Materials Issues Associated with EGR Systems

DOE 2009 Vehicle Technologies Annual Merit Review and Peer Evaluation Meeting

May 21, 2009

Michael J. Lance and C. Scott Sluder

Oak Ridge National Laboratory

This presentation does not contain any proprietary, confidential, or otherwise restricted information.
Overview

Timeline

- Start: February 2009
- End: September 2011
- 4% complete

Budget

- Total Project Funding
  - DOE-$1.6M

Funding received:
- FY08: $0
- FY09: $174K

Barrier

- After-treatment systems have energy penalties that reduce the overall engine/after-treatment system efficiency.

Targets

- Optimize cooled exhaust gas recirculation (EGR) for maximum NO\textsubscript{X} reduction and minimum PM emission, mitigating durability concerns with EGR through materials engineering and operational controls.

- By 2012, develop the supporting materials technology required to enable prototypical heavy-duty engine efficiency of 55 percent while meeting prevailing EPA emissions standards.

Partners

- Caterpillar, Cummins, Detroit Diesel, Ford, GM, John Deere, Navistar, PACCAR and Volvo/Mack.
Background: High-Pressure Exhaust Gas Recirculation (HP-EGR)

- High-pressure EGR is the dominant NO$_x$-reduction technology.
- Exhaust gas laden with PM flows through the EGR cooler which causes deposits to form through thermophoresis and condensation.
- The deposit thermal conductivity is very low, which reduces the effectiveness of the EGR system.
- Increasing demands placed on the technology by more stringent NO$_x$ emissions, advanced combustion, increasing use of non-petroleum-based fuels, and engine/aftertreatment system optimization requirements are leading to expansions of the technology into operational conditions that are relatively unknown or known to be problematic.
Background: High-Pressure Exhaust Gas Recirculation

- Information about deposit formation and removal is needed:
  - Thermo-physical and chemical properties of the deposit are needed for modeling.
  - Effectiveness of EGR systems often decline but then reach a plateau. Why?
  - The deposit changes with time due to temperature and HC/water condensation.
  - What is the adhesion mechanism and how can we stop it?
  - How does the deposit affect the EGR valve.

- Bio-based fuels produce different exhaust gas chemistry and PM.
Project Objective: Provide information to industry specialists about fouling deposit properties

Aim is to enable improved models and potential design improvements to reduce fouling and its impact on performance

– Characterize the thermo-physical properties of the deposit under different operating conditions on model EGR cooler tubes.

– Determine the long-term changes in deposit properties due to thermal cycling and water/HC condensation.

– Leverage existing project funded by the DOE Fuels program to allow more in-depth analyses on samples from biodiesel operation.

– Determine deposit adhesion mechanisms and methods to minimize them.
Milestones

- **FY2009**
  - Feb-09 Milestone: Assembled EGR Advisory Team from industrial experts at 9 diesel engine OEMs.
  - Feb-09 Go/No-Go Decision
    - Survey EGR Team Members as to what the greatest materials issues are relating to EGR systems. The survey results clearly indicated EGR cooler fouling as the primary concern.
  - Sep-09 Milestone: Task 1-Establish Experimental Setup

- **FY2010**
  - Dec-09 Milestone: Task 2-Complete Analysis of Industry provided EGR coolers.
EGR Materials Advisory Team

• An advisory team consisting of chief engineers responsible for EGR systems from nine diesel engine OEMs was assembled.

• EGR team companies included light-duty, heavy-duty and off-road diesel truck manufacturers:
Approach

- **Task 1: Experimental Setup**
  - We are pursuing a traditional engine-on-dynamometer to generate fouling deposits on model tubes.

- **Task 2: Obtain and Evaluate Representative (Half-Useful-Life) EGR Coolers from Industry Members**
  - This will provide a reference point that will guide our future research.
  - It will also provide an opportunity to refine effective characterization tools:
    - Chemical Analysis: TGA/DTA, XRF, FTIR, XPS, Raman, GC-MS.
    - Thermal Analysis: Heat Capacity, Thermal Conductivity
    - Microstructural Analysis: SEM, TEM, Electron Microprobe, Optical Microscopy
    - Neutron Tomography
FY2009 Accomplishments

- Task 1: Experimental Setup
  - We have begun purchasing equipment.

- Task 2: Analysis of Industrial Samples
  - As of March 2009, five coolers have been received and are being cut open for analysis.
Future Work

- Extensive analysis of industry provided EGR coolers will be conducted. Coolers will be compared from multiple platforms (i.e. light-duty, heavy duty, off-road) to see if any common chemical/physical features of the deposits emerge.

- With these industrial reference points, we will design controlled experiments using the EGR cooler tube sampler.
Future work: In-situ studies with new portable gas manifold

• Testing to begin early summer 2009 after safety approvals.
Summary

- EGR will remain a key emissions technology for the foreseeable future as EPA regulations worsen degradation issues associated with PM.

- A team of industry advisors has been assembled that will help guide future research directions of this pre-competitive research.

- Team members were polled to determine the greatest material problem facing EGR systems. The vote was for EGR cooler fouling.

- Team members are providing EGR coolers for analysis.

- An engine and a sampler tube system for laying down controlled PM deposits is being designed and purchased. A portable gas manifold for controlled post-deposition aging is being built.
