CERTIFICATION OF "CONFORMANCE TO DOE OBJECTIVES"

The undersigned certifies that the identified wastes contained within the container conforms to the performance objectives established by the DOE and based upon process knowledge, operational procedures and radiological analysis that this waste meets all release criteria established by the DOE

A copy of this certification, and the below cited attachments shall be affixed to any container so certified.

Container No. 5700

1. External Radiation Survey (form 732-A) DPP 11/19/92

2. Uniform Hazardous Waste Manifest No. (form DHS 8022A 1/88) 89861575
(for Hazardous Wastes only)

APPENDIX H

The Energy Technology Engineering Center (ETEC) has supplied Environmental Protection (D543) with all available laboratory analytical data for the following container(s):

1029, 5942, 5700, 0220, 0216
(Bin, tank, roll-off, or box identification numbers)

The analysis was performed by the following laboratory, with the following identification numbers:

92-886-168
Sample No. (B886 sample log)

Laboratory Name: SSFL, BCA

Laboratory Report Number: _____

Laboratory Sample Identification Number (s):

92110483
92110434
92110470

The data is attached and has been reviewed by Environmental Protection. Based upon this review, the material has been determined to fall into the following category:

Non-hazardous- Clean — D543 (signature of reviewer)

Non-hazardous- Selectively Contaminated Acceptable for Class III disposal — D543 (signature of reviewer)

Non-hazardous- Contaminated above Class III disposal limits — D543 (signature of reviewer)

Hazardous- Non-RCRA-California Regulated — [signature] D543 (signature of reviewer)

Hazardous- RCRA not requiring treatment — D543 (signature of reviewer)

Hazardous- RCRA requiring treatment — D543 (signature of reviewer)

NOTE
Only a waste that was determined to contain less than detectable radioactivity may be categorized as any of the above categories (refer to Appendix B).

California Land Disposal Restriction Notice and Certification

Generator Name Rockwell Int'l Corp Rocketdyne Div STR 56D	Manifest Number 89861575
California Hazardous Waste Code(s) 181, 611	CWM Profile Number BF 6640

This form is submitted to Chemical Waste Management, Inc. in accordance with the requirements of CCR Title 22, Chapter 18, Article 1 which restricts the land disposal of certain hazardous wastes. I have marked the appropriate box (boxes A. through D.) below to indicate how my waste must be managed to conform to the land disposal restrictions. A copy of all applicable treatment standards and waste analysis data, where available, is maintained at the Chemical Waste Management facility identified on the manifest referenced above. I have entered the appropriate California Waste Code and checked the appropriate box in the table below to indicate the applicable non-RCRA hazardous waste listing from 22 CCR § 66268.29.

✓		State of California Restricted Waste Description Listed in 22 CCR § 66268.29	Prohibition Effective Date	Corresponding Treatment Standard (from 22 CCR)
	1	Metal-containing aqueous waste identified in 22 CCR 66268.29(a).	1/29/90	66268.107(a)
	2	PCB wastes identified in section 66268.29(b).	1/27/90	66268.110
	3	Auto shredder waste identified in section 66268.29(c).	5/8/91	66268.106(a)(1)
	4	Nonwastewater solvent waste identified in section 66268.29(d).	5/8/91	66268.107(b)
	5	Hazardous waste foundry sand identified in section 66268.29(e).	1/1/91	66268.106(a)(2)
	6	[reserved] (for city petroleum wastes)		
X	7	Metal-containing solid waste identified in 66268.29(g).	5/8/92	66268.106(a)(3)
	8	Fly ash, bottom ash, retort ash or baghouse waste identified in 66268.29(h).	1/1/91	66268.106(a)(4)
	9	Baghouse waste from foundries identified in 66268.29(i).	1/1/91	66268.106(a)(5)
	10	Aqueous and liquid organic waste identified in 66268.29(j).	5/8/92	66268.112
	11	Solid waste containing organics identified in 66268.29(k).	5/8/92	66268.113

☐ **A. RESTRICTED WASTE REQUIRES TREATMENT**
I am the generator of the waste identified above which must be treated to meet the applicable treatment standards set forth in CCR Title 22, article 4 or article 11 of Chapter 18.

☐ **B.1 RESTRICTED WASTE TREATED TO PERFORMANCE STANDARDS**
"I certify under penalty of law that I have personally examined and am familiar with the treatment technology and operation of the treatment process used to support this certification and that, based upon my inquiry of those individuals immediately responsible for obtaining this information, I believe that the treatment process has been operated and maintained properly so as to comply with the performance levels specified in article 4 and article 11 of chapter 18, division 4.5, Title 22, CCR and all applicable prohibitions set forth in section 66268.32 or RCRA section 3004(d) (42 U.S.C. section 6924(d)) without impermissible dilution of the prohibited waste. I am aware that there are significant penalties for submitting a false certification, including the possibility of a fine and imprisonment."

☒ **C. RESTRICTED WASTE SUBJECT TO A VARIANCE**
The waste identified above is subject to a capacity variance which expires on 1 January 1995.

☐ **D. RESTRICTED WASTE CAN BE LAND DISPOSED WITHOUT FURTHER TREATMENT**
"I certify under penalty of law that I personally have examined and am familiar with the waste through analysis and testing or through knowledge of the waste to support this certification, that the waste complies with the treatment standards specified in CCR Title 22, division 4.5, chapter 18, article 4 and article 11 and all applicable prohibitions set forth in CCR Title 22, section 66268.32 or RCRA section 3004(d)(42 U.S.C. section 6924(d)). I am aware that there are significant penalties for submitting a false certification, including the possibility of a fine and imprisonment."

I hereby certify that all information submitted in this and all associated documents is complete and accurate to the best of my knowledge and information.

GENERATOR'S CERTIFICATION
I hereby certify that all information submitted in this and all attached documents contain a true and accurate description of this waste. Any sample submitted is representative as defined in 40 CFR 261 - Appendix I for the waste stream described. All relevant information regarding known or suspected hazards in the possession of the generator has been disclosed. I authorize CWM to obtain a sample for my waste stream for purposes of recertification.

United States Government | Department of Energy

memorandum

RECEIVED
JAN 15 1993
ORF 0079

DATE:
REPLY TO ATTN OF: EM-331
SUBJECT: Approval of Waste Shipment from the Energy Technology Engineering Center's Sodium Disposal Facility

TO: James T. Davis, SF

The December 11, 1992, memorandum from Alex Dong to Lee Stevens (attached), requesting to ship offsite all soils designated as nonradioactive wastes has been received and reviewed by this office. In consideration of the Energy Technology Engineering Center's (ETEC's) demonstrated knowledge of the waste, and procedures to assure that only those Sodium Disposal Facility (SDF) wastes showing no detectable activity will be designated as nonradioactive, this office believes that no Department of Energy (DOE)-added radiation is present in these wastes.

ETEC has to date, not provided information acceptable to lift the moratorium site-wide. For this request, the information submitted for the SDF wastes specified above is sufficient. This office concurs with your request to ship all SDF wastes found to have no DOE-added radiation offsite as nonradioactive. The moratorium remains in effect for all RCRA/TSCA wastes at ETEC, which are not specifically excavated soils from the remediation activity at the SDF.

John E. Lytle

Page

1. Introduction

The Former Sodium Disposal Facility (T886) at the Rockwell International Santa Susana Field Laboratory was used primarily for cleaning sodium heat transfer system components (pipes, valves, tanks) and for disposal of scrap sodium by reaction with water. However, during its use, small quantities of a variety of other materials were disposed of there, including radioactively contaminated components and material. As a result, small amounts of radioactive contamination became dispersed in the T886 pool, and in the lower basin and adjacent areas. The pool and related structure, and all the soil in the lower basin, were removed during a remediation project lasting from 1991 through 1994. At the completion of the radiological remediation, a final gamma radiation survey and a sampling of soil and rock were performed to demonstrate the satisfactory removal of the radioactive contamination. The gamma radiation survey was summarized in ETEC document number 886-ZR-0007 (Ref. 1).

Following removal of all potentially radioactively contaminated soil from the former Sodium Disposal Facility, the soil and rock samples were independently taken by ICF-Kaiser Environment and Energy Group. These samples were analyzed by Oak Ridge Institute for Science and Education (ORISE), and the results reported to the Radiation Protection and Health Physics Services Group (now Environmental Remediation) at Rocketdyne. This report summarizes those results and presents comparisons with local background values.

2. Summary and Conclusions

To confirm the satisfactory radiological remediation of this area, a sampling and analysis plan was developed by the Environment and Energy Group of ICF Kaiser Engineers (Ref. 2) . ICF Kaiser personnel collected 63 soil samples and 15 rock samples for analysis according to this plan. Figure 1 shows the layout of the Former Sodium Disposal Facility and its subdivision into grids to provide a basis for the sampling. (Figures and Tables follow the text of this report.)

The ICF Kaiser samples were sent to ORISE where they were individually analyzed by gamma spectrometry, and analyzed by various radiochemistry procedures in composited groups. Sample material is available for confirmatory analyses by the State of California Department of Health Services - Radiologic Health Branch.

The gamma spectrometry showed low concentrations of Cs-137, the primary radioactive contaminant at the Former Sodium Disposal Facility, and normal amounts of natural K-40, and the thorium and uranium decay chains. The Cs-137 concentrations are similar to, though in some instances somewhat greater than, local background surface soil concentrations due to global fallout from nuclear weapon testing. The radiochemistry showed low concentrations of Sr-90, similar to the Cs-137 concentrations, and somewhat higher than local background surface soil concentrations. Radiochemistry with alpha spectrometry for thorium and uranium showed concentrations that agreed well with values expected for naturally occurring minerals, and in agreement with the daughter activities found by gamma spectrometry. This comparison shows that the thorium and uranium activities are a natural occurrence.

Gamma spectrometry of the rock samples showed natural concentrations of K-40 and the thorium and uranium decay chains, in agreement with the concentrations found in the soil, but no Cs-137. Radiochemistry showed natural equilibrium in the thorium chain but some

disequilibrium in the uranium chain, with the Th-230 activity (and its daughters) exceeding that expected from the parent uranium activities. This is commonly found in geological materials.

Radiochemistry with alpha spectrometry for plutonium (Pu-238, Pu-239/240) showed no concentrations in soil or in rock that differed statistically from zero.

The small amounts of Sr-90 and Cs-137, which may represent residue from the contaminated soil that was removed, are well below proposed guidelines for residual radioactivity in soil, for release without radiological restrictions (Ref. 3). No other indications of possible remaining contamination were found.

No samples indicated the presence of significant levels of radioactive contaminants. All results were well below proposed acceptable limits for radioactive contamination in soil. The results of this sampling and analysis program confirm that the area is acceptable for release for use without radiological restriction.

3. Sampling

For the purpose of providing a uniform basis for sampling the Former Sodium Disposal Facility area, four regions were established, relating to the history of the facility. These regions were subdivided into 50-foot square grids, and sample locations were selected within the grids by use of random numbers.

Surface soil samples were collected by hand, with a trowel, providing somewhat more than 1 kg of soil for each sample. Soil samples were placed in jars for transport to the ORISE laboratory. Subsurface samples were collected at a depth of about 4 feet below the surface by use of a hand auger. Bedrock samples were broken after core-drilling from the local rock.

Sample locations were identified, relative to the grid shown in Figure 1, by use of a 12-character code. The first digit indicates the region (1-4), the next 2 digits indicate the block number for that region, the next 2 digits give the distance in feet to the north from the southeast corner of the block, the next 2 digits give the distance in feet to the west from the same corner, and the next digit (0 or 1) indicates a surface sample (0) or a 4-foot subsurface sample (1). The type of sample is indicated by S for soil and B for bedrock. The samples taken for radionuclide analysis were further identified by RN. Scheduled samples, as distinct from QC samples, were identified by a final 0.

After the initial gamma spectrometry had been reported for all the individual samples, portions of selected samples were grouped together at the ORISE laboratory to form composite samples for the radiochemistry analyses. This was done to use the analytical funding as effectively as possible, since gamma spectrometry is relatively inexpensive, compared to analyses requiring chemical separation.

The composite groups were selected by first associating the gamma spectrometry results for each sample with the region, and then combining nearby samples with similar radiological characteristics, as determined from the gamma spectrometry. Some samples were kept separate for individual analysis. The sample groupings are shown on the layout map of the area in Figure 2.

4. Analysis

Samples were analyzed at ORISE in Oak Ridge, Tennessee, under contract to DOE/OAK. The gamma spectrometry used a high-purity germanium detector with a computer based multichannel analyzer. The standard Canberra software for interpretation of photopeaks was used. The uncertainties reported with the results are determined by the computer processing and are specified at the 2-sigma level.

Radiochemistry was done to quantify Sr-90 and the requested alpha emitters. Chemical separation provides a strontium precipitate, beta counting serves as the determination of the activity. Similarly chemical separation provides separate deposits for thorium, uranium, and plutonium. Alpha spectrometry is used to determine the individual isotopic activity for each element. Uncertainties for the radiochemical results are also reported at the 2-sigma level.

5. Results

The results of the ORISE analyses are listed in Tables 1A, 1B, and 1C. These tables provide the sample location code number, as described above, and the activity concentration and 2-sigma uncertainty, in pCi/g. All scheduled samples are included here, with the results for 3 field duplicate soil samples. Blank entries in the uncertainty (unc) column indicate that the activity for that radionuclide was not detected, and so one-half of the Minimum Detectable Activity (MDA) has been entered as the result for that sample. Table 1A lists all sample results obtained by gamma spectrometry. Table 1B lists the results obtained by radiochemistry. Table 1C lists the MDA values for all the radionuclide analyses that were performed.

The groups of individual samples that were composited for the radiochemistry analyses are listed in Table 2, with the associated Lab ID, Lab composite ID, and the designated composite number.

6. Interpretation

Individual results from the analysis of soil and rock are presented as cumulative probability plots in Figures 3a through 3q. In these plots, measured values are shown with a small or large error bar associated with the data symbol. The error bars indicate the 2-sigma uncertainty estimated for the result. Non-detected results, set to one-half the MDA, are shown without an error bar. In a cumulative probability plot, data with a normal (or Gaussian) distribution fall along a straight line. The plot shows, as a diagonal line, the theoretical Gaussian distribution calculated from the arithmetic mean and standard deviation of the dataset.

Most of the radionuclides detected show a distribution that is close to Gaussian. The distribution for Cs-137 in soil (Figure 3b) shows several values that are somewhat higher than expected, but not entirely outside the range of environmental fallout activity in surface soil. Only 3 samples, at 0.57, 0.30, and 0.30 pCi/g, are above the upper 95% bound for local background of 0.27 pCi/g. The highest value, 0.57, corresponded to the sample with the highest Sr-90 result. All results are well below the proposed SSFL site limit for Cs-137 in soil, 8.6 pCi/g (Ref. 3). This limit was determined by a pathways analysis using the DOE code RESRAD Version 5.61, for a maximum annual dose of 10 mrem in a residential setting.

The results for Sr-90 in soil (Figure 3i) also show some elevated values. Of the 19 composite sample analyses performed, 14 were reported at levels that were below the MDA. Only 4 composite soil samples, at 0.57, 0.49, 0.40, and 0.26 pCi/g, are above MDA for this analysis. The

highest value, 0.57, corresponded to the sample with the highest Cs-137 result, also 0.57 pCi/g. One composite rock sample, at 0.28 pCi/g, was above the MDA of 0.27. All results are well below the proposed SSFL site limit for Sr-90 in soil, 24 pCi/g. This limit was determined by the same pathways analysis.

The distribution for U-235, in both soil and rock (Figure 3h), as determined by gamma spectrometry, is distorted by the many non-detected values. There is no indication of contamination in these results, and higher quality values determined by radiochemistry with alpha spectrometry (Figure 3n) confirm this conclusion.

The analyses for plutonium, both Pu-238 and Pu-239 (including Pu-240), show no results that indicate contamination. While the analyses for Pu-238, which is found in global fallout, showed 6 (out of 19) results above the MDA, none of the analyses for Pu-239, a suspect SSFL contaminant, were above the MDA. The reported values result from random variability in the background of the analyses.

The determination of background distributions of the radionuclides reported here, for soil, is based on two sets of data covering large local areas. One collection is from the McLaren-Hart Multimedia Study of the Brandeis-Bardin Institute and Santa Monica Mountains Conservancy properties near SSFL (Ref. 4), as supplemented by some recent samples collected offsite by Rocketdyne. (This set is identified as "... in Background Soil".) The other consists of results from the Rocketdyne Area IV Radiological Characterization Study (Ref. 3), using only those results that are clearly unaffected by contamination. (This set is identified as "... in Area IV Soil (background)".) These measured background distributions, representative of the local area, are shown in Figures 4a through 4k.

For comparison, the average value and 2-sigma uncertainty for each radionuclide measured in soil from the Former Sodium Disposal Facility are listed below, with the corresponding values from the two background sets.

Radionuclide	Former Sodium Disposal Facility	Background Soil	Area IV Soil
K-40	21.7 ± 3.14	21.9 ± 3.44	19.0 ± 4.72
Sr-90	0.13 ± 0.29	0.047 ± 0.080	0.040 ± 0.080
Cs-137	0.069 ± 0.189	0.103 ± 0.166	0.079 ± 0.141
Th-228	1.43 ± 0.35	0.98 ± 0.95	1.00 ± 0.53
Th-230	1.21 ± 0.26	0.28 ± 0.57	0.82 ± 0.46
Th-232	1.34 ± 0.35	0.37 ± 0.83	0.99 ± 0.51
U-234	0.96 ± 0.27	0.35 ± 0.84	0.77 ± 0.35
U-235	0.044 ± 0.024	0.018 ± 0.045	0.042 ± 0.022
U-238	0.95 ± 0.26	0.36 ± 0.79	0.78 ± 0.33
Pu-238	0.027 ± 0.040	-----	0.0006 ± 0.0052
Pu-239	0.009 ± 0.043	-----	0.003 ± 0.007

While there are some variations from background, some above, some below, the averages look quite similar.

Further evidence that the thorium and uranium activity detected in the Former Sodium Disposal Facility soil is natural, can be seen in comparisons of the daughter activities. Thorium and uranium are naturally occurring radioactive elements that slowly decay to stable isotopes of lead. The sequence of radionuclides in the major decay chains is shown below, with those radionuclides that were detected by the present analyses shown in boldface:

thorium chain	---- uranium chain ---- (U-238)	(U-235)
Th-232	**U-238**	**U-235**
Ra-228	**Th-234**	Th-231
Ac-228	Pa-234	Pa-231
Th-228	**U-234**	Ac-227
Ra-224	**Th-230**	Th-227
Rn-220	Ra-226	Ra-223
Po-216	Rn-222	Rn-219
Pb-212	Po-218	Po-215
Bi-212	**Pb-214**	Pb-211
Po-212	**Bi-214**	Bi-211
Pb-208 (stable)	Po-214	Po-211
	Pb-210	Pb-207 (stable)
	Bi-210	
	Po-210	
	Pb-206 (stable)	

In each chain, one longer-lived radionuclide acts as a "bottleneck" to the development of equilibrium activity after chemical purification of the element. Ra-228, with a half-life of 5.76 years, delays full development of equilibrium activity in the thorium chain by about 25 years. Th-230, with a half-life of 75,000 years, delays development of the uranium chain by 300,000 years. Several of these daughters (and the U-235 "cousin" to U-238) were measured in the soil from the Former Sodium Disposal Facility. The activities detected are shown in Figure 5. The straight diagonal lines show the theoretical variation of the daughter activity with the parent. The good agreement of the measured values with the theoretical variation shows that these activities are natural.

7. Quality Assurance

Several sets of measurements were done to provide quality control checks on the analytical procedure. These measurements were directed towards demonstrating the precision and accuracy of the analytical results. The QC samples consisted of field duplicates (which were reported in the main section of this report, but are also discussed here), laboratory replicate analyses, matrix spikes (laboratory control samples), and blind spikes. The Data Quality Objectives are considered to be satisfied if the observed differences are less than 3 times the estimated standard deviation of the difference (Ref. 4). (Standard laboratory reporting provides the uncertainties (unc) as 2 times the estimated standard deviation of the result. For the QC comparisons, the derived uncertainty must be multiplied by 1.5 to obtain the 3-sigma value.)

Duplicate soil samples were made from 3 original samples: 21346220, 30113170, and 42455090. The original samples were individually mixed, and "split" samples were taken from

the bulk material. These samples then proceeded through the balance of the sampling and analysis as though they were independent samples. The results are compared in Table 3. These results show good agreement, with the differences between separate paired soil samples generally being less than the estimated uncertainty. Of 31 comparisons, 5 failed to satisfy the 3-sigma test. Of these, 4 were among the alpha spectrometry analyses, which are sensitive to non-uniformity in the soil.

Laboratory duplicate analyses were done extensively for the gamma spectrometry, less so for the more complicated radiochemistry analyses. These results are shown in Table 4. The comparison is made by calculating the relative difference between the results of the two analyses, and the estimated uncertainty for this relative difference. For a perfect comparison, the relative difference would be zero. Because of random variations, some deviations from zero will occur. These should generally be less than the uncertainty. Of 79 comparisons, 15 failed the 3-sigma test. Two of these failures were for uranium in one of the blind laboratory spike samples, and may have resulted from lack of homogeneity.

Laboratory matrix spikes were prepared for gamma spectrometry by adding a calibrated solution of Cs-137 to selected soil samples. These results are shown as the first 9 entries in Table 5A. A "recovery" value of 1.000 indicates perfect detection of the added spike activity. Of the 9 ORISE-spiked samples, all results are within the required range of 3 times the estimated standard deviation of the difference.

Blind spikes were obtained through a commercial laboratory, by adding calibrated solutions of Sr-90, Cs-137, Th, U, and Pu-239 to 3 selected soil samples. These results are shown as the last 3 entries for Table 5A and all the entries in Table 5B. (The calibration sheets for these blind spikes are presented in the Appendix.) Gamma spectrometry showed the required agreement for 2 of the 3 comparisons. The radiochemistry showed disagreement for 14 of the 32 comparisons. In some of these cases, the differences may reflect the difficulty in making a bulk sample that is adequately homogeneous on the small scale of the analytical aliquots. (Gamma spectrometry measures the radioactivity in a large sample, 600-1000 grams, averaging throughout its volume, while the radiochemical procedures use relatively small aliquots, 3-5 grams, for processing and analysis.)

The results of the QC tests are summarized below as percentages of comparisons satisfying the 3-sigma test.

	Field Duplicates	Lab Duplicates	Matrix Spikes	Blind Spikes	Aggregate Total
K-40	3/3	9/10	---	---	12/13
Sr-90	1/1	1/1	---	2/4	4/6
Cs-137	3/3	10/10	9/9	2/3	24/25
Pb-212	3/3	6/10	---	---	9/13
Pb-214	3/3	3/10	---	---	6/13
Bi-214	3/3	10/10	---	---	13/13
Ac-228	2/3	10/10	---	---	12/13
Th-228	0/1	1/1	---	2/4	3/6
Th-230	1/3	1/1	---	---	2/4
Th-232	0/1	1/1	---	2/4	3/6
Th-234	3/3	9/10	---	---	12/13
U-234	0/1	0/1	---	0/4	0/6
U-235	1/1	1/1	---	4/4	4/6
U-238	0/1	0/1	---	1/4	1/6
Pu-238	1/1	1/1	---	4/4	6/6
Pu-239	1/1	1/1	---	3/4	5/6

The overall score for these comparisons is 74%.

8. Documentation

Backup documentation for this sampling and analysis project is stored in the Former Sodium Disposal Facility (T886) decommissioning file.

10. Appendix A

The Certificates of Calibration for the blind spike samples prepared by Isotope Product Laboratories are presented here. The activity values, uncertainties, and isotopic fractions stated on these sheets have been used in the intercomparisons discussed in this report.

CERTIFICATE OF CALIBRATION
MULTINUCLIDE STANDARD SOURCE

Customer: ROCKWELL INTL/ ROCKETDYNE **P.O.No.:** R54PJO-95162004
Catalog No.: EG-0075 **Reference Date:** September 1 1995 12:00 PST.
Source No.: 506-2-1 **Total Radioactivity:** 28.9 nCi.
Total Radioactivity: 1,068 Bq.

Description of Source

a. Capsule type: Customer supplied bottle
b. Nature of active deposit: SrCl2, CsCl, Th(NO3)4, UO2(NO3)2, and Pu(NO3)3 dispersed in a sand matrix
c. Active diameter/volume: Approximately 1.0 L (Mass of sand = 1,125.60 g)
d. Backing: Glass
e. Cover: Glass

Nuclide	Half-life	Activity. (nCi)	Concentration (pCi/g)	Systematic Uncert.	Random Uncert.	Total Uncert.
Sr-90	28.5 ± 0.2 years	2.76	2.45	2.0%	0.9%	2.2%
Cs-137	30.17 ± 0.16 years	5.92	5.26	1.0%	0.7%	1.2%
Th-232	(1.405 ± 0.006) x 10^10 years	9.05	8.04	3.0%	2.0%	3.6%
U-238	(4.468 ± 0.005) x 10^9 years	7.87	6.99	3.0%	2.0%	3.6%
Pu-239	24,110 ± 30 years	3.26	2.90	2.1%	0.3%	2.1%

Method of Calibration

This source was prepared from weighed aliquots of solutions whose concentrations, in nCi/g, were determined as follows: 1) for Sr-90 and Pu-239 by a liquid scintillation counter. 2) for Cs-137 by a well type ionization chamber, and 3) for Th-232 and U-238 by specific activity and mass calculations. Sr-90 has a daughter(Y-90) in equilibrium. U-238 and Pu-239 have attached technical data sheets for impurities and daughters.

Daughter decay scheme for Th-232

Ra-228 -> Ac-228 -> Th-228 -> Ra-224 -> Rn-220 -> Po-216 -> Pb-212 -> Bi-212 -> Po-212 -> Tl-208 -> Pb-208

NIST Traceability

This calibration is implicitly traceable to the National Institute of Standards and Technology.

Leak Test(s)

See reverse side for Leak Test(s) applied to this source.

Notes

1. IPL participates in an NIST measurement assurance program to establish and maintain implicit traceability for a number of nuclides, based on the blind assay (and later NIST certification) of Standard Reference Materials (As in NRC Regulatory Guide 4.15).
2. Overall uncertainty is calculated at the 95.5% confidence level.

Pu-239 TECHNICAL DATA

The Pu-239 used to prepare your order was taken from Isotope Products Laboratories Lot #6617-1 and had the following composition as of October 1, 1994.

NUCLIDE	ATOM%	ACTIVITY%	TOTAL α ACTIVITY %
Pu-238	0.002	0.337	0.388
Pu-239	97.933	79.717	91.887
Pu-240	2.056	6.124	7.058
Pu-241	0.010	13.241	N/A
Pu-242	0.001	0.000	0.000
Am-241	-----	0.582	0.671

Note: Pu-241 is beta active.

Isotopic composition provided by New Brunswick Laboratory.

11. Appendix B - Interpretation of Results

All soil sample analytical results are well below the approved limits for release of land areas for use without radiological restrictions (see "Proposed Sitewide Release Criteria for Remediation of Facilities at the SSFL", B. M. Oliver and R. J. Tuttle, Rocketdyne Document N001SRR140127, 8/22/96). That document provided single-isotope limits for all radionuclides that are possible contaminants at SSFL, and those limits were approved by the Department of Energy, Oakland Operations Offiice, and by the State of California Department of Health Services, Radiologic Health Branch. Potential doses to future users of the site, for residential, industrial, and wilderness use situations were considered, and concentrations were calculated that provided a Total Effective Dose Equivalent (TEDE) equal to the limit of 15 mrem/year recommended by the EPA. For the two radionuclides detected in the soil sampling survey, Sr-90 and Cs-137, the limits are 36.0 and 9.2 pCi/g, respectively. All analytical results were well below these limits. The maximum value for Sr-90 was 0.569 pCi/g, or 1.58% of the single-isotope limit. The maximum value for Cs-137 was 0.567 pCi/g, or 6.16% of the single-isotope limit. Combining these two percentages to test for the combined sum of fractions rule, results in a percentage of 7.74%, far below the allowable 100%.

To demonstrate the satisfactory condition of the radiologically remediated Former Sodium Disposal Facility, a pathways analysis was performed to estimate potential dose to a hypothetical resident of the area. This analysis used the pathways code, RESRAD (version 5.61), with the same parameters that were used in establishing the generic limits on radioactivity in soil at SSFL. The Former Sodium Disposal Facility was represented as a slightly smaller area, 8,200 m^2, than the generic reference case, 10,000 m^2.

The residual contamination of the site was assumed to be equal to the average of the measured values, for Sr-90 and Cs-137, the only contaminants detected in the radiometric analyses. These values were, respectively, 0.131 pCi/g for Sr-90 and 0.069 pCi/g for Cs-137. Residual contamination was assumed to be uniformly distributed through the upper 1 meter of the soil. (This is a conservative assumption, since much of the area was excavated down to bedrock and only a very thin residual layer of soil remains. For this calculation the top 1 meter of the site is considered to be soil. Studies of the depth distribution of the original contamination showed that the radioactivity, which had initially been deposited on the surface of the soil, had not penetrated beyond about 18 inches.)

RESRAD calculates the dose from a variety of exposure pathways. The only significant pathways were direct radiation from the ground for the Cs-137, and plant uptake (in vegetables) for the Sr-90. If the Former Sodium Disposal Facility had been occupied in a residential manner immediately after completion of the soil sampling, that is, in August 1995, the first-year dose is calculated to be 0.166 mrem. This is small compared to the recommended limit of 15 mrem per year, established by the EPA, and trivial compared to the natural dose from "clean" soil approximately 80 mrem/year. The estimated dose declines with time into the future. This is

shown in Figure A.1, where the dose becomes essentially zero after 100 years.

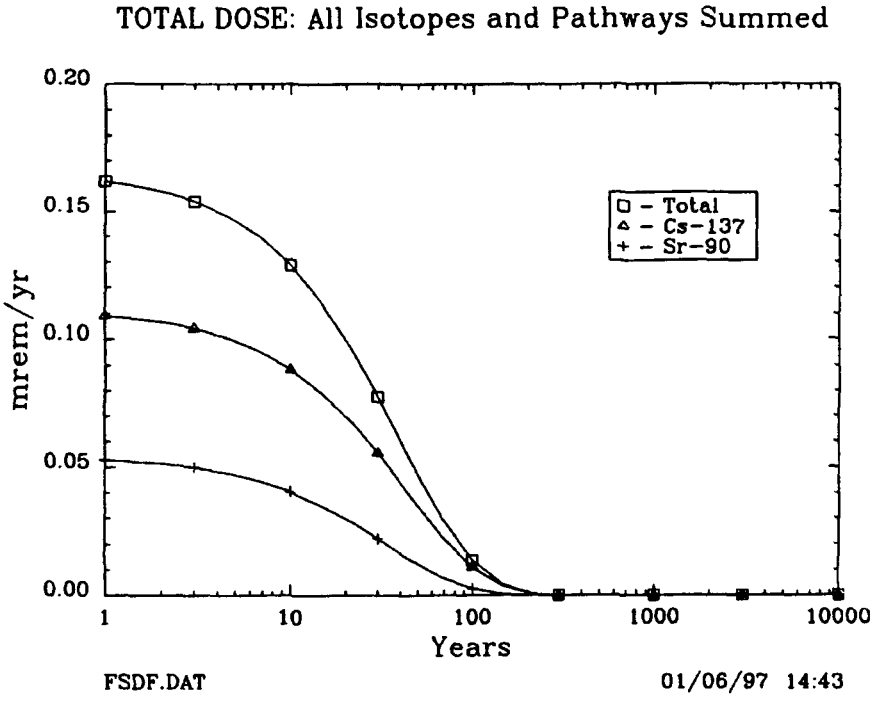

Figure A-1. Calculated potential dose to resident of remediated Former Sodium Disposal Facility.

The average values assumed for contamination are comparable to the fallout background found in surface soil in this region. Subtraction of background activities is not suitable in this case, however, because many of the samples are from deep below the original surface of the soil where the background activity of these radionuclides is essentially zero. Therefore, a comparison calculation was performed, representing an undisturbed plot of land with the same characteristics and usage as proposed for the Former Sodium Disposal Facility, except that the residual contamination was replaced by the values of activity found for the surrounding, unaffected, terrain. These background values were derived from the Area IV Characterization Survey results, by excluding all samples that were suggestive of possible contamination, and the deliberately selected offsite (background) soil sample results. (See "Area IV Radiological Characterization Survey - Final Report", ETEC Document A4CM-ZR-0011, Revision A, Volumes I-IV, August 15, 1996.) For unaffected soil, contaminated only by fallout activity, the activity was assumed to be limited to the upper 10 cm of the soil (4 inches). This calculation shows that the dose on unaffected, and unremediated, land would be 0.171 mrem in the first year, slightly more than for the remediated Former Sodium Disposal Facility. When naturally occurring concentrations of potassium-40, uranium (plus daughters) and thorium (plus daughters) are included in the "clean" soil, a similar RESRAD calculation yields 81.74 mrem/year, as an additional, natural dose from the natural radioactivity alone.

As a further demonstration of the conservatism in the cleanup conducted here, a RESRAD calculation was also done with the assumption that the entire site was contaminated at the level found in the single most contaminated sample, that is, the sample taken at location 3030904, in the former Lower Pond. (All soil had been removed from the Lower Pond, so that only bedrock remains.) This calculation showed that these greater amounts of Sr-90 (0.569 pCi/g) and Cs-137

(0.567 pCi/g) would produce only 1.157 mrem/year in the first year, still far below the limit of 15 mrem/year and the natural dose of 81.74 mrem/year.

This study shows that the Former Sodium Disposal Facility is in compliance with the recommended acceptance limit of 15 mrem per year for radiological exposure, and is essentially no different, radiologically, from any similar unaffected plot of land.

ABSTRACT

A comprehensive baseline radiological survey for ambient gamma exposure rate was conducted in 1991 (Reference 3) just prior to the site remediation of the former Sodium Disposal Facility (SDF) (T886). That survey covered the lower and upper pond areas of the SDF and was used as a guide in beginning remediation (i.e., excavation). After the remedial efforts were completed (which included numerous operational gamma surveys) the stage was set for the post-remedial ambient gamma exposure survey. This survey covered the lower and upper pond areas as well as adjacent land.

Results of this survey show the ambient gamma exposure rates of the former SDF and surrounding land to be indistinguishable from each other. These results presented here along with the planned soil sampling by an outside contractor will serve as a basis to release the SDF for use without radiological controls. This document represents the ambient gamma survey as performed in accordance with Reference 1.

1.0 INTRODUCTION

This report documents the post-remediation radiological ambient gamma survey of the former Sodium Disposal Facility (SDF) (T886) and subsequent data analyses. The post-remediation ambient gamma survey was undertaken to evaluate the radiological conditions after the completion of the site remediation. The surveyed areas included the remediated lower and upper pond basins, the surrounding land, and the site drainage pathways. The ambient gamma exposure rate results used in conjunction with the soil sampling analyses as outlined in Reference 1 will serve as a basis to quantitatively release the SDF from radiological controls. This document represents the gamma survey as performed in accordance with Reference 1.
