

Section 2: Office Technology Research, Development, Demonstration, and Deployment Plan

The Bioenergy Technologies Office’s research, development, demonstration, and deployment (RDD&D) efforts are organized around three key technical and three key cross-cutting elements (see Figure 2-1). The first two technical elements—Feedstock Supply and Logistics R&D and Conversion R&D—primarily focus on research and development (R&D). The third technical area—Demonstration and Deployment—focuses on Integrated Biorefineries and Distribution Infrastructure. The cross-cutting elements—Sustainability, Strategic Analysis, and Strategic Communications—focus on addressing barriers that could impede adoption of bioenergy technologies. This organization of the work allows the Office to allocate resources for pre-commercial technology development, as well as for demonstration of technologies across the biomass-to-bioenergy and bioproducts supply chain.

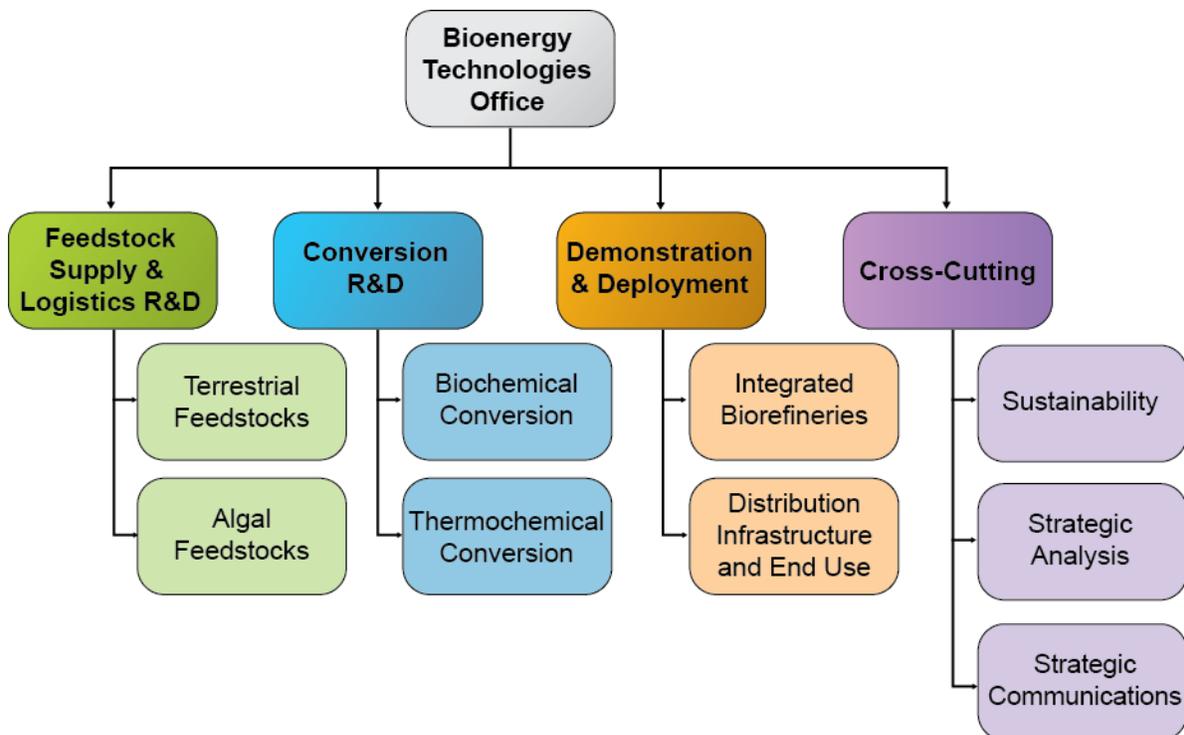

Figure 2-1: Bioenergy Technologies Office work breakdown structure

Bioenergy Technologies Office Organization

Research and Development

The R&D activities sponsored by the Office are focused on addressing technical barriers, providing engineering solutions, and developing the scientific and engineering underpinnings of emerging biofuels, bioproducts, and biopower industries. Near- to mid-term R&D is focused on moving current feedstock and conversion technologies from concept to bench to pilot scale. The goal of longer-term-focused R&D is to accelerate implementation of the technologies by developing deeper knowledge of terrestrial and algal biomass, feedstock supply systems,

biological systems, and biochemical and thermochemical conversion processes. This knowledge can ultimately be used to develop new or improved technologies that increase available low-cost biomass supplies, improve conversion efficiency, and reduce conversion cost while reducing carbon dioxide equivalent emissions and water use. Office-funded R&D is performed by national laboratories, industry, and universities.

The Office's R&D includes two technical elements:

- **Feedstock Supply and Logistics R&D** is focused on developing technologies to provide a reliable, affordable, and sustainable¹ biomass supply to enable a nascent and growing bioenergy industry. This R&D is focused on two areas—terrestrial feedstocks and algal feedstocks. R&D for development and production of terrestrial biomass feedstocks is led by the U.S. Department of Agriculture (USDA) in partnership with the U.S. Department of Energy (DOE) and other federal agencies, and it is coordinated through the Biomass R&D Board, which was established by the Energy Policy Act of 2005 (EPAAct 2005). The Bioenergy Technologies Office's primary focus in this area is on feedstock resource assessment and feedstock logistics (i.e., harvesting, storage, preprocessing, and transportation). R&D for the algal feedstocks area is led by DOE and includes resource assessment, strain improvement, efficient cultivation systems, harvest/dewatering, sustainable intermediate production, and stabilization (for details, see Section 2.1).
- **Conversion R&D** is focused on developing commercially viable technologies to convert terrestrial and algal feedstocks into liquid fuels, as well as bioproducts and biopower. The Office's Biochemical Conversion R&D efforts focus on pathways that produce sugars, other carbohydrate intermediates, and lignins from biomass, and converting those intermediates into fuels, chemical intermediates, or products. The Office's Thermochemical Conversion R&D efforts focus on pathways that produce oil, vapor, and gaseous intermediates from biomass, and converting these intermediates into fuels, chemical intermediates, products, and/or power (for details, see Section 2.2).

Demonstration and Deployment

The Office's Demonstration and Deployment activities focus on validating integrated biorefinery (IBR) applications at increasing engineering scale and biofuel distribution infrastructure and end use. For biofuels, the goal of demonstration and deployment activities is to develop emerging conversion technologies beyond bench scale to pre-commercial demonstration scale, reducing technical risk at increasing complexities and scale, culminating in the construction of pioneer biofuels production plants by industry. The second technology demonstration and deployment goal is to develop the supporting infrastructure needed to enable a fully developed, operational, and sustainable biomass-to-bioenergy value chain in the United States. Demonstration and

¹ The Bioenergy Technologies Office's approach to sustainability is consistent with Executive Order 13514, which provides the following definition: To create and maintain conditions, under which humans and nature can exist in productive harmony, that permit fulfilling the social, economic, and other requirements of present and future generations. For more on sustainability, see Section 2.4.

deployment is conducted via Office partnerships with industry and other key stakeholders and includes two technical elements:

- **IBR** activities focus on demonstration of integrated conversion processes at an engineering scale sufficient to demonstrate and validate commercially acceptable cost, performance, and environmental targets. IBR activities address problems encountered in the so-called “Valley of Death” between pilot-scale and pioneer-scale first-of-a-kind demonstration, as illustrated in Figure 2-2. These efforts are industry-led, cost-shared, and competitively awarded projects. Intellectual property and geographic and market factors will determine the feedstock and conversion technology options that industry will choose to demonstrate and commercialize. Government cost share of biorefinery development is essential due to the high technical and financial risk of first-of-a-kind biofuels production at increasing scale. The Office will continue to fund a number of pilot-scale, demonstration-scale, and commercial-scale biofuel production facilities over the next 10 years (see Section 2.3.1).
- **Biofuels Distribution Infrastructure and End Use** activities focus on coordinating with other federal agencies and DOE offices to develop the required biofuels distribution and end-use infrastructure. These activities include evaluating the performance; material compatibility; and environmental, health, and safety impacts of advanced biofuels and biofuel blends (see Section 2.3.2).

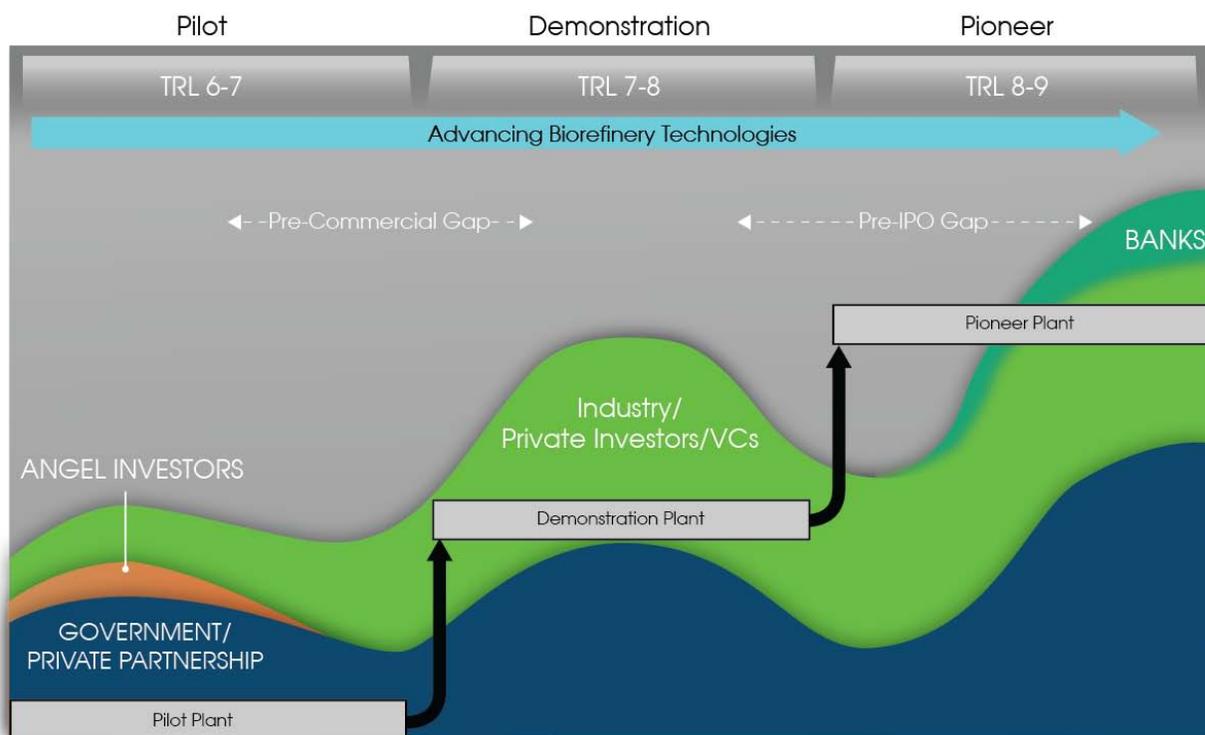

Figure 2-2: Technology development and scale-up to first-of-a-kind pioneer facility

Cross-Cutting Activities

- **Sustainability** activities focus on developing the resources, technologies, and systems needed to grow a bioenergy industry in an environmentally sustainable way. While petroleum displacement is at the core of the Office’s mission, improving long-term sustainability is also important. The existing and emerging bioenergy industry—which includes such diverse sectors as agriculture, waste management, automobile manufacturing, and fuel distribution—will need to invest in systems based on economic viability and market needs, while also addressing the more overarching concerns such as food security and environmental sustainability. The Office is working to articulate the challenges related to sustainable bioenergy production and partnering with other agencies and DOE offices to address these challenges through basic and applied research and analysis (see Section 2.4).
- **Strategic Analysis** includes a broad spectrum of cross-cutting analyses to support programmatic decision making, demonstrate progress toward goals, and direct research activities. Programmatic analysis helps frame the overall Office goals and priorities and covers issues that impact all technology areas, such as life-cycle assessment (LCA) of carbon dioxide equivalent emissions from bioenergy and bioproducts. These analyses provide inputs into DOE and Office of Energy Efficiency and Renewable Energy (EERE) strategic plans—including the President’s Climate Action Plan—and help define the impact of bioenergy on petroleum utilization in the transportation sector. Technology area analysis helps to monitor Office accomplishments in each technology area. Continued public-private partnerships with the bioenergy scientific community and multi-laboratory coordination efforts will help ensure that the model assumptions and analysis results from the Office are transparent, transferable, and comparable (see Section 2.5).
- **Strategic Communications** focuses on identifying and addressing non-technical and market barriers to bioenergy adoption and utilization in an effort to promote full-scale market penetration. It fosters awareness and acceptance by engaging a range of stakeholders in meaningful collaborations, promoting Office strategies, and increasing consumer acceptance. Strategic Communications activities include distributing information to stakeholders and conveying key Office goals, priorities, activities, and accomplishments (see Section 2.6).

The Office’s Technology Pathways Framework

The technology pathways framework integrates efforts among the technical elements and aligns with major bioenergy industry market segments. Figure 2-3 illustrates how the Office elements seek to leverage the broad diversity of potential bioenergy feedstocks while reducing supply risks through developing a wide range of conversion technologies to produce and distribute bioenergy and bioproducts.

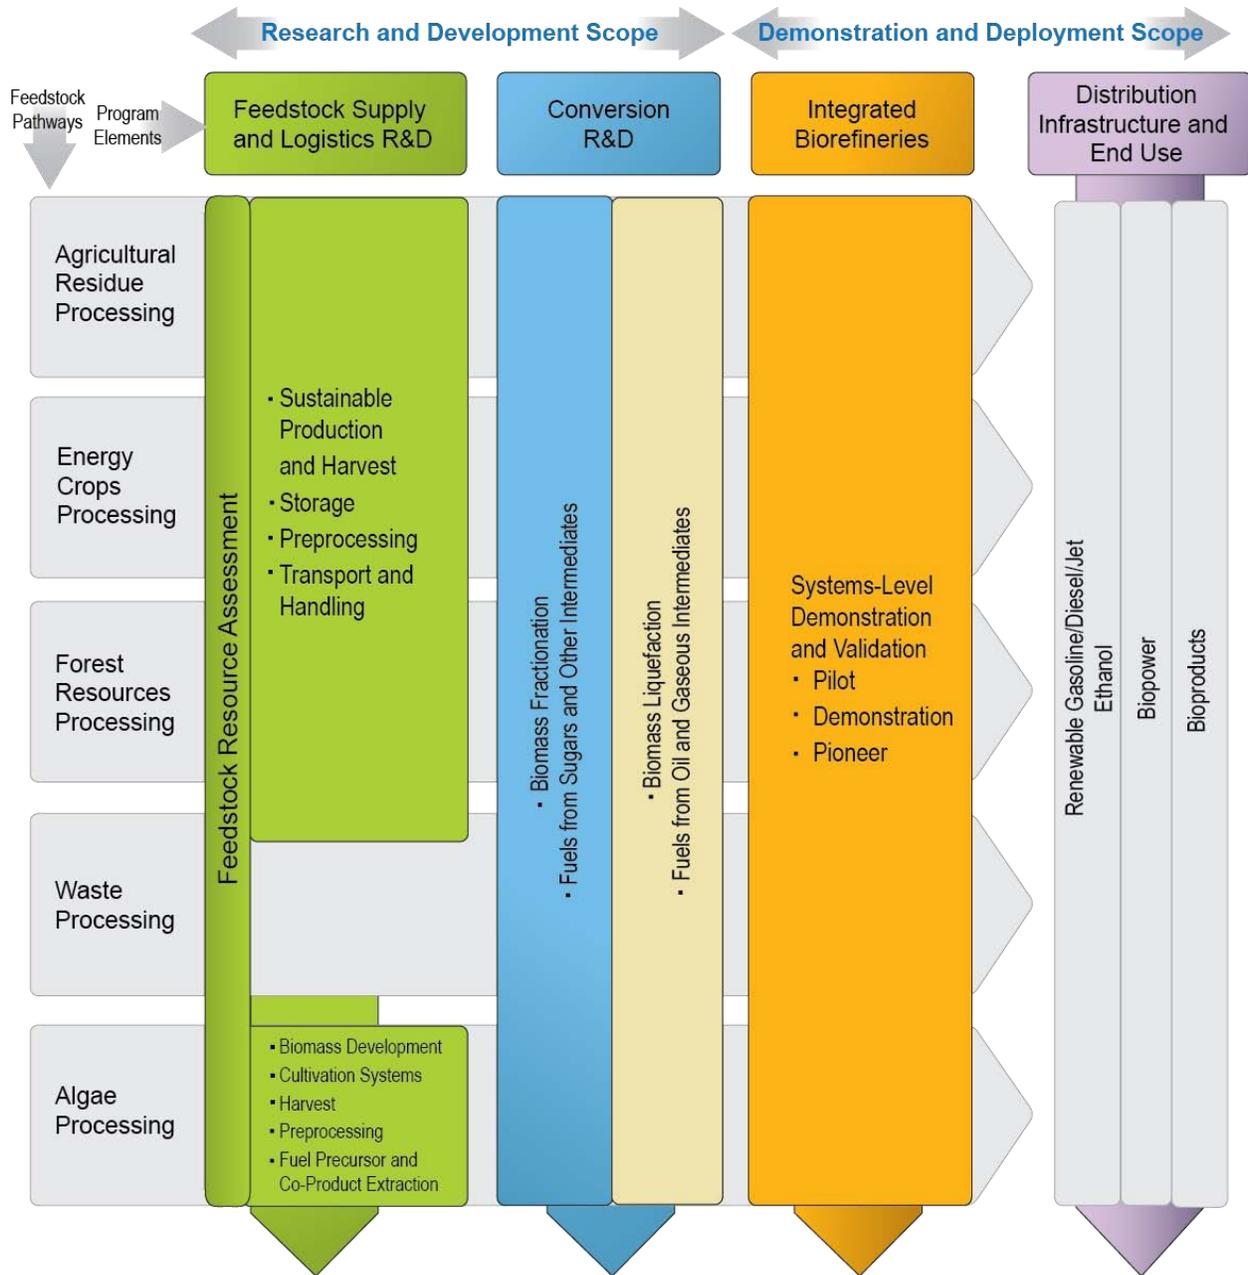

Figure 2-3: Office technical element links to technology pathway framework

The Office uses this technology pathway framework to identify research, development, and demonstration (RD&D) priorities and balance the activities that are expected to have the greatest impact on achieving Office goals.

Office Element Discussion

The remainder of Section 2 details plans for each Office element:

- Feedstock Supply and Logistics R&DSection 2.1
- Conversion R&D.....Section 2.2

Demonstration and Deployment	Section 2.3
Sustainability	Section 2.4
Strategic Analysis	Section 2.5
Strategic Communications	Section 2.6

Each element discussion is organized as follows:

- Brief overview of the element process concept and its interfaces with other elements of the Office (in the context of the biomass-to-bioenergy supply chain)
- Element strategic goal, as derived from the Office strategic goals
- Element performance goals, as derived from the Office performance goals
- Technical and market challenges and barriers
- Strategies for overcoming barriers, the basis for element work breakdown structures (WBS; tasks and activities with links to barriers)
- Prioritization, milestones, and timelines.

2.1 Feedstock Supply and Logistics Research and Development

The strategic goal of Feedstock Supply and Logistics (FSL) is to *develop technologies to provide a sustainable, secure, reliable, and affordable biomass feedstock supply for the U.S. bioenergy industry*, in partnership with USDA and other key stakeholders.

As the starting material for biofuels, bioproducts, and biopower production, reaching industrial scale will require availability of and access to a reliable supply of affordable, high-quality biomass. As shown in Figure 2-4, FSL research and development (R&D) relates directly to, and strongly influences, all downstream elements of the biomass-to-bioenergy supply chain, as well as the achievement of all Office goals and objectives.

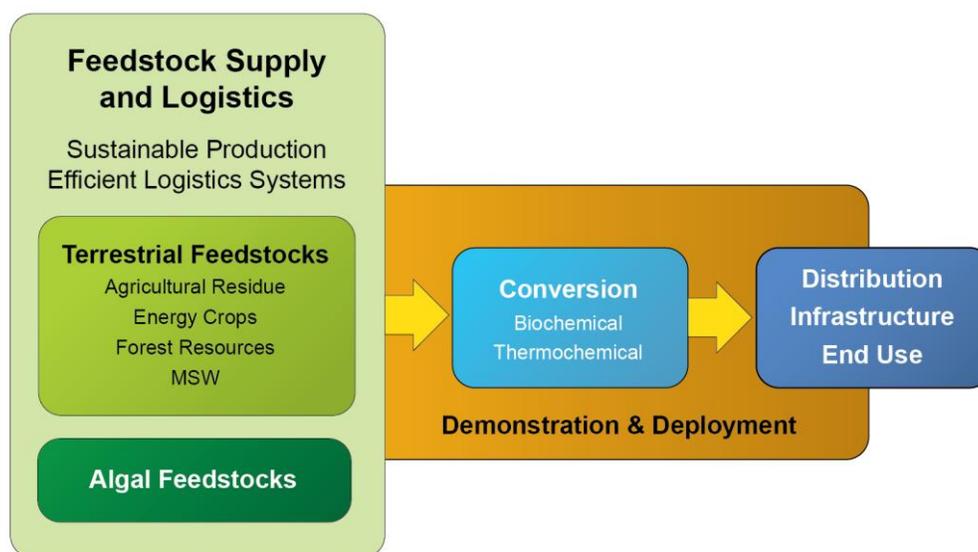

Figure 2-4: Feedstock supply and logistics as the starting point for the bioenergy supply chain

FSL distinguishes “biomass” from “feedstock.” “Biomass” is defined as the raw, field-run material obtained at the site of production (e.g., field, forest, or pond). Examples of biomass include corn stover, switchgrass, miscanthus, energy cane, sweet sorghum, high biomass sorghum, hybrid poplars, shrub willows, the sorted organic portion of municipal solid waste (MSW), and whole algae. “Feedstock” denotes biomass materials that have undergone preprocessing, such as drying, milling or chopping, size fractionation, de-ashing, blending and formulation, densification, or extraction to make them acceptable for feeding into a biorefinery process that converts them to biofuels, biopower, and/or bioproducts.

FSL R&D is organized into two broad categories of feedstock: (1) terrestrial feedstocks, which include lignocellulosic feedstocks such as agricultural residues, forest resources, dedicated energy crops,² and select MSW resources; and (2) algal feedstocks. Research objectives for these

² Energy crops are produced with the primary function being a feedstock for energy production, as opposed to an agricultural or forest residue, which is produced as a byproduct of another valuable commodity, such as grain or lumber.

two categories of feedstocks are discussed separately. Section 2.1.1 is focused on terrestrial feedstocks, and Section 2.1.2 is focused on algal feedstocks.

The Office anticipates that USDA will lead the federal government's terrestrial feedstock production efforts, in accordance with the February 3, 2010, White House release of "Growing America's Fuel."³ However, the Office continues to lead the federal government's terrestrial feedstock logistics efforts. The Office will work with USDA to coordinate USDA's and other's efforts to support the development of a robust and sustainable domestic bioenergy industry.

The Office anticipates playing a leading role in the federal government's algae strain development, as well as production and logistics efforts related to algal feedstock systems. Algae production systems include open ponds, closed photobioreactors, mixotrophic growth, attached growth, and on- and off-shore macroalgae cultivation. Heterotrophic algae fermentation strategies are discussed in the Biochemical Conversion R&D section of the MYPP (Section 2.2.1).

The FSL program coordinates with other DOE offices and federal agencies to stimulate the development and growth of the U.S. bioenergy industry, including the following:

- DOE—Advanced Research Projects Agency for Energy (ARPA-E); Office of Science via the Joint Genome Institute, as well as its three Bioenergy Research Centers and selected Energy Frontier Science Centers
- USDA—Agricultural and Food Research Institute's Regional Bioenergy Coordinated Agricultural Projects; Agricultural Research Service (ARS) and U.S. Forest Service (USFS) Regional Biomass Research Centers; ARS National Programs #213 ("Bioenergy") and #301 ("Plant Genetic Resources, Genomics and Genetic Improvement")
- DOE-USDA—Office of Science's and National Institute of Food and Agriculture's joint annual solicitation on feedstock genomics
- Interagency—Biomass Research and Development Board; Biomass Research and Development Initiative (both terrestrial and algae)
- National Science Foundation—Directorate for Engineering, partnership on Interagency Opportunities in Metabolic Engineering
- EPA—Office of Research and Development algae program; Office of Pollution Prevention and Toxics Biotechnology Program (genetically modified organisms)
- U.S. Department of Defense—Defense Production Act.

³ For more information, see http://www.whitehouse.gov/sites/default/files/rss_viewer/growing_americas_fuels.pdf.

2.1.1 Terrestrial Feedstock Supply and Logistics Research and Development

Feedstocks are essential to achieving Office goals because the cost, quality, and volume of feedstock available and accessible at any given time will determine the maximum amount of biofuels that can be produced. The *U.S. Billion-Ton Update*⁴ report provided biomass supply scenarios that show the potential biomass resource that could be developed, leading to a sustainable national supply of more than 1 billion tons of biomass per year by 2030.

Terrestrial FSL focuses on (1) reducing the delivered *cost* of sustainably produced feedstock, (2) preserving and improving the *quality* of harvested feedstock to meet the needs of biorefineries and other biomass users, and (3) expanding the *volume* of feedstock materials accessible to the bioenergy industry. This is done by identifying, developing, demonstrating, and validating efficient and economical systems for harvest and collection, storage, handling, and preprocessing⁵ raw biomass from a variety of crops to reliably deliver high-quality, affordable feedstocks to biorefineries as the industry expands.

Terrestrial FSL R&D includes two thrusts: (1) identifying and quantifying current and future land-based biomass resources and costs associated with their production, and (2) designing integrated and efficient purpose-designed systems capable of delivering large volumes of feedstock that meet the quality specifications required by conversion facilities (see Figure 2-5).

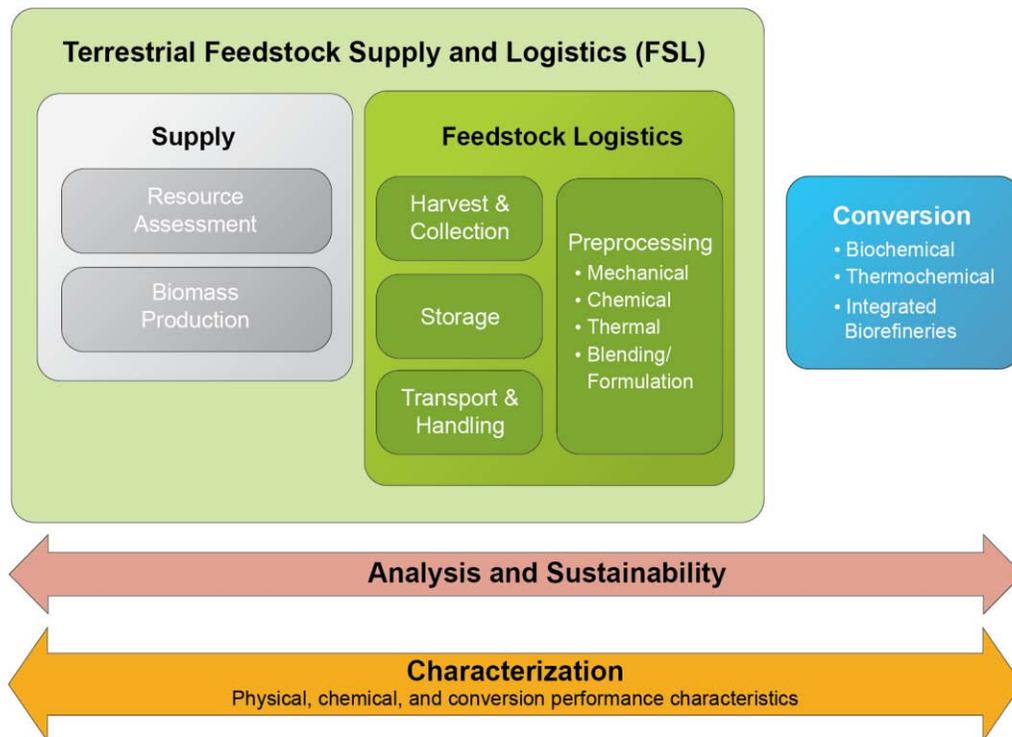

Figure 2-5: Terrestrial feedstock supply and logistics systems diagram

⁴ U.S. Department of Energy. 2011. *U.S. Billion-Ton Update: Biomass Supply for a Bioenergy and Bioproducts Industry*. R.D. Perlack and B.J. Stokes (Leads), ORNL/TM-2011/224. Oak Ridge National Laboratory, Oak Ridge, TN. http://www1.eere.energy.gov/biomass/pdfs/billion_ton_update.pdf.

⁵ Note that some preprocessing research is detailed in the sections describing conversion programs, while other research is detailed under the feedstock logistics portfolio.

Analysis and sustainability are cross-cutting areas that span both of these categories—analysis⁶ activities often incorporate both production and logistics data in the same way as sustainability⁷ activities and principles, including continuous improvement and minimization of inputs, such as water and soil conservation.

Supply: Supply includes assessing the potential availability and quality of biomass resources, as well as the production of biomass to demonstrate crop performance and estimate production costs under a variety of real-world conditions.

Resource Assessment involves estimating current and future domestic biomass resources by type and geographic distribution at different price points, understanding quality attributes (e.g., moisture, ash, and carbon content) associated with those resources as a function of geography and price, and evaluating the environmental sustainability constraints associated with accessing those biomass resources over time.

Characterization focuses on understanding biomass and feedstock quality and identification of physical, chemical, and conversion performance characteristics that can significantly impact conversion process yield, kinetics, and profitability, as well as logistics operations. Characterization involves analysis of raw biomass samples to identify a wide range of physical and chemical parameters, and the relationships of those parameters to conversion, to identify key variables and quantify their impact on overall production cost. It also includes the development of efficient, reliable, and affordable wet chemical and calibrated rapid analytical methods to measure biomass quality characteristics for woody and herbaceous crops, as well as relevant MSW fractions. Characterization research includes collaborative interface efforts between the Terrestrial FSL, Biochemical Conversion (see Section 2.2.1), and Thermochemical Conversion (see Section 2.2.2) Technology Areas.

Biomass Production involves all of the operations, associated costs, and sustainability issues related to site preparation, crop establishment, growth, and maintenance of terrestrial biomass crops to the point of harvest and collection. The Office partners with USDA in these efforts.

Feedstock Logistics: Feedstock logistics refers to all of the operations that occur after the biomass is produced and is standing in a field or forest ready for harvest and before it is introduced into the conversion facility in-feed system (also referred to as the “reactor throat”).

Harvest and Collection involves the cost-effective and sustainable removal of raw biomass from the field or forest. These operations play a critical role in expanding the amount of biomass resources accessible to the bioenergy feedstock supply system. The harvest window for different crops varies with the growth cycle of the crop, and harvest timing may be constrained by the growing season of a primary crop (e.g., grain), as well as by weather conditions during the harvest window. Harvest timing and strategy may affect the resulting herbaceous and woody feedstock quality parameters, such as chemical

⁶ Analysis is further described in Section 2.3.

⁷ Sustainability is further described in Section 2.4.

composition and structural features. Collection format (e.g., bales, loose chop, round wood, chips, etc.) can impact the efficiency and cost associated with downstream handling, storage, and transportation operations.

Storage includes methods and practices to cost-effectively store seasonally available herbaceous and woody biomass until required for processing, while minimizing degradation, material loss, and undesirable changes in quality characteristics. This includes inventory management to monitor and maintain biomass and feedstock quality, enable longer storage times, and minimize losses due to handling operations, microbial degradation, etc.

Preprocessing involves operations that transform raw, field-run biomass into stable, standardized format feedstocks with physical and chemical characteristics that meet the required quality specifications of conversion facilities and enable the use of existing, high-volume transportation and handling systems.⁸ Preprocessing upgrades biomass for stability during longer-term storage and improves durability and performance in handling, transport, and conversion. Preprocessing also can reduce the physical and chemical variability of raw biomass to enable more reliable, predictable, and efficient conversion performance.

Preprocessing includes mechanical, thermal, or chemical treatments, as well as blending and formulation. Any or all of these treatments can occur at various points in the logistics chain.

Mechanical preprocessing includes size reduction, separation based on particle size or density, and fractional deconstruction to reduce particle size and break down the raw biomass to achieve desired physical and/or chemical characteristics. Mechanical preprocessing also includes densification treatments, such as pelletization, to increase the bulk and energy density of raw biomass, improve stability during storage and handling, and create flowable feedstocks that are compatible with existing handling infrastructure systems. Although baling is a densification process, it is considered part of the Harvest and Collection operation.

Thermal preprocessing, such as drying and torrefaction, reduces moisture content and increases the energy density of the material to improve stability during storage, transport efficiency, and—potentially—conversion performance.

Chemical preprocessing upgrades biomass quality by reducing ash content, reducing recalcitrance to cell wall deconstruction, and potentially increasing downstream microbial conversion of biomass to products. Examples of chemical preprocessing include leaching or washing, treatment at basic pH, and dilute-acid treatment. Additional information on chemical preprocessing technologies can be found in the Biochemical Conversion R&D section (Section 2.2.1).

⁸ Note that some preprocessing operations are discussed under other program sections.

Formulation and blending mitigate inherent variability in raw biomass qualities to produce feedstock with more consistent physical and chemical characteristics, to reduce conversion performance variability, and/or to lower the overall cost of feedstocks. By combining biomass with different chemical, physical, and cost characteristics, feedstock quality and performance can be adjusted to required conversion process specifications and improve overall process economics. Blending and aggregation are examples of formulation processes. Including lower-quality or small-volume biomass materials as components of a blend or formulation can reduce the overall cost or adjust the physical or chemical characteristics of the blend. This can expand the volume of biomass available to biorefineries to mitigate feedstock supply risk and improve overall process economics.

Handling feedstocks in existing high-volume, high-throughput systems can be challenged by the low-density, non-uniform characteristics of raw biomass. Formatting raw biomass to be compatible with these systems as early in the supply chain as practical can leverage existing high-capacity bulk handling and transportation infrastructures, such as those designed for the grain industry, and help to reduce delivered feedstock cost.

Transport involves moving raw biomass from the field or forest to the site of preprocessing and moving preprocessed feedstocks to the throat of the conversion reactor. Biomass and feedstocks may be transported by truck, train, or barge using existing transportation infrastructure.

Connecting the Nation's Diverse Biomass Resource to the Bioenergy Industry

Sustainably supplying the required volumes of quality, affordable feedstock to the emerging biorefining industry will be achieved through a transition from logistics systems that have been designed to meet the needs of conventional agriculture and forestry systems (termed “conventional” logistics systems) to more advanced, purpose-designed, economically advantaged systems (termed “advanced” logistics systems).⁹

Conventional Logistics Systems: Conventional logistics systems have been developed for traditional agriculture and forestry systems and are designed to move biomass short distances for limited-time storage (i.e., less than one year). Conventional systems do not address the physical and chemical variability of biomass and do not access the full volume of the diverse, nationally distributed U.S. biomass resource potential. Conventional systems constrain biorefinery locations to areas where there are sufficient supplies of biomass within a limited distance, limit the scale-up capacity of the biorefinery, and expose the biorefinery and its investors to increased risk from potential local feedstock disruptions.¹⁰

Advanced Logistics Systems: Advanced logistics systems are designed to deliver infrastructure-compatible feedstocks with predictable physical and chemical characteristics, longer-term

⁹ J. Richard Hess, Christopher Wright, et al. “Uniform-Format Solid Feedstock Supply System: A Commodity-Scale Design to Produce an Infrastructure-Compatible Bulk Solid from Lignocellulosic Biomass,” Idaho National Laboratory, INL/EXT-08-14752 (2009), www.inl.gov/bioenergy/uniform-feedstock.

¹⁰ J. Richard Hess, Christopher Wright, et al., as above.

stability during storage, and high-capacity bulk material handling characteristics that facilitate economic transport over longer distances. These properties are needed for the development of a commodity-based, specification-driven supply system analogous to U.S. grain and coal commodity systems.

Logistics systems designed for the purpose of bioenergy production can eliminate inefficiencies in conventional harvest and delivery systems. Reducing the number of operations, pieces of equipment, and labor required per delivered ton of feedstock will enable implementation of additional operations, such as preprocessing, that do not occur in conventional systems. Methods will also be developed to estimate feedstock quality characteristics at critical points in the supply chain.

Figure 2-6 shows a high-level depiction of how an advanced logistics system could draw in presently inaccessible resources via local preprocessing depots that transform biomass into a stable, bulk, densified, and flowable feedstock. The formatted feedstock is transported into a network of supply terminals, where material aggregated from a number of depots can be blended or further preprocessed to meet biorefinery needs.

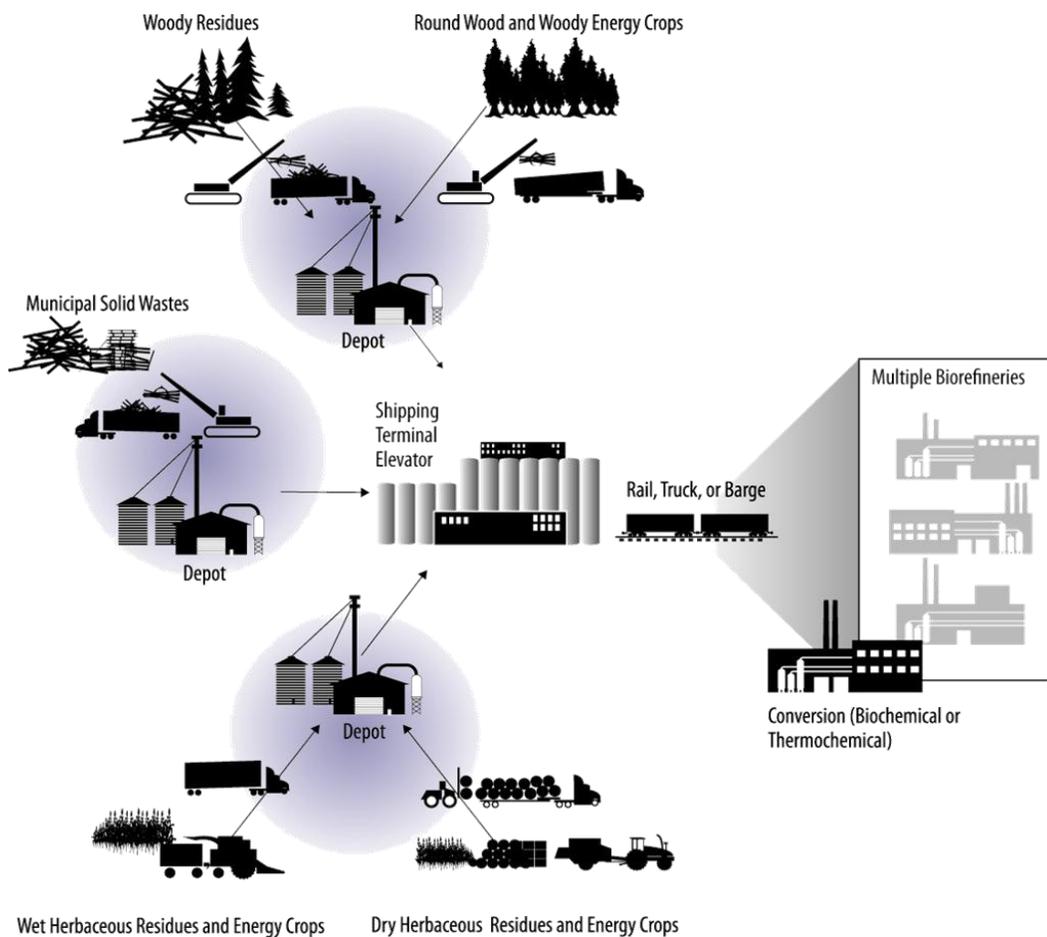

Figure 2-6: The advanced logistics system depot concept

2.1.1.1 Terrestrial Feedstock Supply and Logistics Research and Development Support of Office Strategic Goals

The strategic goal of Terrestrial FSL R&D is to *develop technologies to enable a sustainable, secure, reliable, affordable supply of acceptable-quality terrestrial feedstock for the U.S. bioenergy industry*, in partnership with USDA and other key stakeholders. This supports the long-term (beyond 2030) goal to develop technologies and methods that could sustainably supply more than 1 billion tons of biomass per year.

The Terrestrial FSL R&D program directly addresses and supports resource assessment, production, harvest, collection, storage, preprocessing, and delivery of feedstock for all potential biomass conversion pathways.

2.1.1.2 Terrestrial Feedstock Supply and Logistics Research and Development Support of Office Performance Goals

The performance goals for Terrestrial FSL R&D are as follows:

- Validate efficient, low-cost, and sustainable feedstock supply and logistics systems that can deliver feedstock to the conversion reactor throat at required conversion process input specifications, at or below \$80/dry ton (\$2011) by 2017 (including grower payment/stumpage fee¹¹)
- Establish geographic, economic, quality, and environmental criteria under which the industry could operate at 250 million dry ton per year scale (excluding biopower) by 2017¹²
- By 2022, develop and validate feedstock supply and logistics systems that can economically and sustainably supply 350 million dry ton per year at a delivered cost of \$80/dry ton to support a biorefining industry (i.e., multiple biorefineries) utilizing a diversity of biomass resources.

Terrestrial Feedstock Supply and Logistics Research and Development Milestones

Terrestrial FSL R&D has several milestones charting the path to 2017 and 2022.

¹¹ Grower payments are those made to feedstock producers over and above the costs incurred for harvest, collection, storage, preprocessing, and transport. For crop residues, the grower payment covers the environmental value of the residue removed (e.g., nutrients and organic matter), as well as profit. For woody residues, these payments cover the value of the residue. For dedicated energy crops, grower payments cover pre-harvest machine costs, variable inputs such as fertilizers and seed, and amortized establishment costs for perennial crops, which do not typically reach mature yields until at least the third growing season. The payments must also reflect what profit the land could produce if planted with other crops. Other factors also affect grower payments include profits to growers for investment returns and risk taking, alternative financial arrangements (e.g., cooperatives), fixed pricing mechanisms, shared-equity arrangements between growers and processors, and other competitive uses. Note that the grower payment listed is the maximum amount required to acquire the specified volume of biomass (i.e., there are biomass resources available for a lower cost; however, none of the resources required would cost more). For a more extensive list of feedstocks and their associated grower payment, see Oak Ridge National Laboratory's Bioenergy Knowledge Discovery Framework at <https://www.bioenergykdf.net>.

¹² Table B-1 in Appendix B.

Supply

- By 2014, establish a framework for promoting sustainable biomass production practices that consider productivity, soil quality, water quality and quantity, greenhouse gas emissions, air quality, biodiversity, and social aspects of sustainability.¹³
- By 2015, integrate feedstock quality criteria and blending strategies to generate more comprehensive supply scenarios, meeting biorefinery in-feed specification targets at the lowest possible feedstock price.
- By 2016, produce an updated, fully integrated assessment of potentially available feedstock supplies under previously established environmental and quality criteria.
- By 2017, establish available resource volumes for non-woody MSW and algal feedstocks at \$80/dry ton delivered cost. (Note that woody MSW is currently incorporated into resource assessments.)
- By 2018, establish sub-county-level environmental impact criteria and logistics strategies.
- By 2019, determine the impact of international trade and competing feedstock demands (e.g., biopower and pellet exports) on feedstock supply and price projections.
- By 2021, determine the impact of advanced blending and formulation concepts on available volumes that meet quality and environmental criteria, while also meeting the \$80/dry ton cost target.

Feedstock Logistics

- By 2015, develop a blendstock formulation for one conversion pathway based upon meeting pathway cost, quality, and volume targets.
- By 2017, validate sustainable feedstock supply and logistics cost of \$80/dry ton at conversion reactor throat (including grower payment and logistics cost) for at least one biochemical conversion process and one thermochemical conversion process.
- By 2022, validate one blendstock for thermochemical conversion and one blendstock for biochemical conversion at a scale of 1 ton per day.

2.1.1.3 Terrestrial Feedstock Supply and Logistics Research and Development Technical Challenges and Barriers

Supply

Ft-A. Terrestrial Feedstock Availability and Cost: Reliable, consistent feedstock supply is needed to reduce financial, technical, and operational risk to biorefineries and their financial partners. Reaching federally mandated national volumes of biofuels will require large amounts of sustainably available, quality-controlled biomass to enter the market at an affordable price. Conventional logistics systems restrict the amount of biomass that can be cost-effectively delivered to the biorefinery, resulting in large amounts of biomass that cannot cost-effectively enter the system (i.e., “stranded resources”).

Credible data and projections on current and future cost, location, environmental sustainability, quality, and quantity of available biomass are needed to reduce uncertainty for investors and

¹³ The framework will be implemented in Office-funded activities and updated as best management practices are identified.

developers of emerging biorefinery technologies. Estimates of current and potential feedstock resources are limited in scope and do not adequately represent how major potential advances in genetics, production technologies, and supply chain strategies will impact future biomass availability, cost, and quality.

Ft-B. Production: The range of and improvements in energy crop yields have not been well-documented for deployment of energy crops at commercial scale. Reliable production data are needed over several growing seasons and across wide geographies to make well-substantiated productivity projections. Comprehensive data are also needed to measure the environmental effects of energy crop production and biomass collection systems to provide data for complete life-cycle analysis of biorefinery systems and address sustainability questions such as water and fertilizer inputs, or establishment and harvesting impacts on soil. Production and sustainability gaps also exist for conventional crop residues.

Ft-C. Terrestrial Feedstock Genetics and Development: The productivity and robustness of terrestrial feedstock crops used for biofuel production could be increased by developing improved varieties through screening, breeding and selection, and/or genetic engineering. This will require extensive ecological, genetic, and biochemical information that is currently lacking for the majority of non-domesticated terrestrial energy crops.

Feedstock Logistics

Ft-D. Sustainable Harvesting: Current crop harvesting machinery is unable to selectively harvest preferred components of cellulosic biomass while maintaining acceptable levels of soil carbon and minimizing erosion. Actively managing biomass variability imposes additional functional requirements on biomass harvesting equipment. Current systems cannot meet the capacity, efficiency, or delivered price requirements of large cellulosic biorefineries.

Ft-E. Terrestrial Feedstock Quality and Monitoring: A better understanding is needed regarding the physical, chemical, microbiological, and post-harvest physiological variations in biomass that arise from differences in genetics, degree of crop maturity, geographical location, climatic events, and harvest methods. This variability presents significant cost and performance risks for bioenergy systems. Currently, processing standards and specifications for cellulosic feedstocks are not as well-developed as for mature commodities.

Ft-F. Biomass Storage Systems: Biomass that is stored with high moisture content or exposed to moisture during storage is susceptible to spoilage, rotting, spontaneous combustion, and odor problems. Therefore, the impacts of these post-harvest biological processes must be controlled to ensure a consistent, high-quality feedstock supply. Characterization and analysis of different storage methods and strategies are needed to better define storage requirements to preserve the volume and quality of harvested biomass over time and maintain its conversion yield.

Ft-G. Biomass Material Properties and Variability: Available data and information are extremely limited on biomass quality and physical characteristics and how those properties influence conversion performance. Methods and instrumentation also are lacking for quickly, accurately, and economically measuring chemical, physical, and mechanical properties of biomass.

A better understanding is needed regarding the inherent variability in biomass physical and chemical quality parameters and cost between different species, within a species, and even between tissues of the same individual plant. Acceptable ranges of quality parameters for different conversion processes are poorly understood, and few genetic or preprocessing strategies have been developed to limit or control variability in biomass quality. Since many quality factors vary independently, it is not clear what fraction of available biomass materials will actually be able to meet in-feed specifications for the various conversion processes being developed and commercialized.

Ft-H. Biomass Physical State Alteration: The initial sizing and grinding of cellulosic biomass affects conversion efficiencies and yields of all downstream operations, yet little information exists on how specific differences in these operations on each type of cellulosic biomass impact conversion cost and yields. New technologies and equipment are required to economically process biomass to meet biorefinery specifications, such as particle-size distribution.

Ft-I. Biomass Material Handling and Transportation: Raw herbaceous biomass is costly to collect, handle, and transport because of its low density and fibrous nature. Existing conventional, bale-based handling equipment and facilities cannot cost-effectively deliver and store high volumes of biomass, even with improved handling techniques. Current handling and transportation systems designed for moving woodchips can be inefficient for bioenergy processes due to the costs and challenges of transporting, storing, and drying high-moisture biomass.

Ft-J. Overall Integration and Scale-Up: Conventional supply systems used to harvest, collect, store, handle, and transport biomass are not designed for the large-scale needs of a nationwide system of integrated biorefineries. The infrastructure for feedstock logistics has not been defined for the potential variety of locations, climates, feedstocks, storage methods, processing alternatives, etc., which will occur at a national scale. Integration of one or more aspects of the feedstock supply system—either alone or in combination with biorefinery operations—should lead to net gains in efficiency; however, the lack of analysis quantifying the relative benefits and drawbacks of potential integration options is a barrier to realization of cost savings, biorefinery efficiency improvement, and reduction of technical and financial risk.

2.1.1.4 Terrestrial Feedstock Supply and Logistics Research and Development Approach for Overcoming Challenges and Barriers

The Terrestrial FSL R&D approach for overcoming feedstock supply and logistics challenges and barriers is outlined in the work breakdown structure (WBS) and organized around the following key activities, as shown in Figure 2-7: Resource Assessment (including Analysis and Sustainability), Biomass Production, Harvest and Collection, Preprocessing, Transport and Handling, Conversion Interface, and Storage.

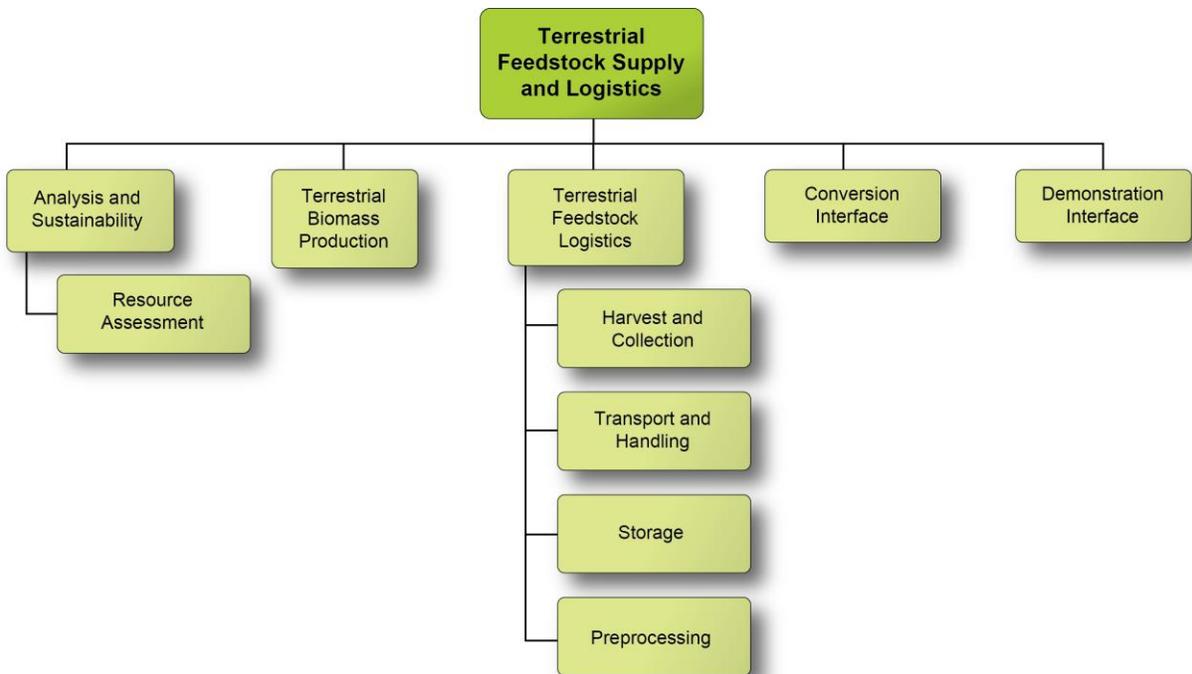

Figure 2-7: Terrestrial feedstock R&D work breakdown structure

Office-funded Terrestrial FSL system activities are performed by national laboratories, universities, industry, consortia, and a variety of state and regional partners.

The R&D approach of each WBS activity is described below.

Analysis and Sustainability

Primary areas of work within Analysis and Sustainability include resource assessment, system cost analyses, and risk assessment. Resource assessment provides critical data for establishing and measuring progress toward Office goals by determining the volume of biomass available and at what price, as well as the location of the biomass. Location and yield of biomass, as well as price, are necessary for determining total delivered feedstock cost. Resource assessment includes establishing a national inventory of biomass resource potential and assessing current and future environmentally sustainable biomass availability under conservative and optimistic scenarios relating to yield improvements over time. County-level terrestrial biomass supply curves,¹⁴ most recently updated in a 2011 resource assessment,¹⁵ will be updated as projections for technology improvements and underlying market conditions evolve. This information will be maintained in the Bioenergy Knowledge Discovery Framework (KDF), as discussed in Section 2.5.4.¹⁶

¹⁴ Modeling is based on county-level data provided by the USDA National Agricultural Statistics Service among other sources, hence outputs are provided at the county level. See De la Torre Ugarte and Ray (2000) for application of POLYSYS to biomass feedstocks.

¹⁶ “Bioenergy Knowledge Discovery Framework,” U.S. Department of Energy, <http://www.bioenergykdf.net>.

Analysis also includes developing techno-economic assessments (TEAs) to help set goals and targets, as well as tracking the progress of R&D through state-of-technology (SOT) assessments of feedstock supply systems across specific feedstock/conversion technology pathway combinations. Attaining TEA targets requires working closely with researchers who are developing thermochemical and biochemical conversion processes to ensure that the delivered feedstock meets the conversion process material in-feed requirements, as well as tracking conversion and environmental performance. These activities also include risk assessments (strategic, economic, and operational risk) and incorporating those assessments into TEAs/LCA.

Terrestrial Biomass Production

The primary focus of feedstock production is developing and validating sustainable biomass production processes and systems to overcome biomass production barriers and provide information to producers that enables lignocellulosic feedstock production regionally. This is implemented through the DOE Sun Grant Regional Feedstock Partnership (“the Partnership”), which includes numerous land-grant universities, two national laboratories, and USDA-ARS researchers. The Partnership, dedicated to the assessment and sustainable production of terrestrial biomass in five Sun Grant regions, is establishing a productivity baseline for selected herbaceous energy crops, short-rotation woody crops, and agricultural residues through a series of multi-year, replicated field trials across wide geographical range. Selected trial sites for each crop being investigated are being used to collect environmental sustainability data, such as soil carbon, water use, and greenhouse gas emissions. The data from the field trials are also helping to support research on integrated landscape management strategies that integrate energy crop production with vegetative barriers to prevent soil and chemical runoff, and include cover crops in field management in environmentally sensitive areas to improve overall biomass yield while reducing environmental impacts.

The Office actively engages with USDA-, DOE Office of Science-, and ARPA-E-sponsored efforts in the areas of terrestrial crop variety improvement, crop genetics, genomics, and genetic engineering. The Office also monitors and coordinates the development of best management practices for energy cropping systems with USDA and with DOE’s Office of Science and ARPA-E to ensure their production efforts support the attainment of Office and national goals. Sustainable production of herbaceous and woody biomass for bioenergy will be the major focus at two BETO-sponsored workshops in Fiscal Year 2014.

Terrestrial Feedstock Logistics

Near-term R&D continues to focus on reducing conventional system costs, while developing and demonstrating strategies for increasing the volumes of feedstock that can meet quality and affordability criteria for a variety of biomass conversion processes.

Mid-term work focuses on meeting the cost, quality, and volume requirements associated with a growing biorefinery industry by developing and demonstrating strategies and technologies that address the limitations of conventional feedstock logistics technologies. This will involve designing, constructing, demonstrating, and validating field-scale equipment that (1) eliminates steps in the conventional process (for example, single-pass harvesting eliminates windrowing), (2) increases operational efficiencies and capacity, (3) employs preprocessing strategies capable of upgrading the quality and reducing the variability of harvested biomass, and, ultimately, (4)

lowers overall logistics costs. Also, Terrestrial FSL supports the research that expedites technology deployment by reducing or eliminating the need to develop entirely new equipment and systems. Purpose-designed equipment developed to supply the bioenergy industry will also stimulate the U.S. farm and forestry manufacturing sector and create jobs in urban and rural communities across the country.

Longer-term efforts focus on developing advanced preprocessing strategies and technologies that convert raw biomass into high-quality, infrastructure-compatible commodity feedstocks, while meeting conversion process in-feed specifications and balancing delivered feedstock costs against conversion performance characteristics to optimize overall process economics.

Conversion Interface

Feedback between Terrestrial FSL systems and conversion process performance is critical to developing an optimized feedstock supply chain. Conversion interface efforts correlate the effect of feedstock quality on conversion performance to define ranges of tolerable conversion process input specifications to attain required conversion targets. This area therefore develops and produces preprocessed feedstocks for testing in bench-scale conversion reactors for different pathways. As required, larger quantities of feedstock meeting conversion specifications are prepared for scaled-up testing of conversion process performance.

Specific ongoing activities include collecting, organizing, and archiving raw biomass samples; assessing chemical and physical properties (including after preprocessing operations); preparing feedstock materials for testing of conversion processes; compiling the resulting data into the Biomass R&D Library; and correlating those data sets to understand relationships among all performance parameters. The Biomass R&D Library includes three elements: physical sample cataloging and archiving, characterization of physical and chemical attributes of collected biomass samples, and a database in which all the characteristics of these samples are stored and made available to the research community and public. The Library database includes information on sample origin and treatments, related publications, and all data related to each raw or preprocessed biomass sample, enabling all subsequent analyses conducted on that sample to be linked to its source. The Library enables the understanding of the impact of feedstock variability on conversion process performance characteristics and biofuels production cost.

Demonstration Interface

Demonstration Interface activities extend development of the advanced processing strategy system outlined above to address feedstock supply and logistics systems at scales to meet the needs of integrated biorefinery operations. These efforts include the design, operation, and validation of advanced processing technologies and integrated supply chain components at demonstration scale.

2.1.1.5 Prioritizing Terrestrial Feedstock Supply and Logistics Research and Development Barriers

To achieve the Terrestrial FSL R&D goal of developing sustainable technologies that provide a secure, reliable, and affordable feedstock supply for the U.S. bioenergy industry, the challenges and barriers identified above need to be prioritized and addressed as funding permits. However, the following issues are considered most critical and will be emphasized within the program's efforts:

- Increase the volume of sustainable, acceptable-quality, cost-effective feedstock available to biorefineries by developing advanced feedstock supply systems and strategies
- Incorporate sustainability and feedstock supply risk into the resource assessments
- Work with conversion technology areas to understand the range of acceptable physical and chemical in-feed specifications for the various conversion technologies
- Develop high-capacity, high-efficiency, low-cost, commercial-scale feedstock supply and logistics systems that deliver stable, dense, flowable, consistent-quality, infrastructure-compatible feedstock.¹⁷

In the past, Office-funded Terrestrial FSL research focused on modifying conventional terrestrial feedstock logistics systems that were designed and manufactured for traditional agricultural and forestry industries. Conventional systems are suitable for high biomass-yielding regions, but not for medium-to-low-yield areas. Supplying feedstock to a growing bioenergy industry requires increasing the accessible volumes of lignocellulosic feedstock, while increasing the emphasis on quality, as well as reducing variability and risk. One approach to achieving this is applying preprocessing techniques, such as blending¹⁸.

Quality targets have large impacts on whether or not a particular feedstock is cost effective in the context of a particular conversion process, as well as how much material is available for conversion. As an example, the inherent variability of one aspect of biomass quality, namely ash, for Midwestern corn stover is illustrated in Figure 2-8.¹⁹

¹⁷ Note that Section 2.1.1.2 lists fewer milestones between the years 2017 and 2022. Terrestrial FSL has the strategic goals listed in that section; however, more specific milestones during out years will be determined once some initial research is conducted through 2017.

¹⁸ Kenney et al. 2013. "Feedstock Supply System Design and Economics for Conversion of Lignocellulosic Biomass to Hydrocarbon Fuels-Conversion pathway: biological conversion of sugars to hydrocarbons." INL/EXT-13-30342. <https://inlportal.inl.gov/portal/server.pt?open=512&objID=421&parentname=CommunityPage&parentid=4&mode=2>.

¹⁹ For a more in-depth discussion of biomass variability, see K. Kenney, W. Smith, G. Gresham, T. Westover. 2013. Understanding Biomass Feedstock Variability. *Biofuels* 4(1).

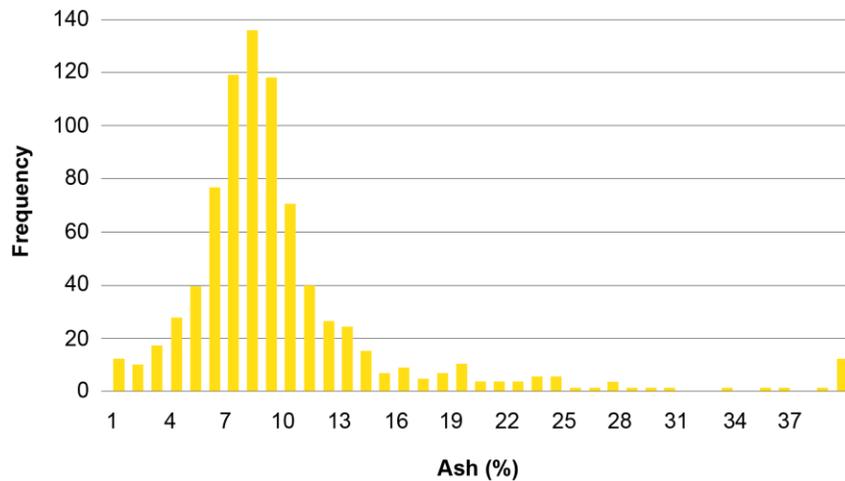

Figure 2-8: Demonstration of the variability in total ash content in corn stover²⁰

Ash is the inorganic or mineral content of biomass, and biomass ash content varies considerably among and within biomass materials types. Understanding biomass ash content, variability, and its origination requires differentiation of the sources of ash, including structural ash associated with the plant cell walls, vascular ash in the plant, and introduced ash resulting from soil contamination. Ash cannot be converted to a biofuel product and causes operational problems in downstream conversion processes, including increased equipment wear, quenching of catalysts, increased corrosivity and instability of pyrolysis oils, slagging and fouling in thermochemical equipment, and costs associated with ash disposal. Also, the proportion of convertible biomass content decreases with increasing ash content, effectively increasing the cost of feedstocks. Even though it is unlikely any single conversion technology will be capable of handling the full range of biomass variability, the variability of biomass quality necessitates the development of more robust biofuel conversion technologies.

By combining analyses using biomass price projections with quality information obtained from the Biomass R&D Library, gains in the projected volumes available at cost and biorefinery specifications can be realized by transitioning to a blended feedstock approach. Figure 2-9—projected supply curves for terrestrial biomass in 2022—shows a step-wise supply curve that indicates increased cellulosic feedstock supplies in the market with increasing farmgate prices between \$20 and \$200 per dry ton, marginal price, and average price²¹ (white line). The average price is less than the nominal price for a single feedstock.

²⁰ Data was extracted from the Biomass R&D Library. The data set includes 840 samples, including corn stover, miscanthus, and wheat straw.

²¹ For the purpose of this study, farmgate price is defined as the price needed for biomass producers to supply biomass to the roadside. It includes, when appropriate, the planting, maintenance (e.g., fertilization, weed control, pest management), harvest, and transport of biomass in the form of bales or chips (or other appropriate forms—e.g., billets, bundles) to the farmgate or forest landing. The term “marginal price” is used in biomass supply analysis to convey the price needed to supply an additional ton of biomass to either the farmgate, forest landing, biomass depot, or conversion facility. “Average price” is used in biomass supply analysis to convey the average price to acquire a stream of biomass, from the first to the last ton, over a specific period of time.

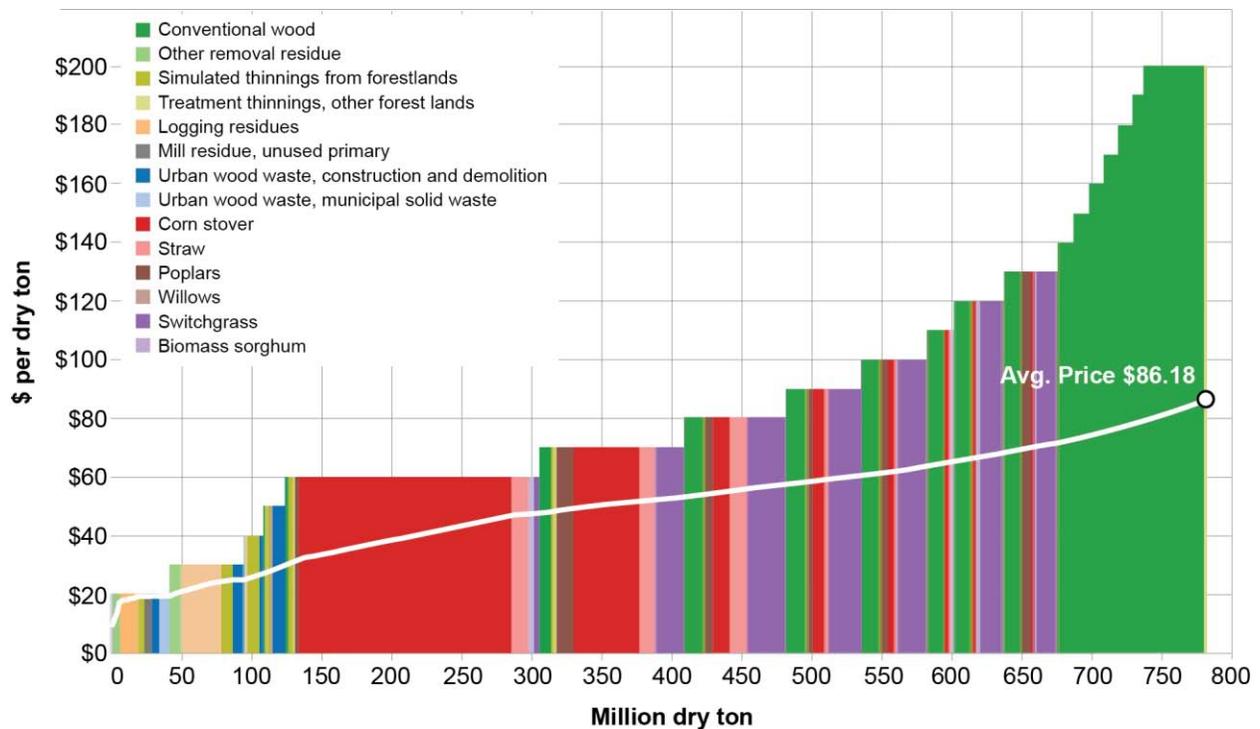

Figure 2-9: Biomass supply projections at marginal prices between \$20 and \$200 per ton in 2022

Feedstock blending allows a biorefinery to collect less of any one feedstock and thus move down the cost versus supply curve, enabling biorefineries to pay a lower average price. Note that this does not change the supply versus cost curves for each resource, but it instead describes a system where purchasers are using a combination of least-cost resources and blending them to reach the biorefinery’s desired cost and quality specifications.²²

Formulating a designed feedstock through blending and other preprocessing methods allows low-cost and typically low-quality biomass to be blended with biomass of higher cost and typically higher quality to achieve the specifications required at the in-feed of a conversion facility. The use of low-cost biomass allows the supply chain to implement additional preprocessing technologies that actively control feedstock quality, while also bringing more biomass into the system. This analysis and design approach is referred to as the “least-cost formulation” strategy.

Using a least-cost formulation analysis, Table 2-2 illustrates that modeled feedstock cost and quality targets can be met for the bio-oil conversion pathway (fast pyrolysis). This pathway is currently designed for an ash content of less than 1% on a dry weight basis.²³ In the example, low-cost, low-quality logging residues; switchgrass; and construction and demolition (C&D)

²² Dave Muth, Jacob J. Jacobson, Kara Cafferty, Robert Jeffers. “Define feedstock baseline scenario and assumptions for the \$80/DT target based on INL design report and feedstock logistics projects.” ID#: 1.6.1.2.DL.4, 11.2.4.2.A.DL.2. Joule, WBS #: 1.6.1.2/11.2.4.2, Completion Date: 3/31/13, INL/EXT-14-31569.

²³ Jones et al. 2013. Process Design and Economics for the Conversion of Lignocellulosic Biomass to Hydrocarbon Fuels: fast pyrolysis and hydrotreating bio-oil pathway. PNNL-23053, NREL/TP-5100-61178. http://www.pnnl.gov/main/publications/external/technical_reports/PNNL-23053.pdf.

waste are processed and blended with higher-cost, higher-quality debarked pine chips to meet conversion specifications. The exact quantity of each feedstock depends on the cost and characteristics of the individual feedstocks, as well as the target in-feed requirements. The modeled formulation uses 45% purpose-grown pine, 32% residues, 3% switchgrass, and 20% C&D waste as an example of this least-cost formulation strategy to obtain feedstocks that have an average delivered cost of \$80/dry ton and cumulative ash content below 1% on a dry weight basis.

Table 2-2: Example of Modeled Costs and Specifications for Preprocessed Woody Feedstocks and Blends for Fast Pyrolysis and Subsequent Upgrading to a Hydrocarbon Fuel

Feedstock	Modeled Feedstock Cost* to Reactor Throat (\$/dry ton)	Formulation Fraction (%)	Ash Content at Reactor Throat (%) ²⁴
Purpose-Grown Pine (wood)	99.49	45	0.5
Logging Residues ²⁵	67.51	32	1.0
Switchgrass	66.68	3	4.0
C&D waste	58.12	20	1.0
Delivered Formulation Totals	\$80.00	100%	<1%

*Includes grower payment and logistics costs

Modeled costs for forest thinnings and logging residues are estimated using supply chains that incorporate technologies and strategies that are currently under development, such as an innovative ash-reduction unit operation, at costs below the \$80/dry ton target. While the 45% fraction of debarked purpose-grown pine in Table 2-2 exceeds the \$80/dry ton cost target (at a modeled cost of nearly \$100/dry ton), it provides very low-ash material that helps the feedstock meet the thermochemical conversion quality specifications. When blended, the formulation meets both the cost and feedstock quality targets.

Prior to the transition to advanced systems that incorporate concepts such as blending, Terrestrial FSL research was focused on improving conventional systems. Through 2012, conventional woody supply system costs were reduced by improving existing equipment efficiencies, adopting innovative ways of mitigating moisture content, and increasing grinder performance. The cost target of \$46.37/dry ton (2007\$, excluding grower payment) was achieved in 2012,²⁶ supporting Office goals at the time. The year 2013 marked the transition from conventional feedstock

²⁴ Note that Table 2-3 is intended as a demonstration of the blending concept and is not intended to represent future quality targets for ash. Values for pulpwood, residues, and C&D from: E. m, S. Larsson, D. m, M. Ohman. 2010. Slagging Characteristics during Combustion of Woody Biomass Pellets Made from a Range of Different Forestry Assortments. *Energy & Fuels* 24(6); Switchgrass value extracted from: Turn, S.Q., C.M. Kinoshita, and D.M. Ishimura. 1997. Removal of inorganic constituents of biomass feedstocks by mechanical dewatering and leaching. *Biomass and Bioenergy* 12(4).

²⁵ For the purposes of this analysis, residue costs do not include harvest and collection, as they are moved to the landing while attached to the merchantable portion of the tree.

²⁶ Erin Searcy, J Richard Hess, Christopher Wright, Kevin Kenney, Jacob Jacobson. "State of Technology Assessment of Costs of Southern Pine for FY10 Gasification," October 2010, INL/LTD-10-20306.

supply systems to advanced systems and non-ideal feedstock supply areas, based on the desire to increase the total volume of material that can be processed and enable more biorefinery options, to address quality, and to meet the 2017 cost target of \$80/dry ton delivered to the throat of the biorefinery, including grower payment.

Figure 2-10 and Table 2-3 show potential reductions in the delivered feedstock costs from 2013 through 2019 for a fast pyrolysis conversion process.

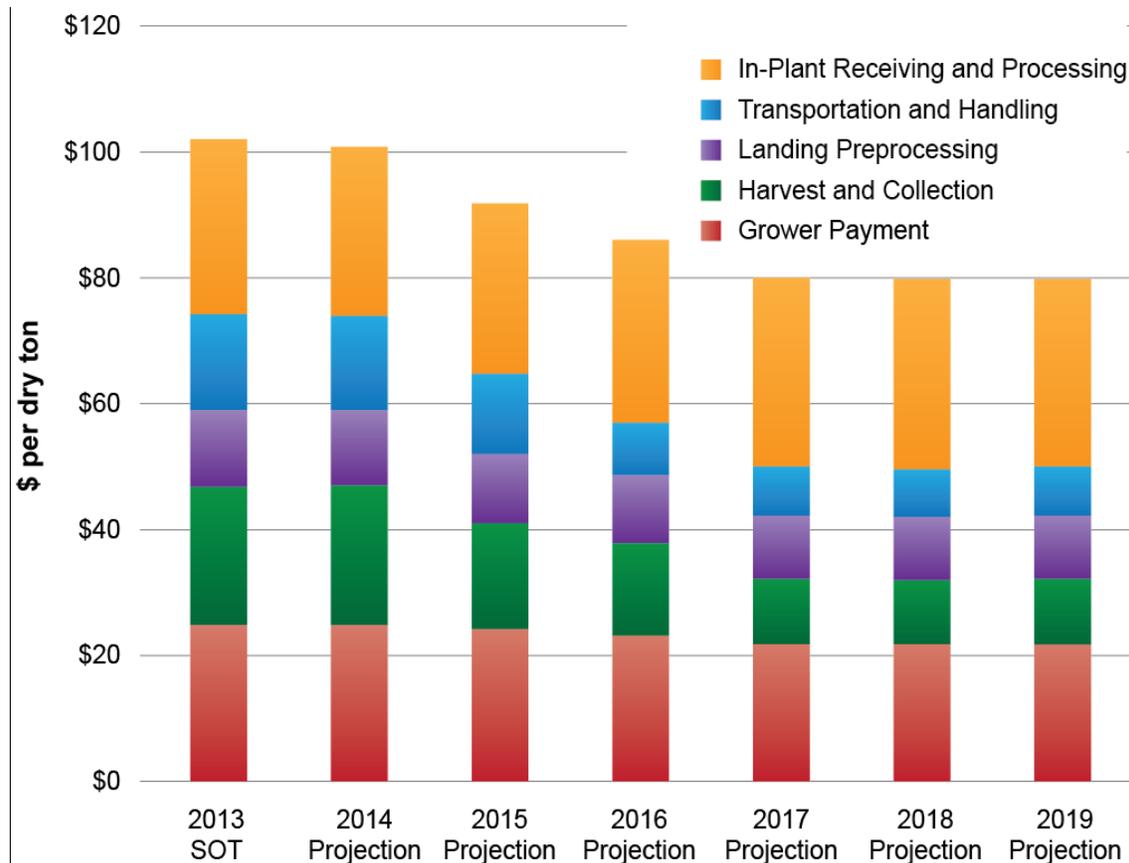

Figure 2-10: Historical and projected delivered feedstock costs, modeled for pyrolysis conversion

Total modeled feedstock cost decreases through 2017 as the result of capacity and efficiency improvements, innovative design strategies (such as blending), novel preprocessing approaches, and integrated landscape management strategies. For example, blending reduces the harvest and collection cost. The 2013 SOT is based on purpose-grown trees, which incur a harvest and collection cost. Harvest and collection costs associated with residues, however, are allocated to the cash crop, such as timber or pulpwood. Switchgrass has a lower harvest and collection cost than purpose-grown wood, and C&D waste does not have a harvest cost. Therefore, blending these materials will result in a decreased harvest and collection cost. Note that the modeled costs do not decrease between the years 2017 and 2019; however, the volume of biomass available at

the \$80/dry ton target increases.²⁷ Table 2-3 shows a reduction in grower payment of just over \$3/dry ton from 2013 to 2019, while concurrently increasing biomass resources available.

Table 2-3: Feedstock Costs for a Pyrolysis Conversion Process²⁸

2011 Dollars	2013 SOT	2014 Projection	2015 Projection	2016 Projection	2017 Projection	2018 Project	2019 Projection
Feedstock Type	Pine	Pine	Blend	Blend	Blend	Blend	Blend
Total Delivered \$/dry ton	\$ 102.12	\$ 101.45	\$ 92.36	\$ 86.72	\$ 80.00	\$ 80.00	\$ 80.00
Grower Payment/dry ton	\$ 25.00	\$ 25.00	\$ 24.43	\$ 23.45	\$ 21.90	\$ 21.90	\$ 21.90
Total Feedstock Logistics \$/dry ton	77.12	76.45	67.93	63.27	58.10	58.10	58.10
Harvest and Collection	22.24	22.24	16.68	14.46	10.47	10.47	10.47
Landing Preprocessing	12.17	12.17	11.37	11.02	10.24	10.24	10.24
Transportation and Handling	14.84	14.84	12.47	8.48	7.52	7.52	7.52
In-Plant Receiving and Processing	27.87	27.20	27.41	29.31	29.87	29.87	29.87
Total Feedstock Logistics \$/gal total fuel	0.92	0.91	0.81	0.75	0.69	0.69	0.69
Harvest and Collection	0.26	0.26	0.20	0.17	0.12	0.12	0.12
Landing Preprocessing	0.14	0.14	0.14	0.13	0.12	0.12	0.12
Transportation and Handling	0.18	0.18	0.15	0.10	0.09	0.09	0.09
In-Plant Receiving and Processing	0.33	0.32	0.33	0.35	0.36	0.36	0.36
Gallons total fuel/dry ton	84	84	84	84	84	84	84

Preliminary results suggest that blending multiple preprocessed feedstocks enables the acquisition of higher biomass volumes and reduces feedstock variability to meet biorefinery in-feed specifications, while delivering feedstock to the biorefinery at \$80/dry ton. Research is needed on blending strategies; on the performance of blended material; and on other advanced design technologies to meet cost, quality, and volume targets.

One metric that is used to assess sustainability of logistics systems is greenhouse gas emissions. A greenhouse gas emissions assessment was conducted on the 2013 SOT shown in Table 2-3. The assessment included process inputs, fuels (diesel, natural gas), and electricity for all operations from harvest through reactor in-feed.²⁹ The total greenhouse gas emissions from logistics was found to be 230 kg CO₂e/dry ton.

2.1.1.6 Terrestrial Feedstock Supply and Logistics Research and Development Milestones and Decision Points

The key Terrestrial FSL program milestones, inputs/outputs, and decision points to complete the tasks described in Section 2.1.4 are summarized in Figure 2-11.

²⁷ See Table B-1 in Appendix B.

²⁸ Note that the grower payment for 2017 projection is the weighted average associated with a blend scenario. Growers payment includes harvest, collection, and landing preprocessing costs, but these costs are also reflected in the feedstock logistics cost to demonstrate all logistics components.

²⁹ Biomass production inputs, such as fertilizer, and greenhouse gases associated with feedstock conversion were not included.

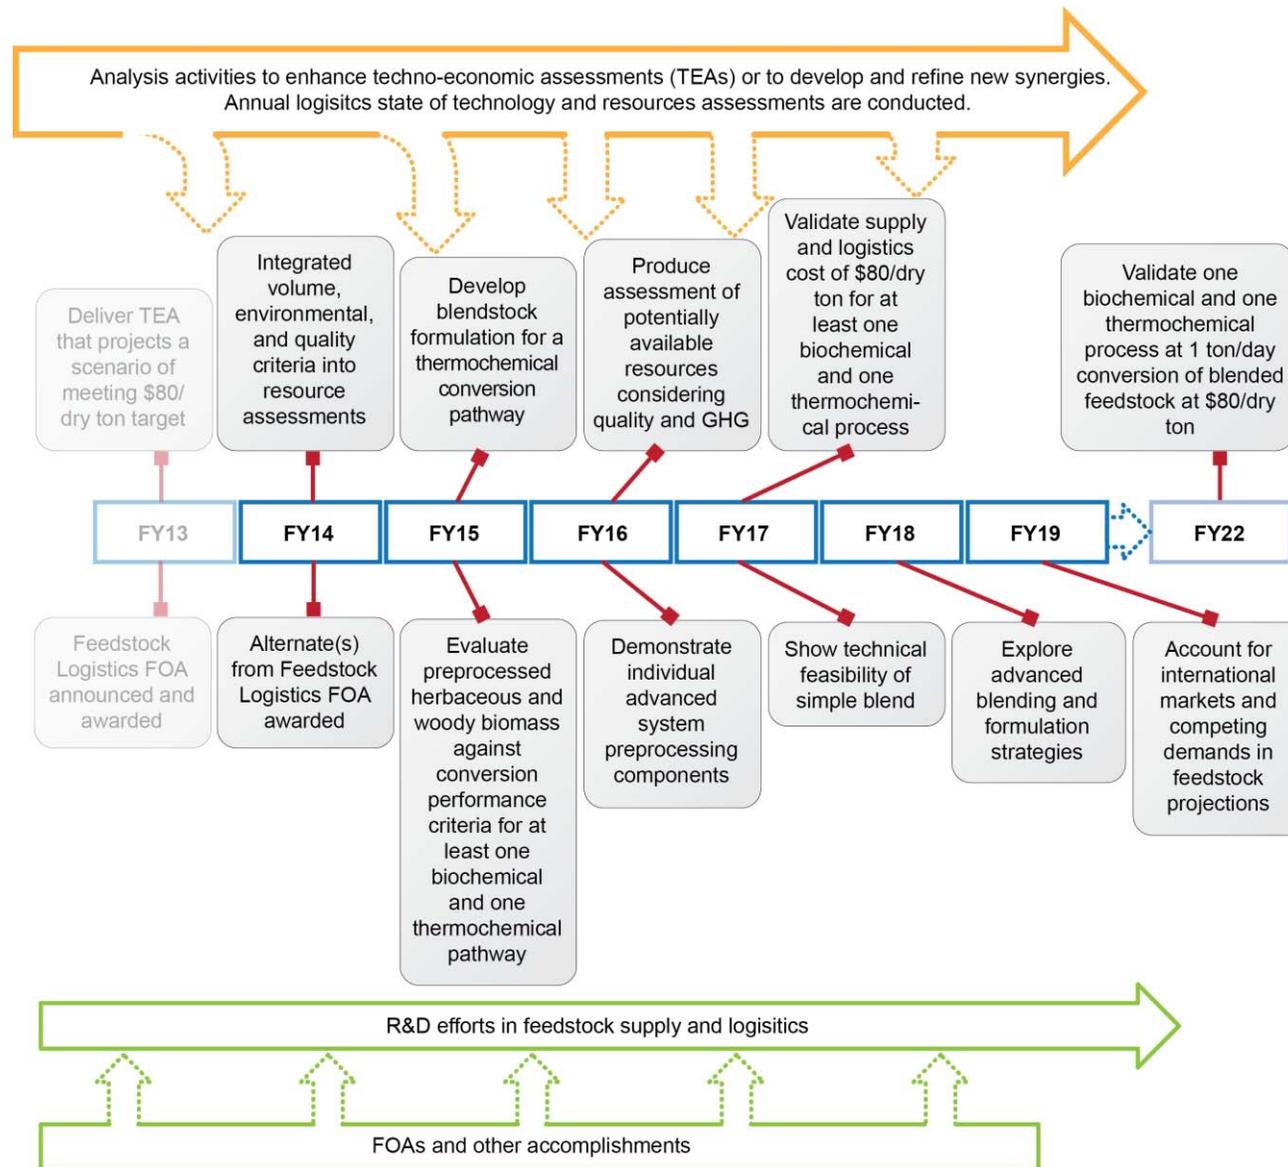

Figure 2-11: Terrestrial feedstock supply and logistics R&D key milestones and activities

2.1.2 Algal Feedstocks Research and Development

Biofuel intermediate feedstocks derived from algal biomass can contribute significantly to expanding the domestic, advanced biofuel resource potential. This is based on the potential for the high productivity of algae while using non-arable land, brackish water, or salt water, and on the possibility of using waste nutrients and effluents. Also, due to the ability of algae to accumulate significant amounts of lipids, algae can be particularly well-suited for conversion to hydrocarbon-based fuels, such as renewable diesel and jet.

Algal Feedstocks R&D focuses on overcoming technical barriers to the cost-effective production of algal biomass and intermediates, as well as on developing logistics systems for producing commercially viable algae-based biofuels and bioproducts. Algal biomass includes micro- and macro-algae, as well as cyanobacteria. These efforts are broadly classified into algal biomass production, which includes development of algae strains, and development of algae cultivation systems (e.g., open-pond and closed photobioreactor systems) able to cost-effectively produce commercial levels of algal biofuels and bioproducts.

Developing algal feedstocks to achieve advanced biofuel goals requires breakthroughs along the entire algal biomass value chain. Algal Feedstocks R&D focuses on demonstrating progress toward achieving high-yield, low-cost, environmentally sustainable algal biomass production and logistics systems that produce biofuel intermediate feedstocks that are well-suited for conversion to fuels and other valuable products.

Algal Biofuel Intermediate Supply System

The conceptual flow diagram in Figure 2-12 outlines the main elements of a generic algae supply and logistics system to provide biofuel intermediate feedstocks suitable for conversion to advanced biofuels. This diagram represents many—but not all—possible algae systems and describes the design basis used to establish cost projections. A range of alternative systems are discussed in the *National Algal Biofuels Technology Roadmap*.³⁰ The conceptual diagram in Figure 2-12 establishes a common baseline to communicate the relationship of system components and provide a basis for consideration of alternative and innovative processes and methods to achieve the cost goals needed for commercial applications.

This generic model of the algal biofuel intermediate supply system is based on literature and bench-scale and development unit efforts undertaken since 2009. Uniform specifications have not been established and will require a harmonized approach to integrating resource assessment, life-cycle analysis, techno-economics, and close coordination with conversion areas. Much of the analysis around algal biomass is in early stages of development, and significant refinements are expected as R&D investments mature.

³⁰ U.S. Department of Energy, *National Algal Biofuels Technology Roadmap* (2010), Washington: Government Printing Office, http://www1.eere.energy.gov/biomass/pdfs/algal_biofuels_roadmap.pdf.

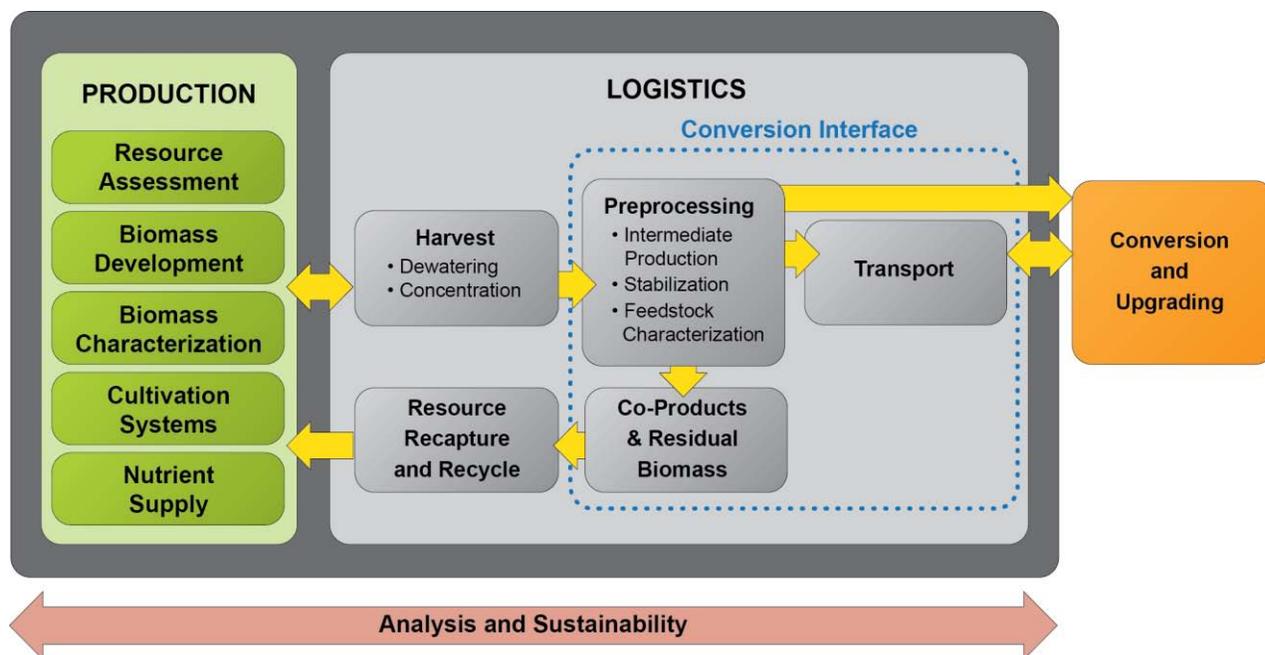

Figure 2-12: Generic algal biofuel intermediate feedstock supply and logistics flow diagram

Production: The production component of the supply system includes both resource assessment and technology development. Production technology development focuses on algal biomass development and characterization, cultivation system technologies, and nutrient supply systems.

Resource Assessment: Resources necessary to operate sustainable algal systems include sufficient solar resource, non-arable land, non-potable water, waste-nutrient streams, waste CO₂, and supporting transport infrastructure to access downstream conversion processing. Development of an algal biofuel industry requires scaling-up from hundreds of acres currently in domestic algae cultivation to millions of acres. Algae resource assessment activities include (1) identification of potential geographic locations for algae farms based on resource access and availability, (2) cost estimates for current and future resources, and (3) the environmental sustainability of the use of these resources.

Biomass Development: Algal biomass includes micro- and macro-algae, as well as cyanobacteria. Biomass development activities include (1) strain prospecting and isolation to identify types of algae with desirable growth properties, and (2) investigation of potential biological improvements from breeding, modification, and genetic engineering. Systems biology approaches to improve advantageous traits for production are also part of biomass development.

Biomass Characterization: Biomass characterization includes understanding the fundamental components (lipids, starches, and proteins) of algal biomass and correlating those characteristics to favorable production of biofuels and bioproducts. Understanding the biomass characteristics of algae with confidence at different time points in the growth cycle is critical in developing cultivation management strategies, downstream processes, and ultimate product valuations.

Cultivation Systems: Algae cultivation systems include—but are not limited to—open mixed ponds, attached growth systems, and closed photobioreactors. Cultivation systems must optimize resource supply, materials cost, and operability while maximizing productivity. Cultivation strategies include crop protection, integration of co- or polycultures, water and nutrient management, light optimization, temperature management, and seasonal succession.

Nutrient Supply: Nutrient supply encompasses feeding algae both micro and macro nutrients, as well as CO₂ and recycled water necessary for their growth.

Logistics: The downstream processing of cultivated algal biomass takes place in the logistics components of the system, which include harvest, preprocessing, and transport of processed biofuel intermediates to the conversion facility. Logistics also encompasses co-products and residual processing, as well as resource recapture and recycle.

Harvest: Optimizing harvesting operations is critical to maximizing algal biomass yields while ensuring sustainability of the production system. Algal biomass can be harvested continuously or in daily or weekly batches. Harvest timing throughout the growth cycle may affect composition and structural features of the harvested algae. Water remaining after the algae are harvested must be recycled back into the cultivation system to minimize resource use. Macroalgae and attached growth systems that cultivate multicellular algae require a lower dewatering intensity.

Dewatering: Microalgae and cyanobacteria cultivated in water grow at dilute concentrations, with assumed solids at harvest typically ranging from 0.1 grams/liter to 4.0 grams/liter. Dewatering technology—such as those used in wastewater treatment processes and the mining industry—isolates solids from high-volume, low-concentration effluents.

Concentration: Dewatered algal biomass may still be too dilute for effective preprocessing; it will require further concentration to boost algal biomass slurry concentrations to at least 15%–20% solids to be efficiently preprocessed, with the final target to be dictated by the preprocessing interface. Centrifugation or membranes are typically used for concentrating the solids.

Preprocessing: The preprocessing of algae refers to the on-farm production of transportable intermediate products from the harvested algal biomass. Algal biofuel intermediates should be energy-dense and compatible with existing handling, transport, and storage infrastructure. Preprocessing may improve algal biomass for long-term storage, handling, and transport, as well as prepare the raw material for efficient conversion. A path for algae to bypass transportation represents routes where biochemical and/or thermochemical conversion reactions are utilized in the production of a biofuel intermediate, such as treatment with enzymes or hydrothermal liquefaction. Algal feedstock preprocessing steps may include the following:

Intermediate Production: Intermediate production is defined as the deconstruction and/or preprocessing of algal biomass into products such as extracted lipids and lipid-extracted biomass. Maximizing throughput and efficiency while producing

both energy-dense biofuel intermediates and useful remaining biomass are key objectives for intermediate production technology. Regardless of which technology is used, the interface between feedstock characterization and downstream product requirements will play a role in determining appropriate intermediate production technology (e.g., a biofuel process requiring neutral lipids will need an intermediate stream of non-polar solvent extracted lipids). Thermal processing of whole algae, such as through hydrothermal liquefaction, is discussed in more detail in Section 2.2.2. under Thermochemical Conversion Research and Development.

Stabilization: The stability of intermediate products is an important consideration, particularly when the biofuel intermediate is transported offsite to a refinery for further upgrading. Methods of stabilization and storage may also have significant impacts on co-product generation.

Feedstock Characterization: The impact of preprocessing operations and reaction conditions on the resulting product streams has important implications for conversion and upgrading, as well as co-products. Methods to characterize these streams and develop predictive models of reaction kinetics will enable robust integrated process development.

Transportation: Algal biofuel intermediate products may be transported using existing transportation infrastructure. This provides some advantages to using lower-cost methods, such as rail, but it also provides a number of challenges that still need to be addressed, such as local codes, standards, and U.S. Department of Transportation regulations. In addition, longer-term implementation may require specific handling or materials of construction to avoid contamination or fermentation. As with the transportation of other biomass and feedstocks, these transportation details must be further investigated as more processes and intermediates are developed.

Co-Products and Residual Processing: The algae components that will not be directly converted to advanced biofuels can comprise 40%–75% of the biomass moving through the logistics system. Processing this residual biomass can provide nutrients and power back to the production and logistics systems. Components of algal biomass not sent for conversion to biofuel or not recaptured for reuse in cultivation may be converted to valuable co-products, such as animal feeds, commodity chemicals, or other products.

Resource Recapture and Recycle: Recycling residual salts and organic material remaining after preprocessing and/or residual processing enables the recapture of valuable nitrogen, phosphorus, other minor nutrients, and carbon that can displace the need for fresh fertilizer inputs upstream in cultivation and reduce the potential for buildup of inhibitory compounds within the cultivation system. Life-cycle analyses results suggest that the recapture of nitrogen in particular is a critical component of a favorable GHG emissions profile for algal biofuels

Conversion Interface: The production of clean, energy-dense, stable, and transportable intermediates suitable for biofuel refining is inherently integrated with work conducted by the Conversion R&D and Demonstration and Deployment (D&D) Technology Areas. The Algal

Feedstocks Technology Area coordinates with these areas on preprocessing, transportation, and co-product R&D efforts.

Analysis and Sustainability: Algal Feedstocks R&D uses techno-economic analyses and life-cycle assessments to identify key parameters with the greatest impact on the sustainability of a fully integrated algae system. These analyses guide the management of RD&D projects and provide the rationale to down-select technologies that cannot achieve Office goals.

2.1.2.1 Algal Feedstocks Research and Development Support of Office Strategic Goals

The strategic goal of the Algal Feedstocks R&D Technology Area is *to develop algae production and logistics technologies that if scaled-up and deployed could support the production of 5 billion gallons per year of sustainable, reliable, and affordable algae-based advanced biofuels by 2030.*

The strategic goal directly addresses and supports production of algal feedstocks for use by all potential conversion pathways to both biofuels and bioproducts.

2.1.2.2 Algal Feedstocks Research and Development Support of Office Performance Goals

The performance goal for the Algal Feedstocks R&D Technology Area is as follows:

- Demonstrate technologies to produce sustainable algal biofuel intermediate feedstocks that perform reliably in conversion processes to yield renewable diesel, jet, and gasoline fuels in support of the Office's \$3/gasoline gallon equivalent (GGE) advanced biofuels goal by 2022.

The Office has established two initial priority pathways: (1) algal lipid extraction and upgrading, and (2) whole algae hydrothermal liquefaction and upgrading. Design cases for these two pathways (to be released in 2014) will highlight key challenges, provide a framework for prioritizing R&D, and track progress toward performance goals.

Milestones and technical targets for achieving the performance goal have been developed using baseline reports, and they will be revised as design cases and accompanying state-of-technology reports become available. Each pathway assumes photoautotrophic cultivation of algal biomass in open raceway ponds. The pathways may differ in types of algae cultivated, as well as harvesting, preprocessing, conversion, and recycle/wastewater treatment operations.

The current baseline prior to Office investments in the algal lipid extraction and upgrading pathway is described in a recent technical report.³¹ The report represents a baseline assessment of algal biofuel technologies prior to the Office investment in algal biofuels. This baseline was constructed using literature-based parameters vetted through a 2011 stakeholder workshop and an external peer review process.

³¹ Davis et al., "Renewable Diesel from Algal Lipids: An Integrated Baseline for Cost, Emissions, and Resource Potential from a Harmonized Model," Argonne National Laboratory, ANL/ESDA/12-4 (2012), <http://greet.es.anl.gov/publication-algae-harmonization-2012>.

The design case for the hydrothermal liquefaction was published at the same time as this MYPP revision.³² A design case model for the conversion of extracted algal lipids will be delivered in 2014. The publication of design cases may result in subsequent updates to the Algal Feedstocks R&D performance goal and milestones.

Alternative designs for innovative operations and additional products continue to be developed and evaluated, and they will be incorporated into the Office's strategic plans as they show promise.

Algal Feedstocks Research and Development Technology Milestones

Milestones in support of the Algal Feedstocks R&D performance goal are to evaluate the potential domestic supply of algal biomass through the following steps:

- By 2014, demonstrate at research scale algae yield of 1,500 gallons of equivalent biofuel intermediate per acre per year.
- By 2016, review integrated R&D approaches for high-yielding algal biofuel intermediates to evaluate potential approaches for achieving the 2018 and 2022 milestones.
- By 2017, model the sustainable supply of 1 million metric tonnes ash free dry weight (AFDW) cultivated algal biomass.
- By 2018, demonstrate at non-integrated process development unit scale algae yield of 2,500 gallons or equivalent of biofuel intermediate per acre per year.
- By 2022, model the sustainable supply of 20 million metric tonnes AFDW cultivated algal biomass and demonstrate at non-integrated process development unit-scale algae yield of 5,000 gallons biofuel intermediate per acre per year in support of nth plant model \$3/GGE algal biofuels.
- By 2025, demonstrate at integrated process development unit-scale algal productivity of greater than 5,000 gallons biofuel intermediate per acre per year.
- By 2030, validate production of algae-based biofuels at total production cost of \$3/GGE (2011\$), with or without co-products.

³² Jones et al. "Process Design and Economics for the Conversion of Algal Biomass to Hydrocarbons: Whole Algae Hydrothermal Liquefaction and Upgrading" Pacific Northwest National Laboratory Report 23227 (2014), http://www.pnnl.gov/main/publications/external/technical_reports/PNNL-23227.pdf.

2.1.2.3 Algal Feedstocks Research and Development Technical Challenges and Barriers

Algae Production

Aft-A. Biomass Availability and Cost: The lack of credible data on potential price, location, seasonality, environmental sustainability, quality, and quantity of available algal biomass feedstock creates uncertainty for investors and developers of emerging biorefinery technologies. Established biomass production history is required to assure investors and other funding sources that the feedstock supply risk is sufficiently low. Reliable, consistent, and sustainable biomass supply is needed to reduce financial, technical, and operational risk to a biorefinery and its financial partners.

Aft-B. Sustainable Algae Production: Existing data on the productivity and environmental effects of algae production and biomass collection systems are not adequate to support life-cycle analysis of biorefinery systems. A number of sustainability questions (e.g., water and fertilizer inputs, land conversion, and liner use) have not been comprehensively addressed. New production technologies for algae are also required to address cost, productivity, and sustainability issues.

Aft-C. Biomass Genetics and Development: The productivity and robustness of algae strains used for biofuel production could be improved by selection, screening, breeding, and/or genetic engineering. This will require extensive ecological, genetic, and biochemical information, which is currently lacking for most algal species. Any genetically modified organisms deployed commercially will also require regulatory approval by the appropriate federal, state, and local government agencies.

Algal Feedstocks Logistics

Aft-D. Sustainable Harvesting: Current algal biomass harvesting and dewatering technologies are costly and energy- and resource-intensive. Microalgae grown in liquid suspension are dilute (0.1–0.5 grams per liter) and require multiple concentration steps to yield a harvested biomass that can be processed. While dewatering technology exists in wastewater treatment processes and the mining industry to isolate solids from high-volume, low-concentration effluents, these existing technologies may be too energy-, capital-, and reagent-intensive for the development of algal biofuels.

Aft-E. Algal Biomass Characterization, Quality, and Monitoring: Physical, chemical, biological, and post-harvest physiological variations in harvested algae are not well researched or understood. The fundamental components (lipids, starches, and proteins) of algal biomass vary greatly, both among strains and in comparison to plants. A better understanding of the effects of wide variability in feedstock characteristics on biorefinery operations and performance is needed. Standard procedures to reliably and reproducibly quantify biomass components from algae and close-mass balances are not readily available—a significant challenge as compared to traditional plant-based biomass.

Aft-F. Algae Storage Systems: Characterization and analysis of different algae storage methods and strategies are needed to better define storage requirements; these storage methods should preserve harvested algal biomass and maintain its potential product yield over time.

Aft-G Algal Feedstock Material Properties: Data on algal feedstock quality and physical property characteristics in relation to conversion process performance characteristics are extremely limited. Methods and instruments for measuring physical, chemical, and biomechanical properties of biomass are lacking.

Aft-H. Overall Integration and Scale-Up: Integration of co-located inoculation, cultivation, primary harvest, concentration, and preprocessing systems is an expensive and challenging endeavor requiring interdisciplinary expertise. In addition, the potential for co-location with other related bioenergy technologies to improve balance of plant costs and logistics has not been evaluated to determine what cost savings could be achieved.

Aft-I. Algal Feedstock Preprocessing: After cultivation and harvesting of algal feedstocks, algal biomass may require processing or fractionation into lipids, bio-oils, carbohydrates, and/or proteins before these individual components can be converted into the desired fuel and/or products. Current technologies for algal fractionation and product extraction are not commercial. Process options for commercial scale-up have been identified and are being researched (e.g., conversion of whole algal biomass via thermal liquefaction), but few data exist on the cost, sustainability, and efficiency of these processes.

Aft-J. Resource Recapture and Recycle: Residual materials remaining after preprocessing and/or residual processing may contain valuable nitrogen, phosphorus, other minor nutrients, and carbon that can displace the need for fresh fertilizer inputs in upstream cultivation. The recapture of these resources from harvest and logistics process waste streams may pose separation challenges, and the recovered materials may not be in biologically available chemical forms. In closed-loop systems, the potential for buildup of inhibitory compounds also exists.

2.1.2.4 Algal Feedstocks Research and Development Approach for Overcoming Challenges and Barriers

Algal Feedstock R&D focuses on overcoming barriers in four key components of the feedstock supply and logistics system:

- Robust productivity of large-scale algae cultivation
- Harvest and processing efficiency
- Resource efficiency (water, nutrient, electricity, and land use)
- Yield of stable biofuel intermediates that can be converted to advanced biofuels.

The Algal Feedstocks R&D approach for overcoming the key challenges and barriers is outlined in its work breakdown structure (WBS), organized around five elements, as shown in Figure 2-13 and further summarized in Table 2-4. R&D activities are performed by national laboratories, universities, industry, consortia, and a variety of state and regional partners.

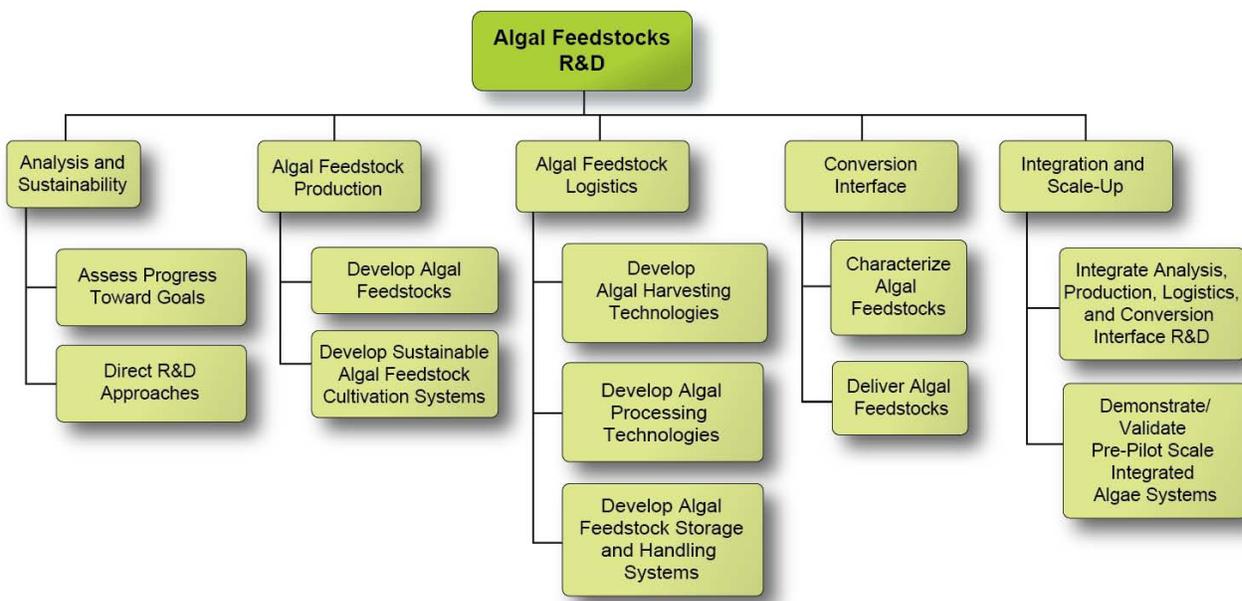

Figure 2-13: Algal feedstocks R&D work breakdown structure

Analysis and Sustainability

The primary work within the analysis and sustainability element focuses on assessing progress toward technical targets and cost goals and guiding the direction of R&D. Resource assessment is a second key area that includes establishing an inventory of national feedstock resource potential and assessing environmentally sustainable feedstock availability now and in the future. Planned R&D analysis activities for algal feedstock and processing systems include techno-economic and life-cycle analyses for multiple algal biomass production and processing scenarios.

Algal Biomass Production Research and Development

The primary focus of algal biomass production R&D is enabling the sustainable production of algae-derived biofuels by developing abundant, cost-effective, and sustainable algal biomass supplies in the United States. Algal Feedstocks R&D focuses on two main areas: algal feedstock development and cultivation systems development. Algal feedstock development focuses on developing stable algal strains that produce high yields, resist predators, and are suitable for cultivation in large-scale algal biofuel feedstock farming operations. Cultivation systems development focuses on developing materials, systems, and strategies to sustainably grow algal biomass suitable for downstream conversion.

Algal Feedstock Logistics Research and Development

The primary algal feedstock logistics R&D focus is to develop, test, and demonstrate technologies for the harvesting and processing of cultivated algae to create biomass feedstocks suitable for conversion to biofuels. Algal feedstock logistics focuses on three main areas: algae harvesting, harvested algae processing, and processed algae stabilization and transport.

Conversion Interface Research and Development

The conversion interface element aims to identify key algal feedstock characteristics and standards for downstream conversion processes. A unique aspect of the conversion interface is the extent to which feedstock processing and biofuel conversion technologies, such as extraction or hydrothermal liquefaction, are physically integrated with algae production. Efficient and effective linkage between algal feedstock and conversion processes is critical to facilitate the functioning of the entire value chain. The conversion interface area primarily addresses the effect of algae processing operations on conversion technology performance characteristics. These efforts will help to develop and optimize conversion process input specifications so that process economic targets can be achieved.

Integration and Scale-Up

Integration and scale-up is a particularly important aspect of algal feedstock supply. Specifically with current algal biomass production, promising algal feedstock development may be developed in laboratory settings under ideal and tightly controlled environments. However, algae production in non-simulated environments with exposure to variability, contamination, and stochastic events is critical to understanding and demonstrating progress relevant to real-world cultivation conditions. Similarly, integration between production and logistics operations is important. A challenge for research and pre-pilot-scale integration is aligning production capacity with harvest and processing unit operations, as this can require significant commitment of human capital and financial resources. Scale-up activities may ultimately be handed off to the D&D team for construction of pilot and demonstration facilities.

Table 2-4: Algal Feedstocks R&D Activity Summary

WBS Element	Description	Barrier(s) Addressed
Analysis and Sustainability	<p>Analyze availability, cost, and sustainability of algal feedstock production and logistics systems through development of techno-economic analysis and life-cycle analysis models and collection of life-cycle analysis and SOT data.</p> <ul style="list-style-type: none"> - Assess and quantify the geospatial volumetric supply potential of algal feedstocks and aggregate to national scale, incorporating technical, environmental, economic, and sustainability factors. Analyze factors that determine multiple and competing uses of algal feedstocks. - Analyze and model the performance of algal feedstock production and logistics systems. - Analyze impacts of algal feedstock production and logistics systems on human, animal and plant health, and biodiversity. 	<p>AfT-A: Biomass Availability and Cost AfT-B: Sustainable Production AfT-D: Sustainable Harvesting AfT-G: Feedstock Characterization, Quality, and Monitoring AfT-H: Storage Systems AfT-J: Material Properties AfT-M: Integration and Scale-Up AfT-N: Algal Feedstock Processing</p>
Production	<p>Develop productive and robust algal feedstocks, and develop, test, and demonstrate sustainable algal feedstock production systems.</p> <ul style="list-style-type: none"> - Develop algal germplasm and enable development of genetic technologies. - Explore and identify underlying biological phenomenon and traits in algae that convey desirable characteristics for large-scale cultivation. - Discover, breed, or engineer productive and robust algae strains for increased production scales and lower operational costs. - Develop laboratory tools and technologies to expedite the development of algal strains for large-scale cultivation. - Develop materials, systems, and strategies to utilize advanced algal feedstock development to sustainably grow algal biomass suitable for downstream conversion. - Develop, test, and demonstrate open, closed, hybrid, and/or offshore cultivation system technologies for improved productivity and reduced costs. - Develop technologies and management strategies for efficient use of system resource requirements, such as water, nutrients, CO₂, and light. - Integrate fundamental learning from community and systems ecology into cultivation design and practice to maximize productivity and resilience. 	<p>AfT-A: Biomass Availability and Cost AfT-B: Sustainable Production AfT-C: Feedstock Genetics and Development</p>

2.1.2.5 Prioritizing Algal Feedstocks Research and Development Barriers

The key barriers to the development of algal feedstocks are the cost, quality, and volume of available biomass to supply the growing biobased industry for biofuels, bioproducts, and biopower. Design cases and accompanying state-of-technology reports will be used once they are published to describe discreet barrier areas to achieving large volumes of low-cost, high-quality algal biofuel intermediates. The following are critical emphasis areas:

- Developing biology and culture management approaches to unlock algal biomass productivity potential.
- Developing low-cost, scalable cultivation systems that maximize reliable annual yield and minimize water consumption, land use, and nutrient additions.
- Developing low-cost, high-throughput harvest technologies that can be integrated with cultivation systems.
- Performing integrative analysis to identify critical barriers and evaluate impacts on overall yield to developments in biology, cultivation, and processing.

Priority areas, technical targets, and accompanying cost projections for production of algal biomass that can be used as a biofuel intermediate were developed from sensitivities around the 2012 Harmonized Baseline.³³ That analysis suggests that the key sensitivities are productivity and lipid content, which can be represented as a single metric: biofuel intermediate yield per acre per year. Other important areas are harvest efficiency, nutrient and water recycle, and processing efficiency, as well as capital costs of the production system.

Figure 2-14 and Table 2-5 show projected minimum intermediate prices for extracted algal lipids based on the yields and accompanying technical projections described in Appendix B, Table B-2. This is based on literature studies and will be updated in 2014. The projections show that the greatest opportunity to reduce costs is in the production systems. This is expected to be achieved through improved biomass yield and reduced cultivation capital costs. Significant cost improvements are also projected in feedstock harvest and preprocessing. To achieve the 2022 projection, biomass yield is targeted for a 5X improvement through increased productivity and extractable lipid content, halving of capital costs for pond construction, and significant capital and operability improvements in harvest and preprocessing.

³³ Ryan Davis, Daniel Fishman, Edward Frank, et al., “Renewable Diesel from Algal Lipids: An Integrated Baseline for Cost, Emissions, and Resource Potential from a Harmonized Model,” Argonne National Laboratory, ANL/ESDA/12-4 (2012), <http://greet.es.anl.gov/publication-algae-harmonization-2012>.

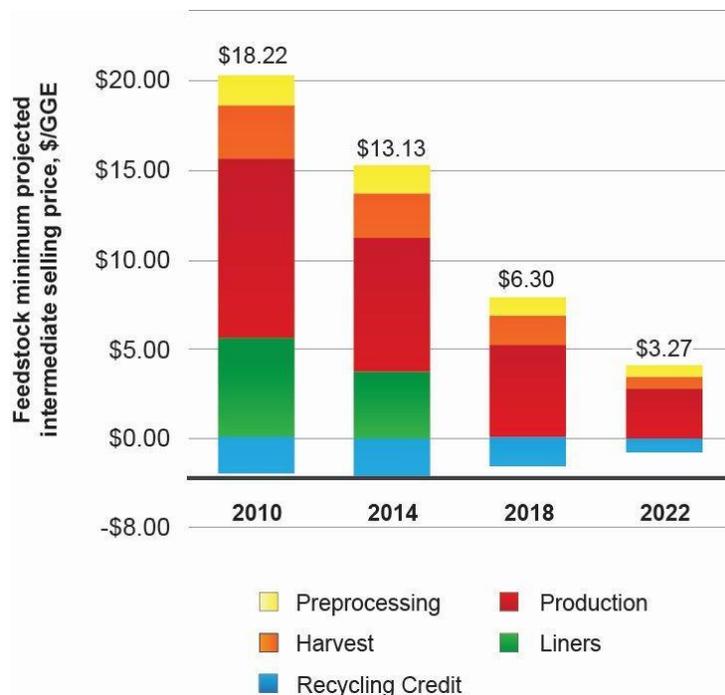

Figure 2-14: Production of high-lipid algal biomass and extraction of neutral lipids

Table 2-5: Lipid Extraction and Upgrading

	\$2011	2010 Baseline	2014 Projection	2018 Projection	2022 Target
Total Algal Feedstock Cost	\$/GGE Algal Oil	\$18.22	\$13.13	\$6.30	\$3.27
Production Cost	\$/GGE Algal Oil	\$15.60	\$11.18	\$5.17	\$2.63
Harvest Cost	\$/GGE Algal Oil	\$2.99	\$2.52	\$1.65	\$0.67
Preprocessing Cost	\$/GGE Algal Oil	\$1.72	\$1.56	\$1.11	\$0.77
Recycle/Co-Product Credit	\$/GGE Algal Oil	-\$2.08	-\$2.14	-\$1.63	-\$0.80

Figure 2-14 and Table 2-5 explicitly show the value of the recycling credit achieved from processing the residual biomass via anaerobic digestion to produce onsite power and recover nitrogen and phosphorus. Diverting the residual biomass to other uses would eliminate the recycling credit, but could potentially allow for higher-value uses for the residual biomass that would contribute to a lower overall minimum fuel selling price. Conversion of extracted algal lipids via hydrotreating is projected to add \$0.50–\$1.00/gallon,³⁴ the design case for this pathway is expected to be developed in 2014. The American Society for Testing and Materials (ASTM) has certified hydrotreated algal lipids for use in commercial aviation fuels (See ASTM D7566).

³⁴ Ryan Davis, Daniel Fishman, Edward Frank, et al., “Renewable Diesel from Algal Lipids: An Integrated Baseline for Cost, Emissions, and Resource Potential from a Harmonized Model,” Argonne National Laboratory, ANL/ESDA/12-4 (2012), <http://greet.es.anl.gov/publication-algae-harmonization-2012>.

2.1.2.6 Algal Feedstocks Research and Development Milestones and Decision Points

The key upcoming milestones and decision points for Algal Feedstocks R&D over the next five years (2013–2018) in support of the R&D approach to achieve the technology area’s 2022 performance goal are described above in Section 2.1.2.2 and illustrated below with accompanying decision points in Figure 2-15.

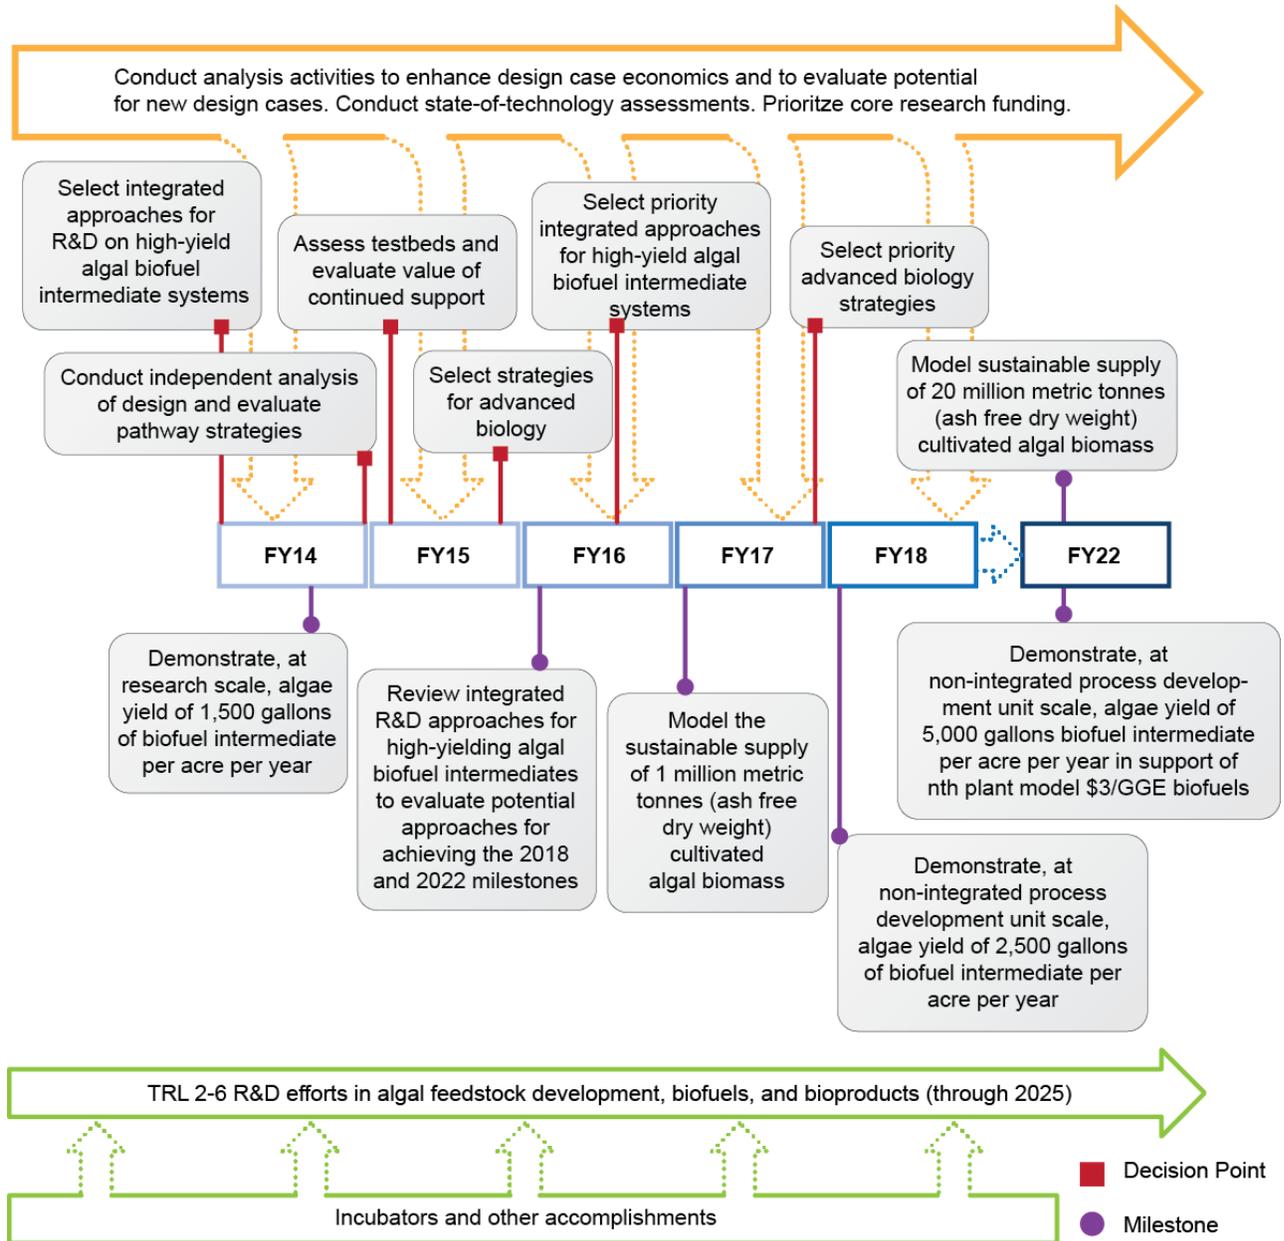

Figure 2-15: Algal feedstocks R&D key milestones and decision points

2.2 Conversion Research and Development

The strategic goal of Conversion R&D is to *develop commercially viable technologies for converting biomass feedstocks into energy-dense, fungible, liquid transportation fuels, as well as bioproducts or chemical intermediates and biopower*. Biomass resource diversity results in a need to develop multiple conversion technologies that can efficiently deal with the broad range of physical and chemical characteristics of various feedstocks. Investing in multiple conversion technologies also reduces the risk that any specific technology could fail to reach commercial viability. The Office divides its Conversion R&D efforts into two areas: (1) Biochemical Conversion R&D, which focuses on pathways using sugars, other carbohydrates, and lignin intermediates; and (2) Thermochemical Conversion R&D, which focuses on pathways using bio-oil and gaseous intermediates. These focus areas are shown in Figure 2-16. Within each area, there are many possible variations, but the main differences are in the intermediate building blocks produced and the primary catalytic system employed.

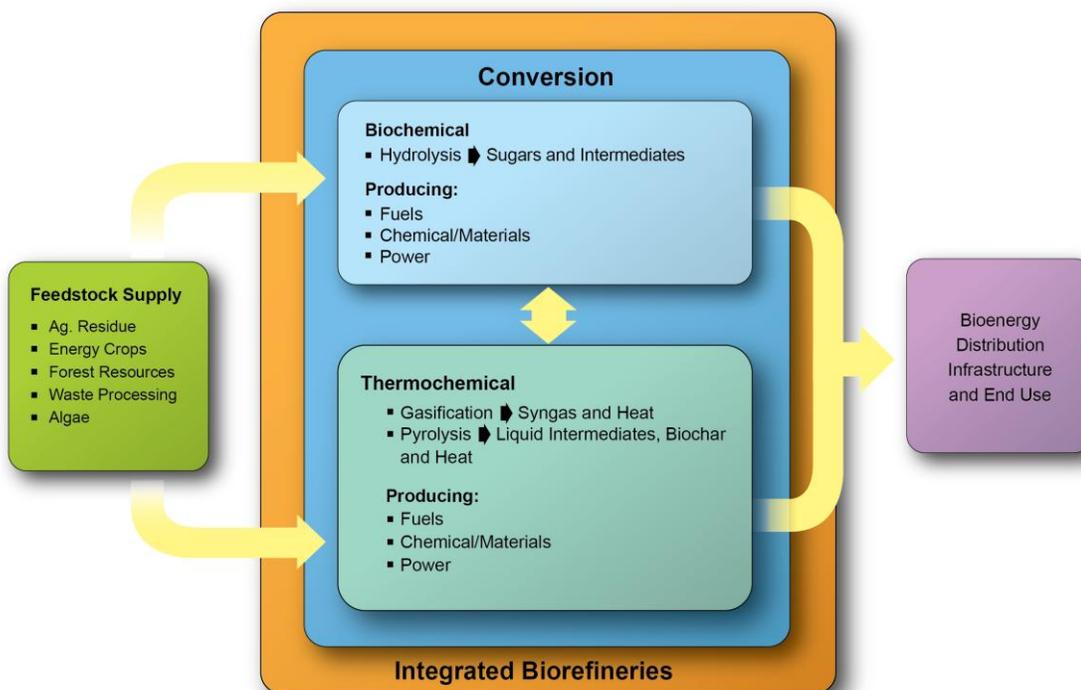

Figure 2-16: Conversion routes for biomass to bioenergy

While the Office addresses Conversion R&D needs through two separate technology routes—biochemical and thermochemical—it is envisioned that the combined use of technologies from both areas offers the greatest opportunity for optimizing biomass conversion into a variety of different fuels, chemicals, and energy products. The early years of the industry may not see such complex biorefineries, but complexity may be added as technologies evolve over time.

The Office also actively pursues R&D in technology areas that do not fit neatly into the two routes. This includes work on emerging technology, such as efforts in waste to energy, synthetic biology, and hybrid technology pathways.

2.2.1 Biochemical Conversion Research and Development

Biochemical Conversion R&D is focused on reducing the cost of converting lignocellulosic biomass to products such as liquid transportation fuels or chemicals via mixed, dilute sugars and other processable intermediate compounds. The critical steps in the conversion of biomass to fuels and chemicals include feedstock production, processing, storage, transport, and feeding; cost-effective pretreatment; high-yield conversion of intermediates to products; and product separation and purification. The key to effective and efficient conversion of biomass to finished products is obtaining high yields of desired intermediates along the supply chain.

Pretreatment typically involves mechanical, thermal, and/or chemical processes that disrupt the structure of biomass to produce the desired intermediates, which can then be further converted into the targeted products. In a typical biochemical conversion process (e.g., production of corn or cellulosic ethanol), biocatalysts—such as enzymes and microorganisms—in addition to physical forces and chemical catalysts, are used to convert the carbohydrate portion of the plant cell walls (i.e., hemicellulose and cellulose) into an intermediate sugar stream. The resulting sugars are intermediate building blocks, which are then biologically or chemically converted to various liquid fuels and chemicals. Other intermediates can include the oligomeric sugars derived from cellulose and hemicellulose, lignin, oleaginous materials, and by-products of the deconstruction steps, such as hydroxymethylfurfural and furfural.

Biological conversion processes typically utilize organisms such as yeast, filamentous fungi, bacteria, or algae with optimized metabolic pathways to convert these intermediates to targeted fuels and/or chemicals. Alternatively, chemical conversion employs catalysts to drive the reactions from intermediates to specific product suites. The remaining lignin portion of the feedstock has multiple uses, such as generation of heat and power (due to its relatively high energy content) or production of additional fuels and chemicals via thermochemical or catalytic (chemical or biological) processes.

Building on recent successes in the biochemical conversion of biomass to cellulosic ethanol, the Office is investigating a broad range of biological and chemical conversion routes to advanced biofuels, such as renewable gasoline, diesel, and jet fuel. Enabling the industry to reach its volumetric goals will require development of technologies that can achieve the following: (a) more feedstock-flexible and robust conversion processes, enabling use of a greater variety of feedstocks; (b) higher conversion yields, including increased product selectivity; (c) increased utilization of all feedstock components to enhance process economics; and (d) improved unit operations, including advanced bioreactor systems, better process control and monitoring, and increased process efficiencies. New biochemical conversion routes may also be able to leverage existing capital investment in biorefinery infrastructure, such as corn wet and/or dry mills and the new cellulosic biorefineries coming online in the near future.

Production of chemicals from intermediates does not only need to be considered as enhancing biorefinery economics; biological and chemical conversion methods can also be well-suited for specialty chemicals (rather than fuels) production in single-purpose facilities. One benefit of some of these conversion processes is that they produce specific, single-molecule chemicals with relatively high yields, with a few in excess of 1 gram of product per gram of glucose. These chemical building blocks can directly displace conventionally derived petroleum materials,

addressing the Office’s goal to replace the entire suite of products produced from an imported barrel of oil. Examples of value-added chemicals from biomass that have attractive market potential and are technically feasible include—but are not limited to—succinate; 2,5-furan dicarboxylic acid; and glutamate.^{35, 36}

Biochemical Conversion Process Steps

The conceptual block flow diagram in Figure 2-17 outlines the main technologies or unit operations of the biological and chemical feedstock-to-fuel process. There are multiple routes to fuels and chemicals, as shown in the various feedstock pathways in Appendix A. New routes to other advanced biofuels can be analogous to the Office’s published TEA for cellulosic ethanol,³⁷ with the addition of appropriate conversion organisms and modifications to the product upgrading and recovery processes. In addition, industry has recently developed alternative approaches, including non-fermentative routes that chemically or catalytically convert intermediates into fuel and chemical products.^{38, 39, 40, 41}

⁴¹ <http://www.virent.com/news/virent-receives-doe-award-for-jet-fuel-development-2/>.

Figure 2-17 depicts a high-level view of the primary unit operations within the scope of biochemical conversion R&D to create desired biomass-derived products. These products can include finished fuels, fuel precursors, chemicals, or high-quality intermediates, such as sugars. Specific process operating conditions, inputs, and outputs vary within and between each step. These process variations impact key performance outcomes (titer, rate, and yield), which in turn determine economic viability during scale-up of the process. LCAs are also performed and environmental impacts assessed for conversion pathways.

Pretreatment: In pretreatment, feedstocks undergo processes to mechanically and/or chemically fractionate the lignocellulosic complex into soluble and insoluble components. This operation also opens up the physical structure of the plant cell walls to facilitate subsequent enzyme or chemical deconstruction to sugars and other intermediates. Soluble components include mixtures of five- and six-carbon sugars (xylose, arabinose, mannose, galactose, and glucose) and soluble oligomers of sugars. Insoluble components include other sugar oligomers, cellulosic polymers, and lignin (and anything else that may be linked to those insoluble constituents). Because the specific mix of sugars and oligomers released depends on the feedstock and the pretreatment technology employed, pretreatment technologies are selected based upon initial feedstock characteristics (proportions and types of carbohydrates and lignin) and the downstream process requirements. Pretreatment processes also affect lignin properties, including the molecular weight of the recovered lignin.

Conditioning: In some process configurations, the pretreated material goes through a hydrolysate conditioning and/or neutralization process to adjust the pH of the slurry. Conditioning, such as deacetylation to remove acetate groups, can remove undesirable by-products from pretreatment that are toxic to the downstream fermenting organism.⁴² In some cases, conditioning and hydrolysis can be combined into a single process step.

Hydrolysis: In hydrolysis, the pretreated material is further decomposed, releasing glucose—a readily fermentable sugar. This can be done with enzymes, such as cellulases, or by using strong acids. Addition of other enzymes in this step, such as xylanases, may allow for less severe pretreatment conditions, potentially resulting in a reduced overall pretreatment and hydrolysis cost. Depending on the process design, enzymatic hydrolysis requires several hours to several days to complete, after which the mixture of sugars and any unreacted cellulose is transferred to the fermenter. Current processes typically use purchased enzymes or enzymes manufactured on site, based on the economics of the specific process. Some processes combine the hydrolysis and conversion steps (i.e., simultaneous saccharification and fermentation). On the forefront of technology development are processes that consolidate hydrolysis, saccharification, and conversion in the same reactor. Consolidated bioprocessing has started to show some promise.⁴³ In other technologies, such as those using strong acids for hydrolysis, acid recovery is important for viable economics and to reduce downstream wastewater treatment.

⁴³ http://www1.eere.energy.gov/bioenergy/pdfs/ibr_demonstration_mascoma.pdf.

Conversion: Intermediates are transformed into fuels and chemicals through either biological or chemical conversion processes.

Biological Conversion: Currently, the most common approach uses an inoculum of an organism added to feedstock hydrolysates. In this approach, sugars are converted at the same time the remaining cellulose is being hydrolyzed to glucose. After a few days of continued saccharification and conversion, nearly all of the sugars are converted to biofuels, precursors to hydrocarbons, or other chemicals of interest. The resulting aqueous mixture or two-phase broth is sent to product recovery.

Chemical Conversion: Chemical or chemical catalytic conversion can be used in place of, or in addition to, biological organisms to convert the intermediates to a desired end product. A variety of catalysts and reaction conditions can be employed to target different fuels and chemicals. Research is aimed at identifying optimal process conditions with respect to process efficiency, feedstock utilization, cost, sustainability, and finished product characteristics.

Product Upgrading and Recovery: Product recovery and upgrading varies based on the type of conversion used and the type of product generated, but generally involves any of a number of biological and chemical transformations, distillation, or other separation and recovery methods. This may include some clean-up processes to separate the product from the water and residual solids. Residual solids are composed primarily of lignin and ash, which can be burned for combined heat and power generation (a low-value product), chemically converted to intermediate chemicals, or converted to synthesis gas or bio-oil intermediates for fuels and chemicals.

Biochemical Conversion Interfaces

Feedstock Logistics Interface: A feedstock supply chain will need to be capable of providing preprocessed feedstock materials that meet the chemical and physical input requirements (e.g., composition, particle size, handling characteristics, rheology, density chemical characteristics, etc.) established by a baseline biochemical conversion process configuration. These input requirements are expected to vary, depending on the process configuration, feedstock, and geography. Close coordination with the FSL R&D Technology Area (see Section 2.1) is necessary to ensure that the feedstock and the conversion process are optimized in relation to each other, such that feedstock materials of sufficient quantity and quality are readily available for the lowest overall cost and highest possible conversion efficiency.

Demonstration Interface: Demonstration of biological and chemical processes in facilities of increasing scale can provide information relevant to process integration and commercial plant design. Additionally, challenges encountered during demonstration at all scales can be addressed through R&D performed at bench scale.^{44, 45, 46} The impacts of conversion technologies on

⁴⁴ http://www1.eere.energy.gov/bioenergy/pdfs/ibr_arra_logos.pdf.

⁴⁵ http://www1.eere.energy.gov/bioenergy/pdfs/ibr_arra_myriant.pdf.

⁴⁶ http://www1.eere.energy.gov/bioenergy/pdfs/ibr_arra_ineos.pdf.

wastewater treatment and heat and power integration are especially significant. Research, development, and demonstration (RD&D) accomplishments are incorporated into the design of the pioneer-scale integrated biorefineries, as demonstrated by the success of projects within the Office's Demonstration and Deployment portfolio, including INEOS, Abengoa, and POET. Additionally, biofuels and chemicals leaving a biorefinery must meet all applicable federal, state, and local codes and standards, necessitating feedback along the RD&D pipeline.

Analysis Interface: Conversion technologies are evaluated by TEA and LCA, necessitating interfaces between research, analysis activities, and the cross-cutting Strategic Analysis and Sustainability Technology Areas (Sections 2.4 and 2.5). TEAs and LCAs inform strategic planning on optimal R&D areas and document progress toward achieving the programmatic goals. Data on greenhouse gas emissions, as well as energy and water use, also inform the Office's sustainability analysis activities.

2.2.1.1 Biochemical Conversion Research and Development Support of Office Strategic Goals

The strategic goal of the Biochemical Conversion Technology Area is to *develop commercially viable technologies for converting feedstocks via biological and chemical routes into energy-dense, fungible, liquid transportation fuels and chemicals.*

The R&D portfolio directly addresses and supports development of technologies necessary for producing fuels and chemicals from high-impact feedstocks, including herbaceous, woody, energy crop, and algal feedstocks, as well as from some sorted portions of MSW.

2.2.1.2 Biochemical Conversion Research and Development Support of Office Performance Goals

The overall performance goal of Biochemical Conversion R&D is to reduce the estimated mature technology processing cost⁴⁷ for converting intermediates derived from cellulosic feedstocks to hydrocarbon fuels via biological or chemical pathways:

- By 2017, achieve an nth plant modeled conversion cost of \$3.30/GGE utilizing blended feedstock via a biochemical or chemical conversion pathway. This contributes to a minimum fuel selling price (MFSP) of \$5.10/GGE in 2011 dollars, an interim target on the path to \$3.00/GGE fuels.⁴⁸ The interim target only considers the production cost of the fuel; concurrent production of chemicals may enable an overall MFSP of \$3.00/GGE by 2017.

⁴⁷ Estimated mature technology processing cost means that capital and operating costs are assumed to be for an "nth plant" where several plants have been built and are operating successfully, so additional costs for risk financing, longer startups, under performance, and other costs associated with pioneer plants are not included.

⁴⁸ R. Davis, L. Tao, et al. "Process Design and Economics for the Conversion of Lignocellulosic Biomass to Hydrocarbons: Dilute-Acid and Enzymatic Deconstruction of Biomass to Sugars and Biological Conversion of Sugars to Hydrocarbons." NREL/ TP-5100-60223. (2013). Golden, CO: National Renewable Energy Laboratory. <http://www.nrel.gov/docs/fy14osti/60223.pdf>.

- By 2022, achieve the conversion cost necessary to contribute to the overall Office performance cost goal of \$3/GGE (\$2011).

The current near-term performance milestones for Biochemical Conversion R&D are as follows:

- By 2014, establish out-year cost goals and technical targets for catalytically derived hydrocarbon fuels based on TEA for one technology pathway.
- By 2017, validate the production of a hydrocarbon fuel or fuel blendstock from cellulosic or algal feedstock via at least one biological or chemical route at bench scale to measure progress against an interim modeled conversion cost goal (nth plant, \$2011) of \$3.30/GGE.

Preliminary analyses suggest that achievement of Office cost goals will require economic contributions from coproduct development in addition to technological advancements from R&D for biofuels.

2.2.1.3 Biochemical Conversion Research and Development Challenges and Barriers

The challenges and barriers listed in this section highlight areas in which improvements to processes are crucial to advancing the Office's mission. The aim for all processes is an increase in both carbon and energy efficiency relative to the theoretical maximum. The challenges are categorized into two areas: (1) those that relate to the inherent physical properties of biomass and feedstocks and its use in biological and chemical processes, and (2) those that relate to the processing of feedstock within conversion systems. The challenges addressed in the first area include compositional variability, various physical properties, and recalcitrance to chemical and biological processing. In the second area, challenges in processing technologies such as hydrolysis, saccharification, microbial fermentation, and downstream separations are identified.

Technical Research and Development Challenges and Barriers Inherent to Feedstocks Utilization

Bt-A. Biomass and Feedstock Variability: Feedstock variability can affect overall conversion process performance, including conversion rate and product yield, which directly impacts process economics, environmental factors, and—ultimately—the viability of the process. The characteristics of biomass can vary widely in terms of physical parameters (e.g., size, shape, bulk density, surface area, pore volume, etc.) and chemical composition (e.g., moisture, ash, carbohydrate, lignin, etc.), even within a single species. This variability can make it difficult (or costly) to reliably supply biorefineries with formatted feedstocks of consistent, acceptable quality year-round and maintain adequate process control.

Bt-B. Biomass and Feedstock Recalcitrance: The fundamental role that cell wall architecture and composition play in determining its resistance to decomposition is not well-understood. Lignocellulosic feedstocks are naturally resistant to chemical and/or biological degradation. This knowledge gap highlights the efforts needed to improve the cost effectiveness and efficiency of pretreatment and other fractionation and conversion processes.

Technical Research and Development Challenges and Barriers to Processing Feedstocks

Bt-C. Reactor Feed Introduction: Several variables impact the behavior of materials while being fed into a conversion process, including feedstock type (and feedstock blend), format, particle size, shape, and size distribution, as well as conversion reactor design and process conditions. Several new feedstocks will be examined for use in the suite of conversion technologies being developed. These feedstocks may vary significantly from those historically used in biochemical conversion systems. This variability may make reactor infeeding a significant challenge and can impact conversion performance. The performance of feedstock blends and formats needs to be evaluated to reduce technical risks to commercial scale-up.

Bt-D. Pretreatment Processing and Selectivity: Chemical, mechanical, and/or thermal pretreatments can be employed to alter the structure of biomass to increase the efficiency of subsequent cell wall carbohydrate polymer hydrolysis or to carbohydrate intermediates. The resulting lignin and degradation products can inhibit the downstream processing steps following pretreatment; therefore, optimal process parameters need to be developed to maximize production of the desired intermediates while minimizing production of inhibitors or removing them altogether.

Bt-E. Pretreatment Reactor Design and Optimization: Pretreatment reactors typically require expensive construction materials to resist acid or alkali attack at elevated temperatures and pressures. In addition, the impact of reactor configuration and reactor design on chemical cellulose prehydrolysis is not well-understood. Developing lower-cost pretreatment depends on the ability to process the feedstock in reactors fabricated from cost-effective materials that are designed for maximum solids content and compatibility with process conditions.

Bt-F. Hydrolytic Enzyme Production: Hydrolytic enzymes remain a significant portion of the projected production cost of converting sugars from cellulosic feedstocks. Significant progress has been made through targeted public and private R&D efforts; however, the cost and efficiency of enzyme production continues to impact the economics of an integrated process. Unique proteins that target deconstruction of residual substrates need to be identified in order to augment process yields, and the production strains for these enzymes need to be optimized for commercial production. This includes R&D activities to increase efficiency and reduce the cost of other deconstruction enzymes, such as lignin-modifying enzymes.

Bt-G. Enzyme Efficiency: Reducing the cost of enzymatic hydrolysis depends on identifying more efficient enzyme preparations and hydrolysis parameters that enable cost-effective release of sugars, intermediates, or lignin. The target is to reduce the ratio of enzyme protein mass required to solubilize the substrate (i.e., increased specific activity). In addition, commercially available enzymes are not sufficiently thermostable and also suffer from substantial end-product inhibition. Developing enzymes that enable low-cost enzymatic hydrolysis technology requires a better understanding of the fundamental mechanisms underlying the biochemistry of enzymatic hydrolysis, including the impact of feedstock architecture on the ability of enzymes to decrystallize cellulose during hydrolysis. Additional efforts aimed at understanding both the interaction of enzymes with substrates and the optimal molecular-level hydrolysis environment

are needed to achieve the targeted specific activity improvements that can further reduce enzyme cost.

Bt-H. Cleanup/Separation: Solutions produced during pretreatment and hydrolysis contain a mixture of sugars and non-sugar components. Potential impurities include acetic acid released during hemicellulose hydrolysis, lignin-derived phenolics solubilized during pretreatment, inorganic acids or alkalis, other compounds introduced during pretreatment, various salts, and hexose and pentose sugar degradation or transglycosylation products. The presence of some impurities can inhibit the function of downstream biological and chemical catalysts. Low-cost purification technologies need to be developed that can remove impurities from hydrolysates and provide concentrated, clean feedstocks to manufacture biofuels and biobased chemicals.

Bt-I. Catalyst Efficiency: There is a need for efficient biological and inorganic catalysts that can transform the carbohydrate mixture and other hydrolysate components into advanced biofuels, chemicals, and fuel intermediates. Significantly lower capital and operating costs may be achieved through improvement in the productivity, efficiency, selectivity, regeneration time and lifetime, and robustness of catalysts (bacterial, fungal, algal, or inorganic) and their ability to utilize hydrolysate or synthesis gas. Developing lower-cost catalysts depends on the ability to efficiently convert and upgrade intermediates in reactors fabricated from cost-effective materials that are optimized to process conditions.

Bt-J. Biochemical Conversion Process Integration: Process integration remains a key technical barrier hindering development and deployment of biochemical and chemical conversion technologies. These conversion technologies currently present large scale-up risks given the lack of high-quality performance data on integrated processes carried out at the high solids conditions required for commercially viable industrial operations. The effect of feed and process variations throughout the process must be understood to ensure efficient operations and profitability. Process integration work is essential for characterizing the complex interactions that exist between many of the processing steps, including identifying unrecognized separation requirements, optimizing reactor design, minimizing waste streams, addressing bottlenecks and knowledge gaps, and generating integrated performance data. This integrated performance data is necessary to develop predictive mathematical models that can guide process optimization and scale-up. Wastewater and heat and power generation impacts upon integrated processes need to be identified and addressed through R&D. Simply, characterizing the various integration issues for biochemical processing will lower risks in successfully building and operating pilot- and demonstration-type facilities.

Bt-K. Product Acceptability and Performance: Biofuels leaving a biorefinery must meet all applicable federal, state, and local codes and standards. As the Office broadens its Biochemical Conversion R&D portfolio from ethanol to include infrastructure-compatible hydrocarbons, close coordination with the Demonstration and Deployment Technology Area and traditional petroleum refiners will be essential to ensure that desired product quality characteristics are met. Additionally, these same considerations would need to be made for any bio-intermediates entering conventional petroleum refineries. Lastly, chemicals produced via biological or chemical upgrading processes must meet various technical performance criteria and end-use

specifications, all of which should be considered during the R&D phase to help direct the research and measure project progress.

2.2.1.4 Biochemical Conversion Research and Development Approach for Overcoming Challenges and Barriers

The approach for overcoming conversion technical challenges and barriers is outlined in the WBS depicted in Figure 2-18.

The Office's current Biochemical Conversion activities generally fall into seven broad groupings:

- *Analysis and Sustainability:* To understand the impact of biochemical and chemical conversion technologies with respect to environmental and economic metrics
- *Feedstock Interface Activities:* To understand the impact of feedstock quality conversion performance characteristics
- *Deconstruction Processes:* To overcome biomass and feedstock recalcitrance
- *Upgrading Processes:* To convert deconstructed feedstocks to fuels, intermediates, and chemicals
- *Integration and Intensification:* To optimize for systems-level performance
- *Conversion Enabling Technologies:* To apply new knowledge and tools to innovate beyond current conversion technologies
- *Validation:* To demonstrate improvements in technologies, sustainability, and economics in an increasingly integrated process setting.

Technical challenges in each of these areas are identified from technology roadmapping, TEAs, stakeholder meetings, industry lessons learned from demonstration and deployment activities, and through active project management of historical and existing projects. Research addressing key technical challenges is performed by national laboratories, industry, universities, and multi-disciplinary consortia. The relevance, impact, and progress of the R&D portfolio toward industrial and commercial applications are ensured via project stage-gate and biennial portfolio reviews with a panel of external experts, partnering with industry as appropriate, and disseminating the results.

The R&D approach of each group of activities is described below, while Table 2-6 summarizes each activity element's work as it relates to specific challenges and technology pathways.

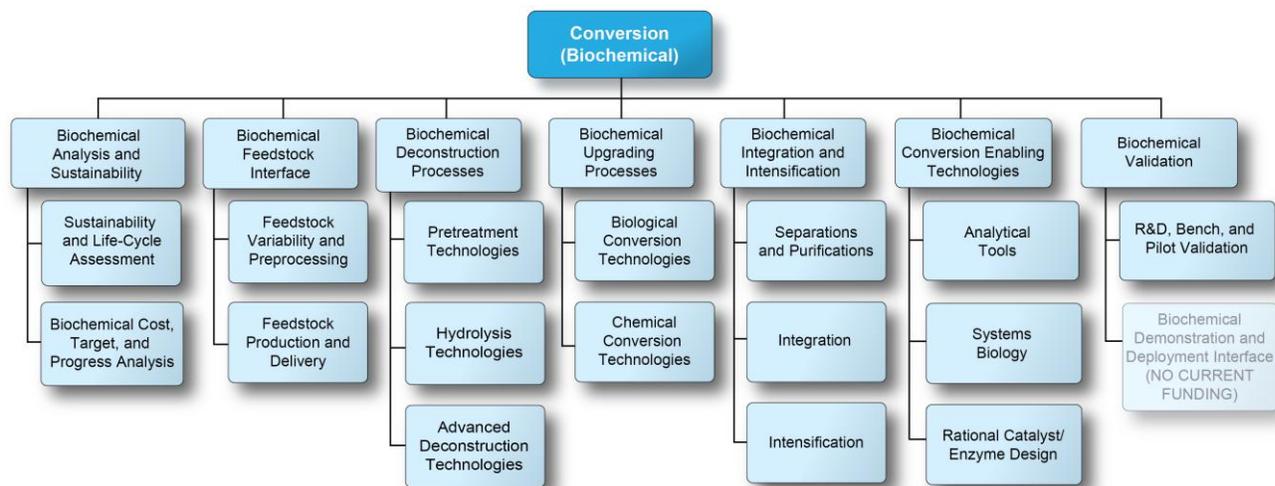

Figure 2-18: Biochemical conversion R&D work breakdown structure

Analysis and Sustainability

Analysis and sustainability activities play a critical role in understanding the feasibility, sustainability, and scalability of new conversion routes to hydrocarbon fuels and biobased chemicals. The process simulation, environmental sustainability assessments, and life-cycle models that are developed through these activities can be used in establishing baselines, developing performance targets, monitoring the progress of the research portfolio, as well as in understanding the tradeoffs among technology options within a systems context. The modeling outputs, including—but not limited to—process TEAs, SOTs, and LCAs will help to continually inform decisions concerning priority conversion pathways and opportunities to accelerate a unit operation, as well as identify additional R&D for efficient and environmentally benign conversion processes. Examples of environmental sustainability metrics include life-cycle greenhouse gas emissions, fossil energy consumption, consumptive water use, wastewater generation, air pollutants, biomass carbon-to-fuel efficiency, renewable energy production, value of additional products, and total fuel yield.

Feedstock Interface

Biochemical and feedstock interface activities include the R&D necessary to determine a desirable specification range for feedstocks intended for biochemical conversion processes. Additionally, this area includes the tasks necessary to produce the required volumes of feedstock at the optimal format and material specifications to support R&D and other scale-up activities. Linking feedstock harvest, collection, and transport processes with conversion processes allows for the evaluation of technology options and tradeoffs on both sides of the processing interface, ensuring a fully integrated supply chain from stump or field to fuel. Additionally, the Office is investigating the development of preprocessing options (e.g., densification, blending, and physical formats such as pellets, shredded material, and slurries) and simultaneously assessing the impact on conversion efficiency when such preprocessed feedstocks are introduced into a process.

Deconstruction Processes

Overcoming biomass and feedstock recalcitrance is a key challenge in deconstructing feedstock into sugars or other soluble carbon intermediates for subsequent fuel or biobased chemicals synthesis. The pretreatment subactivity focuses on developing cost-effective pretreatment options that consider reaction chemistry and reactor design associated with deconstructing or partially deconstructing feedstocks into intermediate compounds. The pretreated material is then exposed to chemicals or microbial enzymes during the hydrolysis step in which the carbohydrate polymers are hydrolyzed to largely monomeric glucose and xylose molecules. Advanced deconstruction processes or technologies that seek to combine or bypass the pretreatment and saccharification steps are also being developed and optimized. Deconstruction technologies that enhance the value of lignin are also sought.

Biochemical Upgrading

Soluble sugars and other carbon intermediates are upgraded to hydrocarbons, fuel precursors, and biobased chemicals using biological and/or non-biological conversion technologies. Upgrading technologies, whether biological or chemical, must produce fuels, fuel precursors, or chemicals that maximize the available carbon from the feedstock. Within the biological upgrading subactivity, the primary objective is identification of robust microorganisms capable of converting complex intermediates to desired target molecules in the presence of inhibitors at high rates, titers, and yields. Within the chemical upgrading subactivity, the primary objectives are development of specific and durable inorganic catalysts with appropriate selectivity, improved regenerability, catalyst supports, and optimization of process conditions to improve rates and yields.

Integration and Intensification

Investigating pretreatment and hydrolysis technologies together with downstream upgrading can help identify the interfacial issues and opportunities for integration. These could include separations, integration of individual unit operations into a process, and advanced process intensification efforts, such as consolidated processing and similar strategies. By starting to integrate the biofuels production steps in Process Demonstration Units and other user or pilot facilities, the overall process efficiency and costs can be improved in a systems context, which is a necessary precursor for scale-up activities. In addition, the effect of feed and process variations throughout the process must be understood to ensure robust, efficient biorefineries that produce fuels and chemicals on a consistently cost-effective basis. Lessons learned from these activities will be shared with the biochemical conversion-related integrated biorefineries to promote technology transfer and, vice-versa, to identify remaining R&D challenges.

Conversion Enabling Technologies

Efficient and highly productive biological and non-biological catalysts for biofuel production are necessary. Optimization of hydrolytic enzymes or a platform microorganism requires a fundamental understanding of the biological processes governing culture and host selection, gene expression, protein folding, modification, secretion, metabolic flux, and the metabolite transport. In addition, a fundamental understanding of the factors and causes underlying biomass

recalcitrance to biochemical degradation is needed to enable more specific feedstock processing at a lower cost. The development of tools such as molecular modeling and cell wall microscopy will enable a more complete understanding of biomass structure and the most appropriate methods to deconstruct cell walls into components.⁴⁹ Other approaches, such as systems and synthetic biology, will be examined for their ability to make potential transformational changes in conversion technology efficiency and costs. For chemical and inorganic catalyst development, catalyst inactivation and support structures need to be understood on a mechanistic level to enable rational designs that enhance catalyst productivity and specificity. The further development and implementation of new technologies, like kinetic and multi-scale modeling, that can be validated with authentic feedstocks advance the state-of-the-art technology and will also be sought to enable conversion-enhancing parameters that positively impact yields, efficiencies, and costs.

Validation

The ultimate verification that ongoing R&D activities have progressed and achieved desired outcomes is demonstration of biochemical conversion technology routes that enable price-competitive production of finished fuels or bio-intermediates for refineries, as compared to petroleum-based counterparts. Integration and scale-up efforts at the bench and pilot scale generate data that is used to assess progress against technical performance and environmental metrics, as well as cost targets. This operational data is also used to inform analysis and sustainability efforts to model nth plant costs and technical projections for each biochemical conversion pathway. The Office leverages industry and demonstration partner feedback to understand emerging issues and R&D opportunities.

2.2.1.5 Prioritizing Biochemical Conversion Research and Development Barriers

In order to achieve the Biochemical Conversion R&D goals, all of the challenges and barriers identified need to be addressed. However, the following issues are considered critical and will be emphasized within near- to mid-term Biochemical Conversion R&D efforts:

- Develop innovative biomass deconstruction approaches to lower the cost of intermediates
- Enable high-performance separations technologies to increase product yields and decrease cost
- Develop a broader range of biochemical conversion technologies to hydrocarbon fuels and chemicals.

The progress and future direction of the Office's R&D is monitored and evaluated to determine the annual R&D priorities necessary to overcome technical barriers identified in Section 2.2.1.3. These technology assessments help prioritize which biochemical conversion pathways could support the Conversion R&D 2022 \$3/GGE cost goal. From now through 2022, R&D activities will focus on developing and validating additional feedstock and conversion processes that can meet a \$3/GGE cost goal in order to maximize biofuels production in conjunction with value-adding chemicals.

To identify new approaches and technology routes, additional TEAs are being conducted to reflect the progress and potential impact of the Office's diverse R&D portfolio. Two TEAs (one existing and one in development) have been selected as the biochemical conversion design cases, representing a model process for each of the biological and catalytic pathways described. Additional TEAs can provide an understanding of other conversion pathways that produce hydrocarbon fuels, and when factored in with other criteria such as environmental performance, will help the program reprioritize and allow for the development of additional design cases for new, innovative conversion pathways. Periodic evaluations of the SOT also serve as "on ramps" and "off ramps" for conversion pathways or technologies that may or may not meet Office goals. Additionally, qualitative public input through stakeholder workshops (such as the Conversion Technologies for Advanced Biofuels Workshop held in December 2011) and the biennial Peer Reviews informs research priorities.

The design case model for biological production of diesel blendstocks details a model process that includes unit operations such as pretreatment, enzymatic hydrolysis, solid/liquid separations, and aerobic fermentation (biological conversion), followed by hydroprocessing. This design case and subsequent design report shows one potential path, based on current knowledge, to a \$3/GGE cost goal for biofuels with an interim cost goal of \$5/GGE in 2017. The cost projections associated with the technical improvement targets to meet this intermediate 2017 biochemical milestone are illustrated in Figure 2-19. Note that the achievement of the \$3/GGE cost goal for biofuels will likely require incorporating the co-production of a biobased chemical with higher value than fuel.

Certain routes to co-produced biobased chemicals are expected to be more complementary to select conversion processes than others on the basis of theoretical yields or production volumes, which can be a driving factor for biorefinery product slate selection. Another driving factor is environmental sustainability. Biobased competitors are expected to provide environmental

advantages to the conventional production methods for some chemicals currently produced by the petrochemical refining processes while providing similar performance and cost. As technology advances and processes mature, we expect to be able to better define a path to the \$3/GGE Office performance goal.

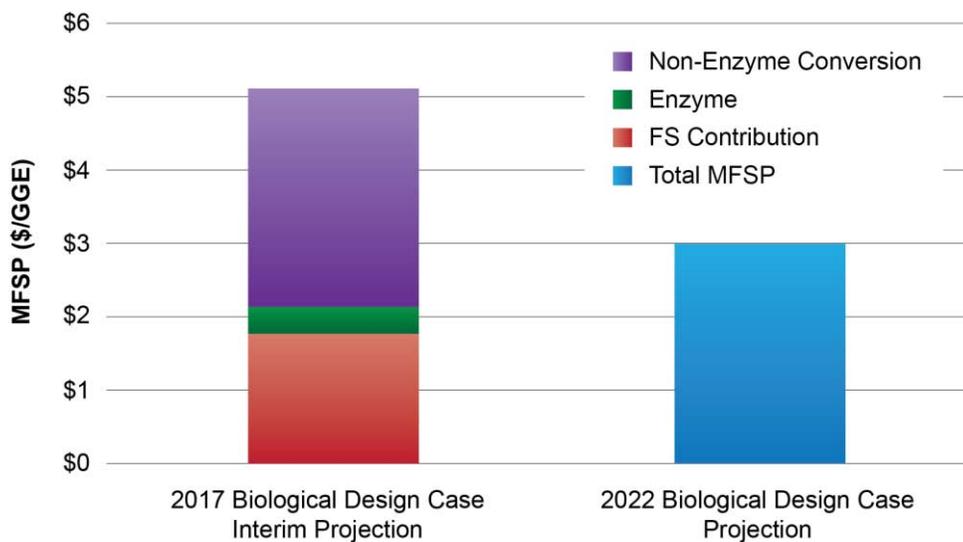

Figure 2-19: Biochemical conversion R&D barrier areas and example metrics

In addition to setting technical targets and cost projections, the Office is assessing the environmental performance of conversion pathways to enable continual evaluation and improvement of the designs throughout the technology R&D phase. The following environmental sustainability indicators are currently being assessed:

- Greenhouse gas emissions
- Fossil energy consumption
- Fuel yield
- Biomass carbon-to-fuel efficiency
- Consumptive water use
- Wastewater generation.

This set of environmental sustainability metrics will be expanded and updated as more experimental data become available. Work is currently in progress to quantify additional metrics, such as criteria air pollutants. The refined analysis will enable the Office to establish targets for environmental sustainability metrics to guide their improvement alongside the techno-economic performance. See Appendix C for more information on the Office’s approach to establishing environmental sustainability targets.

While the Energy Independence and Security Act of 2007 requires EPA to conduct its own greenhouse gas assessments to determine fuel qualification, it is essential that LCA be performed during the development of these pathways in order to predict and facilitate improvement of environmental performance. This will better enable conversion technologies to meet legislated

goals, such as greenhouse gas reductions required by the Renewable Fuel Standard, and achieve other social and environmental benefits.

2.2.1.6 Biochemical Conversion Research and Development Milestones and Decision Points

The high-level Biochemical Conversion R&D strategy program decision-making process, including milestones and decision points, is summarized in Figure 2-20.

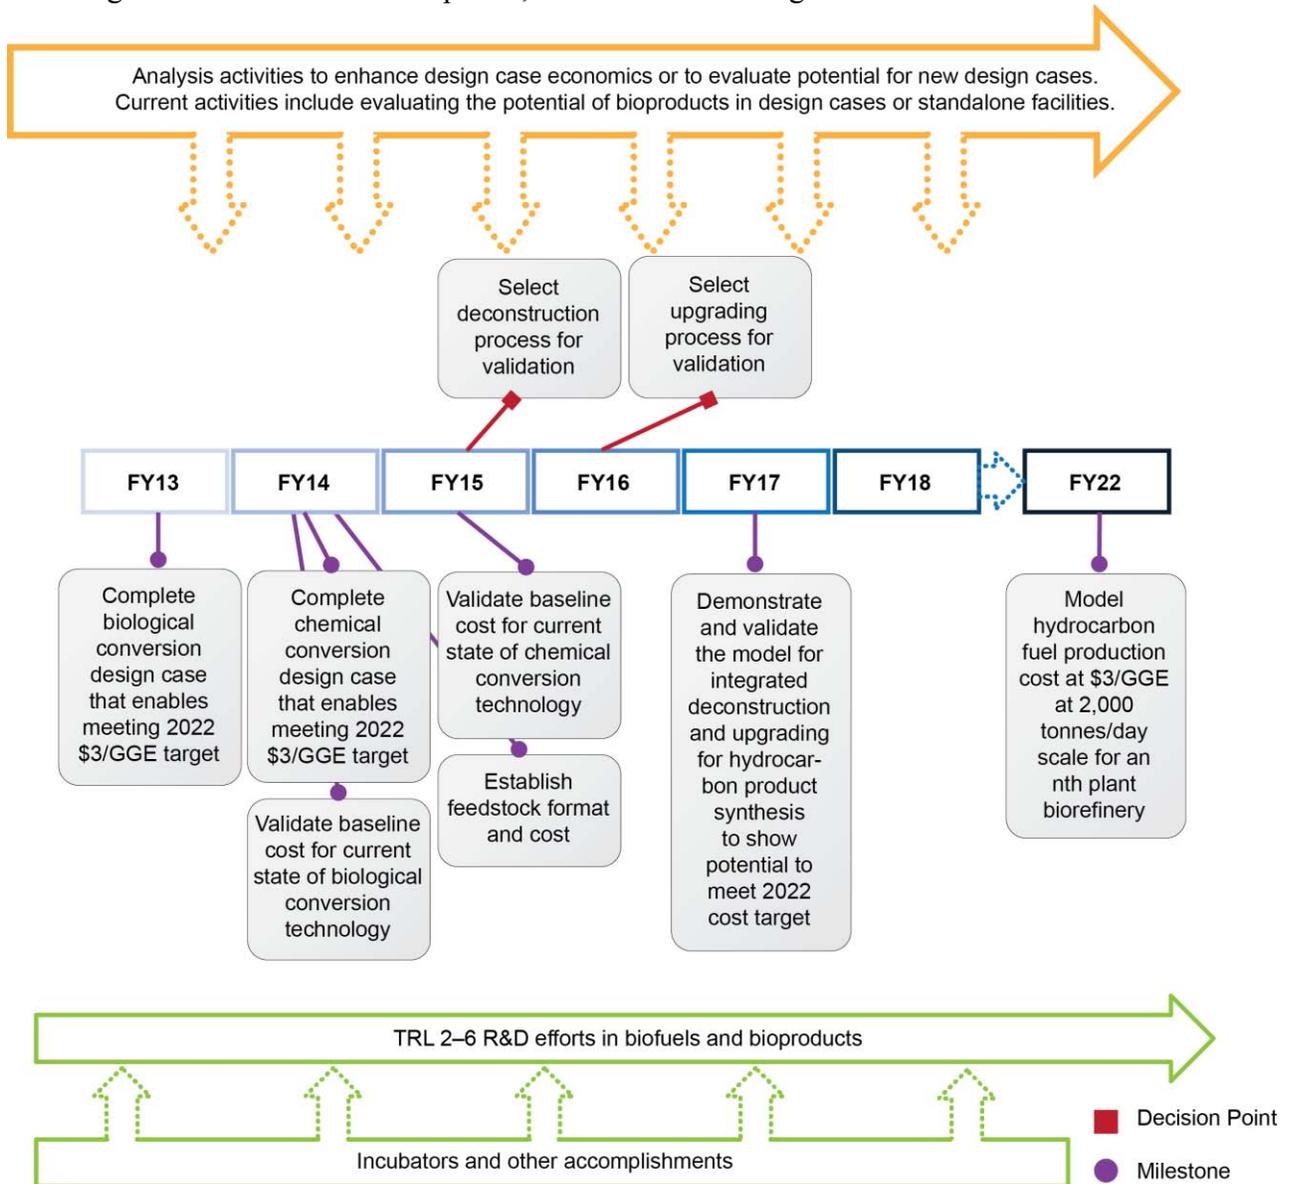

Figure 2-20: Biochemical conversion R&D key milestones and decision points

2.2.2 Thermochemical Conversion Research and Development

Thermochemical Conversion R&D focuses on developing technology that converts biomass first to a liquid, vapor, or gaseous intermediate and then to a fuel or other product. Pathways such as fast pyrolysis, catalytic fast pyrolysis (i.e., *ex situ* vapor phase upgrading or *in situ* vapor phase upgrading), hydrothermal liquefaction (HTL), solvent liquefaction, or hydropyrolysis yield a liquid or vapor intermediate known as a bio-oil. Gasification pathways produce a gaseous intermediate that primarily consists of carbon monoxide, carbon dioxide, and hydrogen. Bio-oils and gaseous intermediates can be further converted to finished fuels—such as gasoline, diesel, and jet fuels—or to other products, including home heating oil, waxes, liquid smoke, etc.

In general, pyrolysis processes convert biomass to condensable vapors, non-condensable gases, char, and coke in the absence of oxygen at elevated temperatures. Depending on the process conditions (such as the temperature, catalyst, and presence of a reductant), one or two liquid phases are formed upon quenching the condensable vapors. For example, a fast pyrolysis process results in a single-phase bio-oil with high water content, whereas a hydropyrolysis process results in a bio-oil phase and an aqueous phase. The bio-oil phase is upgraded through separations, hydroprocessing, and fractionation steps to produce petroleum refinery intermediate feedstock or finished fuels. The off-gases from the pyrolysis and upgrading steps may be used to generate process heat and power and to produce hydrogen for use in upgrading of the bio-oils. The aqueous phase may contain organic acids, aldehydes, ketones, and phenols, which also can be used to produce additional fuel precursors, hydrogen, or other products. The non-condensable gases are often recycled and used as fluidizing gas in the pyrolysis reactor. Char and coke can be used to produce process heat and power.

Other thermochemical conversion processes—such as solvent liquefaction (including HTL, a specific case where the solvent is water)—can convert high-moisture feedstocks to liquid bio-oils, char, and gases. These solvent liquefaction technologies are typically performed at higher pressures and lower temperatures than pyrolysis. Hydrothermal and solvent liquefaction technologies are well-suited for wet feedstocks such as algae because, unlike pyrolysis and gasification, they can tolerate high levels of moisture in the feedstock. As such, HTL R&D is an area of interface tasks between Thermochemical Conversion R&D and Algal Feedstocks R&D.

In contrast to conversion pathways that form a bio-oil intermediate, gasification processes form a gaseous intermediate, which could include synthesis gas (syngas) or synthetic natural gas. Syngas is composed primarily of hydrogen, carbon monoxide, and some carbon dioxide, and can be generated via gasification of biomass. Synthetic natural gas is composed primarily of methane and is generated by processes such as catalytic hydrothermal gasification or anaerobic digestion. Synthetic natural gas may also be obtained from landfill gas. Each of these gaseous intermediates may be further converted to fuels, chemicals, or other liquid intermediates via biological and/or catalytic processes.

Thermochemical Conversion Process Steps

The conceptual block flow diagram in Figure 2-21 outlines the main technologies or unit operations of thermochemical biomass-to-fuel processes for converting biomass to gasoline, diesel, and jet fuel.

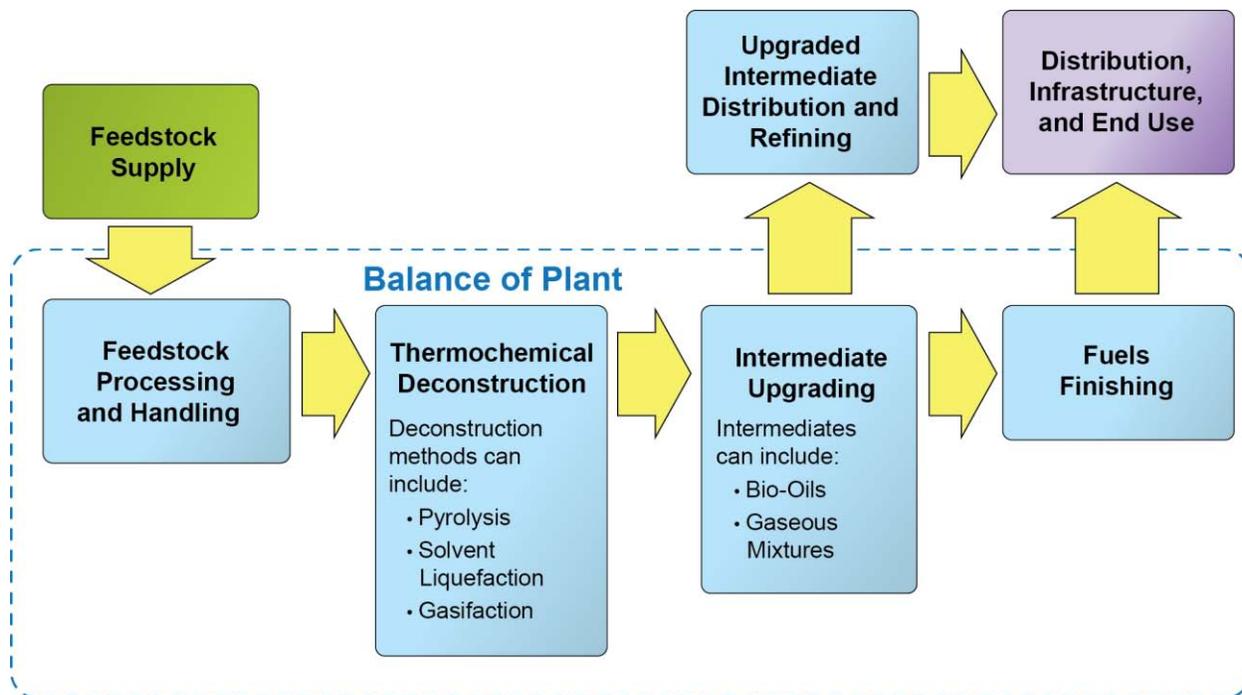

Figure 2-21: Thermochemical conversion process steps for biomass to biofuels

Feedstock Preprocessing and Handling: Feedstock preprocessing and handling includes preprocessing and formulating biomass to control particle size, porosity, and elemental composition. Feedstock characteristics are controlled, for example, through operations such as feedstock grinding, sizing, blending, densification, leaching, and/or torrefaction. Decisions about cost, quality, volume, and energy tradeoffs must be made between feedstock preprocessing and blending in the feedstock supply system versus within the conversion process. Most gasification and pyrolysis processes require further biomass drying, while solvent liquefaction approaches can use high-moisture biomass, such as whole, wet algae.

Thermochemical Deconstruction Processes: Thermochemical deconstruction of biomass involves heating biomass to achieve rapid thermal decomposition of a lignocellulosic feedstock. Process variables such as temperature, pressure, residence time, and the amount of oxygen in the reactor will determine if the intermediate formed is solid, liquid, or gas. These deconstruction processes are generally categorized as direct or indirect liquefaction.

Deconstruction to Form Bio-Oil Intermediates: In general, pyrolysis is the thermal and chemical decomposition of biomass without the introduction of oxygen to produce a bio-oil intermediate. Fast pyrolysis is typically performed at 375°C–550°C and atmospheric pressure and produces either a single- or two-phase liquid product (a bio-oil phase and an aqueous phase), along with gases and char. Generally, lower-temperature processes

(375°C–450°C) form a single-phase liquid product, whereas higher-temperature processes, particularly when in the presence of reductants and/or catalysts, produce a biphasic product. Catalytic fast pyrolysis and hydrolysis employ a catalyst during a vapor phase upgrading step to produce a biphasic product and a bio-oil phase with lower oxygen content than conventional fast pyrolysis. Other direct liquefaction technologies, such as hydrothermal or solvent liquefaction, can be used to deconstruct high-moisture feedstock directly to bio-oils, typically at higher pressures and lower temperatures than pyrolysis (250°C–350°C and 5–25 megapascal). Each of these deconstruction technology produces bio-oil with unique characteristics—including oxygen content, water content, carbon yield, and viscosity—that depend on the processing conditions and reactor type.

Deconstruction to Form a Gaseous Intermediate: Crude gaseous intermediates are produced by thermally deconstructing biomass (e.g., indirect liquefaction such as gasification or catalytic gasification), followed by gas cleanup and conditioning. Unlike pyrolysis processes, where no oxygen is introduced to the reactor, gasification processes require the addition of an oxygen carrier. For example, biomass gasification is a high-temperature conversion process that begins with the rapid thermal decomposition of a lignocellulosic feedstock. This is followed by partial oxidation or reforming of the resulting compounds with a gasifying agent or oxygen carrier—usually air, oxygen, or steam—to yield a gaseous intermediate (crude syngas). This all occurs in the same reactor within seconds. The crude gas composition and quality are dependent on a range of factors, including feedstock composition, type of gasification reactor, gasification agents, stoichiometry, temperature, pressure, residence time, and the presence or lack of endogenous or added catalysts.

Intermediate Upgrading: Thermochemical intermediates include crude bio-oils and gaseous intermediates.

Bio-Oil Intermediate Stabilization and Upgrading: Bio-oil stabilization and upgrading involves mitigating the effects of reactive compounds to improve storage and handling properties. This may encompass hydroprocessing, separation, and/or fractionation steps to remove water, coke, catalyst, char, and ash particulates, or other destabilizing components, such as metals and oxygenated species, from bio-oil. Hydrodeoxygenation (HDO) saturates unsaturated hydrocarbons and reduces the total oxygen and acid content, thereby increasing stability. Crude bio-oil must undergo one or more of these stabilization and upgrading steps before it can be processed to finished fuel specifications and fractionated into fuel cuts in either an existing petroleum refinery under conventional hydroprocessing conditions (e.g., high temperature and pressure) or in a standalone biorefinery.

Syngas Cleanup and Gaseous Intermediate Upgrading: Syngas cleanup is the removal of contaminants from crude biomass-derived synthesis gas. It involves an integrated multi-step approach that varies depending on the intended end use of the product gas. Gas cleanup normally entails removing or reforming tars and acid gas, ammonia scrubbing, capturing alkali metal, and removing particulates, followed by conditioning. Typical gas conditioning steps include sulfur polishing to reduce levels of hydrogen sulfide to

acceptable amounts for fuel or product synthesis catalysts, and may require water-gas shift to adjust the final hydrogen-carbon monoxide ratio for optimized fuel or product synthesis. The required degree of gas cleanup and conditioning depends on the method used to convert the gas in subsequent process steps to a fuel.

Gaseous intermediate upgrading is the conversion of clean gaseous intermediates to fuels or mixed oxygenates via biological organisms (e.g., syngas fermentation) or catalytic processes (e.g., Fischer-Tropsch synthesis). The production of fungible liquid transportation fuels from these intermediates also yields high-value biobased products and chemicals. Because catalytic fuel synthesis is typically exothermic, heat recovery and temperature control are essential to maximize the process efficiency and catalyst life.

Fuel Processing: Fuel processing includes additional hydroprocessing needed to remove oxygen and other impurities to produce distillate range hydrocarbons that meet finished fuel specifications for gasoline, diesel, or jet fuel. Hydrocracking and separations (i.e., distillation) are also necessary to produce these various fuel cuts.

Balance of Plant: Balance of plant encompasses the process units and site operations that support the main biomass-to-fuel conversion steps. These operations may include hydrogen generation, emissions abatement, wastewater treatment, heat and power generation, and solid waste disposal, and some of these may represent a significant cost contribution to the final fuel cost. Cost reductions may be achieved through more efficient hydrogen and carbon usage (such as minimizing organics in the aqueous phase or char production), as well as improvements in process heat recovery, emission reductions, wastewater treatment, and process recycle streams.

Thermochemical Conversion Research and Development Interfaces

Analysis Interface: Conversion technologies are evaluated by TEA and LCA, necessitating interfaces between research analysis activities and the cross-cutting Strategic Analysis and Sustainability Technology Areas (see Sections 2.4 and 2.5). TEAs and LCAs performed within Thermochemical Conversion R&D inform strategic planning and document progress toward achieving the programmatic goals. Data on emission and energy and water use also inform the Office's sustainability analysis activities.

Terrestrial and Algal Feedstock Supply and Logistics Interface: The Feedstock Supply and Logistics R&D and Algal Feedstocks R&D Technology Areas develop feedstock preprocessing technologies that reduce inherent biomass variability to deliver feedstock that meets the specifications (composition, size, surface area, moisture content, inorganic content, etc.) of thermochemical conversion processes. This includes evaluating the impact on process efficiency and fuel production cost of using mechanically and/or chemically treated feedstock. Close coordination with the Feedstock Supply and Logistics Technology Areas (see Section 2.1) and Algal Feedstocks R&D (see Section 2.1.2) is required to (1) understand the tradeoffs between feedstock cost, quantity, and quality to meet the conversion specification requirements of the biorefinery; and (2) identify positive synergies to improve efficiencies and production costs.

Intermediate Distribution and Refining: Of the possible intermediates produced from thermochemical conversion, bio-oil intermediates present an opportunity to explore a variety of distribution and refining schemes. Three general distribution strategies are being explored. The first strategy involves fully upgrading to finished fuel specifications for gasoline, diesel, or jet fuel within an integrated biorefinery. The second strategy involves intermediate stabilization, which occurs at several distributed locations, and then stabilized intermediates are transported to a centralized upgrading biorefinery for fuel finishing to gasoline, diesel, and jet fuel specifications (commonly referred to as the “hub and spoke” model). The third strategy involves production of stable, upgraded intermediates that are suitable for use in a petroleum refinery, thus leveraging existing infrastructure for fuel finishing. Information regarding the physiochemical properties, reactivities, and compatibilities of intermediates for fuel finishing are required to successfully implement any of these strategies.

Biofuels Distribution Infrastructure Interface: The next step in the supply chain is the distribution of the gasoline, diesel, or jet fuels for blending. In order for blending stations or refineries to accept them, biofuels have to meet regulated fuel specifications. Being officially certified by EPA for Renewable Identification Number credits also enhances the marketability of the fuel or intermediate. Biofuels properties, such as cetane and octane, as well as flash points, smoke points, cloud or pour points, and distillation curves, must be verified against established gasoline, diesel, and jet fuel specifications. Understanding the miscibility and other behavior of biofuels when blended with petroleum-derived fuels and fuel-handling systems/engines is particularly critical.

Demonstration and Deployment Interface: Demonstration of thermochemical processes in biorefineries can provide information relevant to scale-up and process integration. The information gained through validation at pilot, demonstration, and pioneer scales can be applied to processes being developed at smaller scales, especially impacts of conversion technologies on wastewater and heat and power integration. This information can identify R&D necessary to mitigate negative impacts and opportunities. Additionally, challenges encountered during demonstration can be addressed through R&D performed at bench and larger scale.

2.2.2.1 Thermochemical Conversion Research and Development Support of Office Strategic Goals

The strategic goal of Thermochemical Conversion R&D is to *develop commercially viable technologies for converting biomass into energy-dense, fungible, finished liquid fuels, such as renewable gasoline, jet, and diesel, as well as biochemicals and biopower.*

Activities in this area directly address and support the production of gasoline, diesel, and jet fuels from on-specification feedstock that may be comprised of algae; woody biomass; energy crops; agricultural residues; sorted, dry MSW (i.e., yard and construction waste); and other biomass. These conversion technologies also indirectly support the production of biochemicals and biopower.

2.2.2.2 Thermochemical Conversion Research and Development Support of Office Performance Goals

The overall performance goal of Thermochemical Conversion R&D is to reduce the projected mature technology processing costs for converting algae or lignocellulosic biomass to hydrocarbon fuels via a thermochemical pathway. A variety of thermochemical pathways via bio-oil intermediates or gaseous intermediates are being explored in the R&D portfolio, and they will continue to be assessed and reprioritized to achieve the Office's \$3/GGE performance goal in 2017, 2022, and 2030. There are and will be several design cases with cost targets and technical goals that outline how the Office might achieve this performance goal through RD&D over the near, mid, and long term. One specific example of a near-term thermochemical pathway is the Fast Pyrolysis and Hydrotreating Bio-Oil Pathway.⁵⁰ This analysis established the following thermochemical conversion cost target:

- By 2017, achieve an nth plant modeled conversion cost of \$2.50/GGE via a thermochemical pathway. This contributes to a minimum gasoline and diesel blendstock fuel selling price of \$3.50/GGE in 2011 dollars.

A benchmark case of this goal is illustrated in the 2013 design report (Jones et al. 2013) for fast pyrolysis of on-specification woody feedstock followed by catalytic upgrading of the condensed vapors to produce gasoline and diesel blendstock fuel, as illustrated in Appendix B, Table B-3. The report builds upon Jones et al. (2009) and is updated with the most recent DOE national laboratory data, as well as publicly available experimental data from industry and universities.

Performance milestones for the thermochemical pathways under investigation are as follows:

- By 2014, establish out-year conversion cost projections and technical targets for achieving the \$3/GGE goal based on a TEA for at least one gaseous intermediate pathway that produces gasoline and diesel blendstock fuels.
- By 2015, select at least one thermochemical pathway for initially integrated operations to validate the Office's performance goal of \$3/GGE by 2017 by evaluating R&D data from bench-scale, semi-integrated thermochemical pathways that produce gasoline and diesel blendstock fuels.
- By 2017, validate the R&D performance goal of \$2.50/GGE nth plant modeled conversion cost and thus the Office's performance goal of \$3.00/GGE MFSP by performing integrated operations using on-specification feedstock via a thermochemical pathway that produces gasoline and diesel blendstock fuels.
- By 2020, select another thermochemical pathway for integrated operations to validate the 2022 Office performance goal of \$3/GGE by evaluating R&D data from bench-scale, semi-integrated thermochemical pathways that produce gasoline and diesel blendstock fuels.
- By 2022, validate the Office performance goal of \$3/GGE by performing integrated

⁵⁰ Jones, S. et al. "Process Design and Economics for the Conversion of Lignocellulosic Biomass to Hydrocarbon Fuels: Fast Pyrolysis and Hydrotreating Bio-Oil Pathway." PNNL-23053. (2013). Richland, WA: Pacific Northwest National Laboratory. http://www.pnnl.gov/main/publications/external/technical_reports/PNNL-23053.pdf.

operations using on-specification blended, low-cost feedstock via a thermochemical pathway that produces gasoline and diesel blendstock fuels.

2.2.2.3 Thermochemical Conversion Research and Development Technical Challenges and Barriers

The challenges and barriers listed in this section are specific to Thermochemical Conversion R&D. Additional challenges can be found in the Strategic Analysis section (2.4), the Sustainability section (2.5), and the Feedstocks Supply and Logistics section (2.1).

Tt-A. Feeding Dry Feedstock: Several variables impact the behavior of materials during in-feed into a conversion process, including feedstock type (and feedstock blend), format, and molecular composition (e.g., lignin concentration), as well as conversion reactor design and pressure. This variability makes reactor in-feed challenging and can impact conversion performance. The performance of dry feedstock formats and species needs to be evaluated, particularly in pressurized feeder systems, to reduce technical risks to process scale-up.

Tt-B. Feeding Wet Biomass: Improved processes are needed to feed whole, wet algal biomass slurries (of approximately 20%–30% solids in water) and wet cellulosic feedstocks into the liquefaction reactor, or for pumping lipids extracted from algae into upgrading systems. Determination of optimal operating conditions and economics of pumping systems is needed for whole, wet algae slurries and lipid-extracted algae oils.

Tt-C. Relationship between Feedstock Physical and Chemical Properties and Conversion Processes: Research is needed to map the relationship between the physical properties, the chemical composition of feedstocks, and the effects on the efficacy of a conversion process. Problematic chemical species, particle size, reactor type/geometry, and other factors need to be identified. Notable physical properties include thermal-specific heat, thermal diffusivity, bulk density, skeletal density, particle size/shape distributions, and mass diffusivities for product gases and liquids. These parameters greatly influence the temperature and chemical species distributions during the conversion process.

Tt-D. Biomass Pretreatment: Preprocessing operations are often necessary to address feedstock variability and to produce feedstocks that meet conversion quality needs. For instance, removing ash components in the feedstock may be important to preserving catalyst life and performance in downstream processing.

Tt-E. Deconstruction of Biomass Feedstocks to Form Gaseous Intermediates: This includes developing an understanding of indirect liquefaction (i.e., gasification) options and their chemistries for materials, including wood; energy crops; sorted, dry MSW; and agricultural residues high in minerals and lignin.

Tt-F. Deconstruction of Biomass to Form Bio-Oil Intermediates: Development of direct liquefaction technologies (including fast pyrolysis, catalytic fast pyrolysis, hydropyrolysis, or solvent liquefaction)—and process parameters to produce a higher bio-oil yield—are critical. Understanding the technical and cost tradeoffs for producing a higher-quality bio-oil versus a higher bio-oil yield from these various technologies is necessary for balancing severity and costs

of upgrading steps. This includes testing these conversion technologies on various biomass blends and formats to understand the impact of feedstock characteristics on bio-oil yield and quality.

Tt.-G. Gaseous Intermediate Cleanup and Conditioning: There is a need for gas cleaning and conditioning catalysts and technology that can cost effectively remove contaminants such as tars, particulates, alkali, sulfur, and other inorganics. The interactions between the catalysts used for gas cleanup and conditioning, and the gasification conditions and feedstock, need to be better understood. These interactions require careful attention to trace contaminants and are important for efficient cleanup and conditioning of syngas in conjunction with optimal lifetimes of the catalyst(s). These interactions are specific to each type of fuel synthesis catalyst.

Tt.-H. Bio-Oil Intermediate Stabilization and Vapor Cleanup: Crude bio-oil is acidic and thermally unstable due to the presence of a complex mixture of reactive species like carboxylic acids, aldehydes, ketones, and olefins. Bio-oil is sensitive toward thermal degradation, and the viscosity is known to increase over time due to ill-defined condensation and polymerization reactions. Understanding the composition of bio-oil is critical for improving current cleanup, stabilization, and upgrading processes. In particular, higher molecular weight components of bio-oil, which can be highly detrimental to the stability of the bio-oil, cannot be characterized by current methods. Knowing the types of intermediates that are formed and their rates of formation as a function of reaction conditions will aid in identifying optimum bio-oil production and upgrading technologies. In addition to better characterization and understanding of the composition of bio-oil, catalytic reactions, separations technologies, and other processes need to be developed to generate stabilized bio-oils that are compatible with known upgrading technologies.

Tt.-I. Catalytic Upgrading of Gaseous Intermediates to Fuels and Chemicals: New, more durable technologies and processes are needed for converting biomass-derived syngas into fuels and chemicals. The Office's prior success in producing mixed alcohol streams from biomass syngas illustrated that commercial-scale production of fungible hydrocarbon liquids is still limited by a variety of factors, including poor selectivity, low product yields, and catalyst deactivation. More robust processes and catalysts (chemical and biological) are needed for producing mixed alcohols, olefins, and alkanes. Significant efforts are needed to develop and improve processes and catalysts that can produce hydrocarbon fuels and chemicals and meet reasonable performance targets and commercially viable capital and operating costs. Desirable improvements include increased productivity and selectivity; extended catalyst lifetimes (in high- and low-temperature environments); and process intensification/smaller scales that are cost effective and commensurate with biomass feedstock supply.

Tt.-J. Catalytic Upgrading of Bio-Oil Intermediates to Fuels and Chemicals: The number of hydrotreating steps needed to meet a finished fuel specification depends on the quality of the bio-oil after the initial upgrading step. In this context, the bio-oil could be the result of a fast pyrolysis process or triglyceride refining of extracted algal oils after solvent separations. Hydrotreating catalysts that are highly selective to desired end products and are stable in the presence of impurities are ideal. Bio-oils may be upgraded to varying degrees, allowing several entry points within petroleum refineries for fuel finishing.

Developing and optimizing catalysts used in the first stage of upgrading, whether in liquid phase or vapor phase, for improved bio-oil quality and yield is critical. Greater understanding is needed regarding the tradeoffs between the amount and quality of bio-oil produced after HDO and the impact on additional downstream catalytic hydroprocessing steps required to meet a finished fuel or refinery feedstock specification. The primary objective is to design catalysts and catalyst regeneration systems that reduce costs by maximizing catalyst life, stability, productivity rates, and yields. Understanding catalyst coking and contamination issues is essential.

Tt-K. Product Finishing: After hydroprocessing, the fuel intermediates are fractionated or distilled to light molecules (~C4), naphtha, distillates, and heavy oil (if any). If heavy oil fractions are present, hydrocracking processes are necessary to convert these molecules to fuel cuts. Distillation technologies are commercially available; however, jet and diesel cetane, gasoline octane, flash point, smoke points, cloud or pour points, and distillation curves must be verified to determine that hydrocarbon fuel products meet necessary finished fuel specifications. It is also critical to understand and determine bio-oil requirements for fuel finishing within petroleum refineries, as well as understand the limitations of the distribution infrastructure.

Tt-L. Knowledge Gaps in Chemical Processes: Understanding the fundamental chemical processes that occur during biomass feedstock deconstruction and intermediate upgrading can inform technology breakthroughs and drive optimization. These improvements target increasing carbon, hydrogen, separations, and energy efficiencies. For example, a fundamental understanding of reaction mechanisms and kinetics using tools such as computational modeling can enable improvements to catalyst design, process configuration, and reactor design.

Tt-M. Hydrogen Production: Hydrogen production is essential for all thermochemical pathways. It is presumed that off-gases from thermochemical deconstruction and upgrading steps—as well as wastewater treatment—could be sent to a conventional hydrogen production plant that may consist of a steam reformer, water-gas shift reactor, pressure swing absorption unit, and heat recovery. Improvements to hydrogen recovery and production can lower the hydrogen cost contributions to fuels produced from each pathway.

Tt-N. Aqueous Phase Utilization and Wastewater Treatment: The aqueous phase from thermochemical deconstruction and upgrading may contain organic acids, aldehydes, ketones, and phenolics. Research is needed to characterize organics in the aqueous phase and to convert these organics to hydrogen, biochemicals, or hydrocarbon fuels. Alternative wastewater treatment should also be explored, such as catalytic hydrothermal gasification.

Tt-O. Separations Efficiency: Improvements are needed in a variety of separations technologies that can assist in vapor or gas phase cleanup; bio-oil stabilization; removing contaminants; preventing fouling; reducing the severity of upgrading steps; protecting catalysts from poisoning; catalyst regeneration; aqueous phase reforming; hydrogen production; and nutrient recycling. This may include processes such as solid/gas separation (e.g., hot gas filtration), solids/liquid separation, gas/liquid separation, and liquid/liquid separation. In the case of HTL of whole algae, filtering of the reactor effluent is an essential means of solids recovery to recycle nutrients back to the algae ponds.

Tt-P. Materials Compatibility: Due to the highly oxygenated nature of biomass-derived intermediates, materials that were designed for use with petroleum-derived intermediates might not be appropriate for biomass-derived intermediates. For instance, at relatively low temperatures (50°C), crude bio-oil can be corrosive to common structural materials like carbon steel. Corrosion of storage tanks, transport facilities, etc., could result if bio-oil is not processed sufficiently. Thus, it is critical to study the corrosive nature of bio-oil upgraded to varying degrees to reduce the corrosive nature of bio-oil to a level that is compatible with storage options.

Tt-Q. Sensors and Controls: Effective process control will be needed to maintain plant performance and regulate emissions at target levels with varying load, fuel properties, and atmospheric conditions. Commercial control systems need to be evaluated for thermochemical processes and the presence of chemical species, and new systems need to be developed where necessary.

Tt-R. Process Integration: Process integration currently presents large engineering scale-up risks because of the lack of operational data on fully integrated systems over extended periods of time that would be required for successful commercialization. The effect of feed and process variations must be understood to avoid fouling, plugging, corrosion, or other disruptions in biorefinery operations. Process integration is essential for (1) characterizing the complex interactions that exist between unit operations, (2) identifying impacts of trace components on catalytic and thermal systems, and (3) enabling the generation of predictive engineering models that can guide process optimization or scale-up efforts and enable process control.

Tt-S. Petroleum Refinery Integration of Bio-Oil Intermediates: Producing a bio-oil intermediate suitable for use in one or more insertion points within a petroleum refinery (e.g., hydrotreaters, reformers, fluid catalytic crackers, cokers, isomerization units, or hydrocrackers) provides a unique opportunity to leverage existing infrastructure for fuel finishing. Information is needed about the physiochemical properties, reactivities, and compatibilities of bio-oil intermediates for fuel finishing within an existing petroleum refinery. This requires obtaining direct input from a refinery regarding the chemical and physical specifications required for an acceptable bio-oil feedstock. An analysis of compatibility with materials of construction is also necessary. The market potential of bio-oils as a feedstock for petroleum refineries is largely unknown. There is a need to gather information to understand the technical risks and to illustrate the economics and sustainability of integration so that refineries will consider the bio-oil intermediate an acceptable refinery feedstock.

Tt-T. Heat Integration and Power Generation: Off-gases that are not needed for hydrogen generation are typically sent to a boiler for combustion (occasionally along with char) to generate superheated steam for a turbine. Steam could be extracted from the turbine for process use, or a lower-pressure boiler could be used to solely generate process steam. Depending on the overall plant configuration, power demand in the conversion plant might be balanced by either purchasing or selling electricity to the grid.

2.2.2.4 Thermochemical Conversion Research and Development Approach for Overcoming Challenges

The R&D approach for overcoming the key thermochemical conversion technical challenges and barriers is outlined in the WBS depicted in Figure 2-22.

The Office's current Thermochemical Conversion activities generally fall into seven broad groupings:

- *Analysis and Sustainability*: To understand the impact of technologies with respect to environmental sustainability, economic metrics, and the current SOT
- *Feedstock Interface Activities*: To understand the impact of feedstock quality on conversion efficiency and economics
- *Deconstruction Processes*: To produce useful intermediates from biomass
- *Upgrading Processes*: To convert intermediates to fuels and chemicals
- *Integration and Intensification*: To optimize for systems-level performance
- *Conversion Enabling Technologies*: To apply new knowledge and tools to innovate beyond current conversion technologies
- *Validation*: To demonstrate technical, sustainability, and economic improvements in an integrated process setting.

Thermochemical Conversion R&D investments include a variety of deconstruction and upgrading technologies to produce gasoline and diesel blendstock fuels, as well as chemicals or heat and power. R&D to overcome the related challenges is performed by DOE national laboratories, industry, nonprofits, and universities.

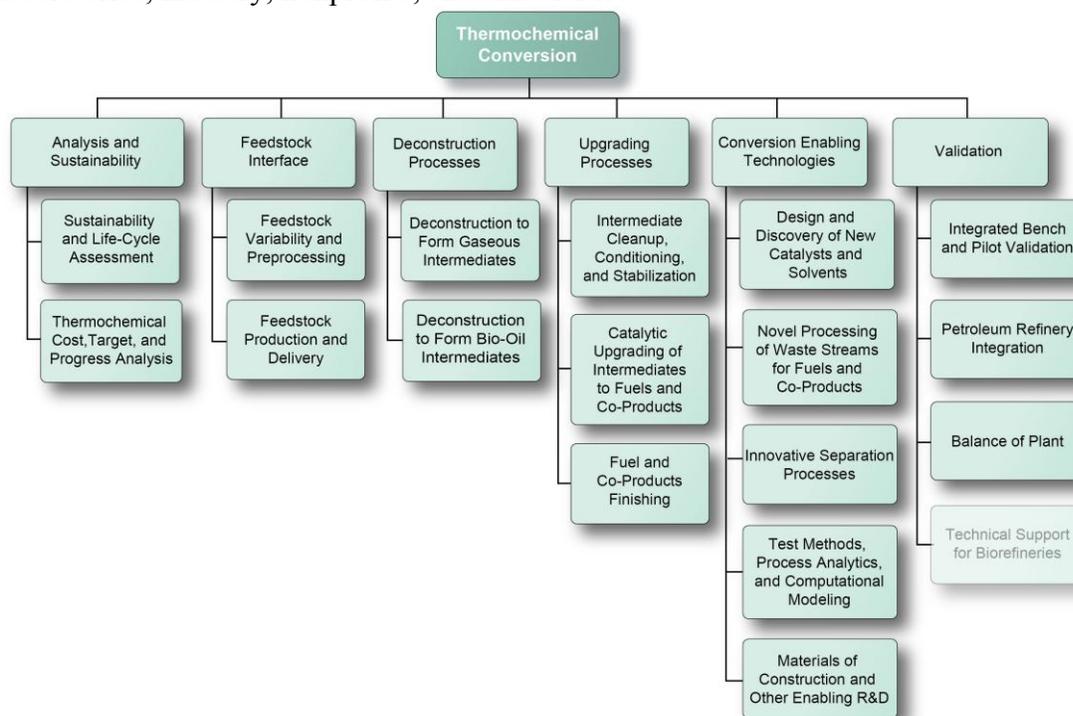

Figure 2-22: Thermochemical conversion R&D work breakdown structure

The WBS illustrated in Figure 2-22 is described below. Table 2-7 summarizes each task element's work as it relates to specific R&D activities, challenges, and DOE-funded performers.

Analysis and Sustainability

Modeled, integrated conversion process designs are developed to assess techno-economic feasibility, establish and measure progress toward technical performance targets, evaluate environmental sustainability metrics, and improve sustainability of each feasible bio-oil pathway. Environmental sustainability metrics include lifecycle greenhouse gas emissions, fossil energy consumption, consumptive water use, wastewater generation, air pollutants, biomass carbon-to-fuel efficiency, and total fuel yield. Experimental data are obtained from DOE-funded R&D projects (including the DOE national laboratory user facilities) and publicly available sources to monitor progress and direct future research efforts. Techno-economic and process data from integration and scale-up efforts can be used to validate existing models, inform SOT updates, and verify the accuracy of modeled cost projections.

Feedstock Interface

For biorefineries, it is important that feedstock specifications are met while balancing feedstock processing within total system cost. Specifically, the key challenges will be to stabilize and efficiently transport and handle biomass, as well as economically preprocess biomass to the required specifications to enable process optimization. Research activities address feedstock issues occurring within the biorefinery plant boundaries, such as feedstock handling, preprocessing, and reactor in-feed. Relevant feedstock interface R&D for the production of biofuels may also be utilized by biopower technologies. Feedstock interface tasks address the challenge of feedstock supply and quality by assessing the benefits of mechanically and chemically treated, formulated biomass. This includes development of feedstock logistics systems that sustainably supply feedstock of the appropriate specification to the biorefinery, while balancing conversion yield and quality with feedstock costs. To do this, it is necessary to understand the downstream conversion impact of various biomass components, such as ash, bark, and moisture content.

Deconstruction Processes

Improved technologies are needed for thermochemical deconstruction of biomass to form a gaseous or bio-oil intermediate. To fully realize the benefits of an integrated biorefinery, robust and cost-effective biomass thermal conversion processes are under development that can convert a variety of biomass materials to suitable clean and high-quality intermediates for subsequent conversion to biofuels, biochemicals, or biopower. Maintenance of catalyst activity is particularly important with feedstocks containing sulfur or other inorganic content (e.g., N, P, K, O, Cl, Ca, Na, Si, etc.).

Upgrading Processes

Once a crude bio-oil or syngas is produced, technologies for cleanup, conditioning, and/or stabilization are needed for upgrading to a finished fuel or co-product. This involves mitigating reactive compounds to improve storage and handling properties. Bio-oil upgrading processes include the removal of water, char, and ash particulates, as well as destabilizing components such as metals and oxygenated species. Specifically for bio-oils, hydroprocessing and similar thermal-catalytic processing techniques reduce the total oxygen and acid content, thereby increasing stability. This processing is required before a bio-oil intermediate can be upgraded under conventional hydroprocessing conditions (e.g., high temperature/pressure) in a standalone biorefinery, or before it can become a suitable feedstock for a petroleum refinery. For syngas, cleanup normally entails removing or reforming tars and acid gas, ammonia scrubbing, capturing alkali metal, and removing particulates. Typical gas conditioning steps include sulfur polishing (to reduce levels of hydrogen sulfide to acceptable amounts for fuel synthesis) and water-gas shift (to adjust the final hydrogen-carbon monoxide ratio for optimized fuel synthesis).

Conversion Enabling Technologies

The advancement of thermochemical conversion pathways requires the development of next-generation catalysts and solvents; separations technologies; hydrogen production; aqueous phase reforming; and other, yet-to-be-discovered technology breakthroughs. Fundamental understanding of reaction mechanisms and kinetics of conversion processes using tools such as computational modeling can enable these improvements. New knowledge informs the development of processes that are more energy, carbon, and hydrogen efficient (and thus cost efficient). Complementary to the enabling technology of catalysis are advances in the biomass pretreatment technologies that will improve feedstock logistics and the accessibility of the biomass molecular moieties to subsequent conversion processes. Advanced pretreatment will enable greater yield and quality of biomass intermediates and biofuels, thus improving energy efficiency. This work bridges the gap between discoveries made by DOE's Office of Science, ARPA-E, and the National Science Foundation, with applied R&D conducted by DOE's Bioenergy Technologies Office.

Validation

Demonstrating that improved thermochemical conversion and upgrading technologies are cost competitive with their petroleum-based counterparts for producing finished fuels is critical to advancing thermochemical conversion pathways. This includes processing bio-oils in an existing petroleum refinery to make finished fuels. The Office leverages industry feedback to understand emerging issues and R&D opportunities. Integration and scale-up efforts are at the bench and pilot scale and generate data that are used to assess progress against technical and cost targets, as well as environmental sustainability metrics. The operational data are also used to model nth plant costs and technical projections for each thermochemical conversion pathway.

2.2.2.5 Prioritizing Thermochemical Research and Development Barriers

In order to achieve the Thermochemical Conversion R&D goals, all of the challenges and barriers discussed in Section 2.2.1.4 need to be addressed. However, the following issues are critical and will be emphasized within near- to mid-term Thermochemical Conversion R&D efforts:

- Understand the relationship between feedstock quality and conversion
- Develop strategies for conserving carbon and hydrogen in conversion and upgrading processes
- Enable high-performance separations technologies to improve yields
- Work with petroleum refiners to address integrating biofuels into refinery processes.

Prioritization of R&D to overcome technical challenges is based on periodic evaluation of the Thermochemical Conversion R&D portfolio, as well as information on technologies being developed without government involvement. Annual technology assessments are conducted to help prioritize which thermochemical pathways support achievement of Office goals. Over the longer term, R&D is focused on validating additional biomass feedstock and innovative conversion processes to maximize biofuels production potential.

To this end, additional TEAs are being conducted to more accurately reflect the Office's diverse R&D portfolio, which includes other thermochemical pathways to produce hydrocarbon fuels.³ These TEAs, combined with other criteria such as environmental performance, will help the program reprioritize the development of additional design cases for new, innovative conversion pathways. Periodic evaluations also serve as “on ramps” and “off ramps” for conversion pathways. Additionally, qualitative public input through stakeholder workshops (such as the Conversion Technologies for Advanced Biofuels Workshop held in December 2011) and the biennial Peer Reviews informs research priorities.⁵¹

Thermochemical Conversion R&D is focused on validating additional feedstock blends and innovative conversion processes that can meet long-term cost goals and maximize the volume of U.S. biomass resources that can be accessed for biofuels production. Other potential thermochemical pathways under development within the program portfolio and in the private and academic sectors may contribute to meeting program performance goals. As such, the performance milestones discussed in this section involve periodic evaluation of the entire technology landscape to reprioritize the thermochemical pathways that could support 2017 and

S.B. Jones, C. Valkenburg, C.W. Walton, et al. “Production of Gasoline and Diesel from Biomass Via Fast Pyrolysis, Hydrotreating and Hydrocracking: A Design Case.” PNNL-18284. (2009). Richland, WA: Pacific Northwest National Laboratory. http://www.pnnl.gov/main/publications/external/technical_reports/pnnl-18284.pdf

2022 cost goals. These periodic evaluations will serve as “on ramps” and “off ramps” for thermochemical pathways, based on techno-economic and environmental performance assessments that use credible experimental data.

The recently updated fast pyrolysis design report (Jones 2013), which uses a blended, formatted woody biomass to produce gasoline and diesel blendstock fuel in 2017, is an example of how the \$3/GGE cost goal can be achieved by 2017, as illustrated in Figure 2-23 and Table 2-8. Relevant environmental sustainability metrics are outlined in Table 2-9. More details are provided in Appendix B, Table B-3.²¹

This is only one example of how the Office could achieve the \$3/GGE goal. Two more design reports are anticipated in 2014 as example thermochemical pathways with the potential to achieve the Office \$3/GGE performance goal. The design reports include conversion cost projections and technical targets, as well as environmental sustainability metrics. The reports have been peer reviewed, and they are or will be made public.⁴ Annual SOT updates will be conducted to track progress toward the Office’s \$3/GGE goal.

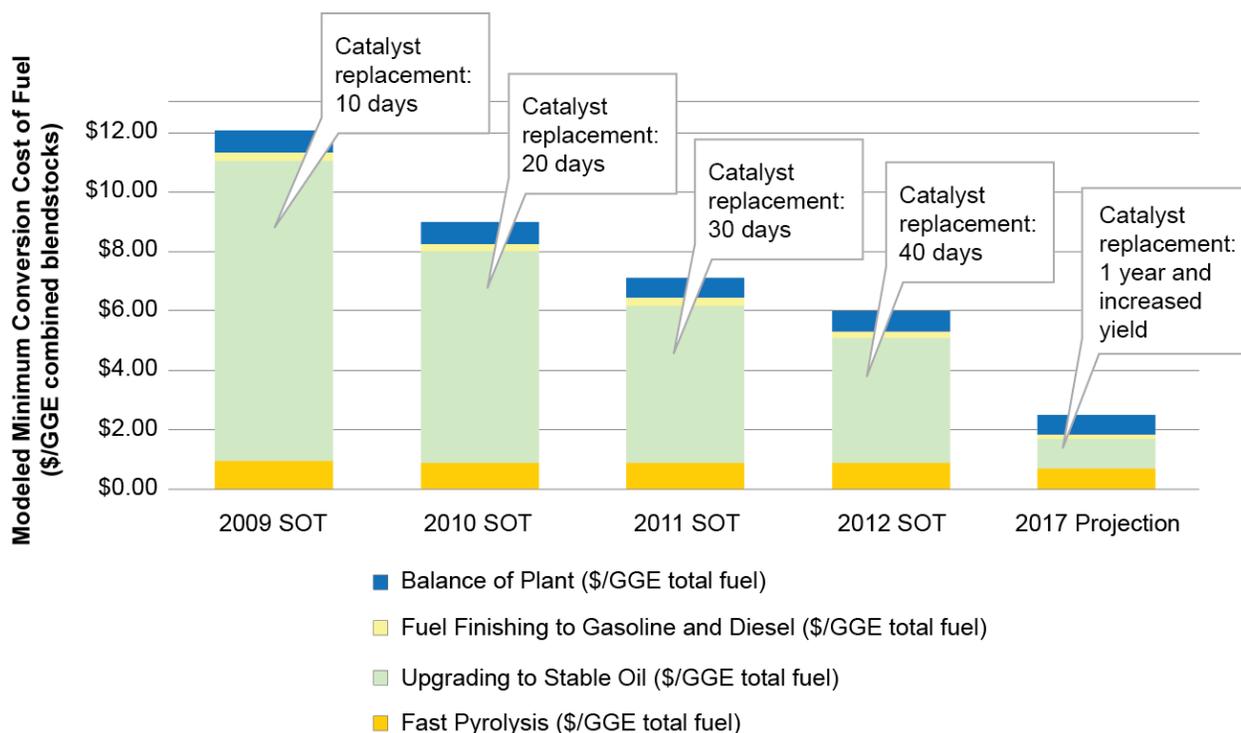

Figure 2-23: Conversion of woody feedstocks to renewable gasoline and diesel finished fuels via fast pyrolysis

Based on the 2013 design report for fast pyrolysis, Figure 2-20 shows that a total potential cost reduction of 80% can be achieved between 2009 and 2017 with improvements in all four R&D areas listed. The projections are modeled nth plant production costs assuming a 2,000 dry tonnes feedstock per day, using both publicly available data and experimental data from the national laboratories for bench-scale fast pyrolysis and subsequent hydrotreating. More details behind this fast pyrolysis design case are provided in Appendix B, Table B-3.

Table 2-8: Conversion of Woody Feedstocks to Renewable Gasoline and Diesel Finished Fuels via Fast Pyrolysis (Does not include feedstock cost)

	2009 SOT	2010 SOT	2011 SOT	2012 SOT	2013 SOT	2017 Projection
Conversion Contribution (\$/gal gasoline)	\$12.40	\$9.22	\$7.32	\$6.20	\$4.51	\$2.44
Conversion Contribution (\$/gal diesel)	\$13.03	\$9.69	\$7.69	\$6.52	\$5.01	\$2.70
Conversion Contribution (\$/GGE total fuel)	\$12.02	\$8.94	\$7.10	\$6.02	\$4.59	\$2.47
Fast Pyrolysis (\$/GGE total fuel)	\$0.97	\$0.93	\$0.91	\$0.90	\$0.78	\$0.76
Upgrading to Stable Oil (\$/GGE total fuel)	\$10.07	\$7.05	\$5.23	\$4.17	\$2.88	\$0.95
Fuel Finishing to Gasoline and Diesel (\$/GGE total fuel)	\$0.25	\$0.24	\$0.24	\$0.24	\$0.25	\$0.14
Balance of Plant (\$/GGE total fuel)	\$0.74	\$0.72	\$0.71	\$0.71	\$0.68	\$0.63

In addition to setting technical targets and cost projections, the Office is assessing the environmental performance of conversion pathways to enable continual evaluation and improvement of the designs throughout the technology R&D phase. The following environmental sustainability considerations are currently being assessed: greenhouse gas emissions, fossil energy consumption, fuel yield, biomass carbon-to-fuel efficiency, consumptive water use, and wastewater generation. Table 2-9 shows the estimated metric values for the conversion plant for the updated fast pyrolysis and upgrading design case.⁵² This set of environmental sustainability metrics is not intended to be all-inclusive and will be expanded and updated as more experimental data become available. Work is in progress to quantify additional metrics, including criteria air pollutants and wastewater quality. The refined analysis will enable the Office to establish targets for environmental sustainability metrics to guide their improvement alongside the TEA. See Appendix C for more information on the Office's approach to establishing environmental sustainability targets.

Table 2-9: Environmental Sustainability Metrics for Fast Pyrolysis and Upgrading

Environmental Sustainability Metric	2017 Projected
Greenhouse Gases (g CO ₂ -e/MJ fuel) – (fossil emission; biogenic emissions) ¹	18.9; 85
Fossil Energy Consumption (MJ fossil energy/MJ fuel product) ²	0.301
Total Fuel Yield (gal/dry ton wood; GGE/dry ton wood)	84; 87
Biomass Carbon-to-Fuel Efficiency (C in fuel/C in biomass)	47%
Water Consumption (m ³ /day; gal/GGE) ³	1050; 1.4
Wastewater Generation (m ³ /day; gal/GGE fuel) ⁴	932; 1.3

Table Notes:

1. Biogenic emissions include those contained in the char combustor exhaust, the heat from which is used in the biomass dryer (not part of the conversion plant).
2. Fossil energy consumption does not include grinding of the feedstock prior to the pyrolysis step.

⁵² S. Jones, E. Tan, J. Jacobson, et.al. "Process Design and Economics for the Conversion of Lignocellulosic Biomass to Hydrocarbon Fuels Fast Pyrolysis and Hydrotreating Bio-oil Pathway." PNNL-23053, NREL/TP-5100-61178. (2013). Pacific Northwest National Laboratory, National Renewable Energy Laboratory, and Idaho National Laboratory. http://www.pnnl.gov/main/publications/external/technical_reports/PNNL-23053.pdf See also Appendix B.

3. Water consumption and wastewater generation include only direct use/emissions and do not include water associated with upstream production of materials and energy used at the plant.
4. Wastewater generation includes both wastewater from hydrotreating and blowdown from the cooling towers.

The environmental sustainability metrics fit within the framework of sustainability indicators published by Oak Ridge National Laboratory (McBride et al. 2011; Efroymsen et al. 2012), which covers the entire biomass supply chain. The metrics will be used to complete TEAs for the pathway using Argonne National Laboratory's GREET model (the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation model) and water footprint model.

While the Energy Independence and Security Act of 2007 requires EPA to conduct its own greenhouse gas assessments to determine fuel qualification, it is essential that LCA be performed during the development of these pathways in order to predict and facilitate improvement of environmental performance. This will enable conversion technologies to meet legislated goals, such as greenhouse gas reductions required by the Renewable Fuel Standard, and achieve other social and environmental benefits.

2.2.2.6 Thermochemical Conversion Research and Development Milestones and Decision Points

The key milestones and decision points to complete the tasks described in Section 2.2.2.1.4 are summarized in Figure 2-24.

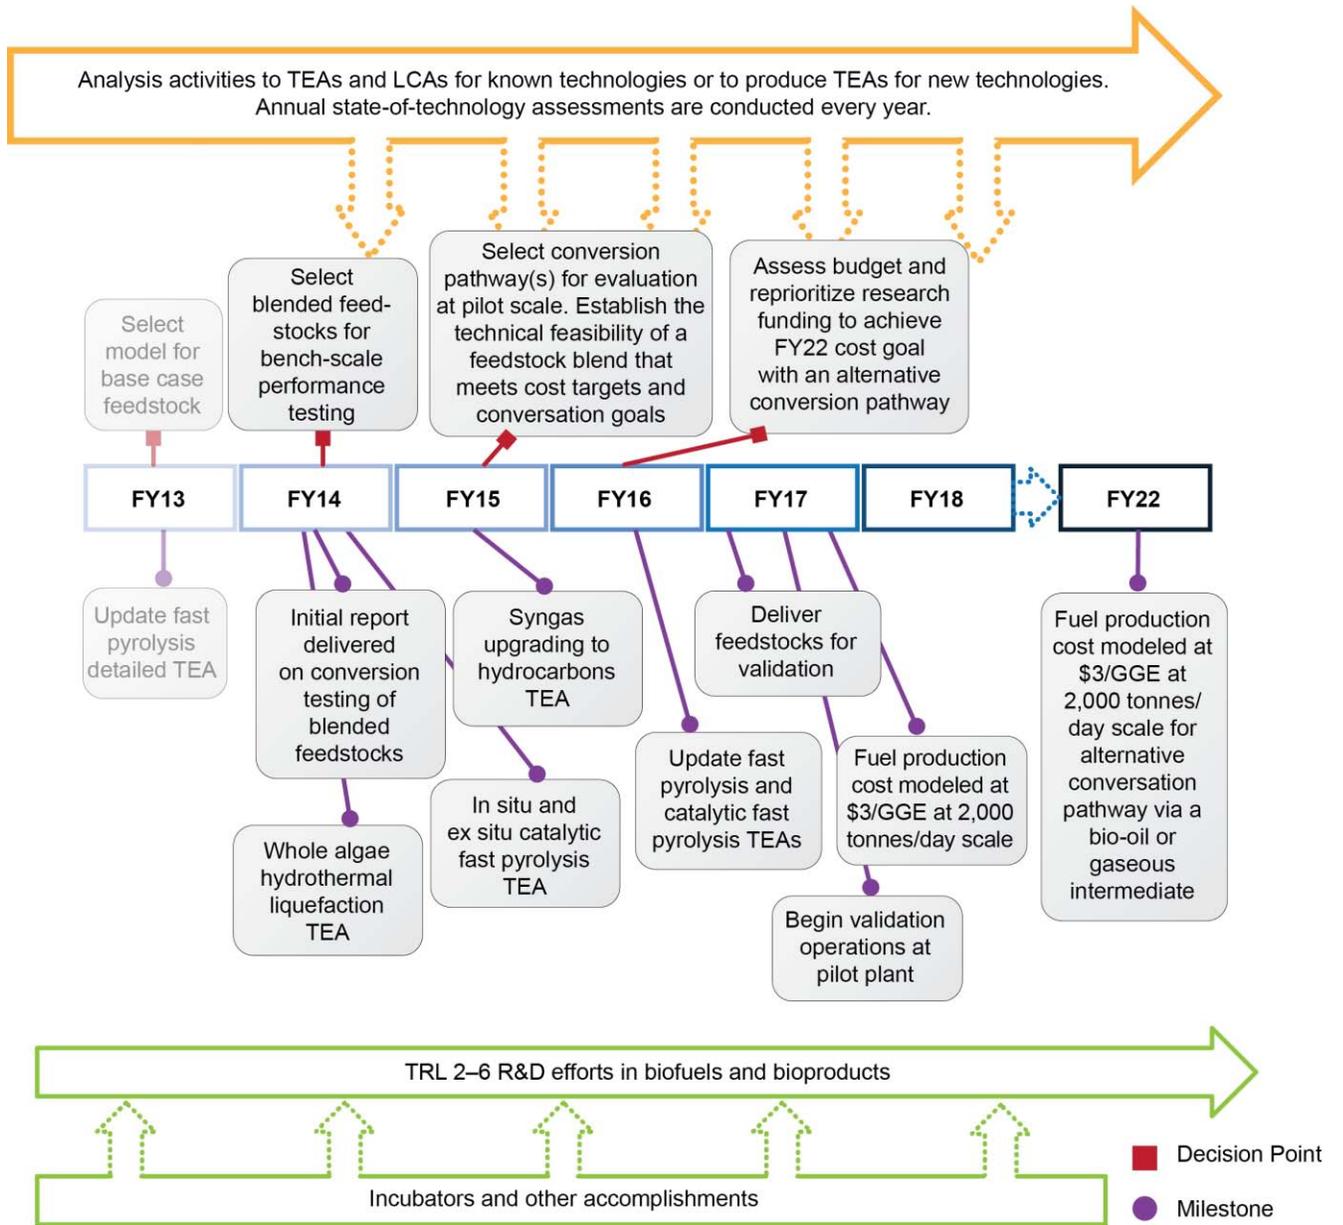

Figure 2-24: Thermochemical conversion R&D key milestones and decision points

2.3 Demonstration and Deployment

The Demonstration and Deployment (D&D) goal is to de-risk bioenergy production technologies through validated proof of performance at the pilot, demonstration, and pioneer scales and to remove any additional barriers to commercialization. This is achieved through public-private partnerships that build and operate integrated biorefineries (IBRs) and through projects focused on infrastructure and end-use market barriers. These activities are essential to resolve key issues in the construction and scale-up of IBR systems, primarily by reducing risk to help overcome the commercial financing barriers that are currently facing the bioenergy industry. By creating a pathway to market, D&D helps address the final links of the bioenergy supply chain and works to enable a robust demand for end products.

The advanced bioenergy industry includes production of biofuels, bioproducts, and biopower. Similar to other process industries, the advanced bioenergy industry faces significant challenges and risks in the scale-up to pilot, demonstration, and pioneer scales. These include risks related to technology, construction, environmental impact, feedstock supply, operations, market offtake, and financing.⁵³ The specific risks of feedstock supply and market offtake are more pronounced for advanced biofuels than other renewable sources of energy because of the variability inherent in biomass and the lack of long-term offtake agreements in the fuel and chemicals markets. Advanced infrastructure-compatible fuels require an extra level of certification for end use, such as in automotive and jet engines, as well as infrastructure compatibility testing for integration into refinery equipment, pipelines, rail cars, and storage tanks. D&D activities are targeted to reduce these barriers for the private sector by facilitating large-scale projects that address these risks and further catalyze the desired transformation in the U.S. transportation fuel supply from fossil-based to renewable.⁵³

The Office is uniquely positioned to leverage both its legislative authority for financial assistance and DOE's successful track record in technology commercialization to assist developers through validated proof of performance at pilot, demonstration, and pioneer scales. A recent study that assumed a standard biorefinery size of 40 million gallons of ethanol equivalent fuel per year determined that meeting the goals of the Energy Independence and Security Act of 2007 will require more than 500 new biorefineries.⁵⁴ Of the approximately 200 U.S. companies currently working to develop advanced biofuels, only a fraction have progressed beyond in-house laboratory or very small-scale pilot testing.⁵⁵ Of these, an even smaller number have been able to raise the funds to move into the full pilot or demonstration phase of development without some form of government financial assistance.⁵⁶ During the Office's May 2013 Peer Review, experts

⁵³ Koonin, S.E., Gopstein, A.M. "Accelerating the Pace of Energy Change." *Issues in Science and Technology*, Winter 2011.

from the refining, chemical, and financial industries made similar conclusions, stating that “the use of grants is necessary for reducing capital investment; providing project credibility; and providing a path for demonstrating technology proof of concept and market viability.”⁵⁷

The D&D Technology Area is investigating high-potential feedstock resources, including agricultural and forest residues; herbaceous and woody energy crops; sorted, dry MSW; and algal feedstocks and intermediates. D&D also investigates a wide range of conversion pathways, including biochemical, thermochemical, and hybrid processes; advanced anaerobic digestion; and other waste-to-energy technologies. Potential product slates include biofuels, renewable home heating oil, and other bioproducts, such as succinic acid, that can replace petroleum-based products made from oil. Each of these alternative resources and conversion pathways must be proven and validated at larger scales in order to sufficiently reduce risk and reach market acceptance.

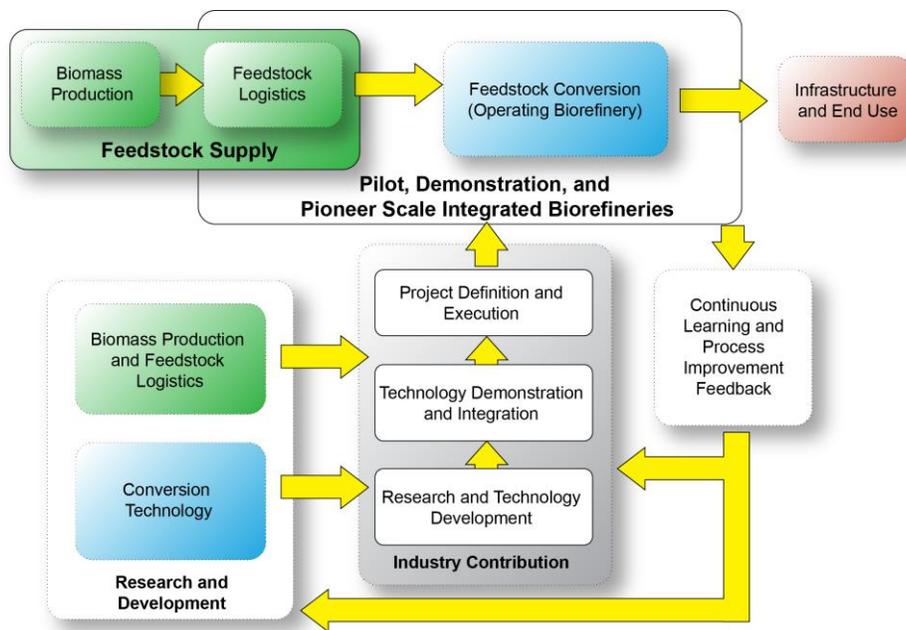

Figure 2-25: D&D technology area scope and connection to R&D efforts

Integrated Biorefinery Definitions and Objectives

An IBR facility is defined by its objectives and operational scale. A large group of stakeholders developed these definitions, including biomass suppliers; technology developers; engineering, procurement, and construction (EPC) companies; and financial firms such as venture capitalists, angel investors, and large commercial banks.

Pilot-scale facilities verify the integrated technical performance of the given suite of technologies from feedstock in through product out at production capacities equal to or greater

⁵⁷ Bioenergy Technologies Office. (2014). “2013 Peer Review Report.” DOE/EE-1014. Washington, D.C.: U.S. Department of Energy. p. 609. http://www1.eere.energy.gov/bioenergy/pdfs/2013_peer_review.pdf.

than 1 dry ton of feedstock per day. A pilot facility integrates key recycle streams to validate the process and techno-economic model, but is not intended to produce cost-competitive fuels due to its small scale of operations. Any problems identified in the pilot stage must be corrected prior to further scale-up, or it is unlikely that the next plant will achieve its design capacity, operability factor, and profitability.⁵⁸ Integrated pilot testing also generates the performance data and equipment specifications required to design a demonstration-scale facility, as well as to determine process sustainability metrics such as water use and greenhouse gas emissions. Successful integrated pilots strengthen projects at larger scales and encourage private investment.

Demonstration-scale facilities verify performance at a scale sufficient to provide data and equipment specifications required to design a pioneer-scale facility. Demonstration facilities, typically between one-fiftieth and one-tenth of the pioneer scale, prove all recycle streams and heat integration for more than 1,000 hours of operations. This length of testing validates process robustness across the variability of biomass feedstock and operating conditions while still meeting the product specifications. Demonstration-scale operational data is used to validate commercial equipment specifications and design factors for the pioneer facility. This data is used to balance sustainability performance across economic, social, and environmental dimensions, such as balancing the feedstock availability with site infrastructure and workforce requirements, or balancing emissions through heat integration or wastewater treatment. Demonstration-scale projects are not meant to produce positive cash flow, but instead to identify process design improvements and develop more precise cost estimates for the pioneer plant. In some cases, 1,000 hours of continuous operational data is sufficient to allow for a performance guarantee on the pioneer facility from a major EPC firm. An EPC performance guarantee is an important step in obtaining commercial financing for larger-scale facilities. To determine if a project is ready for demonstration scale, integrated pilot testing of all critical process steps must have been successfully completed.

Pioneer-scale, or “first-of-a-kind,” facilities prove economical production at commercial volumes on a continuous basis with a reliable feedstock supply and production distribution system and verify environmental and social sustainability performance. These facilities have a higher capital cost than subsequent plants, which reflects the uncertainty and flexibility required in a first-of-a-kind process. Future plants benefit from refinements due to pioneer operations. Successful design, construction, and operation of a pioneer facility are greatly dependent on prior development of integrated pilot- and demonstration-scale facilities that have generated the necessary performance data and equipment specifications. Once the pioneer facility achieves operation at full design capacity and reaches positive cash flow, the technology application can be replicated through commercial debt or project financing.

Figure 2-26 depicts the progression of a conversion technology from pilot to demonstration to pioneer plant. The concentric ovals indicate that each stage is inclusive of the prior stage and builds upon its results, while the table below it describes the unique objectives at each stage.

⁵⁸ Marton, A. (2011). “Research Spotlight: Getting off on the Right Foot – Innovative Projects.” Independent Project Analysis Newsletter, 3(1).

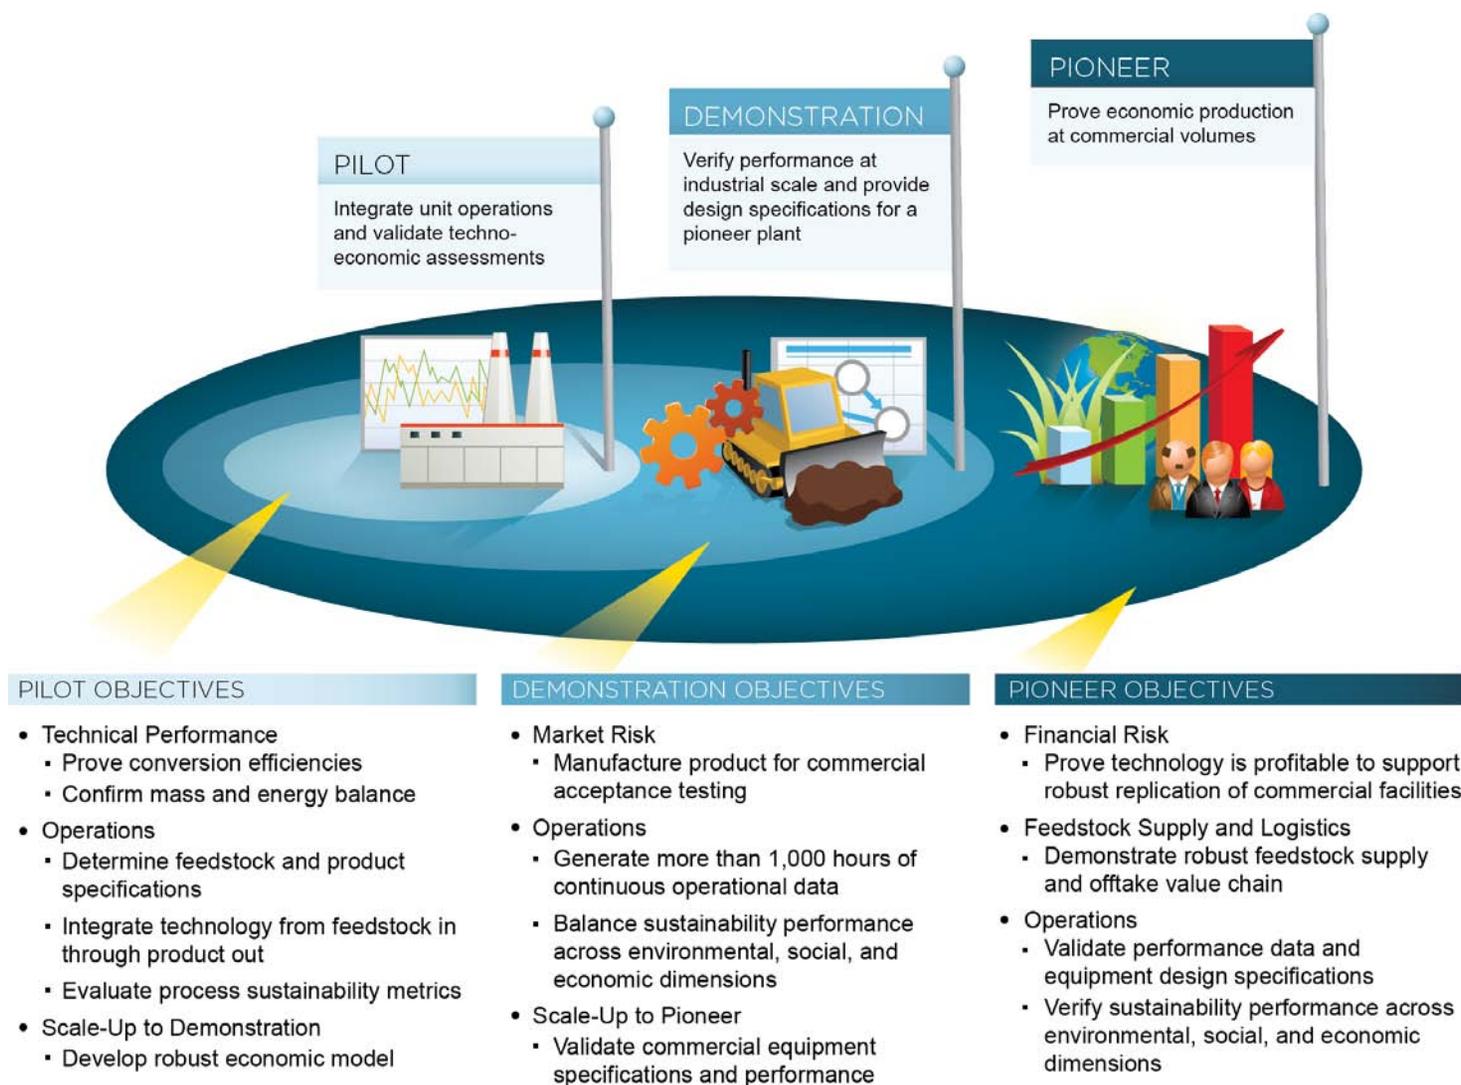

Figure 2-26: Description of key objectives at each integrated biorefinery scale

Infrastructure and End Use

Once biofuel, bioproduct, or biopower is produced, a number of distribution challenges remain for full market deployment. Biofuel use is constrained in some cases by fuel blending limits, integration with refinery process units, or existing pipelines and storage tanks infrastructure. In addition, infrastructure-compatible hydrocarbon biofuels require extensive certification testing, especially for the jet fuel market. Market acceptance of renewable home heating oil faces similar challenges and constraints, including blending limits and compatibility with home furnaces and transport and storage equipment. Bioproducts, whether used to replace fossil-based products or in a completely new market, will need to consistently meet the associated specifications. In addition, any biopower generated at a biorefinery may require capacity upgrades or reliability improvements to the local electricity grid.

Demonstration and Deployment Interfaces

The Office's R&D areas are focused on developing the scientific and engineering underpinnings of a bioenergy industry by understanding technical barriers and providing process and engineering solutions. The D&D projects then build upon these R&D efforts and create a feedback loop that uncovers additional barriers to commercial success at larger scale. The data and lessons learned from both R&D and D&D efforts are then used jointly for overall Office strategic planning.

Feedstock Research and Development

Successful commercialization of bioenergy technologies relies on a feedstock supply chain that can cost-effectively supply adequate volumes of a specified quality of feedstock to the biorefinery. Plant operations are dependent on a continuous, consistent feedstock supply of known quality attributes to achieve their performance targets. Feedstock cost, availability, variability, quality control, and storage are all parameters that greatly affect the performance of a facility. In addition to economic and technical parameters, feedstock handling and storage facilities must meet existing construction, safety, and fire codes that were not typically written for large-scale lignocellulosic biomass operations. Updating these codes to address the unique characteristics of biorefinery feedstock materials will require ongoing feedstock R&D to determine relevant material properties and optimal design standards.

Conversion Research and Development

Continued R&D to improve the conversion of biomass to biofuel, bioproducts, and biopower is necessary to increase conversion efficiency and lower costs. These efforts reduce the technological risk of the process and increase the probability of commercial success. Several existing D&D projects have been directly supported, and most have indirectly benefitted from the Office's past and current conversion R&D efforts.

2.3.1 Demonstration and Deployment Support of Office Strategic Goals

The strategic goal of the D&D Technology Area is to *develop commercially viable biomass utilization technologies through public-private partnerships that build and validate pilot-, demonstration-, and pioneer-scale integrated biorefineries; and to develop supporting infrastructure to enable a fully operational and sustainable biomass-to-bioenergy value chain in the United States.*

The biorefinery and infrastructure projects are testing advanced biofuels, bioproducts, and biopower from high-impact feedstocks, including herbaceous, woody, and algal feedstocks, as well as from MSW. D&D focuses on reducing risk to the consumer and the private sector and helping overcome challenges to financing the follow-on expansion of the industry, which is required to make a major contribution to our nation's energy independence.

2.3.2 Demonstration and Deployment Support of Office Performance Goals

Specific D&D goals in support of Office performance goals are as follows:

- By 2014, validate three cellulosic ethanol or bioproduct manufacturing processes at pioneer scale
- By 2017, validate a mature technology modeled cost of cellulosic ethanol production, based on actual IBR performance data, and compare to the target of \$2.15/gallon ethanol (\$2007)
- By 2027, validate a mature technology modeled cost of infrastructure-compatible hydrocarbon biofuel production, based on actual IBR performance data, and compare to the target of \$3/GGE (\$2011).

D&D milestones toward reaching these goals include the following:

- By 2018, validate three infrastructure-compatible hydrocarbon biofuel or bioproduct manufacturing processes at pilot scale
- By 2020, validate one to two infrastructure-compatible hydrocarbon biofuel or bioproduct manufacturing processes at demonstration scale
- By 2024, validate one infrastructure-compatible hydrocarbon biofuel or bioproduct manufacturing process at appropriate scale.

The objective of validating these technologies is to prove techno-economic viability and enable commercial production facilities. The 2014 goal reflects the validation efforts of the existing pioneer cellulosic ethanol facilities in the D&D portfolio; the 2018 and beyond goals reflect the focus on infrastructure-compatible hydrocarbon biofuels. Table 2-10 contains the projects expected to contribute to the 2014 performance goal.

Table 2-10: Estimated Project Contribution for 2014 Performance Goal

Project	Production Capacity million gallons	Fuel	Conversion Route	Feedstock
Abengoa	25	Cellulosic Ethanol	Biochemical	Agricultural Residue
Poet	25	Cellulosic Ethanol	Biochemical	Agricultural Residue
INEOS New Planet Bioenergy	8	Cellulosic Ethanol	Thermochemical/ Biochemical Hybrid	Green Waste and MSW

Historically, D&D performance goals were focused on validation of production capacity in a given year. Because the capacity of a pioneer project can be more than 100 times the capacity of a pilot project, these capacity goals relied on a disproportionately small number of pioneer projects. These pioneer projects face significant barriers outside the control of the D&D Technology Area, such as securing financing or long delays in construction and start-up. Also, the efforts to validate technology and reduce risk at pilot and demonstration scale were not reflected. Therefore, future performance goals and milestones will focus on validating a specific number of technologies at various scales instead of a projection of production capacity.

2.3.3 Demonstration and Deployment Challenges and Barriers

Market Challenges and Barriers

Im-A. Inadequate Supply Chain Infrastructure: Feedstock variability and lack of feedstock infrastructure increases the uncertainty associated with a sustainable feedstock supply chain. Variable composition, geographical diversity, and diverse physical characteristics (such as particle size) impact supply chain costs. Producing and delivering a feedstock that meets the conversion specifications and cost targets of the biorefinery in sufficient volumes to support a commercial, advanced biofuels industry will require incentive programs to stimulate the large capital investments needed for feedstock production, preprocessing, storage, and transport to commodity markets. Feedstock infrastructure, such as handling and storage facilities, also must meet existing construction, safety, and fire codes, which, in most cases, were not written for large-scale lignocellulosic biomass operations.

Im-B. Agricultural Sector-Wide Paradigm Shift: Energy production from biomass on a scale sufficient to meet the Energy Independence and Security Act of 2007 Renewable Fuel Standard goals, or those of a future Renewable Portfolio Standard, will require a series of major system changes that will take time to implement. Current terrestrial feedstock logistics systems are designed for high-yielding areas. These logistics systems are inadequate for processing and distributing biomass on the scale needed to support dramatically larger volumes of biofuels production and do not address all of the quality specifications.

Im-C. High Risk of Large Capital Investments: Once emerging biomass technologies have been developed and tested, they must be commercially deployed. Financial barriers are the most challenging aspect of technology deployment. Capital costs for commercially viable facilities are relatively high, and securing capital for an unproven technology is extremely difficult. Lenders are hesitant to provide debt financing for first-of-a-kind facilities where the process performance

cannot be adequately guaranteed. Government assistance to validate proof of performance at the pilot, demonstration, and pioneer scales is critical to successful deployment. Another significant challenge for debt financing of first-of-a-kind commercial facilities is the lack of long-term, consistent federal policies. Lenders will not consider federal incentives and subsidies as income in the consideration of loan applications if it is perceived that federal (and state) policies and financial support mechanisms are uncertain.

Im-D. Lack of Industry Standards and Regulations: The lack of local, state, and federal regulations, as well as inconsistency among existing regulations, constrains development of the biomass industry. The long lead times associated with developing and understanding new and revised regulations for technology can delay or stifle commercialization and full market deployment. Consistent standards and sampling methods are lacking for feedstock supply and infrastructure, as well as for biofuel and other bioproducts, including home heating oil and the associated distribution infrastructure.

Im-E. Cost of Production: An overarching market barrier for biomass technologies is the inability to compete, in most applications, with established fossil energy supplies and supporting facilities and infrastructure. Previous analysis has shown that doubling of cumulative industrial capacity leads to an average reduction of 75% in cost⁵⁹ for process technologies. The accelerated industrial learning that occurs during this capacity growth also has been successful in reducing cost in the fuels and chemicals industry over the past several decades.⁶⁰ Reductions in production costs along the entire biomass supply chain—including feedstock supply, conversion processes, and product distribution—are needed to make advanced biofuels, bioproducts, and biopower competitive with petroleum-derived analogs.

Im-F. Offtake Agreements: Production costs, and therefore selling price and profits, of commodity fuels and chemicals derived from crude oil are dependent on a fluctuating market. Generally, these companies offer products on a contract basis; however, they often sell to the market on the spot to generate the greatest return on investment. Offtake agreements can often take the form of fixed-price contracts for 1–2 years, followed by contracts fixed to a specific index (such as the Chicago Board of Trade pricing). The producer then must adjust its *pro forma* accounting and variable cost structure to account for such market fluctuations. Another challenge with fuel offtake agreements is that the industry standard is 1–2 years, in contrast to the term of debt financing, which can range from 7–15 years or longer. The providers of long-term debt generally require the duration of the offtake agreement to match the length of the loan, which is a difficult challenge when the product selling price is dependent on a fluctuating market.

Im-G. Uncertain Pace of Biofuel Availability: There is uncertainty regarding the pace of development and commercialization of new biofuel technology. Additionally, there is uncertainty surrounding which types of biofuels will be produced and at what volumes over the

⁵⁹ Merrow, E.W. (1989). “An Analysis of Cost Improvement in Chemical Process Technologies,” RAND R-3357-DOE.

⁶⁰ Gummerman, E., Marnay, C. (2004). “Learning and Cost Reductions for Generating Technologies in the National Energy Modeling System (NEMS).” LBNL-52559. Ernest Orlando Lawrence Berkeley National Laboratory, University of California Berkeley.

short and long term, adding risk to investment in biofuels infrastructure. Other factors, such as the price of oil, the pace of economic recovery, climate legislation, and other policy measures, also complicate investment decisions.

Im-H: Availability of Biofuels Distribution Infrastructure: The infrastructure required to distribute and dispense large volumes of ethanol does not currently exist, which puts this biofuel at a disadvantage compared to conventional liquid transportation fuels that already have mature infrastructure. Ethanol is currently transported predominantly by rail and truck. Without large capital investments, these transport modes are expected to encounter significant congestion issues over the coming decades, especially in the Midwest. Higher-level ethanol blends, such as E85 (and other less compatible biofuels), require separate storage tanks and dispensers, and may require other material modifications at refuels stations. Most refueling stations are privately owned with relatively thin profit margins, and owners have been reluctant to invest in new infrastructure until the market is more fully developed. Further, some refueling stations may not have enough space available to add dispensers and new storage tanks. The scarcity of E85 refueling stations makes it difficult for consumers who own FFVs to use E85 and also makes it less likely that potential new consumers will purchase an FFV. Petroleum-compatible biofuels may also require distribution infrastructure investment including east-west pipeline expansion.

Im-I. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative: To be successful in the marketplace, biomass-derived fuels and chemical products must perform as well or better than comparable petroleum- and fossil-based products. Industry partners and consumers must believe in the quality, value, sustainability, and safety of biomass-derived products and their benefits relative to the risks and uncertainties that widespread changes will likely bring. Compared to other renewable technologies, consumer acceptance and awareness of biofuels and bioenergy technologies are varied. Impartial, reliable information regarding the economic and environmental benefits and impacts of increased bioenergy use is not always widely available.

Technical Challenges/Barriers

It-A. End-to-End Process Integration: Successful deployment of the biorefinery business model is dependent on advances in integrated conversion process technologies. The biorefinery concept encompasses a wide range of technical issues related to collecting, storing, transporting, and processing diverse feedstocks, as well as the complexity of integrating new and unproven process steps. The demonstration and validation of total process integration—from feedstock production to end-product distribution—is crucial, as it impacts both performance and profitability.

It-B. Risk of First-of-a-Kind Technology: Pioneer biorefineries will incorporate a variety of new technologies. The number and complexity of new process steps implemented in pilot- and demonstration-scale projects have been shown to be a strong predictor of future commercial performance shortfalls. Heat and mass balances, along with the implications, are not likely to be well-understood in new technologies. In addition, start-up and commissioning the equipment may take longer than expected due to issues that were not observed at smaller scales, including

buildup of impurities in process recycle streams, degradation of chemical or catalyst performance and abrasion, fouling, and corrosion of plant equipment.

It-C. Technical Risk of Scaling and Fully Integrating Biomass Conversion Technologies:

Commercially viable biofuel production requires large scale, complex, capital intensive biorefinery process technologies. Unit operations proven at small scale under laboratory conditions need to be scaled up and integrated at pilot scale to validate process performance. Given the magnitude of capital investment required, scaling from pilot to full commercial scale, as much as a 500-1000X increase in scale, involves a level of technical risk which few investors are willing to assume. Best practices from other process industries suggest more modest scaling factors of 50X from pilot to demonstration scale and of 10-20X from demonstration to first-of-a-kind pioneer scale⁶¹. This step-wise scaling enables full integration of unit operations, more complete validation and optimization of process operations and development of equipment specifications which may enable process performance guarantees.

It-D. Engineering Modeling Tools: The current level of understanding regarding fuels chemistry is insufficient for optimization, scale-up, and commercialization. To better understand how fuel chemistry affects commercial viability, rigorous computational fluid dynamic models are needed. Engineering modeling tools are also needed to address heat integration issues.

It-E. Codes, Standards, and Approval for Use: New biofuels and biofuel blends must comply with federal, state, and regional regulations before introduction to the market. The EPA plays a central role in approving new fuels for use. Technical codes and standards are developed by organizations, including the American Society for Testing and Materials International and Underwriters Laboratory. Safety, health, and environmental standards are developed by the Occupational Safety and Health Administration, the U.S. Department of Homeland Security, and others. Codes and standards are adopted by state and local jurisdictions to ensure product safety and reliability and reduce liability. Limited data and technical information can also delay approvals of technical codes and standards for biofuels and related infrastructure components, including pipelines, storage tanks, and dispensers.

It-F. Engines Not Optimized for Biofuel: Transportation vehicle manufacturers are under pressure to design vehicles with lighter weight and higher overall fuel efficiency to meet the Corporate Average Fuel Economy (CAFE) standards at the same time as biofuels and biofuel blends enter the market place. In current motor vehicle engines, some biofuels result in decreased fuel economy on a miles per gallon basis, relative to petroleum fuels. For instance, ethanol has a lower energy density than gasoline, approximately 76,000 British thermal units (Btu) per gallon of ethanol in comparison to 115,000 Btu per gallon of gasoline,⁶² but it also has a higher octane rating of 115 compared to 85–88 for regular gasoline. The actual fuel economy impact is dependent on a variety of factors, but the negative effects may be mitigated through optimizing engines for higher octane fuel with higher renewable content.

2.3.4 Demonstration and Deployment Approach for Overcoming Challenges and Barriers

The approach for overcoming D&D challenges and barriers includes both how efforts and projects are organized within their WBS, as well as the specific framework used to manage high-profile, large, capital-intensive demonstration projects.

The D&D WBS is outlined in Figure 2-27 and in Table 2-11 below. The current activities generally fall into five categories: Analysis and Sustainability, Technology Interface, Feedstocks, Integrated Biorefineries, and Infrastructure and End Use. D&D activities are primarily performed by industry partners, with national laboratories and universities also making significant contributions.

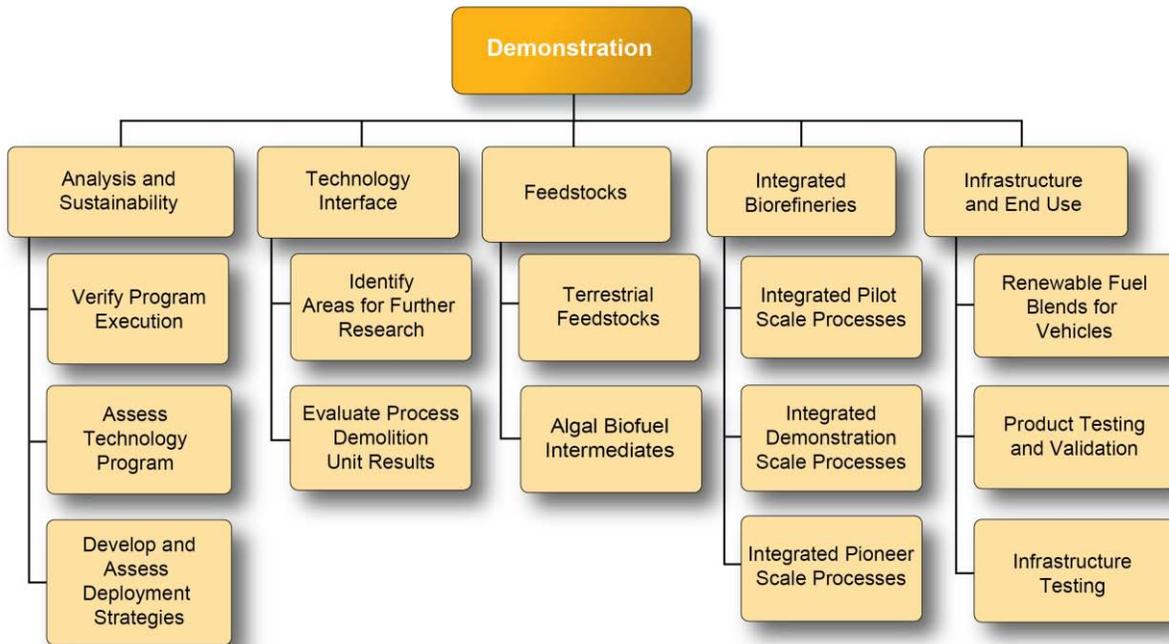

Figure 2-27: Demonstration and Deployment work breakdown structure

Analysis and Sustainability

Both project-specific and portfolio-wide evaluations assess progress toward objectives and sharpen the focus of D&D strategies on the areas with the highest potential impact to the bioindustry. These evaluations, which encompass a broad range of technical performance and economic, social, and environmental sustainability metrics, are updated annually to reflect developments within each project and the industry. Specific metrics include process performance by unit operation; financial data, including pro forma and actual capital and operating costs; and sustainability metrics, including water usage, lifecycle greenhouse gas emissions, and jobs created. This data is used to monitor progress against goals, assess the current SOT for various biomass utilization technologies, and determine the projected commercial impact of various projects.

Technology Interface

D&D projects integrate broad sets of technologies from the Feedstock Supply and Logistics and Conversion R&D Technology Areas. Technology interface activities help identify (1) when technologies are ready for piloting and scale-up, (2) entirely new feedstock logistics systems or conversion technologies, or (3) improvements to a smaller set of unit operations. In addition, new challenges discovered during scale-up are shared in a feedback loop with R&D areas.

Feedstocks

Every IBR starts with feedstock as an input, and efforts to improve the supply and logistics system are essential for commercial operations. These activities span both terrestrial feedstock systems and the production of algal biofuel intermediates to identify areas for improvement in conventional feedstock supply and logistics systems and in the development of advanced feedstock logistics systems.

Integrated Biorefineries

Validating performance at integrated pilot, demonstration, and pioneer scales is essential to de-risk technology and enable financing that will catalyze the transition to large-scale renewable fuel production. Operation at each of these scales systematically addresses many of the market and technical barriers previously identified. Integrated pilots prove the end-to-end process and develop engineering modeling tools. Demonstration-scale facilities then allow for more optimized equipment specifications and can manufacture product for commercial acceptance that can lead to offtake agreements for the pioneer plant. Finally, pioneer plants prove continuous economic operation with large-scale supply chains. Operational data at each scale is also used to address many other barriers, including sustainability.

The success of IBR projects is expected to provide assurances that offtake agreements for biofuels, bioproducts, and biopower can be managed for future commercial financing. Analogous to the petrochemical industry's development of refinery infrastructure, biorefinery projects showing success should translate into better financing potential.

Infrastructure and End Use

In addition to the significant risks involved with scale-up of new technology, other market barriers related to infrastructure and end use also limit the amount of advanced biofuel production. Efforts in this area are focused on enabling higher rates of renewable fuel usage in current markets while addressing barriers for expansion into new markets, such as home heating oil. This includes working closely with DOE's Vehicle Technologies Office to develop and deploy alternative vehicle and fuel technologies through its Clean Cities Program and other avenues.

Table 2-11: D&D Activity Summary

WBS Element	Description	Barrier(s) Addressed
Analysis and Sustainability	Verify progress of projects toward objectives, assess development of overall technologies across the "Valley of Death," and develop strategies to focus on the most promising areas. <ul style="list-style-type: none"> - Verification of technology deployment, including Independent Engineer evaluations of each project. - Assess progress of biorefineries through TEA. - Deploy models and planning processes to assess the impact of D&D projects on overall bioindustry development. Integrated Biorefinery Project Management Framework

The D&D team established a project management framework with additional project management, verification, and oversight procedures to effectively manage the large-scale, capital-intensive IBR activities. The project management framework incorporates DOE standards for management of capital assets, the Office’s priorities, and best practices from industry, including use of an Independent Engineer (IE). The framework, shown in Figure 2-27, is divided into four main sections that correlate contractual Budget Periods (BP) to the Critical Decision (CD) Points identified in DOE Order 413.3B.⁶³

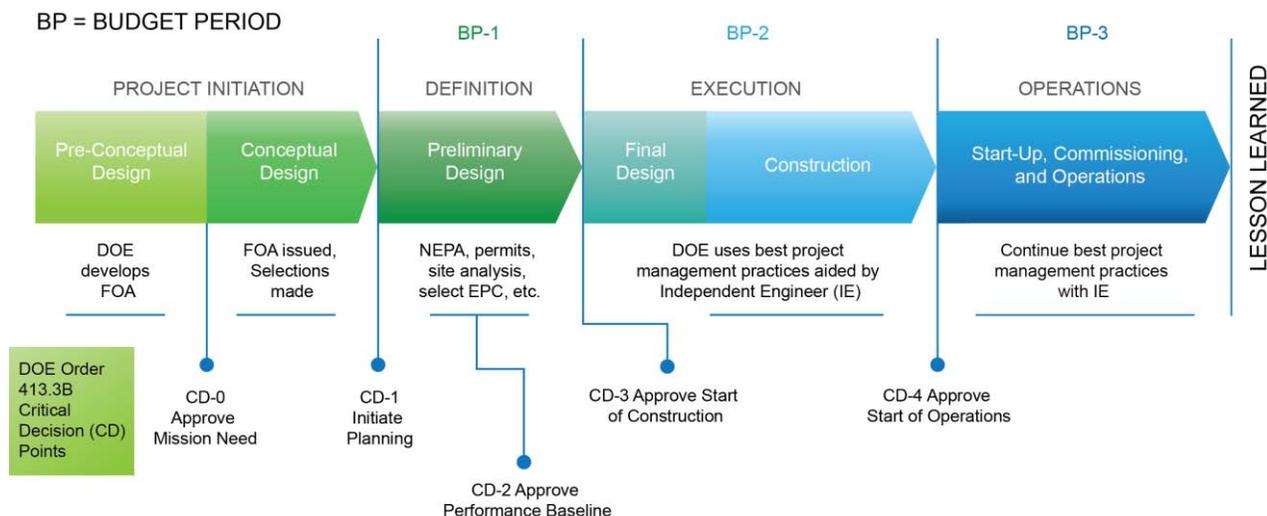

Figure 2-28: Framework for executing DOE project management for integrated biorefinery projects

Critical Decision Points

CD-0 is an internal DOE activity to appropriate funds, determine the nature of a funding opportunity announcement, and execute the competitive selection process. CD-0 effectively ends once the selections are made.

CD-1 begins with the award negotiation and continues with approval of the performance baseline for project scope, schedule, cost, and risk analysis. This corresponds to stage 1 in Front-End Loading (FEL-1) project management practices.

CD-2 occurs when the Project Management Plan (PMP) is put under DOE change control⁶³ and the project locks down its performance baseline. The PMP forms the more detailed basis for the project scope (Statement of Project Objectives) that becomes the contractual basis for the obligation of BP-1 funds to the award. CD-2 also corresponds to an FEL-2 with a -15%/+ 30% cost estimate accuracy for EPC.

⁶³ U.S. Department of Energy. DOE Order 413.3B, Program and Project Management for the Acquisition of Capital Assets. <https://www.directives.doe.gov/directives-documents/0413.3-BOrder-b/view>.

CD-3 requires completing the project financing, submitting the design for bids to EPC contractors, and meeting -5%/+15% cost estimate accuracy (FEL-3). Approval of CD-3 releases the federal funds for BP-2, which typically has the highest associated cost of the three budget periods because of the procurement and construction components.

CD-4 is executed when the project has demonstrated readiness to begin operations. For demonstration and pioneer plants, CD-4 is based on meeting design performance objectives and usually occurs after the performance test has been completed. For some pilot plants, the performance test is what sets the baseline performance targets, so CD-4 is sometimes authorized as part of BP-2 during the start-up/commissioning of the plant.

Independent Engineer Role

The Office retains the services of an IE to assess an awardee's capabilities to successfully execute major capital projects and identify the risks associated with each IBR project. The IE's external independent reviews provide detailed analysis of the technical, organizational, financial, engineering, environmental, economic, and project-related risks at each CD point. The IEs monitor the IBR projects throughout all phases, are called upon to perform independent validation of technical stage gates, and complete formal IBR performance tests. Using an IE firm to perform due diligence reviews is a best practice in many industries, including bioenergy, and a major component of investment decisions by private equity, venture capital firms, and commercial banks.

2.3.5 Prioritizing Demonstration and Deployment Barriers

All of the primary barriers faced in the D&D area must be successfully addressed to produce high volumes of advanced biofuels, bioproducts, and biopower. The following areas are critical and will be emphasized in D&D efforts:

- Validation of proof of performance at integrated pilot, demonstration, and pioneer scales
- Reduction of biorefinery capital and operating costs
- Product qualification testing and offtake agreements.

Financial barriers are the most challenging aspect of technology deployment. Capital costs for commercially viable facilities are relatively high, and securing capital for an unproven technology is extremely difficult. Lenders typically will not provide debt financing for pioneer facilities where the process performance cannot be adequately guaranteed. The D&D Technology Area is uniquely positioned to leverage both legislative authority for financial assistance and DOE's successful track record in commercialization to assist developers in de-risking technologies through validated proof of performance at the pilot, demonstration, and pioneer scales. This assistance is critical to enable equity holder and lender confidence to invest in facility construction and replication at the commercial scale.

Demonstration projects that use federal cost-share funding have shown greater success when the basic technology principles were already proven at smaller scales.⁶⁴ In addition, the use of a pilot

⁶⁴ Baer, W.S., et al. (1976). "Analysis of Federally Funded Demonstration Projects: Executive Summary." RAND

plant led to an increase of almost 50% in the average actual rate of production and a reduction of almost 30% in the start-up duration for a pioneer project—based on a database of more than 1,000 similarly innovative projects.⁵⁸ D&D supports commercialization in the bioprocessing industry through developing a portfolio of a larger number of integrated pilots, a smaller number of demonstrations, and an even smaller number of pioneer-scale plants.

Prioritizing the efforts of the D&D team requires extensive stakeholder input from industry; national laboratories; academia; and other government agencies, such as USDA and the U.S. Department of Defense. Estimating effects of these efforts requires consistent assumptions across a range of market variables, including—but not limited to—national biomass cost and supply curves; biomass logistics systems; projected demand for biofuel, bioproducts, and biopower; learning rates of various conversion technology pathways; and government and tax policies; in addition to any correlation these variables have with each other. The National Renewable Energy Laboratory’s Biomass Scenario Model⁶⁵ was utilized to provide consistent assumptions across various D&D scenarios and gain insight into selecting priorities.⁶⁶

Figure 2-29 shows the estimated effect of prior Office activities as a projection of the number of biorefineries enabled through 2030. The baseline includes the state of the industry and the existing D&D project portfolio. The graph on the right shows the potential impact of expanding the D&D portfolio to meet 2018–2024 D&D milestones. The figure illustrates how D&D efforts are projected to enable a substantial increase in the number of biorefineries by 2030.

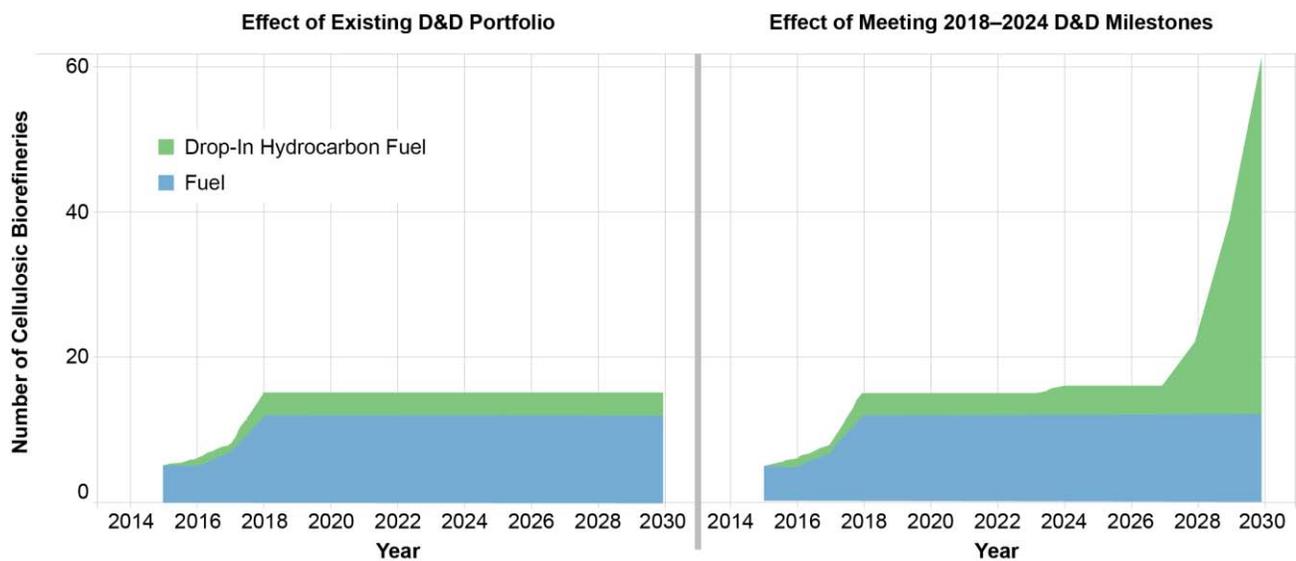

Figure 2-29: Biomass scenario model projection of the number of cellulosic biorefineries enabled by the Office’s D&D efforts

R-1925-DOC. <http://www.rand.org/content/dam/rand/pubs/reports/2006/R1925.pdf>.

⁶⁵ The Biomass Scenario Model is further described in Section 2.5 under Strategic Analysis.

⁶⁶ Vimmerstedt, L. J., Bush, B. W. (2013). “Effects of Deployment Investment on the Growth of the Biofuels Industry.” NREL/TP-6A20-60802. Golden, CO: National Renewable Energy Laboratory. <http://www.nrel.gov/docs/fy14osti/60802.pdf>.

2.3.6 Demonstration and Deployment Milestones and Decision Points

The key D&D milestones and decision points to complete the tasks described in Section 2.3.4 are summarized in Figure 2-30. The validation of integrated conversion technologies includes tracking and reporting the demonstrated performance metrics for each project. Milestones and go/no-go decisions are used to evaluate the progression of each biorefinery award at several stage gates, including the baseline of results achieved prior to award and through project initiation, construction, start-up, and operations.

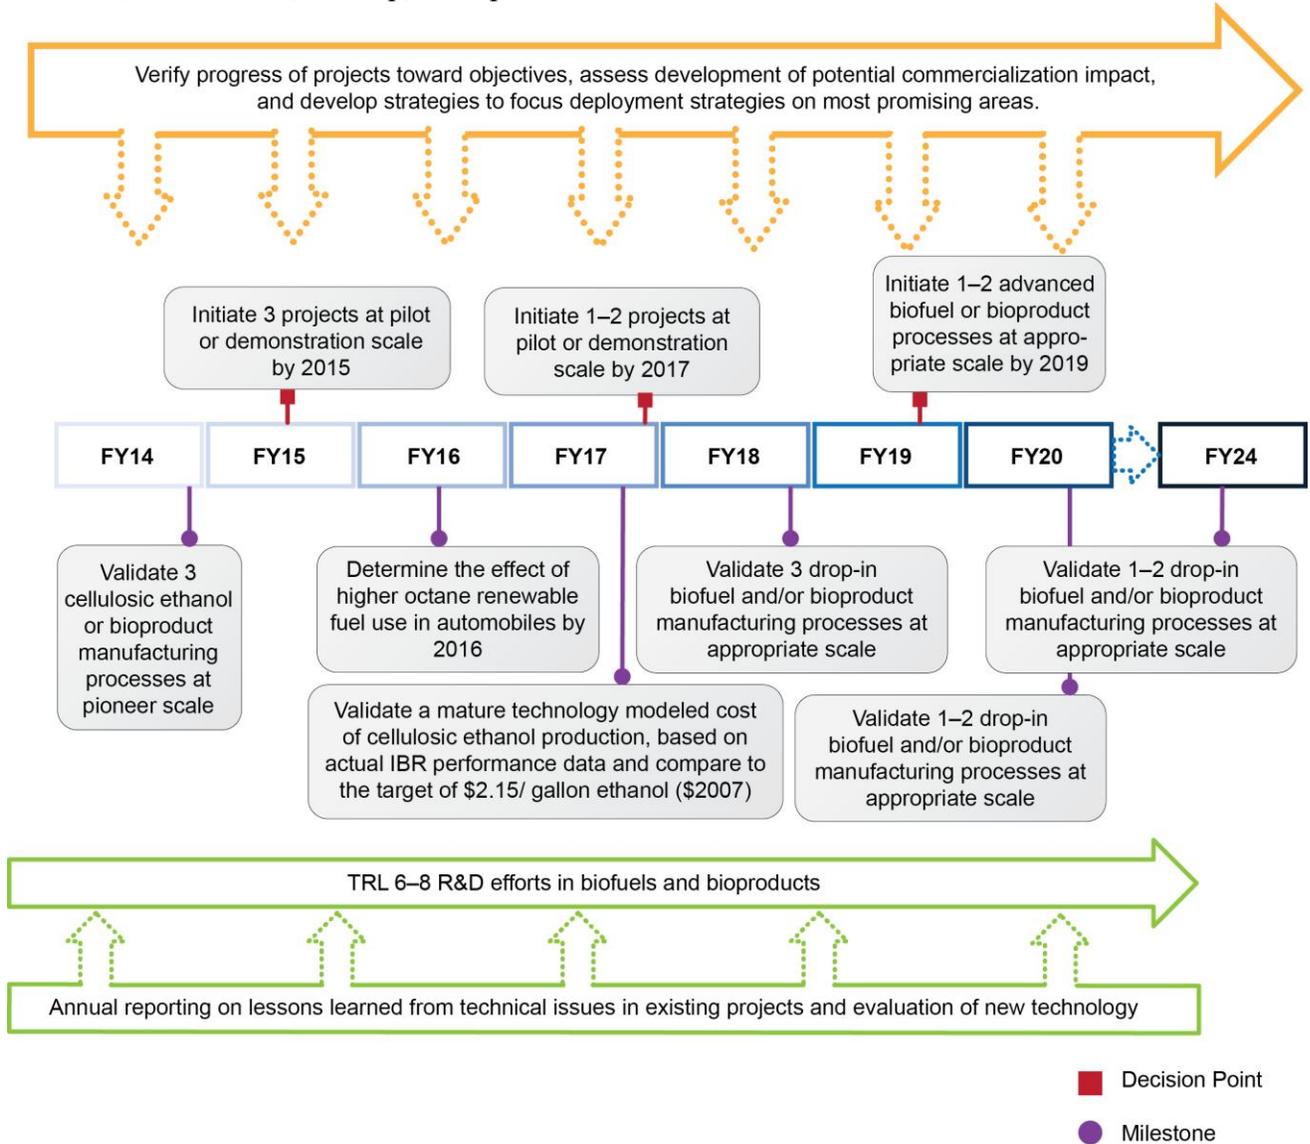

Figure 2-30: Demonstration and deployment key milestones and decision points

2.4 Sustainability

The Bioenergy Technologies Office is committed to developing the resources, technologies, and systems needed to grow a bioenergy industry in a manner that protects natural resources and maximizes economic, social, and environmental benefits. The Office’s Sustainability Technology Area proactively identifies and addresses issues that affect the scale-up potential, public acceptance, and long-term viability of advanced bioenergy systems; as a result, the area is critical to achieving the Office’s overall goals. The existing and emerging biofuels industry will need to develop systems that are not just based on economic viability and market needs, but also on environmental and social aspects such as resource availability and public acceptance. To that end, the Sustainability Technology Area supports analysis, research, and collaborative partnerships to develop and promote practices and technologies that maximize the benefits of bioenergy production activities while mitigating concerns. Sustainability is not an end state or specific goal; rather, the Office is committed to continuous improvement across multiple environmental, economic, and social objectives. The Office collaborates with other government agencies and diverse stakeholders from industry, nongovernmental organizations, research institutions, and international bodies to define those goals and priorities.

Executive Order 13514 (Federal Leadership in Environmental, Energy, and Economic Performance) provides the following definition for sustainability: “To create and maintain conditions, under which humans and nature can exist in productive harmony, that permit fulfilling the social, economic, and other requirements of present and future generations.” Based on this mandate, the Office’s sustainability efforts span environmental, social, and economic dimensions—the three core aspects of sustainability (see Figure 2-31). Maintaining the benefits and services provided by natural resources, promoting economic development, and providing conditions that support human and societal health are all critical components of a sustainable bioenergy industry.

Figure 2-31: Bioenergy Technologies Office sustainability scope

The Office works closely with other federal and international agencies whose missions incorporate bioenergy, such as USDA, EPA, and others. While several federal agencies play important roles along the bioenergy supply chain—such as biomass production within USDA and environmental impacts within EPA—the Office addresses the integration of multiple dimensions of sustainability across all supply chain components. This includes collaborating with relevant research and regulatory entities to enhance the benefits of emerging bioenergy technologies and feedstock varieties, as well as anticipating and mitigating unintended consequences.

The Office also is actively involved in international dialogues on sustainable bioenergy. In coordination with the U.S. State Department and USDA, the Office participates in the Global Bioenergy Partnership to contribute technical expertise and communicate the U.S. experience in evaluating and enhancing bioenergy sustainability. The Office also contributes technical expertise to sustainability efforts led by the International Energy Agency, the Intergovernmental Panel on Climate Change, and the International Organization for Standardization. These international engagements accelerate R&D on sustainable bioenergy production through mutually beneficial technical exchanges and sharing of research results. These collaborations also enable the Office to stay informed of international market developments that affect the U.S. bioenergy industry, as well as help ensure that the U.S. perspective and scientific contributions are represented.

Environmental, Economic, and Social Sustainability across the Bioenergy Supply Chain

Environmental, economic, and social implications are relevant across the full bioenergy supply chain (see Figure 2-32). Evaluating effects and promoting improvements in each sustainability category necessitates different measures and types of activities depending on the stage of the supply chain. For example, certain environmental categories—such as soil quality and biological diversity—are most relevant to biomass production, while others—such as water and air emissions—are monitored across most or all stages.

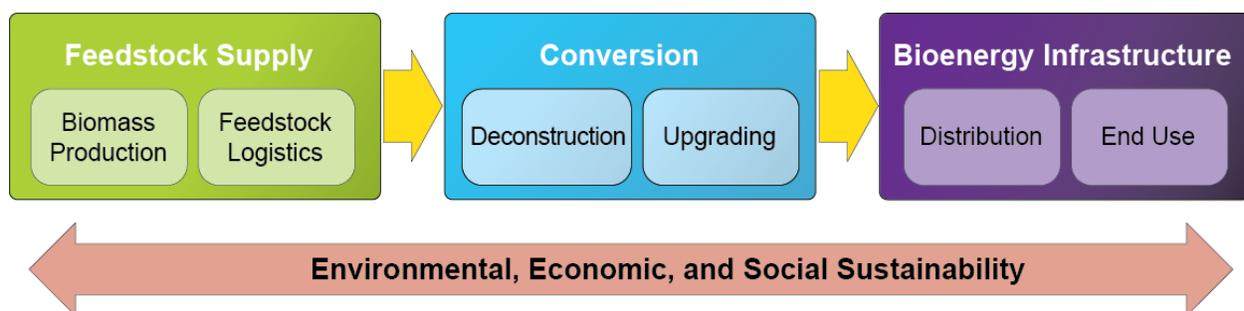

Figure 2-32: Sustainability across the bioenergy supply chain

Environmental Sustainability

Environmental categories of interest are based on the primary effects that many bioenergy systems have or are likely to have on environmental sustainability. These categories and the associated objectives are as follows:

- *Greenhouse Gas Emissions*: Reducing greenhouse gas emissions and climate impacts

- *Soil Quality*: Maintaining or improving soil quality
- *Water Quality and Quantity*: Maintaining or improving water quality, reducing water use, and improving water-use efficiency
- *Air Quality*: Minimizing air pollutants and maintaining or improving air quality
- *Biological Diversity*: Conserving plant and animal diversity and protecting habitat and ecological systems
- *Land Use and Productivity*: Enhancing beneficial land-use management and maintaining or improving land productivity.

Economic Sustainability

The primary goal of the Office is to promote a commercially viable bioenergy industry in the United States. Several economic sustainability categories are critical for measuring progress toward this goal. When assessing and documenting the SOT for promising bioenergy pathways, the primary measurements include return on investment, net present value, process efficiency, and yield of desired products. Economic sustainability is interwoven into the Office's strategic goals. The interaction between economic sustainability and the other two components (social and environmental) is also considered in depth.

Social Sustainability

Social sustainability is critical to ensure that development of the bioenergy industry aligns with societal values and promotes social goals. Social sustainability categories and the associated objectives are as follows:

- *Social Acceptability*: Improving public opinion through science-based information, minimizing risks, maximizing transparency, and ensuring effective stakeholder participation
- *Social Well-Being*: Maintaining or improving prosperity, safety, health, and food security
- *Energy Security and External Trade*: Reducing dependence on foreign oil, increasing access to affordable energy, demonstrating a positive net energy balance relative to fossil fuels, and improving the balance of trade between imports and exports for energy-related materials
- *Resource Conservation*: Minimizing use of non-renewable resources relative to renewable resources and enhancing the energy return on investment
- *Rural Development and Workforce Training*: Creating job opportunities, enhancing rural livelihoods, and developing a skilled bioenergy workforce.

System-Level Sustainability

System-level sustainability considers the relationship within and between the sustainability categories above. System-level sustainability, for example, could focus on optimizing a technology for both economic and environmental factors to find the most beneficial outcome.

2.4.1 Sustainability Support of Office Strategic Goals

Sustainability is an integral part of the Office's vision and strategic goal. The strategic goal of the Sustainability Technology Area is *to understand and promote the positive economic, social, and environmental effects and reduce the potential negative impacts of bioenergy production activities.*

The Sustainability Technology Area interfaces with and impacts all elements of the biomass-to-bioenergy supply chain and at each stage of the development of bioenergy. Considering sustainability early in technology development—rather than after systems are finalized and replicated—enhances the future economic and technical viability of those technologies. Sustainability activities closely align with the feedstock and technology pathways pursued under the Office's R&D and D&D areas. Additionally, the Sustainability Technology Area conducts integrative, cross-cutting, and systems-level activities to understand aggregate effects and identify opportunities for improvement at different scales and across multiple economic and socioeconomic parameters.

2.4.2 Sustainability Support of Office Performance Goals

The Sustainability Technology Area's goals and milestones will be met by evaluating bioenergy systems and demonstrating continuous improvements, or the potential for improvement, across multiple sustainability categories and bioenergy production systems. This includes the feedstocks, logistics systems, and conversion technologies pursued through the Office's R&D and D&D areas.

The overall performance goals for the Sustainability Technology Area are as follows:

- By 2014, quantify the water footprint of cellulosic feedstocks at the county level,⁶⁷ identify modeled feedstock production systems that increase energy crop production and agricultural residue removal by 50%, increase soil quality by at least 5%,⁶⁸ and improve water quality compared to traditional agricultural management
- By 2017, identify conditions under which at least one technology pathway for hydrocarbon biofuel production, validated above R&D scale at a mature modeled price of \$3/GGE, reduces greenhouse gas emissions by 50% or more compared to petroleum fuel, and meets targets for consumptive water use, wastewater, and air emissions⁶⁹
- By 2022, validate landscape design approaches for two bioenergy systems that, when compared to conventional agricultural and forestry production, increase land-use

⁶⁷ See the Water Analysis Tool for Energy Resources (WATER): <http://water.es.anl.gov/>. The water footprint accounts for the water demand, water consumption, and water pollutant loads associated with feedstock production and biorefinery processes.

⁶⁸ Represents a modeled 5% increase in soil organic carbon and soil erosion less than half of the T-value.

⁶⁹ Targets for water consumption will be based on potential process and plant design improvements. Targets for wastewater and air emissions will be based on water quality standards, pollutant discharge regulations, and federal air quality regulations.

efficiency and maintain ecosystem and social benefits, including biodiversity and food, feed, and fiber production⁷⁰

- By 2022, evaluate environmental and socioeconomic indicators across the supply chain for three cellulosic and algal bioenergy production systems to validate greenhouse gas reduction of at least 50% compared to petroleum, socioeconomic benefits including job creation, water consumption equal to or less than petroleum per unit fuel produced, and wastewater and air emissions that meet federal regulations.

The performance milestones for the pathways under investigation are as follows:

Sustainability Analysis and Communication

- By 2015, identify practices that improve sustainability and environmental performance of advanced bioenergy, including results from a comprehensive case study of environmental, social, and economic sustainability indicators for a cellulosic feedstock production and biorefinery system
- By 2016, coordinate with feedstock logistics and conversion R&D areas to set targets for greenhouse gas emissions, consumptive water use, wastewater, and air emissions for at least three renewable hydrocarbon pathways to be validated in 2017 and 2022.

Sustainable System Design

- By 2015, identify conditions under which a national 2030 feedstock production scenario can be achieved that, when compared to the projected USDA baseline, improves average water quality in major feedstock production regions; does not increase consumptive water use per unit fuel produced; maintains soil quality and biodiversity; and does not impact projected needs for food, feed, and fiber production⁷¹
- By 2018, using available field data, validate case studies of feedstock production systems that reduce greenhouse gas emissions and maintain or improve water quality and soil quality compared to conventional agriculture and forestry systems; identify generalizable conclusions and strategies to translate optimized scenarios into practice.

2.4.3 Sustainability Challenges and Barriers

St-A. Scientific Consensus on Bioenergy Sustainability: While there is agreement on the general definition of sustainability, there is no consensus on its specific definition and ways to quantitatively measure bioenergy sustainability (such as approaches, system boundaries, and time horizons).

St-B. Consistent and Science-Based Message on Bioenergy Sustainability: The prevalence of misrepresentations of the effects of bioenergy—including assumptions, scenarios, and model

⁷⁰ Here, landscape design refers to a holistic management process that incorporates bioenergy into existing land uses while maintaining or enhancing the environmental, economic, and social benefits that the landscape provides. Increasing land-use efficiency refers to integrating bioenergy systems in a manner that generates more services relative to required inputs.

⁷¹ See “U.S. Billion-Ton Update.” Feedstock production scenario will be consistent with most current feedstock supply projections.

projections that lack empirical underpinnings—creates confusion about the costs and benefits of bioenergy production and leaves the industry vulnerable to criticism.

St-C. Sustainability Data across the Supply Chain: A fundamental hurdle to improving the sustainability of bioenergy production is the lack of consistent data to evaluate sustainability and compare one biofuel or bioenergy pathway with another. The lack of adequate and accessible temporal and spatial data for measuring sustainability also hinders other critical activities, such as establishing baselines, determining targets for improvement, recommending best practices, and evaluating tradeoffs.

St-D. Implementing Indicators and Methodology for Evaluating and Improving Sustainability: Significant progress has been made in developing a science-based framework for evaluating bioenergy sustainability through environmental and socioeconomic indicators and conducting LCAs to determine the impacts of bioenergy relative to other energy alternatives. The remaining challenge is to implement that framework to assess and improve sustainability with appropriate consideration of spatial, temporal, and other context-specific factors.

St-E. Best Practices and Systems for Sustainable Bioenergy Production: Because bioenergy production from cellulosic and algal feedstocks is relatively new, few “best practices” and sustainable systems are defined for all components of the bioenergy supply chain. Improved practices must be developed and deployed and their effectiveness demonstrated at larger scales and in a variety of contexts.

St-F. Systems Approach to Bioenergy Sustainability: The sustainability of the entire supply chain is not adequately considered in assessments of technical feasibility and economic optimization. Limited tools exist to allow researchers to consider the potential synergies and tradeoffs among different goals (such as energy security, biodiversity protection, or low-cost commodities) and different types of bioenergy systems.

St-G. Land-Use and Innovative Landscape Design: The limitations of existing data sources to capture the dynamic state of land use and management and an incomplete understanding of the drivers of land-use and management changes have undermined efforts to assess the environmental and social effects of bioenergy. Science-based, multi-stakeholder strategies are needed to proactively design and manage landscapes to enhance benefits and minimize negative impacts.

2.4.4 Sustainability Approach for Overcoming Challenges and Barriers

The approach for overcoming biomass sustainability technical challenges and barriers is outlined in the Sustainability Technology Area’s WBS, as shown in Figure 2-33. The WBS is organized around two areas: Sustainability Analysis and Communication and Sustainable System Design.

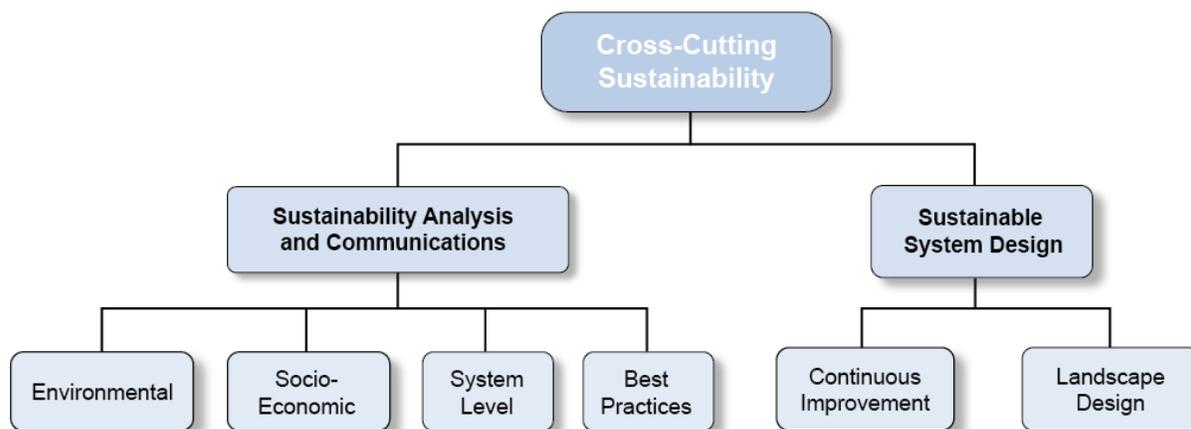

Figure 2-33: Sustainability work breakdown structure

The approach of each Sustainability WBS task element is described below and in Table 2-12. Each element is defined by its primary objectives; however, the two elements are interconnected, and outcomes in one inform activities in another. Both elements seek to develop or identify better practices, assess opportunities for improvement, disseminate technical information, and promote adoption of responsible practices through outreach and communication.

Both WBS elements contain linkages with the Office's technology areas (Terrestrial and Algal Feedstocks Supply and Logistics R&D, Conversion R&D, and Demonstration & Deployment). This includes collecting and evaluating technology-specific data and developing strategies to improve the environmental performance, resilience, and sustainability of bioenergy systems. For instance, the Office is exploring innovative strategies to reduce supply risks and the delivered cost of feedstocks to biorefineries through highly integrated feedstock production system designs.

Sustainability Analysis and Communication

This area focuses on collecting and integrating data, developing analyses and decision-support tools, and synthesizing and communicating information. Activities include measuring and evaluating sustainability through appropriate indicators and metrics, as well as integrative and spatial analyses of bioenergy production scenarios at different geographic scales (field, regional, national, and global) to investigate environmental, economic, and social impacts. Analyses also investigate trends and tradeoffs across multiple supply chain components and sustainability categories. Analyses reflect the latest empirical and modeled data from within and outside the Office's portfolio. Comparing new bioenergy technologies with current and evolving global bioenergy systems is also important; such comparisons enable the Office to assess performance against benchmark systems from other major bioenergy-producing countries.

Results generated from Sustainability Analysis and Communication activities are used by the Office to inform technology RDD&D to maximize beneficial outcomes. Results and best practices are also disseminated and promoted through publications, interagency interactions, and stakeholder outreach. This includes providing scientific input to bioenergy-relevant certification schemes and standards, such as the Roundtable on Sustainable Biomaterials and the International

Organization for Standardization. International collaborations enable the Office to stay informed of international market developments that affect the U.S. bioenergy industry, as well as help ensure that the U.S. perspective and scientific contributions are represented.

Sustainable System Design

This area focuses on performing sustainability field research and data generation, testing innovative concepts, and developing new practices that maintain or improve the environmental and socioeconomic sustainability of bioenergy. Activities include developing innovative methods for spatial and multi-metric optimization, developing and testing landscape design approaches for bioenergy, and demonstrating continuous improvements over time. As better practices are developed and validated, they are incorporated into the Office's technology evaluation approach, encouraged within the Office's RDD&D portfolio, and promoted through interagency coordination and domestic stakeholder interactions.

Table 2-12: Sustainability Activity Summary

WBS Element	Description	Barrier(s) Addressed
Sustainability Analysis and Communication	Collect and analyze data, develop decision-support tools, identify trends, and evaluate tradeoffs among different indicators and pathways. Use results to inform technology RDD&D, best practices, and outreach activities. Disseminate findings and best practices through publications, interagency interactions, and stakeholder outreach. St-C: Sustainability Data across the Supply Chain St-D: Indicators and Methodology St-E: Best Practices St-F: Systems Approach to Bioenergy Sustainability St-G: Land-Use and Innovative Landscape Design

2.4.5 Prioritizing Sustainability Barriers

The following issues are critical and will be emphasized within near- to mid-term Sustainability efforts:

- Advance scientific methods and models for measuring and understanding bioenergy sustainability across the full supply chain
- Disseminate practical tools that support analyses, decision making, and technology development
- Identify, develop, and promote practices that enhance sustainable bioenergy outcomes
- Develop landscape design approaches that increase bioenergy production while maintaining or enhancing ecosystem and social benefits.

To enable data-driven prioritization of sustainability efforts, the Office follows a framework that can be applied to biomass and bioenergy production systems at different scales and contexts, as illustrated in Figure 2-34. This framework helps guide activities for data generation, data collection, and evaluation of current and future scenarios. The framework also is used to develop management practices and technologies that maintain or improve environmental performance and socioeconomic benefits.

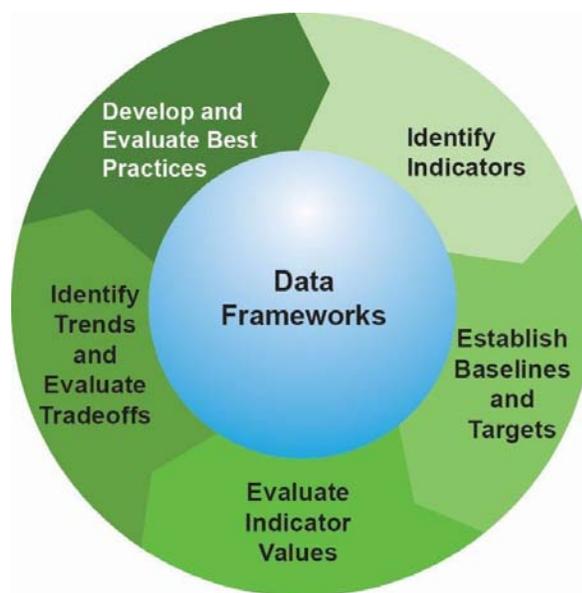

Figure 2-34: Sustainability activities

Implementation of this framework, as described in the following steps, primarily focuses on the categories shown in Figure 2-35. These categories are meant to illustrate the predominant sustainability considerations addressed through Office activities, but they are not exhaustive.

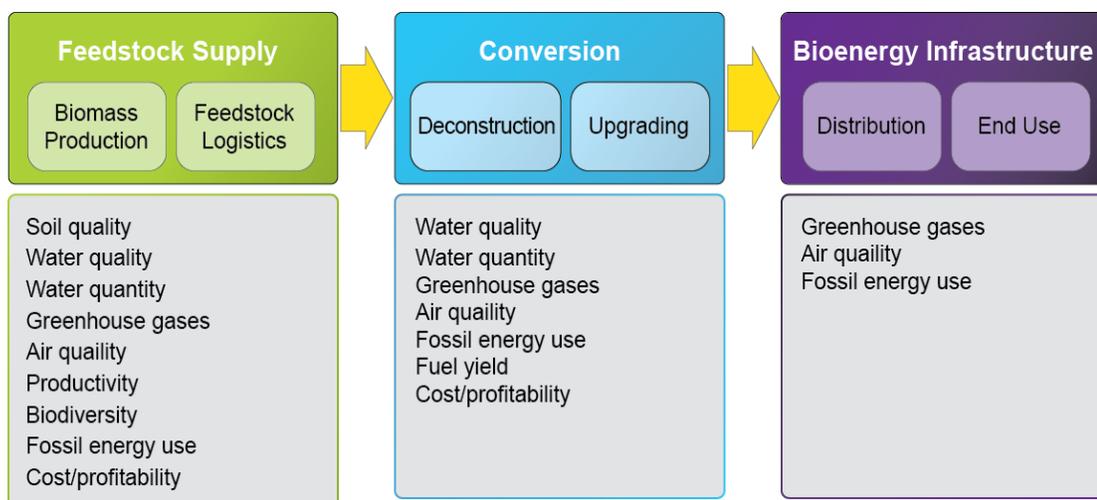

Figure 2-35: Sustainability considerations by supply chain component

- **Identify appropriate indicators and metrics** based on the spatial context and type of biomass/bioenergy system, as well as sustainability goals and selection criteria (e.g., cost of data collection and verification, attribution, comparability across pathways, consistency across agencies, etc.). More information on sustainability indicators for bioenergy are described in McBride et al. 2011 and Dale et al. 2012.^{72,73}
- **Establish baseline and target conditions** consistent with the goals and scales (temporal and spatial) of effects to be measured. Baselines may represent the current bioenergy industry, “business as usual” conditions, or non-optimized systems. Establish relevant sustainability targets based on acceptable, improved, or optimized outcomes. Appropriate targets depend on the type of project and the Office’s ability to influence indicator values:
 - *Scenario Analysis Targets:* Analysis projects develop regional or national scenarios of biomass/bioenergy production to investigate aggregate impacts. Targets reflect beneficial and/or optimized future scenario(s) and can help guide what technology improvements or practices are necessary to best enable meeting beneficial, intended objectives.
 - *Pathway-Specific Targets:* Within the feedstock logistics and conversion R&D areas, sustainability metrics are being assessed alongside the techno-economic parameters and will be increasingly incorporated into SOT assessments as more data are available (see the Thermochemical Conversion R&D section, Figure 2-23). Similar to the cost and technical targets, setting targets for greenhouse gases, air emissions, water consumption, and other relevant sustainability metrics helps promote technologies that achieve multiple economic, technical, and environmental goals.
 - *Site/Project-Specific Targets:* Research and field projects establish site-specific targets that reflect acceptable conditions (e.g., level of soil organic carbon) or

⁷² McBride A., V.H. Dale, L. Baskaran, M. Downing, L. Eaton, R.A. Efroymson, C. Garten, K.L. Kline, H. Jager, P. Mulholland, E. Parish, P. Schweizer, J. Storey. (2011). “Indicators to support environmental sustainability of bioenergy systems.” *Ecological Indicators* 11(1).

⁷³ Dale, V.H., R.A. Efroymson, K.L. Kline, M.H. Langholtz, P.N. Leiby, G.A. Oladosu, M.R. Davis, M.E. Downing, M.R. Hilliard. (2013a). “Indicators for assessing socioeconomic sustainability of bioenergy systems: A short list of practical measures.” *Ecological Indicators* 26(1).

potential for improvement (e.g., reduce nitrogen runoff by 5%). These targets help define practices or guide development of new practices that promote viable operations.

- **Evaluate indicator values** based on established monitoring protocols and consideration of relationships among each supply chain element and indicator. Document status of factors that induce changes in indicator values. Document the presumed degree to which Office intervention can impact indicator values.
- **Identify trends and evaluate tradeoffs** between different indicators and pathway elements. Trends refer to changes in values of sustainability indicators over time. Hypotheses can be developed for forces influencing those trends and tested against relevant empirical data. Tradeoffs between achieving different targets can be explored as a way to improve sustainability.
- **Develop and evaluate best practices based on monitoring, field data, and modeling results.** Compare practices with empirical data to support continuous improvement in sustainability. Review objectives, indicator values and definitions, and best practices upon changing conditions, priorities, and new knowledge. As practices are evaluated for effectiveness, they can be applied to additional projects, locations, and production systems.
- **Maintain data frameworks** for data collection, integration, and visualization to support analysis, research, and adaptive management.

2.4.6 Sustainability Milestones and Decision Points

The key milestones and decision points to complete the tasks described in Section 2.4.4 are summarized in Figure 2-36.

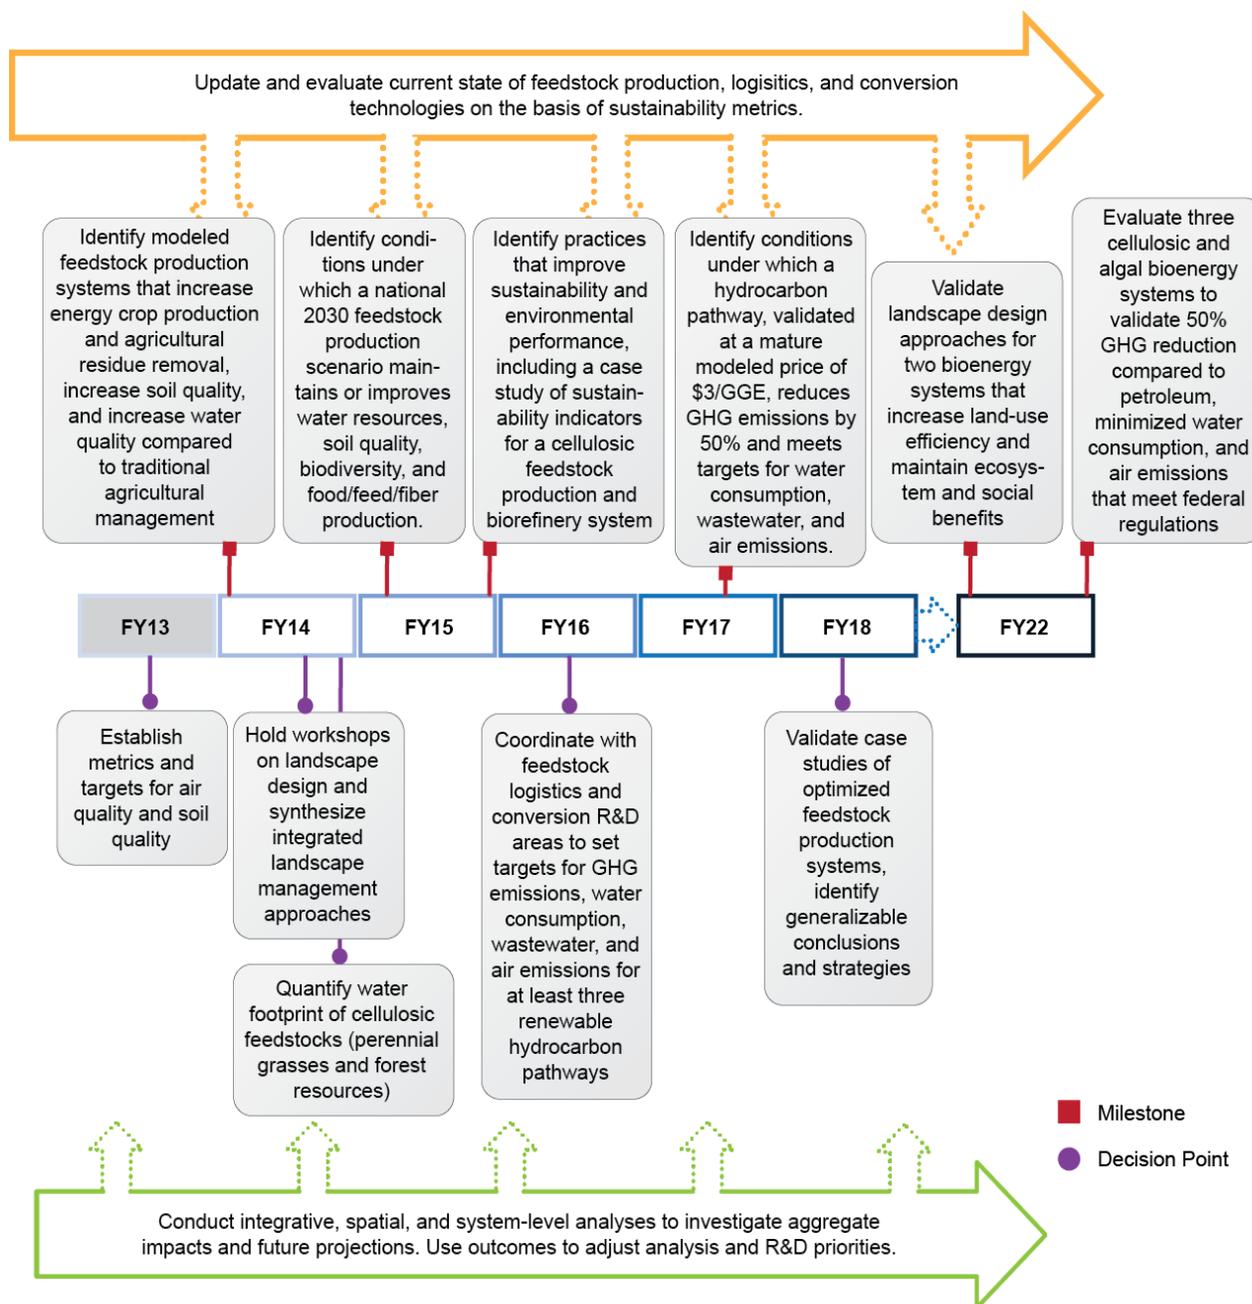

Figure 2-36: Sustainability key milestones and decision points

2.5 Strategic Analysis

Strategic Analysis helps determine overall Office goals and priorities and covers issues that cut across all technology areas. System-level analyses inform strategic direction and planning efforts; they also help the Office focus its technology development priorities and identify key drivers and hurdles for industry growth. Technology-specific analyses explore sensitivities and identify areas where investment may lead to the greatest impacts.

The Strategic Analysis Technology Area plays four main roles in the Office’s decision-making process:

- Provides the analytical basis for planning and assessment of progress
- Defines performance targets and validation strategy for biomass technologies and systems
- Conducts system-level policy, industry, and environmental analyses relevant to bioenergy
- Reviews and evaluates external analyses and studies.

Maintaining these capabilities at the cutting edge ensures that the analysis provides the most efficient and complete answers to internal and external stakeholders. Coordinated multi-lab efforts and continued partnerships with the biomass industry and scientific community help ensure that the Office’s analysis results are peer reviewed, transferable, and comparable.

The majority of Strategic Analysis activities are designed to support Office decision-making processes and track milestones. They validate decisions, ensure objective inputs, and respond to external recommendations. Supporting activities in the Strategic Analysis portfolio strive to advance the state of the science within areas such as land-use change modeling, impact analysis, and LCA. The Office provides ongoing analysis and policy support to other U.S. government agencies and legislative bodies. Emerging issues, interests, and trends raise new questions from a wide variety of stakeholders, including DOE management, members of Congress, other federal agencies, and state governments. Scholarly articles, popular media, and other broader forums are additional sources of questions for analysis.

Figure 2-37 shows how the Strategic Analysis Technology Area supports all elements of the biomass-to-bioenergy supply chain.

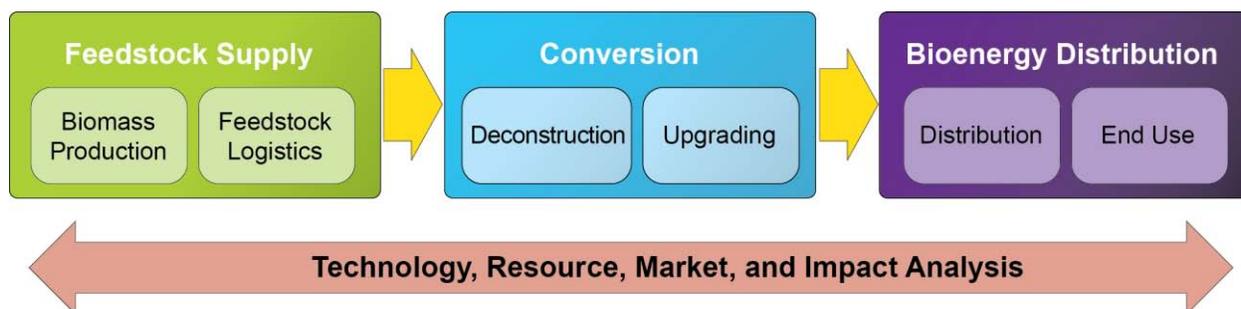

Figure 2-37: Strategic Analysis supports the entire supply chain

2.5.1 Strategic Analysis Support of Office Strategic Goals

The strategic goal of the Strategic Analysis Technology Area is to provide context and justification for decisions at all levels by establishing the basis of quantitative metrics, tracking progress toward goals, and informing portfolio planning and management.

2.5.2 Strategic Analysis Support of Office Performance Goals

The overall performance goals for the Strategic Analysis Technology Area are as follows:

- Ensure high-quality, consistent, reproducible, peer-reviewed analyses
- Develop and maintain analytical tools, models, methods, and datasets to advance the understanding of bioenergy and its related impacts
- Convey the results of analytical activities to a wide audience, including DOE management, Congress, the White House, industry, other researchers, other agencies, and the general public.

Strategic Analysis activities are ongoing; however, the following key milestones will provide the analytical basis for out-year targets and R&D activities for meeting those targets:

- By 2014, coordinate the delivery of new design cases and corresponding LCAs for at least two technology pathways for conversion of biomass to hydrocarbon biofuels
- By 2015, complete an assessment of the size and composition of current and potential markets for biofuels and bioproducts
- By 2016, develop and deploy a consistent methodology for including co-products in TEAs and design cases
- By 2017, identify near-term technology pathways for the Office based on reassessment of current SOT development
- By 2018, complete analysis on impact of advanced biofuels use on gasoline and diesel prices
- By 2022, identify near-term technology pathways for the Office based on reassessment of current SOT development.

2.5.3 Strategic Analysis Challenges and Barriers

Several factors impact the understanding of key drivers and implications for developing and sustainably deploying new biomass technologies. These include the following:

At-A. Comparable, Transparent, and Reproducible Analyses: Analysis results are strongly influenced by the datasets employed, as well as by the assumptions and guidelines established to frame the analysis. Standardized datasets, assumptions, and guidelines are needed to compare and integrate analysis results.

At-B. Analytical Tools and Capabilities for System-Level Analysis: High-quality analytical tools and models are needed to enable the understanding of broader bioenergy supply-chain-wide systems, linkages, and dependencies. Models need to be developed and refined to improve

understanding of these issues and their interactions. Improvements in model components and in linkages are necessary to improve utility and consistency.

At-C. Data Availability across the Supply Chain: Understanding the biomass-to-bioenergy supply chain and its economic, environmental, and other impacts requires complete and comparable data. Filling data gaps and improving data accessibility would improve efforts to understand all relevant dimensions of bioenergy production and use.

2.5.4 Strategic Analysis Approach for Overcoming Challenges and Barriers

The WBS shown in Figure 2-38 and Table 2-13 show the types of analysis activities undertaken by the Office. Strategic Analysis activities are inherently cross-cutting and interface with all other technology areas within the Office. The descriptions below discuss the models and methods used for the various types of analysis conducted by national laboratories, universities, and DOE.

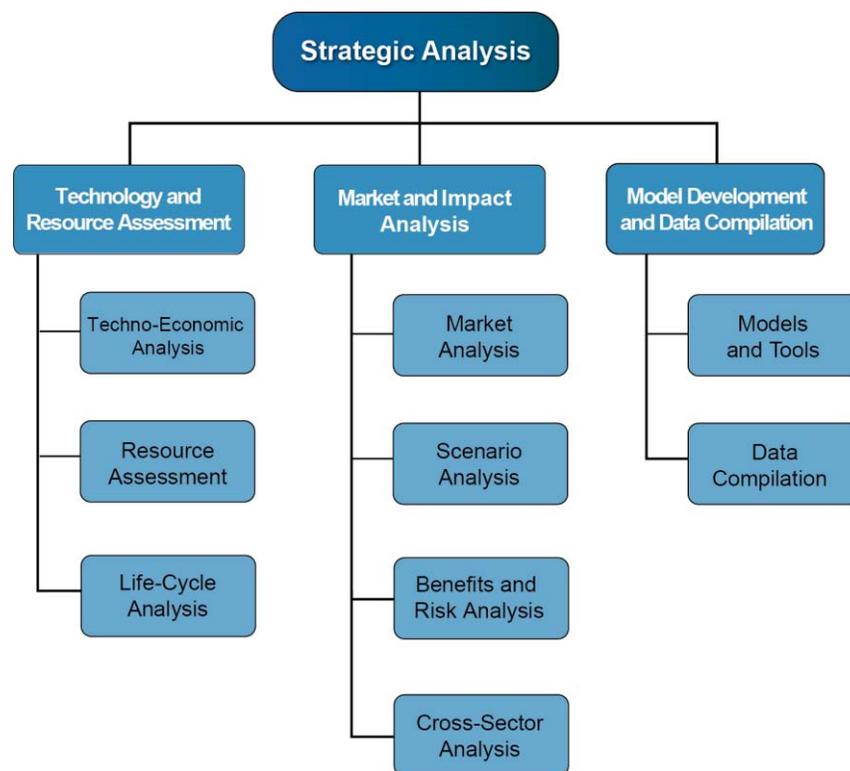

Figure 2-38: Strategic Analysis work breakdown structure

Technology and Resource Assessment

Techno-Economic Analysis: The Office assesses the technical and economic viability of new processes and technologies, identifies the potential for cost reduction, assesses cross-pathway and cross-technology progress, and provides input into portfolio development and technology validation. Technology and economic analysis methods and tools used include

unit operation design flow and information models, process design and modeling (e.g., Aspen Plus®⁷⁴), capital costs (e.g., Aspen Capital Cost Estimator®⁷⁵) and operating cost⁷⁶ determination, discounted cash-flow analysis, and Monte Carlo sensitivity analysis/risk assessment. The Office also assesses the potential cost reductions that can be achieved as the advanced biofuels industry develops and increases capacity beyond first-of-a-kind pioneer facilities. This ongoing analysis effort applies learning rates from relevant, more established industries to estimate the range of possible cost reductions as conversion technologies are commercialized and replicated.

Resource Assessment: Feedstock supply resource assessments identify the geographic location, price, and environmental sustainability of accessing existing and potential future feedstock resources, as well as projecting future supply availability and prices. Strategic Analysis activities utilize these data to understand price effects of competition from various biomass utilization technologies (e.g., biofuel versus biopower), as well as to assess cross-technology impacts of feedstock cost, quantity, and quality.

Life-Cycle Analysis: The Strategic Analysis Technology Area supports Office sustainability efforts through developing and maintaining life-cycle and land-use change models to estimate the environmental impacts of biomass production and utilization technologies. LCA models identify and evaluate the emissions, resource consumption, and energy use of various processes, technologies, or systems to help understand the full impacts of existing and developing technologies and prioritize efforts to mitigate negative effects. The GREET model⁷⁷ is used to estimate fuel-cycle energy use and emissions associated with alternative transportation fuels and advanced vehicle technologies. Strategic Analysis supports updates and enhancements to the GREET model to continually reflect new and evolving bioenergy technologies. Strategic Analysis also supports efforts to better understand and characterize the complex drivers of land-use change and gather more accurate land-use data.

Market and Impact Analysis

Market Analysis: Market assessment helps the Office focus its technology development priorities in the near, mid, and long term by analyzing the potential cost, commercialization time, and market demands for candidate biofuels, biopower, and bioproducts. This analysis draws on a broad range of other analyses, including fossil fuel cost projections; future energy demand forecasts; infrastructure assessments; state of biomass utilization technology development; national and local sustainability analysis; and consumer, economic, and policy

⁷⁴ Aspen Plus® is a process modeling tool for steady-state simulation, design, performance monitoring, optimization, and business planning widely used in the chemicals, specialty chemicals, petrochemicals, and metallurgy industries. More information is available at <http://www.aspentech.com/>.

⁷⁵ For information, see <http://www.aspentech.com>.

⁷⁶ As an example, chemical supply costs are taken from *The Chemical Marketing Report* and labor costs from related industries, such as corn ethanol production.

⁷⁷ For information, see <http://greet.es.anl.gov/>.

scenarios. This analysis also helps identify current and future market attractiveness, gaps, strengths, and risks that may impact producer, investor, and consumer decision making.

Scenario Analysis: Understanding the impacts of changes and development of various elements of the biomass-to-bioenergy supply chain is the key to informing technology portfolio planning and monitoring progress toward national goals. To help understand which supply chain modifications have the greatest potential to accelerate deployment of biofuels, the Office has supported development of the Biomass Scenario Model (BSM). The BSM is a systems dynamics model for conducting biofuels policy analysis through investigation of the systemic effects, linkages, and dependencies across the biomass-to-biofuels supply chain. Figure 2-39 shows the conceptual structure of the model and an overview of the module for each supply chain component. The model considers pathways from starch, lignocellulosic, oilseed, and algal feedstocks to ethanol, butanol, gasoline, diesel, and aviation fuel.

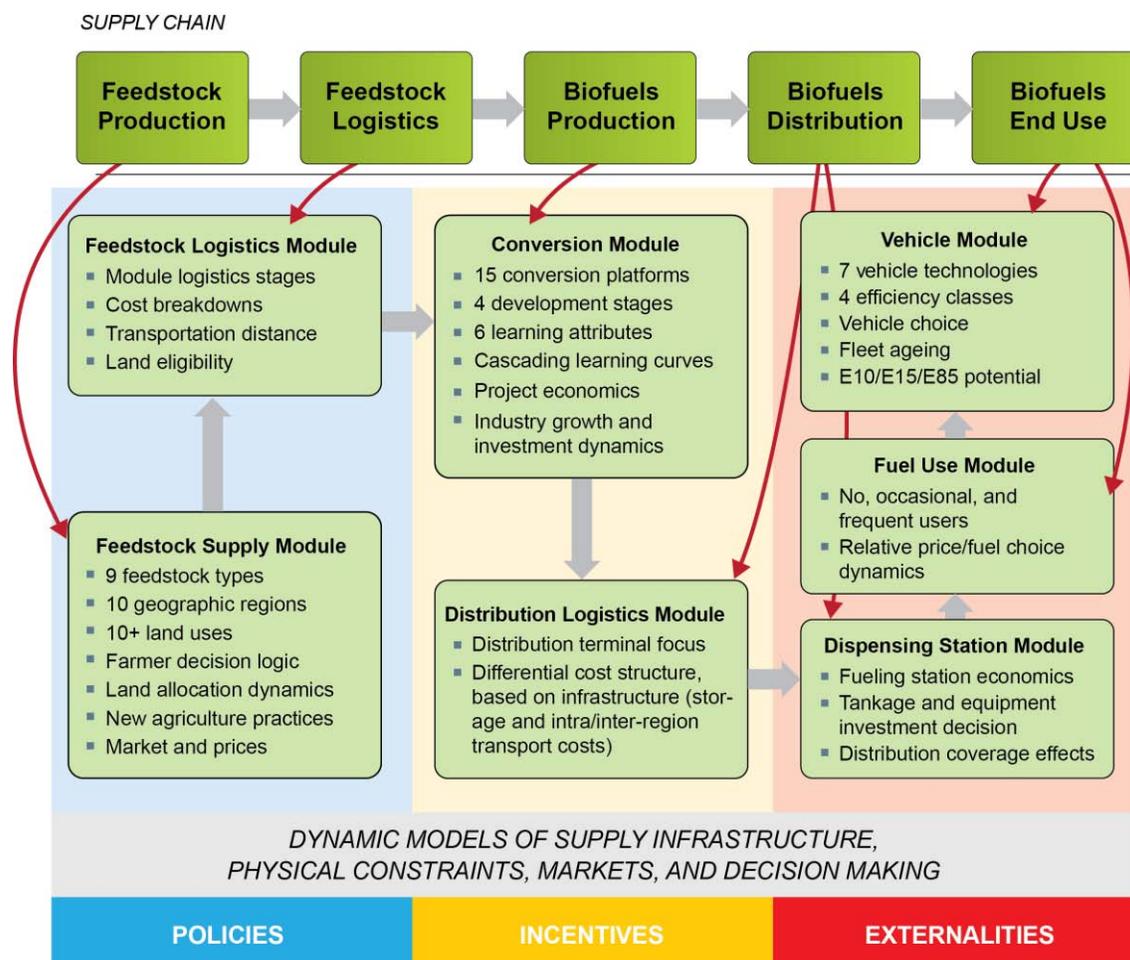

Figure 2-39: Conceptual schematic of the Biomass Scenario Model

Benefits and Risk Analysis: Benefits analysis helps the Office quantify and communicate the long-term benefits of biomass RD&D (e.g., imported oil displacement and greenhouse gas mitigation). The scenarios developed and the quantified costs and benefits are used to evaluate the most viable biomass utilization technologies and routes. Results are also used in

cross-cutting benefits analysis and are a key input to EERE renewable technology portfolio decision making. Risk analysis helps the Office quantify the impact of investments on technology risk over time.

Cross-Sector Analysis: A growing bioenergy industry affects and is affected by other renewable energy and transportation efficiency technologies. Cross-sector analysis includes collaborations with other EERE offices and federal agencies to explore future scenarios for transportation sector growth.

Model Development and Data Compilation

Models and Tools: The Office supports the development and deployment of new analytical tools and methods and guides the selection of assumptions and methodologies to be used for all analyses to ensure consistency, transparency, and comparability of results.

Data Compilation: Many disciplines and sectors are involved in bioenergy RD&D. Developing, compiling, maintaining, and providing easy access to the best available, credible data, models, and visualization tools is critical to supporting sustainable commercialization of biomass utilization technologies. To serve this need, the Office developed the Bioenergy Knowledge Discovery Framework (KDF),⁷⁸ a Web-based data repository, visualization tool, and library. The goal of the KDF is to facilitate planning, development, and management decisions by providing a means to synthesize, analyze, and visualize vast amounts of information in a relevant and succinct manner. The KDF's GIS-based data analysis, mapping, and visualization components draw from dynamic and disparate databases of information to enable users to analyze economic, social, and environmental impacts of various biomass utilization technologies for biomass feedstocks, biorefineries, and infrastructure.

2.5.5 Strategic Analysis Milestones and Decision Points

The key milestones and decision points to complete the tasks described in Section 2.5.4 are summarized in Figure 2-40.

⁷⁸ For more information, visit <https://bioenergykdf.net/>.

Table 2-13: Strategic Analysis Activity Summary

WBS Element	Description	Barrier(s) Addressed
Technology and Resource Assessments	<ul style="list-style-type: none"> - Assess quantity and associated costs of biomass resources. - Assess life-cycle greenhouse gas and air quality impacts of new biofuel pathways and integrate into technical and economic assessments. - Comparative technical and economic assessment of biofuels. - Support the comprehensive integration of annual SOT assessments. - Support feedstock-pathway-wide TEA. 	At-A: Comparable, Transparent, and Reproducible Analysis At-B: Analytical Tools and Capabilities for System-Level Analysis At-C: Data Availability
Market and Impact Analysis	<ul style="list-style-type: none"> - Determine the cost, timing, and market demands for candidate biofuels and biocrudes. - Assess impacts of changes and development of various elements of the biomass-to-bioenergy supply chain and identify impacts of supply chain modifications on deployment of biofuels. - Evaluate and document impact of biofuels on U.S. economies and environment. - Identify, quantify, and evaluate uncertainty and risk of biofuels. 	At-A: Comparable, Transparent, and Reproducible Analysis At-B: Analytical Tools and Capabilities for System-Level Analysis At-C: Data Availability
Model Development and Data Compilation	<ul style="list-style-type: none"> - Ensure results of analytical and research activities are available through the KDF. - Develop new analytical tools and methods, as needed, to address emerging needs. - Establish and maintain standardized assumptions and methods. Figure 2-40: Strategic Analysis key milestones and decision points

2.6 Strategic Communications

The Office's Strategic Communications area is focused on identifying and addressing market and other non-technical barriers to bioenergy adoption and utilization in an effort to reach full-scale market penetration. The activities performed in support of these efforts are geared toward fostering greater stakeholder, public, and congressional awareness and acceptance of significantly increased production of sustainable biofuels, bioproducts, and biopower. This increased production is needed to replace the whole barrel of oil, thus displacing petroleum products and reducing greenhouse gas emissions. Together, these reduce our dependence on foreign oil and secure our nation's economic and energy future. Accordingly, Strategic Communications engages a range of stakeholders in meaningful collaborations, promotes the accomplishments of RD&D projects in first-of-a-kind technologies, increases consumer acceptance, and accelerates the expansion of bioenergy production and use.

Strategic Communications includes distributing technical and non-technical information to internal and external stakeholders through a number of channels, including traditional media; digital media, such as website content; social media; and conferences and events. In addition to conveying key Office goals, priorities, activities, and accomplishments, Strategic Communications also focuses on creating and maintaining public awareness, as well as promoting bioenergy production and use. Informational outreach is targeted at keeping various internal and external stakeholders informed about Office investment strategies, accomplishments, and technologies. Motivational outreach efforts are intended to stimulate demand for and partnership in developing industries that will make up the future bioeconomy.

The Office's target audiences include scientists, engineers, and researchers; industry and investors across the entire bioenergy supply chain; policy makers at all levels of government, including members of Congress and their staffs; the American public, specifically educators and students; and members of rural and farming communities.

The Office's key audiences vary greatly in terms of their level of understanding and opinions about the benefits of sustainable biofuels, bioproducts, and biopower industries. The effectiveness of Office communication efforts is challenged by the information clutter from an increasing number of available communication channels, many of which are designed, over time, to self-engineer and be personalized to unique audience preferences.

Strategic Communications recognizes the growing need for targeted messaging initiatives that align outcome-based messaging frameworks with traditional and emerging communication delivery channels. This requires ongoing analysis that plans and measures outreach efforts that are mapped for specific audiences while simultaneously ensuring integration with other audience initiatives. Desired benefits of this approach target both internal and external audiences to accomplish the following:

- Improve decision making and implementation across BETO programs
- Increase information alignment and bioenergy technology adoption across target audiences

- Proactively diffuse conflicts and conflicting messaging
- Increase opportunities to combine efforts for cumulative impact and higher return on investment.

There are a number of stakeholder classes identified as key to bioenergy industry expansion. As the portfolio of American energy resources diversifies, there is increased competition for market shares, and the current national media landscape demonstrates the need for effective communication campaigns that reach the general public as congressional constituents and consumers of biofuels, bioproducts, and biopower.

Education and Workforce Development

The younger generations are critical stakeholders in the nation's future energy security, and targeted outreach to this audience is important as they prepare to become tomorrow's leaders, select and train for careers, and drive future demand for renewable energy products. As bioenergy technologies emerge in industry and the market transforms, there will also be a need for education and training on the safety, health, and environmental issues related to the transport and use of biofuels, bioproducts, and biopower.

As part of its outreach, the Office can play a significant national role in building this workforce and fostering demand for bioenergy products by engaging America's youth and young adults. Many of the Office's education and workforce development planning and activities are led, coordinated, and/or supported by the Strategic Communications team. Amplifying the Office post-doctoral fellowship and internship programs are part of these activities.

2.6.1 Strategic Communications Support of Office Strategic Goals

The strategic goal of the Strategic Communications Area is *to support and enhance the Office's mission by conducting strategic outreach to target audiences that promotes the benefits of sustainable production of biofuels, bioproducts, and biopower, highlighting the role that a thriving bioeconomy plays in creating green jobs, spurring innovation, benefitting the environment, and achieving national energy security.*

2.6.2 Strategic Communications Support of Office Performance Goals

Strategic Communications aims to achieve the following performance goals and milestones:

- Increase awareness of and support for the Office's advanced biomass RD&D and technical accomplishments, highlighting their role in achieving national renewable energy goals.
 - On an annual basis, complete outreach efforts focused on celebrating specific and timely Office contributions to new technologies, pathways, and directions as Office-supported projects achieve important milestones and deliverables.
 - By the end of 2014, determine three key Office messages that will be amplified throughout all Office outreach.
 - By the end of 2014, complete outreach efforts focused on communicating the Office's successes in cellulosic ethanol to the ethanol-development community.

- By the end of 2014, in collaboration with Office leadership and EERE Strategic Programs, identify highest-value media and target audiences, and set goals for targeted outreach strategies and metrics that rely on appropriate communication channels (traditional and emerging) and carefully tailored messages and sub-messages.
- By the end of 2015, complete a national outreach campaign on the promise and benefits of developing biofuels, bioproducts, and biopower.
- Educate audiences about the environmental, economic, and social benefits of biomass as a viable alternative to fossil fuels, as well as the potential for advanced biofuels to displace petroleum-based transportation fuels.
 - By the end of 2014, complete outreach efforts focused on the greenhouse gas emission reductions resulting from biomass-derived alternative fuels.
 - By the end of 2015, complete outreach efforts focused on landscape-scale environmental benefits of integrated biomass-based alternative fuels production with agricultural and other industrial activities.
 - By the end of 2016, complete outreach efforts focused on future consumers and workforce that will support an emerging bioenergy industry.

2.6.3 Strategic Communications Challenges and Barriers

Accelerating the growth of the bioenergy economy requires addressing market barriers at local, state, and federal levels. Strategic Communications' activities are focused on addressing the following market challenges and barriers.

Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel: To succeed in the marketplace, biomass-derived fuels and chemical products must perform as well as or better than comparable petroleum- and fossil-based products. Industry partners and consumers must perceive the quality, value, sustainability, and safety of biomass-derived products and their benefits, relative to the risks and uncertainties that widespread changes will likely bring. Compared with other renewable technologies, consumer acceptance and awareness of biofuels and bioenergy technologies are varied. Vehicle and engine manufacturers are a particularly influential stakeholder group, as future sustainable transportation designs that work well with biofuels can increase market penetration significantly.

Currently, there is a well-organized and heavily funded campaign of misinformation about biofuels. Only trustworthy, accurate, and up-to-date information can refute these allegations and reassure the public that there are sufficient resources to produce biofuels, bioproducts, and biopower sustainably and economically while benefitting the environment and continuing to meet society's demand for food, feed, and fiber.

Ct-B. Poorly Understood Role of Government versus the Role of Industry: Government-funded R&D focuses on a broad range of emerging technologies. This approach supports a diverse technology portfolio and identifies the most promising targets for industry to pursue in follow-on, industrial-scale demonstration and deployment. Through grants and partnerships with universities, national laboratories, and research groups, the Office helps support basic research that would be too risky for any one private entity to pursue, while advancing the state of

technology development for the entire biomass industry. Once a technology reaches maturity, private industry entities are better equipped to aid in deploying that technology to end users.

Stakeholders and the general public often do not understand these distinct, necessary, and interdependent roles. For example, cellulosic ethanol is now near deployment, causing a shift in the Office's focus to less developed technologies, such as drop-in hydrocarbon biofuels. The Office will need to communicate this shift in focus to its audiences in a clear, transparent manner to avoid misconceptions about the success of cellulosic ethanol. Additionally, the Office must communicate its repositioning as a necessary step in the advancement of technology to meet national energy independence goals, including EISA goals, which will require a diverse array of biobased fuels and products.

Ct-C. Inconsistent and Unpredictable Policy Landscape and Priorities: The Office continues to support new, emerging technologies throughout a constantly changing policy, tax, and economic landscape. Communicating these shifting priorities effectively, accurately, and proactively is an ongoing challenge.

Ct-D. Increasing Information Clutter: As established energy commodities, conventional fossil fuel markets have extensive and compelling national communication campaigns promoting their products. There are also numerous new communication channels that are developing rapidly. While the 'Information Age' increases the reach of traditional media and targets new audiences, it also necessitates greater awareness of specific audience needs, expectations, and sensitivities in order for communication efforts to be effective. This exacerbates the other challenges and barriers and requires a multi-pronged strategic approach to deliver key messaging.

2.6.4 Strategic Communications Approach for Overcoming Challenges and Barriers

Strategic Communications uses a combination of internal and external communication methods that aid the office in disseminating its messages:

- Traditional media
- Website content
- New and digital media
- Conferences and events
- Internal communications

The approach for overcoming Strategic Communications challenges and barriers is outlined in Figure 2-41 and described below.

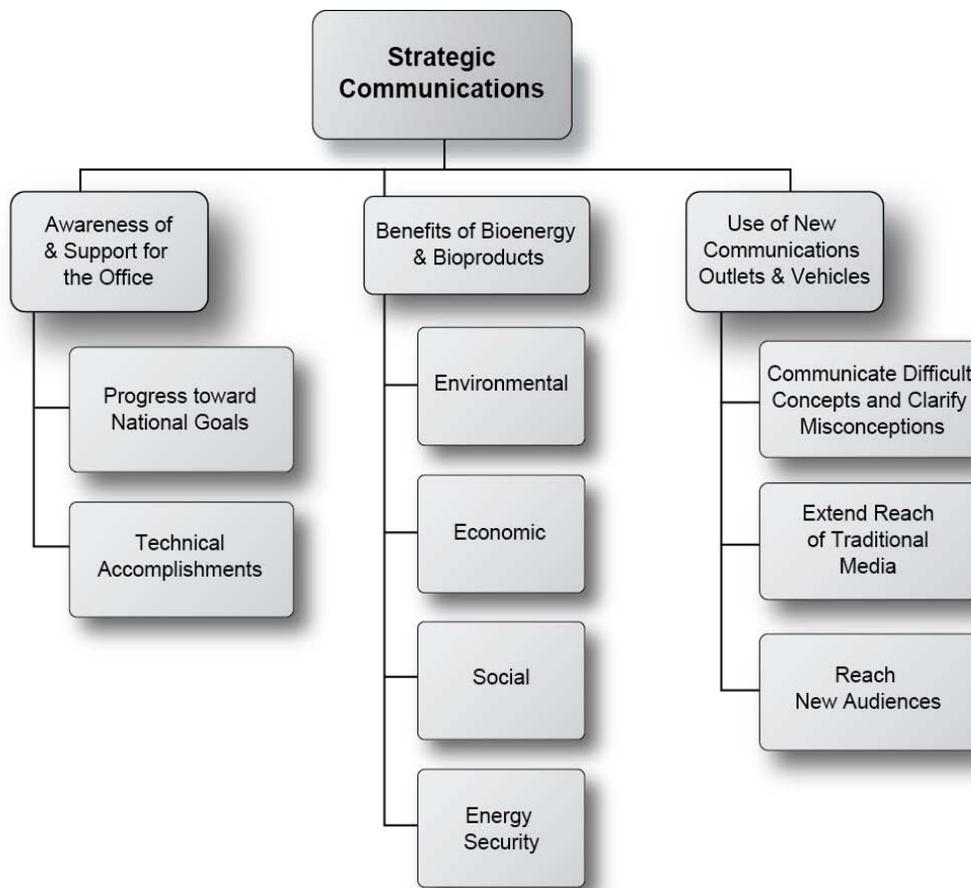

Figure 2-41: Strategic Communications Work Breakdown Structure

Increasing Awareness of & Support for the Office

These activities focus on informing target audiences about Office accomplishments, strategies, and technologies, while calibrating expectations of near- and medium-term RD&D achievements. Near-term activities in this area will focus on promoting the Office's cellulosic ethanol R&D accomplishments, alongside the shift in focus to other infrastructure-compatible fuels suitable for future modes of sustainable transportation. Mid-term activities will highlight deployment and demonstration efforts as first-of-a-kind commercial biorefineries begin and continue production. To disseminate this key messaging, the Office will establish a regular, open line of communication with target audiences through the GovDelivery listserv monthly news blast, the Office's website, press releases and progress alerts, social media, and other outreach channels.

Communicating the Benefits of Bioenergy and Bioproducts

These activities focus on deepening target audiences' understanding of the environmental, economic, social, and energy security benefits of biofuels, biopower, and bioproducts. Mid-term activities will target vehicle and engine manufacturers directly through targeted communication efforts and indirectly through consumer campaigns. The Office will continue its use of regularly scheduled webinars, fact sheets and other publications, the annual Bioenergy Technologies Office conference, and speaking opportunities at industry and partner events to support near- and

mid-term activities. Education and workforce development efforts will largely fall under this approach.

Use of New Communications Vehicles and Outlets

In addition to using traditional media, the Office has planned efforts to make more effective use of new and digital communication vehicles and outlets to address the challenges surrounding bioenergy and draw attention to positive perceptions, results, and accomplishments. Near-term efforts include strengthening communication about the Office's project portfolio by keeping regular lines of communication with target audiences through monthly social media posts and Office Blog posts. Other activities include disseminating Office messaging in graphical and interactive formats that promote understanding, including infographics and website widgets and animations. Long-term efforts include implementing various new channels to disseminate clear and consistent, targeted messaging that will increase the Office's reach beyond current stakeholders, while maintaining costs. This includes continuing to increase use of new and social media and third-party products.

Activities for Strategic Communications are outlined in Table 2-14 and Figure 2-42.

Table 2-14: Strategic Communications Activity Summary

WBS Element	Description	Barrier(s) Addressed
Awareness of & Support for the Office	Use various traditional and emerging media channels to increase awareness of and support for the Office's advanced biomass R&D and technical accomplishments.	
Progress Toward National Goals	Highlight the role the Office plays in achieving national goals, such as meeting EISA requirements for alternative fuels, creating new green jobs, and reducing the nation's dependence on foreign oil by replacing the whole barrel of petroleum-based fuels and products.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel Ct-B. Poorly Understood Role of Government versus the Role of Industry
Technical Accomplishments	Complete outreach efforts focused on celebrating specific Office contributions to new technologies, pathways, and directions as Office-supported projects achieve important milestones and deliverables.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel Ct-B. Poorly Understood Role of Government versus the Role of Industry
Benefits of Bioenergy and Bioproducts	Use various traditional and emerging media vehicles and outlets to increase awareness about the benefits of bioenergy and bioproducts.	
Environmental Benefits	Educate audiences about the environmental benefits of biomass as a viable alternative to fossil fuels, such as outreach efforts focused on the greenhouse gas emission reductions resulting from biomass-based alternative fuels.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel Ct-C. Inconsistent and Unpredictable Policy Landscape and Priorities are Inconsistent
Economic Benefits	Educate audiences about the economic benefits of a strong bioenergy industry, including the contribution to gross national product and keeping U.S. dollars within the United States.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel
Social Benefits	Educate audiences about the social benefits of a strong bioenergy industry, including the creation of new, green jobs.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel
Energy Security Benefits	Educate audiences about the energy security benefits of a strong bioenergy industry, including offsetting imported oil and resources expended securing availability of imported oil.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel
Use of New Communications Vehicles and Outlets	Implement new communications vehicles and outlets to disseminate clear and consistent, targeted Office messaging that will increase the Office's reach beyond current stakeholders, while maintaining costs.	
Communicate Difficult Concepts and Clarify Misconceptions	Strategically use new communications vehicles and outlets to create and distribute products that communicate difficult concepts and clarify misconceptions.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel Ct-B. Poorly Understood Role of Government versus the Role of Industry Ct-D. Increasing Information Clutter
Extend Reach of Traditional Media	Strategically use new communications vehicles and outlets to increase the distribution of traditional Office communications products.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel Ct-B. Poorly Understood Role of Government versus the Role of Industry Ct-D. Increasing Information Clutter
Reaching New Audiences	Strategically use new communications vehicles and outlets, in conjunction with traditional communication efforts, to reach new audiences and targeted demographics.	Ct-A. Lack of Acceptance and Awareness of Biofuels as a Viable Alternative Fuel Ct-B. Poorly Understood Role of Government versus the Role of Industry Ct-D. Increasing Information Clutter

Strategic Communications

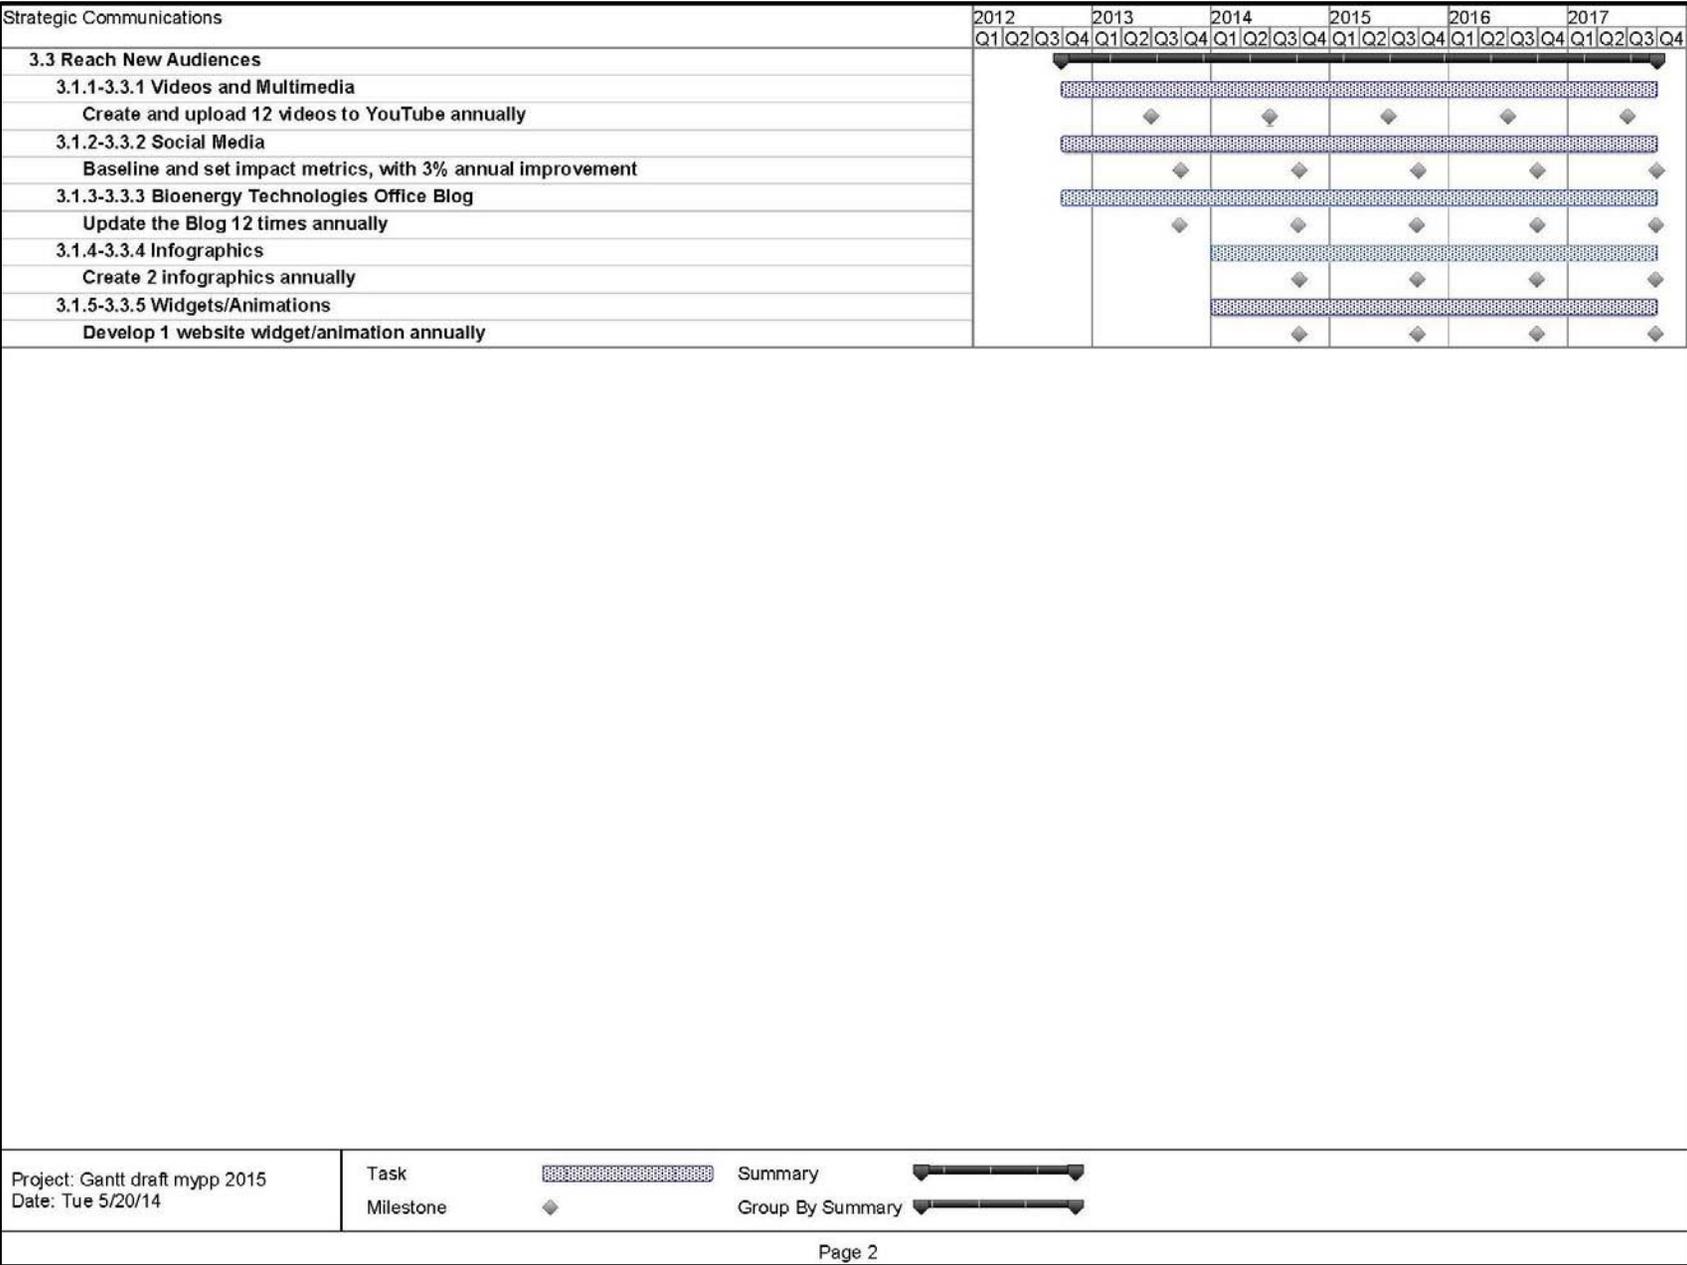

Figure 2-42: Strategic Communications Gantt chart
