Agenda

1. Project Description and Objective
2. Team Members
3. Approach
4. Model Theory, Structure and Assumptions
5. Model Description
   1. Logic
   2. Features
   3. Cost Components (Production, Delivery & Dispensing)
6. Los Angeles Transitional Example
7. Model Flexibility
Team Members & Interactions

Start: May 2005 (effective)
End: Summer 2007

• Directed Technologies, Inc. - Prime
• Sentech, Inc., Research Partner
• Air Products, Industrial Gas Supplier

• Advisory Board
  • Graham Moore, Chevron Technology Ventures
  • Mike Miller, Teledyne Energy Systems
  • Sandy Thomas, H2Gen Innovations, Inc.
  • Rajat Sen, Sentech, Inc.
  • Ira Kuhn Jr., Directed Technologies Inc.
  • Ed Kiczek, APCI

• H2A Interaction
• H₂ Production parameters from Industry
• Coordination with other DOE Transition Analyses
• Coordination with DOE Macro-System Model development
Approach

- Development of a **time-based, computational dynamic model of H₂ production** in the continental US.

- **Use model** and other methods to understand how a H₂ production infrastructure:
  - will develop over time,
  - the factors that will drive it, and
  - the role of externalities, such as policy and technology.

- This model will use consistent financial & technological assumptions to evaluate H₂ production & delivery costs dynamically (as opposed to statically) with changing demand and utilization.
Approach, continued

- Economics modelled from H₂ supplier/investor point of view.
- Annual demand will be postulated and some foresight provided for planning infrastructure.
- Develop a dynamic H₂ production infrastructure economics model.
- Allow dynamic calculation of hydrogen costs, including the effects of changing infrastructure utilization.
- Assess H₂ production facility displacement due to technological and demand changes in time (stranded assets).

- Overall Goal is that the resulting infrastructure and transition will be modelled from the business perspective.
Basic Premises of Model

Simulate decision making process of Hydrogen supplier/investor.

• Business wants to maximize profit.
• Profit is hard to quantify, requires knowledge of H₂ price.
• Will use H₂ cost as surrogate for Price.
• Minimize Cost => Maximizing Profit.
• Cost vs. Price.
  – Price: Dictated by Market.
  – “Profited Cost”: Price to yield a specified real, after-tax IRR.
  – Cost: Total cost to produce with zero profit.
Basic Premise of Model, cont.

• Model is **a tool** to allow infrastructure analysis.

• Model applies to **regions of homogeneous H₂ demand** (constant kg H₂/day/km²).
  
  • Regions are nominally Urban, Rural, or Interstate but can represent any region of uniform demand.

• Regional results may be combined to portray expected production infrastructure development for entire US (2nd iteration of model).

• Model can simulate existing facilities.

• Model is **written in MATLAB**.

• Model will allow interaction with other models.
Model Inputs and Outputs

• Inputs:
  • Production & Delivery Method Data.
    – Capital Cost, Efficiency, Fixed Expenses, etc.
    – For all prod. methods, multiple sizes, for each year.
  • Geographic H₂ Demand (kg/day/km²).
  • Feedstock cost by year.
  • Maximum Distance between service stations.
  • Externalities (Carbon Taxes, tax treatment, existing surplus H₂, etc.).

• Outputs:
  • Determination of each year’s lowest cost H₂ production method
    (minimize objective function).
  • Expected H₂ profited cost by year.
  • Identification/Quantification of stranded production assets.
  • Sensitivity to H₂ production parameters, feedstock cost, changes in H₂ demand, etc.
Infrastructure Options

- Infrastructure Option defined as:

  Infrastructure Option = Production Method + Delivery Means + Dispensing

- $\text{H}_2$ will remain in constant state from production through delivery.
- Options where production is in the forecourt have no delivery costs associated with them.

<table>
<thead>
<tr>
<th>Choices in each segment:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td><strong>Production</strong></td>
</tr>
<tr>
<td>Gaseous</td>
</tr>
<tr>
<td>Liquid</td>
</tr>
</tbody>
</table>

$^1$ No delivery is also an option for forecourt production cases.

$^2$ Liquid H2 arrives at dispensing station and is convert to gaseous prior to dispensing.
Model Inclusive Costs

- Hydrogen costs are based on:
  - Production costs determined by NPV calculations performed dynamically and include effects from:
    - State of technology development,
    - Infrastructure capacity, and
    - Varying plant utilization
  - Delivery costs are determined offline & averaged over analysis period.
  - Dispensing costs are determined offline & averaged over analysis period.
  - Other costs are credits and taxes which can be quantified in $/kg but not directly attributed to a specific segment of the infrastructure.

Cost of Hydrogen [$/kg] at Pump = Production cost + Delivery cost + Dispensing cost + Other Costs
Decision Logic

• An infrastructure development decision will be made once per year.
• In any given year, no more than one type of new infrastructure can be developed.
• Decision criterion: Infrastructures must satisfy demand requirement for the decision year (May exceed current demand, up to future demand as determined by investor knowledge limitations).
  
  \[
  \text{Supply Capacity [YR 20##]} \geq \text{Demand [YR 20##]}
  \]
• Decision is purely economic. Infrastructure option that minimizes objective function is implemented.
  
  \[
  \text{Infrastructure Choice [YR 20##]} = \text{MINIMUM OBJ. FUNCTION (All options)}
  \]
• Objective Function is effectively average cost of \( \text{H}_2 \) over \( X \) year period.
  
  \[
  \]
• Rule: Infrastructure can be developed to meet demand up to \( X \) years in the future (where \( X \) is a model input).
• Logic applies to both Forecourt & Central production options.
Model Logic Diagram

1. Evaluate Installed Capacity for the next B years
2. Determine Additional Infrastructure Needed for next B Years (including effects of stranding assets)
3. Evaluate Objective Function for all Infrastructure Options over next B years using expected plant operating capacity factor
4. Pick Infrastructure Option with lowest Objective Function Cost. (This is infra. Option to be built that year.) Record choice as Selection[CY]
5. Update Installed Capacity
6. Go to next Calendar Year
Description of Specific Approach to:

• Cost Database
• Production Cost Computation
• Delivery Cost Computation
• Dispensing Cost Computation
• “Other Cost” Computation
Cost Assumptions & H2A

• H2A provides **primary/initial source** for cost, performance and model assumptions.

• However, we are free to deviated from H2A assumptions and do so in many areas.

• Database is collection of production costs & performance metrics; other portions of infrastructure costs will be embedded in model.

• Model leverages H2A calculated values for delivery and dispensing portions of model.

• Model also adopts H2A fuel feedstock values for years 2005 to 2070.
32 Production Options

1.0 Fossil Fuel Based Hydrogen Production

1.1 Coal
   1.1.1 Gasification (283 tons/day, 316 tons/day, 247 tons/day)
   1.1.2 Gasification (15 tons/day)
   1.1.3 Gasification (283 tons/day, 316 tons/day, 247 tons/day)
   1.1.4 Gasification (100 kg/day)
   1.1.5 Gasification (1500 kg/day)

1.2 Natural Gas / Hydrocarbon
   1.2.1 Steam Reforming (379 tons/day)
   1.2.2 Steam Reforming (15 tons/day)
   1.2.3 Steam Reforming (100 kg/day)
   1.2.4 Steam Reforming (15 tons/day)
   1.2.5 Steam Reforming with CO2 Sequestration (379 tons/day)
   1.2.6 Steam Reforming with CO2 Sequestration (379 tons/day)

2.0 Water Based Hydrogen Production

2.1 Water
   2.1.1 Electrolysis – Marginal Mix Electricity (100 kg/day)
   2.1.2 Electrolysis – Marginal Mix Electricity (1500 kg/day)
   2.1.3 Electrolysis by Nuclear (673 tons/day)
   2.1.4 Electrolysis – Marginal Mix Electricity (308 tons/day)
   2.1.5 Electrolysis – Marginal Mix Electricity (316 tons/day)
   2.1.6 Electrolysis – Marginal Mix Electricity (247 tons/day)
   2.1.7 Thermal Disassociation of Water using Nuclear Energy (719 tons/day)
   2.1.8 Thermal Disassociation of Water using Nuclear Energy (768 tons/day)

3.0 Renewable Energy

3.1 Biomass
   3.1.1 Gasification (155 tons/day)

26 January 2006
2006-1-26 DOE Transition Workshop
Production Input Sheets

Production cost/performance entered into Excel spreadsheets.

- Each production method is on a separate worksheet tab.
- MATLAB program reads tabs and extracts necessary data.
- Only knowledge of Excel is needed to modify production parameters.
Production Cost Approach

• Based on a Discounted Cash Flow (DCF) approach.

• Approach is identical to H2A.
  • Average H₂ “profited cost” is determined to return a given IRR over analysis period.
  • H2A uses 20/40 year analysis, we nominally use 10/20 years.

• Unlike H2A, % utilization of plant can vary from year to year.

• DCF based on:
  • yearly capital cost expenditures,
  • fixed costs (replacement costs, land, etc.), and
  • variable costs (feedstock, labor, etc.).

• A root-finding approach is used to determine H₂ profited cost that corresponds to the selected IRR (i.e. NPV=0).
Production Only Cost Curves

• Biomass (gaseous) quite cheap (~$1/kg)
• Wind electrolysis options pending

• Nuclear options more expensive (~$2-$4/kg)
Production Only Cost Curves

- Multiple Coal & NG options lead to low cost H₂.
- No delivery cost.
- Electrolysis options relatively expensive (unless very low electric cost)
- Large SMR competitive.
Delivery Options

1. CH2 Truck to 100 kg/day Station
2. CH2 Truck to 1500 kg/day Station
3. LH2 Truck to 100 kg/day Station
4. LH2 Truck to 1500 kg/day Station
5. CH2 Pipeline 100 kg/day Station
6. CH2 Pipeline 1500 kg/day Station
7. No Delivery (used with Forecourt production)

Large City Parameters

Options 8-14:
Same as above but with Small City parameters

Options 15-21:
Same as above but with Interstate Highway parameters
Delivery Cost Approach & Assumptions

• Based on H2A Scenario Model results (but with heavy manipulation)

• Differs from production costs approach wherein a DCF analysis is conducted within the model.

• Delivery costs are only calculated for infrastructure that include central H₂ production (Delivery costs are set to zero for forecourt cases).

• Truck delivery assumes 100% utilized at all times.
  – Limitation imposed by being based on H2A calculations.
  – Delivery cost is function of demand density.

• Pipeline delivery based on H2A but modified
  – Pipeline built for 10-year expected pipeline demand but capped at 5x first year demand
  – Cost reflects underutilization of pipeline
• Graphs show costs at constant full utilization.

• But model will calculate 10-year average cost based on actual utilization for pipelines.
Dispensing Options

1. 100 kg/day Station from CH2 Truck Delivery
2. 1500 kg/day Station from CH2 Truck Delivery
3. 100 kg/day Station from LH2 Truck Delivery
4. 1500 kg/day Station from LH2 Truck Delivery
5. 100 kg/day Station from CH2 Pipeline Delivery
6. 1500 kg/day Station from CH2 Pipeline Delivery
7. 100 kg/day Station from Forecourt Production
8. 1500 kg/day Station from Forecourt Production
Dispensing Cost Approach & Assumptions

- Simplified calcs based on H2A DCF results.
- Dispensing cost is a function of station utilization.
- Dispensing costs as function of time.
  - Equipment costs will decrease in the future with increased H₂ demand and technology improvements.

- Process:
  1. H2A results are entered as tables
  2. Linear interpolation conducted between over utilization & time
  3. Dispensing cost is H₂ weighted average over future 10 year period.
Dispensing Algorithm

Use the infrastructure option matrix to determine which dispensing method to use.

Given the production year and % utilization for the infrastructure, select the 4 data points which bound the space.

Perform 3 linear interpolations to achieve the appropriate dispensing cost for that year & % utilization. Repeat for all production years.

Calculate a weighted average cost of dispensing for the option.

Incorporate this value into the objective function for the infrastructure option.
Los Angeles Dispensing Costs

Station Size and % Utilization are main drivers of H₂ Dispensing Cost.
What constitutes “other costs”? 

- Externalities to include/consider:  
  - GHG emission penalties.  
  - Subsidies for renewable resource usage.  
  - Infrastructure permits.  
  - Hydrogen fuel taxes/rebates/subsidies.  
  - Tax credits. 

- The effects of any externality can be assessed if they can be quantified on a $/kg basis.
Preliminary Results of Los Angeles Hydrogen Transition

Central Coal, NG & Biomass Plants with Pipeline Delivery

Preliminary Results
Next Steps

1. Improve pipeline modeling
2. Increase years of study (out to 2050+)
3. Add new infrastructure pathways
4. Add externality costs
5. Explore stranded assets
6. Change IRR value
7. Change analysis period
8. Explore DOE goal effects
9. Add variable feedstock prices
