mm | Secures the protection of archaeological resources and sites which are on public lands and Indian lands. | – | No public or Indian lands are known within the WVS PEIS project area. Should such lands be identified in the future the appropriate agency would address ARPA requirements. | During subsequent site-specific evaluation as required |
| Bald and Golden Eagle Protection Act of 1940, 16 U.S.C. § 668 et seq. | Prohibits the take, possession, or disturbance of any bald or golden eagle. | U.S. Fish and Wildlife Service | Coordination with the USFWS throughout the WVS PEIS process will ensure identification of bald and golden eagle nesting sites, and avoidance and minimization of effects to bald and golden eagles during implementation. | During subsequent site-specific evaluation as required |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 U.S.C. §§ 9601–9675 | Consistent with ER 1165-2-132, USACE will not participate in clean-up or other response actions related to materials regulated by CERCLA. If an action is present and cannot be avoid a designated CERCLA site, the area must be remediated prior and satisfy the requirements of local regulators. | U.S. Environmental Protection Agency | Evaluation of compliance with CERCLA would occur during site-specific evaluation when on-site alternatives are considered. | During subsequent site-specific evaluation as required |
| Clean Air Act, as amended, 42 U.S.C. § 7401–7671q | Clean Air Act (42 U.S.C. 7401 et seq.) Section 176(c) of the Clean Air Act (CAA) requires that Federal agencies assure compliance with the EPA General Conformity Rule to implement Section 176(c) found at 40 CFR Part 93. Under the General Conformity rule, federal agencies must work with state, tribal and local governments in a nonattainment or maintenance area to ensure that federal actions conform to the air quality plans established in the applicable state or tribal implementation plan. In addition, the rule contains a number of "exempted" or "presumed to conform" activities, which may apply to the Proposed Action(s) under the WVS PEIS. | Oregon Department of Environmental Quality<br><br>U.S. Environmental Protection Agency | When direct emissions or indirect emissions would originate in a nonattainment or maintenance area, USACE will conduct a CAA applicability analysis. If required, a CAA Conformity Determination will be completed during subsequent site-specific evaluation | During subsequent site-specific evaluation as required |
| Clean Water Act, as amended, 33 U.S.C. 1251–1387 § 401 | Requires Federal agencies to comply with state water quality standards.<br>USACE would obtain 401 Water Quality Certification (WQC) associated with the discharge of dredged or fill material from the Oregon Department of Water Quality (ODEQ) in accordance with the requirements Section 401 of the CWA. | Oregon Department of Environmental Quality<br><br>U.S. Environmental Protection Agency | USACE will defer obtaining 401 WQC until subsequent site-specific evaluations occur. Refer to the programmatic NEPA process described in Section 7.2 for additional information on subsequent NEPA reviews and associated compliance with other environmental laws. | During subsequent site-specific evaluations as required |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| Clean Water Act, as amended, 33 U.S.C. 1251–1387, § 402 | A Section 402 permit is needed for projects that may discharge stormwater to surface waters. | Oregon Department of Environmental Quality | USACE or its contractor will acquire construction stormwater permits from permitting agencies for construction activities subject to Section 402 of the Act.<br>Refer to the programmatic NEPA process described in Section 7.2 for additional information on subsequent NEPA reviews and associated compliance with other environmental laws. | During subsequent site-specific evaluations as required |
| Clean Water Act, as amended, 33 U.S.C. 1251–1387 § 404 | Pursuant to 33 CFR Parts 335 to 338, USACE authorizes discharges of dredged or fill material for operations and maintenance of authorized Civil Works projects. USACE does not issue itself a Clean Water Act (CWA) permit to authorize USACE discharges of dredged material or fill material into waters of the United States (U.S.) but does apply the 404(b)(1) guidelines and other substantive requirements of the CWA.<br><br>USACE would also obtain Removal-Fill permits from Oregon Department of State Lands (ODSL) in accordance with Section 404(t) of the CWA for discharges of fill into Waters of the U.S. | U.S. Army Corps of Engineers<br><br>U.S. Environmental Protection Agency<br><br>Oregon Department of State Lands | Measures in the Preferred Alternative that may require the discharge of dredged material or fill material into waters of the U.S. have not been designed to a sufficient level to perform a 404(b)(1) analysis. USACE would evaluate additional site-specific discharges of dredged or fill material during subsequent NEPA evaluations as described in Section 7.2.4. USACE would include site-specific draft and final 404(b)(1) evaluations of discharges of dredged or fill material associated with subsequent actions within the draft and final NEPA documents respectively. USACE will also obtain applicable Oregon DSL Removal/Fill Permit(s) during the site-specific evaluation(s) in accordance with requirements of Section 404(t) of the Act.<br>Refer to the programmatic NEPA process described in Section 7.2 for additional information on subsequent NEPA reviews and | During subsequent site-specific evaluation as required |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| | | | associated compliance with other environmental laws.<br><br>USACE will prepare Statement of Findings (SOF) and include it as part of the environmental documentation in the final site-specific NEPA document.<br><br>See Sections 3.7, and 4.7 for a discussion of broad direct and indirect effects and cumulative effects to wetlands and waters that would be further evaluated as part of a future 404(b)(1) assessment. | |
| Coastal Zone Management Act, 16 U.S.C. 1451 et seq. | Sections 307c(1) and (2) of the Coastal Zone Management Act require that each Federal agency activity within or outside the coastal zone that affects any land or water use or natural resource of the coastal zone or any Federal development project in the coastal zone of a state shall, to the maximum extent practicable, be consistent with approved state management plans. Civil Works activities of USACE in the coastal zone fall within this classification. | Oregon Department of Land Conservation and Development | The Proposed Action would not occur within the Oregon Coastal Zone, nor would it impact coastal resources. | Not applicable |
| Endangered Species Act as amended (16 U.S.C. §§ 1531–1544) | Requires Federal agencies to protect listed species and consult on the federal action. | National Marine Fisheries Service<br>U.S. Fish and Wildlife Service | ESA consultation is ongoing and will be fulfilled prior to completion of the WVS Final PEIS. USACE anticipates consultations would be formal and would result in a Biological Opinion (BiOp) from each consulting agency. | Prior to completion of final WVS PEIS, and during subsequent site- |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| | | | | specific evaluation as required |
| Farmland Protection Policy Act (7 U.S.C. §§ 4201, et seq.) | Avoids or minimizes the unnecessary and irreversible conversion of farmland to nonagricultural uses by Federal projects. | National Resource Conservation Service (NRCS) | USACE will coordinate with NRCS should conversion of farmland to nonagricultural uses occur as a result of construction of structural measure. Coordination would occur during future site-specific evaluation of structural measures. Refer to the programmatic NEPA process described in Section 7.2 for additional information. | During subsequent site-specific evaluation as required |
| Marine Mammal Protection Act (MMPA) of 1972, 16 U.S.C. § 1361 et seq. | Requires U.S. citizens and U.S. -based entities to seek incidental take authorization be obtained for the unintentional "take" of marine mammals incidental to activities including construction projects, scientific research projects, oil and gas development, and military exercises. | National Marine Fisheries Service [for whales, dolphins, and sea lions]<br>U.S. Fish and Wildlife Service [for walrus, manatees, sea otters, and polar bears] | There are no marine mammals within the WVS PEIS and there would be no take of marine mammals as a result of the Proposed Action. | Not applicable |
| Marine Protection, Research, and Sanctuaries Act, 16 U.S.C. § 1431 et seq. and 33 U.S.C. §1401 et seq. (1988) | Ensures that ocean disposal will not unreasonably degrade or endanger human health, welfare, or the marine environment. | U.S. Environmental Protection Agency | The Proposed Action would not involve ocean disposal. | Not applicable |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| Migratory Bird Treaty Act (MBTA) (16 U.S.C. §§ 703-712) | Prohibits the take, possession or disturbance of any migratory bird, nests, or eggs without a federal permit. | U.S. Fish and Wildlife Service | Measures within proposed action are not anticipated to require MBTA permits. If upon site assessment it is determined that an MBTA permit is required to take MBTA species, then USACE will obtain MBTA permits during site-specific evaluation as required | During subsequent site-specific evaluations as required |
| National Historic Preservation Act (NHPA) (54 U.S.C. 300101 et seq.): Protection of Historic Properties | Requires Federal agencies to identify and protect cultural and historic resources. | Oregon State Historic Preservation Office<br><br>Federally recognized tribes | USACE is coordinating with Tribal representatives and the SHPOs. USACE will continue this coordination to meet requirements of Section 106 of the NHPA prior to implementing any measures that may affect cultural resources. The compliance process will continue until conclusion of the NHPA consultation process through the execution of a Programmatic Agreement. Subsequent federal undertakings would be coordinated individually during site-specific evaluations as required. | Prior to completion of final WVS PEIS, and during subsequent site-specific evaluation as required |
| Native American Graves Protection and Repatriation Act (NAGPRA) 25 U.S.C. 3001 et seq. | Protects Native American and Native Hawaiian cultural items. | Federally recognized tribes | Should any Federal or tribal trust lands be identified in the future and any Native American remains or associated cultural items are discovered, the appropriate agency or Tribe would address the NAGPRA requirements. | During subsequent site-specific evaluation as required |
| Resource Conservation and Recovery Act of 1976 (RCRA), 42 U.S.C. § 6901-6987 | Gives EPA the authority to control hazardous waste from the "cradle-to-grave." This includes the generation, transportation, treatment, storage, and disposal of hazardous waste. RCRA also set forth a framework for the management of non-hazardous solid wastes. The 1986 amendments to RCRA enabled EPA to address | U.S. Environmental Protection Agency | USACE identify potential sources of contamination with the WVS Project areas. USACE will maintain a Spill Prevention, Control, and Countermeasure Plan for their facilities and projects. | Prior to completion of final WVS PEIS, and during subsequent site-specific NEPA evaluations as required |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |

| | environmental problems that could result from USTs storing petroleum and other hazardous substances. | | | |
| Executive Order 11988, Floodplain Management, 24 May 1977 | EO 11988 (May 24, 1977) requires a federal agency, when taking an action, to avoid short- and long-term adverse effects associated with the occupancy and the modification of a floodplain. The agency must avoid direct and indirect support of floodplain development whenever floodplain siting is involved. In addition, the agency must minimize potential harm to or in the floodplain and explain why the action is proposed. Additional floodplain management guidelines for EO 11988 were also provided in 1978 by the Water Resources Council. USACE implementation guidance in Engineering Regulation (ER) 1165-2-26 (March 30, 1984). | U.S. Army Corps of Engineers | See section 8.2 | Prior to completion of final WVS PEIS, and during subsequent site-specific evaluation as required |
| Executive Order 11593, Protection and Enhancement of the Cultural Environment | Requires Federal agencies to preserve, restore, and maintain the historic and cultural environment of the U.S. | | USACE policies ensure that all Proposed Actions are performed only after appropriate inventory, management, and protection of cultural resources has occurred. Compliance determination to be made after NEPA evaluation and Section 106 consultation is complete. | Prior to completion of final WVS PEIS |
| Executive Order 11514, Protection and Enhancement of Environmental Quality | Assigns responsibility to Federal agencies to protect and enhance the quality of the Nation's environment. | U.S. Army Corps of Engineers | The proposal minimizes potential environmental impacts, and includes measures to offset the intensity of impacts as described in the Proposed Action. | Prior to completion of final WVS PEIS |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| Executive Order 11990, Protection of Wetlands | Requires Federal agencies to protect wetland habitats. | U.S. Army Corps of Engineers | If wetlands as defined in EO 11990 are identified during site-specific evaluation, USACE will offset unavoidable wetland losses in a manner that results in no net loss of wetlands | During subsequent site-specific evaluations as required |
| Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations | Requires Federal agencies to consider and minimize potential impacts on Environmental Justice (EJ) communities. | U.S. Environmental Protection Agency | Chapter 3.20 documents environmental justice concerns and indicates that there would be no disproportionate impact to low income or minority communities. Detailed analysis of EJ populations is located in Appendix L. | Prior to completion of final WVS PEIS, and during subsequent site-specific evaluation |
| Executive Order 13007, Indian Sacred Sites | Directs Federal agencies to provide access and ceremonial use of sacred sites on Federal lands and avoid affecting their physical integrity. | Federally recognized tribes | USACE and the relevant Federal agency will consult with appropriate Tribes to determine if any sacred sites are located on Federal lands within the WVS. | Prior to completion of final WVS PEIS, and during subsequent site-specific NEPA evaluation as required |
| Executive Order 13045, Protection of Children from Environmental Health Risks and Safety Risks | Under this Executive Order, Federal agencies shall make it a high priority to identify and assess environmental health risks and safety risks that may disproportionately affect children; and shall ensure that its policies, programs, activities, and standards address disproportionate risks to children that result from environmental health risks or safety risks. | U.S. Army Corps of Engineers | Preparation of the PEIS includes evaluation of environmental health and safety risks, and measures necessary to protect all people, including children, from those risks. There are no measures that would disproportionately affect children or any other group. | Prior to completion of final WVS PEIS, and during subsequent site-specific NEPA evaluation as required |
| Executive Order 13175, Consultation and | Directs Federal agencies to recognize Indian sovereignty in government-to-government relationships and to consult with Tribes in | Federally recognized tribes within WVS area | USACE is consulting with Tribal representatives to identify and address Tribal concerns in the WVS PEIS study area. | Prior to completion of final WVS PEIS, and during |

| Relevant Law/Regulation | Requirements | Associated Agencies or Tribes | Compliance Status | Timeframe of Compliance |
|---|---|---|---|---|
| Coordination with Indian Tribal Governments | adopting regulatory policies that have Tribal implications. | | | subsequent site-specific NEPA evaluations |
| Executive Order 13751, Safeguarding the Nation from the Impacts of Invasive Species | Requires Federal agencies to take reasonable measures to prevent the spread and introduction of invasive species as a result of their management or construction actions. | U.S. Army Corps of Engineers | Preparation of the WVS PEIS will document environmental conditions and effects and informs the determination of compliance with EO 13751 within the Section 3.7, 3.8, and 3.9 of the Report. | Prior to completion of final WVS PEIS, and during subsequent site-specific NEPA evaluations |
| Executive Order 13287, "Preserve America" | Enhances practices that protect the cultural heritage of the U.S. | | USACE recognizes the importance of historic properties within the WVS PEIS study area and will work with State and National agencies to determine if any Proposed Actions would affect those properties.". | Prior to completion of final WVS PEIS, and during subsequent site-specific NEPA evaluations |

# CHAPTER 8 - GLOSSARY

## A

**Access point:** A place where people access a site for recreation. An access point might include a boat launch, a campground, a parking area, etc. A recreation area may contain one or more access points.

**Acre-foot:** The volume of water that will cover an area of 1 acre to a depth of 1 foot. Equals 325,851 gallons.

**Ambient air:** Ambient air is the air in the atmosphere surrounding a particular place, such as a powerplant.

**Anadromous fish:** Fish, such as salmon or steelhead trout, that hatch in fresh water, migrate to and mature in the ocean, and return to fresh water as adults to spawn.

**Artifact:** An object of any type made by human hands. Tools, weapons, pottery, and sculptured and engraved objects are artifacts.

**Augment:** Increase; in this application, to increase river flows above rates that would occur under normal operation by releasing more water from storage reservoirs.

**Average megawatt (aMW):** A unit of energy that represents 1 megawatt of electric power capacity continuously over a year. Because there are 8,760 hours in a year, ne aMW is equal to 8,760 megawatts per hour.

## B

**Base flow:** The portion of streamflow that is sustained between precipitation events, fed to streams by delayed pathways.

**Bypass system:** Structure in a dam that provides a route for fish to move through or around the dam without going through the turbines.

## C

**Capacity:** The maximum load that a generator, piece of equipment, substation, transmission line, or system can carry under existing service conditions. Baseload capacity is the power output that can be continuously produced to run at least 70 percent of the time. Firm capacity is the capacity whose availability is ensured to the purchaser.

**Conservation Plan:** A plan prepared annually which provides flow requirements based on the basin water supply for that year.

**Conservation Pool:** the set amount of water in a reservoir dedicated for storage needs for municipal, domestic, agricultural (irrigation), industrial, fish and wildlife, water quality, and/or recreational use.

**Conservation Season**: March through October, including the filling season (spring) and the release season (summer), when the WVS reservoirs impound water for release later in the year.

**Critical water year (or "critical water conditions"):** Represent the historic water year (in this case, 1937) when the capability of the hydropower system produces the least.

**Cubic feet per second (cfs):** A unit of measurement pertaining to flow or discharge of water. One cfs is equal to 449 gallons (1.7 cubic meters) per minute.

**Cultural resources:** The non-renewable evidence of human occupation or activity as seen in any district, site, building, structure, artifact, ruin, object, work of art, architecture, or natural feature that was part of human history at the national, state, or local level.

**D**

**Demand:** For electrical energy, the rate at which it is used, whether at a given instant or averaged over any designated period of time.

**Discharge:** Volume of water flowing past a point at a given time, usually expressed in cubic feet per second.

**Dissolved gas concentrations:** The amount of elements or compounds normally occurring as gases, such as nitrogen and oxygen, which are held in solution in water, expressed in units such as milligrams of the gas per liter of liquid.

**Draft:** Release of water from a storage reservoir.

**Draft rate:** The rate at which water, released from storage behind a dam, reduces the elevation of the reservoir.

**Drawdown:** The distance that the water surface of a reservoir is lowered from a given elevation as water is released from the reservoir. Also refers to the act of lowering reservoir levels.

**E**

**Economic value:** The difference between the maximum amount a recreationist would be willing to pay to participate in a recreational activity and the actual cost of participating in that activity. This is referred to by economists as consumer surplus or net economic value.

**Electricity:** Electric current used or regarded as a source of power.

**Endangered:** A plant or animal species or sub-species which is in danger of extinction throughout all or a significant portion of its range because its habitat is threatened with destruction, drastic modification, or severe curtailment, or because of overexploitation, disease, predation, or other factors; federally endangered species are officially designated by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service and published in the *Federal Register.*

**Endemic:** Native or limited to a certain region.

**Energy:** As commonly used in the electric utility industry, electric energy means kilowatt-hours, or joules (the level of power delivered multiplied by the amount of time that the level of power is delivered). Used interchangeably with, although technically not a synonym of, power.

**Entrainment:** The drawing of fish and other aquatic organisms into tubes or tunnels carrying water for cooling purposes into thermal plants, or for power generating purposes into hydroelectric plants. Entrainment increases mortality rates for those organisms.

**F**

**Firm energy:** Energy considered ensurable to the customer to meet all agreed-upon portions of the customer's load requirements over a defined period. As defined in Bonneville Power Administration's system, electric energy produced under critical water conditions.

**Fishery:** Generally defined as a group of individuals or vessels that catch finfish or harvest shellfish, with specific commonalities in activity, including the fish species or stock targeted, the gear used, the location of activity, and the season of activity.

**Fish hatchery:** A facility in which fish eggs are incubated and hatched and juvenile fish are reared for release to rivers or lakes.

**Fish ladders:** A series of ascending pools constructed to enable salmon or other fish to swim upstream around or over a dam.

**Fish passage facilities:** Features of a dam that enable fish to move around, through, or over without harm. Generally, an upstream fish ladder or a downstream bypass system.

**Flow:** The volume of water passing a given point per unit of time.

**Forebay:** The portion of the reservoir at a hydroelectric plant which is immediately upstream of the generating station.

**Freshet:** A rapid temporary rise in streamflow caused by heavy rains or rapid snowmelt.

**Full pool:** The maximum level of a reservoir under its established normal operating range.

**G**

**Generation:** The act of producing electricity from other forms of energy (e.g., chemical, kinetic, gravitational, potential) or the amount of electrical energy produced.

**H**

**Hydraulic head:** The vertical distance between the surface of the reservoir and the surface of the river immediately downstream from the turbines and dam.

**Hydroelectric:** The production of electric power through use of the gravitational force of falling water.

**Hydrology:** The science that studies the continuous cycle of evapotranspiration, precipitation, and runoff, driven by solar energy.

**Hydrosystem:** An at least partially regulated freshwater system that is made up of water and the associated aquatic environments within a delimited geographical entity that fish use to complete their life cycle.

**I**

**Inflow:** Water that flows into a reservoir or forebay during a specified period.

**Intake:** The entrance to a conduit through a dam or water facility.

**Intertie:** A transmission line or system of transmission lines permitting a flow of energy between major power systems. The Bonneville Power Administration transmission grid has interties to British Columbia, Canada; California; and eastern Montana.

**J**

**Jobs:** Combined full- and part-time jobs on an annualized basis.

**Juvenile:** The early freshwater stage in the life cycle of anadromous fish up to and including when they migrate downstream to the ocean as a smolt.

**K**

**kcfs:** Thousand cubic feet per second; a measurement of water flow equivalent to 1,000 cubic feet of water passing a given point in one second.

**L**

**Labor income**: includes employee compensation and proprietary income. Employee compensation consists of wage and salary payments as well as benefits (e.g., health and retirement benefits) and employer paid payroll taxes (e.g., employer social security contributions and unemployment taxes). Proprietary income consists of payments received by self-employed individuals (such as doctors and lawyers) and unincorporated business owners.

**Levee:** An embankment constructed to prevent a river from overflowing.

**Littoral zone:** The shallower waters near the shore of a reservoir or lake.

**Load:** The amount of electric power or energy delivered or required at any specified point or points on a system. Load originates primarily at the energy-consuming equipment and electrical appliances of customers.

**Load shaping:** The adjustment of storage releases so that generation and load are continuously in balance.

**Low pool:** At or near the minimum level of a reservoir under its established normal operating range.

**M**

**Macrophytes:** Aquatic plants that are macroscopic, or large enough to be seen with the naked eye.

**Mainstem:** The principal river in a basin, as opposed to the tributary streams and smaller rivers that feed into it.

**Maintenance:** Work to restore equipment, assets, facilities or components to design conditions or to conditions that have been determined to be sufficient to meet a prescribed level of performance (vice "activities directed toward keeping assets in an acceptable condition"); replacement of parts, systems, or components; preventive maintenance and inspection/monitoring of facilities or equipment and other activities needed to preserve or maintain the asset. Maintenance and repairs, as distinguished from capital improvements, exclude activities directed towards expanding the capacity of an asset or otherwise upgrading it to serve needs different from, or significantly greater than, its current use.

**Major Maintenance:** A non-repetitive item of work or aggregate items of related work for which the total estimated cost exceeds the limit set forth by Engineering Circular 11-2-222, and which does not qualify as major rehabilitation.

**Major Rehabilitation.** Rehabilitation projects are projects to restore or ensure continuation of project functions or outputs.

**Maximum Pool:** the maximum level to which the reservoir surface is allowed to rise during normal operating conditions.

**Megawatt (MW) and kilowatt (kW):** A watt is a unit of power, equal to one joule of energy per second. One kilowatt equals one thousand watts. One megawatt represents 1,000 kilowatts or 1 million watts. MW is a standard metric describing electric power generating capacity.

**Megawatt hours (MWh) and kilowatt hours (kWh):** MWh and kWh are energy measurements denoting electricity production or consumption. One MWh equals 1,000 kWh. In the electricity context, power (MW) is the rate of producing, transferring, or using energy, and energy (MWh) is power used over a period of time.

**Model:** A mathematical function with parameters that can be adjusted so that the function closely describes a set of empirical data. A "mathematical" or "mechanistic" model is usually based on biological or physical mechanisms and has model parameters that have real-world interpretations. In contrast, "statistical" or "empirical" models involve curve-fitting to data where the math function used is selected for its numerical properties. Extrapolation from mechanistic models (e.g., pharmacokinetic equations) usually carries higher confidence than extrapolation using empirical models (e.g., logic).

**Minimum operating pool (MOP):** The minimum elevation of the established normal operating range of a reservoir.

**N**

**Nature-based structures:** Landscape features that are used to provide engineering functions relevant to flood risk management, while producing additional economic, environmental, and/or social benefits.

**O**

**Operating limits:** Limits or requirements that must be factored into the planning process for operating reservoirs and generating projects. (Also see operating requirements, below.)

**Operating requirements:** Guidelines and limits that must be followed in the operation of a reservoir or generating project. These requirements may originate in authorizing legislation, physical plant limitations, or other sources. Non-power operating requirements pertain to navigation, flood control, recreation, irrigation, and other non-power uses of a river.

**Outages:** Periods, both planned and unexpected, during which the transmission of power stops or a particular power-producing facility ceases to provide generation.

**Outflow:** The volume of water per unit of time discharged at a project.

**P**

**Particulates:** Substances that consist of minute separate particles, such as dust or soot.

**Peak load:** The maximum load in a stated period of time. It may be the maximum load at a given instant in the stated period or the maximum average load within a designated interval of the stated period of time. Peak can also be used to refer to the maximum capacity or energy.

**Peaking or peaking capacity:** The generating capacity available to assist in meeting that portion of the load that is above baseload. Alternatively, the maximum output of a generating plant or plants during a specified peak-load period.

**Phytoplankton:** The plant portion of floating or weakly swimming organisms, often microscopic in size, in a body of water.

**Pool:** Reservoir; a body of water impounded by a dam.

**Power:** The rate of energy production or transfer. Power is expressed in watts (1 watt = 1 joule per second) and used interchangeably with energy, although it is technically not a synonym of energy. Power delivered to a load is also called demand.

**Power Pool:** The reservoir capacity between the inactive and conservation pools and is only designated for reservoirs that have power production capabilities.

**R**

**Record of Decision (ROD)**: A document notifying the public of a decision made by a Federal agency, together with the reasons for making that decision. Records of Decision are published in the *Federal Register.*

**Recreation area**: A reservoir, river reach between reservoirs, or the Pacific Ocean off the coast of Oregon and Washington, used for recreation. A recreation area may have one or more access points.

**Recruits:** The number of offspring that successfully survive and return to breed.

**Redds:** Salmon spawning nests in gravel.

**Refill:** Refers to the annual process of filling a reservoir in the spring to the maximum conservation season elevation, at which point the reservoir is considered “full”.

**Regional economic contributions**: These reflect economic activity within a specific geographic region supported by expenditures for a particular economic sector (e.g., recreational visitation). Contributions are often measured in terms of sales (spending), jobs, income, and value added, though other measures may be used.

**Regulating Outlet (RO):** Lower elevation dam outlet to allow flow through the dam while not using any hydroelectric turbine.

**Reliability:** For a power system, a measure of the degree of certainty that the system will continue to meet load for a specified period of time.

**Replacement potential:** Whether each generation of a salmon species produce enough juveniles to at least replace itself.

**Reregulating dam**: a project whose primary purpose is to enable higher variation in flow from an upstream dam, typically in a sub-daily timeframe and has minimal usable flood or conservation season storage.

**Reservoir elevations:** The levels of the water stored behind dams.

**Reservoir storage:** The volume of water in a reservoir at a given time.

**Resident fish:** Fish species that reside in fresh water throughout their lives.

**Residualize:** When migrating juvenile salmonid smolts lose their urge to migrate, physiologically revert to their freshwater life form, and remain in fresh water rather than migrate to sea.

**Riprap:** Broken rock, cobbles, or boulders placed on the bank of a stream or river for protection against the erosive action of water.

**Rule curves:** Seasonal reservoir elevation targets or restrictions, represented graphically as curves, that guide reservoir operations.

**S**

**Salmonids:** Fish of the taxonomic family Salmonidae, such as salmon, trout (including steelhead), char, and whitefish. Pacific salmonids in the genus *Oncorhynchus* include Chinook (king), coho (silver), sockeye (red), chum (dog), and pink (humback).

**Scoping:** The process of defining the scope of a study, primarily with respect to the issues, geographic area, and alternatives to be considered. The term is typically used in association with soliciting input from the public (e.g., non-governmental organizations, individuals, other government agencies, stakeholders) to help define the scope of environmental documents prepared under the National Environmental Policy Act.

**Sedimentation:** The settling of material (such as dust, silt, or other particles) into water and eventual deposition on the bottoms of streams, rivers, lakes, and reservoirs.

**Simulation:** The representation of an actual system by analogous characteristics of a device that is easier to construct, modify, or understand, or by mathematical equations (i.e., a model).

**Smolt:** A juvenile salmon or steelhead migrating downstream to the ocean and undergoing physiological changes to adapt its body from a freshwater to a saltwater environment.

**Spawning:** The release and fertilization of eggs by fish.

**Spending**: Equivalent to the sales by firms in the region. This can be expressed in terms of (1) recreation expenditures, and/or (2) final demand, which is the total sales by firms in the region from all buyers, including recreationists, as well as businesses and households in subsequent rounds of spending.

**Spill:** Water passed over a spillway or through a regulating outlet without going through turbines to produce electricity. Spill can be forced, when there is no storage capability and flows exceed turbine capacity, or planned, for example, when water is spilled to enhance juvenile fish passage.

**Spillway:** Overflow structure of a dam

**Stochastic:** Involving chance or probability.

**Storage reservoirs:** Reservoirs that have storage for regulating high inflows to reduce downstream flooding or storing spring runoff for use later in the dry season.

**Streamflow:** The rate at which water passes a given point in a stream, usually expressed in cubic feet per second.

**Subyearlings:** Juvenile fish less than 1 year old.

**Surplus energy:** Energy generated that is beyond the immediate needs of the producing system. This energy may be sold on an interruptible basis or as firm power.

**System flood control:** Flood protection provided along the Willamette River and its tributaries downstream of the Willamette Valley System of reservoirs.

**T**

**Tailrace:** The canal or channel that carries water away from a dam.

**Tailwater:** The water surface immediately downstream from a dam or hydroelectric powerplant.

**Thermocline:**

**Threatened:** Legal status afforded to plant or animal species that are likely to become endangered within the foreseeable future throughout all or a significant portion of their range, as determined by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service.

**Transmission path:** A path refers to a route over which the power flows from one point to another (i.e., the direction power flows across a transmission line).

**Tules:** The name commonly applied to fall chinook salmon originating on the lower Columbia River.

**Turbidity:** A measure of the optical clarity of water, which depends on the light scattering and absorption characteristics of suspended and dissolved material in the water.

**Turbine:** Machinery that converts kinetic energy of a moving fluid, such as falling water, to mechanical or electrical power.

**V**

**Velocity:** Speed; the rate of linear motion in a given direction.

**Viable Salmonid Population (VSP):** A salmonid population that meets threshold criteria for spatial structure, diversity, productivity, abundance, and risk of extinction as determined by the NOAA Viable Salmonid Population (VSP) framework (McElhaney et al. 2000). In general, higher VSP scores indicate greater viability. VSP scores are calculated from the output of salmonid population models. These models tend to cover all or most of the salmonid life cycle. Most information comes from the hydrosystem because the ocean phase of the life cycle is less understood.

**W**

**Water conditions:** The overall supply of water to operate the hydroelectric generating system at any given time, taking into account reservoir levels, snowpack, any needs to provide water or retain water to meet various operating constraints (such as the water budget, flood control, flow constraints, etc.), weather conditions, and other factors.

**Water Control Diagram:** A diagram used to illustrate reservoir elevation targets for the reservoirs, known as water-year-based rule curves.

**Water particle travel time:** The theoretical time that a water particle would take to travel through a given reservoir or river reach. It is calculated by dividing the flow (volume of water per unit time) by the cross-sectional area of the channel.

**Water retention time:** The length of time that a particle of water is resident in a lake or reservoir, based on rates of inflow, outflow, and circulation within the waterbody.

**Water rights:** Priority claims to water. In Western states, water rights are based on the principle “first in time, first in right,” meaning older claims take precedence over newer ones.

**Water year:** One hydrologic cycle corresponding to October 1 through September 30. The start of a water year is typically prior to the start of higher winter flows in the Willamette River Basin.

**Y**

**Yearlings:** One-year-old juvenile salmon and steelhead.

**Z**

**Zooplankton:** Aquatic animals that cannot actively swim against the current and cannot make their own food by photosynthesis.

# CHAPTER 9 - LIST OF PREPARERS

**Table 8-1. List of Preparers**
