fission—The splitting of the nucleus of a heavy atom into two lighter nuclei. It is accompanied by the release of neutrons, gamma rays, and kinetic energy of fission products.

fission products—Nuclei (fission fragments) formed by the fission of heavy elements, plus the nuclides formed by the fission fragments' radioactive decay.

fissure—A long and narrow crack in the earth.

floodplain—The lowlands and relatively flat areas adjoining inland and coastal waters and the flood-prone areas of offshore islands. Floodplains include, at a minimum, that area with at least a 1.0 percent chance of being inundated by a flood in any given year. **Base floodplain**—The area which has a 1.0 percent or greater chance of being flooded in any given year. Such a flood is known as a 100-year flood. **Critical action floodplain**—The area which has at least a 0.2 percent chance of being flooded in any given year. Such a flood is known as a 500-year flood. Any activity for which even a slight chance of flooding would be too great (e.g., the storage of highly volatile, toxic, or water-reactive materials) should not occur in the critical action floodplain.

Probable maximum flood—The hypothetical flood considered to be the most severe reasonably possible flood, based on the comprehensive hydrometeorological application of maximum precipitation and other hydrological factors favorable for maximum flood runoff (e.g., sequential storms and snowmelts). It is usually several times larger than the maximum recorded flood.

flux—Rate of flow through a unit area; in reactor operation, the apparent flow of neutrons in a defined energy range. (See *neutron flux*.)

formation—In geology, the primary unit of formal stratigraphic mapping or description. Most formations possess certain distinctive features.

fossil—Impression or trace of an animal or plant of past geological ages that has been preserved in the Earth's crust.

fossiliferous—Containing a relatively large number of fossils.

fugitive emissions—1) Emissions that do not pass through a stack, vent, chimney, or similar opening where they could be captured by a control device; or 2) Any air pollutant emitted to the atmosphere other than from a stack. Sources of fugitive emissions include pumps; valves; flanges; seals; area sources such as ponds, lagoons, landfills, piles of stored material (e.g., coal); and road construction areas or other areas where earthwork is occurring.

fusion—Nuclear reaction in which light nuclei are fused together to form a heavier nucleus, accompanied by the release of immense amounts of energy and fast neutrons.

gamma radiation—High-energy, short wavelength, electromagnetic radiation emitted from the nucleus of an atom during radioactive decay. Gamma radiation frequently accompanies alpha and beta emissions and always accompanies fission. Gamma rays are very penetrating and are best stopped or shielded by dense materials, such as lead or depleted uranium. Gamma rays are similar to, but are usually more energetic than, x-rays.

Gaussian plume—The distribution of material (a plume) in the atmosphere resulting from the release of pollutants from a stack or other source. The distribution of concentrations about the centerline of the plume, which is assumed to decrease as a function of its distance from the source and centerline (Gaussian distribution), depends on the mean wind speed and atmospheric stability.

genetic effects—Inheritable changes (chiefly mutations) produced by exposure of the parts of cells that control biological reproduction and inheritance to ionizing radiation or other chemical or physical agents.

GENII—A computer code used to predict the radiological impacts on individuals and populations associated with the release of radioactive material into the environment during normal operations and postulated accidents.

geology—The science that deals with the Earth: the materials, processes, environments, and history of the planet, including rocks and their formation and structure.

glovebox—A large enclosure that separates workers from equipment used to process hazardous material while allowing the workers to be in physical contact with the equipment; normally constructed of stainless steel, with large acrylic/lead glass windows. Workers have access to equipment through the use of heavy-duty, lead-impregnated rubber gloves, the cuffs of which are sealed in portholes in the glovebox windows.

gray—The International System of Units (SI) unit of absorbed dose. One gray is equal to an absorbed dose of 1 joule per kilogram (1 gray is equal to 100 rad). (The joule is the SI unit of energy.) (See *absorbed dose*.)

groundwater—Water below the ground surface in a zone of saturation.

habitat—The environment occupied by individuals of a particular species, population, or community.

half-life—The time in which one-half of the atoms of a particular radioactive isotope disintegrate to another nuclear form. Half-lives vary from millionths of a second to billions of years.

Hazard Index—A summation of the Hazard Quotients for all chemicals being used at a site and those proposed to be added to yield cumulative levels for a site. A Hazard Index value of 1.0 or less means that no adverse human health effects (noncancer) are expected to occur.

Hazard Quotient—The value used as an assessment of non-cancer-associated toxic effects of chemicals, e.g., kidney or liver dysfunction. It is a ratio of the estimated exposure to that exposure at which it would be expected that adverse health effects would begin to be produced. It is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens.

hazardous air pollutants—Air pollutants not covered by National Ambient Air Quality Standards but which may present a threat of adverse human health or environmental effects. Those specifically listed in 40 CFR 61.01 are asbestos, benzene, beryllium, coke oven emissions, inorganic arsenic, mercury, radionuclides, and vinyl chloride. More broadly, hazardous air pollutants are any of the 188 pollutants to be regulated or renewed under Section 112(b) of the *Clean Air Act*. Very generally, hazardous air pollutants are any air pollutants that may realistically be expected to pose a threat to human health or welfare.

hazardous chemical—Under 29 CFR Part 1910, Subpart Z, hazardous chemicals are defined as “any chemical which is a physical hazard or a health hazard.” Physical hazards include combustible liquids, compressed gases, explosives, flammables, organic peroxides, oxidizers, pyrophorics, and reactives. A health hazard is any chemical for which there is good evidence that acute or chronic health effects occur in exposed employees. Hazardous chemicals include carcinogens, toxic or highly toxic agents, reproductive toxins, irritants, corrosives, sensitizers, hepatotoxins, nephrotoxins, agents that act on the hematopoietic system, and agents that damage the lungs, skin, eyes, or mucous membranes.

hazardous material—A material, including a hazardous substance, as defined by 49 CFR 171.8, which poses a risk to health, safety, and property when transported or handled.

hazardous substance—Any substance subject to the reporting and possible response provisions of the *Clean Water Act* and the *Comprehensive Environmental Response, Compensation, and Liability Act*.

hazardous waste—A category of waste regulated under the *Resource Conservation and Recovery Act*. To be considered hazardous, a waste must be a solid waste under the *Resource Conservation and Recovery Act* and must exhibit at least one of four characteristics described in

40 CFR 261.20 through 261.24 (i.e., ignitability, corrosivity, reactivity, or toxicity) or be specifically listed by the U.S. Environmental Protection Agency in 40 CFR 261.31–261.33.

hazards classification—The process of identifying the potential threat to human health of a chemical substance.

heavy metals—Metallic or semimetallic elements of high molecular weight, such as mercury, chromium, cadmium, lead, and arsenic, that are toxic to plants and animals at known concentrations.

high-efficiency particulate air filter—An air filter capable of removing at least 99.97 percent of particles 0.3 micrometers (about 0.00001 inches) in diameter. These filters generally include a pleated fibrous medium, typically fiberglass, capable of capturing very small particles.

high-level radioactive waste—The highly radioactive waste material resulting from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing and any solid material derived from such liquid waste that contains fission products in sufficient concentrations, and other highly radioactive material that is determined, consistent with existing law, to require permanent isolation.

high-multiplication devices—A critical assembly for producing nondestructive superprompt critical nuclear excursions. These types of devices are sometimes called prompt burst devices. (See *prompt critical device* and *nuclear excursion*.)

highly enriched uranium (HEU)—Uranium in which the abundance of the isotope uranium-235 is increased well above normal (naturally occurring) levels.

HIGHWAY—A computer code used for predicting routes for transporting radioactive material in the United States and calculating route-specific population density statistics.

historic resources—Physical remains that postdate the emergence of written records; in the United States, they are architectural structures or districts, archeological objects, and archeological features dating from 1492 and later.

Holocene—The current epoch of geologic time, which began approximately 10,000 years ago.

hot cell—A shielded facility that requires the use of remote manipulators for handling radioactive materials.

hydrodynamic test—High-explosive non-nuclear experiment to investigate hydrodynamic aspects of primary function up to mid to late stages of pit implosion.

hydrodynamics—The study of the motion of a fluid and of the interactions of the fluid with its boundaries, especially in the case of an incompressible inviscid fluid.

hydrology—The science dealing with the properties, distribution, and circulation of natural water systems.

impingement—The process by which aquatic organisms too large to pass through the screens of a water intake structure become caught on the screens and are unable to escape.

incident-free risk—The radiological or chemical impacts resulting from emissions during normal operations and packages aboard vehicles in normal transport. This includes the radiation or hazardous chemical exposure of specific population groups such as crew, passengers, and bystanders.

indirect economic effects—Indirect effects result from the need to supply industries experiencing direct economic effects with additional outputs to allow them to increase their production. The additional output from each directly affected industry requires inputs from other industries within a region (i.e., purchases of goods and services). This results in a multiplier effect to show the change in total economic activity resulting from a new activity in a region.

indirect jobs—Within a regional economic area, jobs generated or lost in related industries as a result of a change in direct employment.

induced economic effects—The spending of households resulting from direct and indirect economic effects. Increases in output from a new economic activity lead to an increase in household spending throughout the economy as firms increase their labor inputs.

injection well—A well that takes water from the surface into the ground, either through gravity or by mechanical means.

ion—An atom that has too many or too few electrons, causing it to be electrically charged.

ionizing radiation—Alpha particles, beta particles, gamma rays, high-speed electrons, high-speed protons, and other particles or electromagnetic radiation that can displace electrons from atoms or molecules, thereby producing ions.

irradiated—Exposure to ionizing radiation. The condition of reactor fuel elements and other materials in which atoms bombarded with nuclear particles have undergone nuclear changes.

isotope—An atom of a chemical element with a specific atomic number and atomic mass. Isotopes of the same element have the same number of protons but different numbers of neutrons and different atomic masses.

joint test assembly (JTA)—A nonnuclear test configuration with diagnostic instrumentation of a warhead or bomb.

joule—A metric unit of energy, work, or heat, equivalent to 1 watt-second, 0.737 foot-pounds, or 0.239 calories.

lacustrine wetland—Lakes, ponds, and other enclosed open water at least 8 ha (20 acres) in extent and not dominated by trees, shrubs, and emergent vegetation.

latent cancer fatalities (LTF)—Deaths from cancer occurring some time after, and postulated to be due to, exposure to ionizing radiation or other carcinogens.

limestone—A sedimentary rock composed mostly of the mineral calcite, CaCO_3 .

lithic—Pertaining to stone or a stone tool.

loam—A soil composed of a mixture of clay, silt, sand, and organic matter.

long-lived radionuclides—Radioactive isotopes with half-lives greater than 30 years.

low-income population—Low-income populations, defined in terms of U.S. Bureau of the Census annual statistical poverty levels (*Current Population Reports*, Series P-60 on Income and Poverty), may consist of groups or individuals who live in geographic proximity to one another or who are geographically dispersed or transient (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect. (See *environmental justice* and *minority population*.) From an environmental justice standpoint, low-income populations exist in those census tracts where greater than 50 percent of the population is living below the poverty threshold as defined above.

low-level radioactive waste—Waste that contains radioactivity but is not classified as high-level radioactive waste, transuranic waste, spent nuclear fuel, or byproduct material as defined by Section 11e (2) of the *Atomic Energy Act* of 1954, as amended. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level radioactive waste, provided the concentration of transuranic waste is less than 100 nanocuries per gram.

magnitude—A number that reflects the relative strength or size of an earthquake. Magnitude is based on the logarithmic measurement of the maximum motion recorded by a seismograph. An increase of one unit of magnitude (for example, from 4.6 to 5.6) represents a 10-fold increase in wave amplitude on a seismograph recording or approximately a 30-fold increase in the energy released. Several scales have been defined, but the most commonly used are: 1) Local magnitude (ML), commonly referred to as "Richter magnitude"; 2) Surface-wave magnitude (Ms); 3) Body-wave magnitude (Mb); and 4) Moment magnitude (Mw). Each is valid for a particular type of seismic signal varying by such factors as frequency and distance. These magnitude scales will yield approximately the same value for any given earthquake within each scale's respective range of validity.

material access area—A type of security area that is authorized to contain a security Category I quantity of special nuclear material and which has specifically defined physical barriers, is located within a Protected Area, and is subject to specific access controls.

material control and accountability—The part of safeguards that detects or deters theft or diversion of nuclear materials and provides assurance that all nuclear materials are accounted for appropriately.

maximally exposed individual (MEI)—A hypothetical offsite member of the public whose location and habits result in the highest total radiological or chemical exposure (and thus dose) from a particular source for all exposures (e.g., inhalation, ingestion, or direct exposure).

maximum contaminant level—The designation for U.S. Environmental Protection Agency standards for drinking water quality under the *Safe Drinking Water Act*. The maximum contaminant level for a given substance is the maximum permissible concentration of that substance in water delivered by a public water system. The primary maximum contaminant levels (40 CFR Part 141) are intended to protect public health and are federally enforceable. They are based on health factors, but are also required by law to reflect the technological and economic feasibility of removing the contaminant from the water supply. Secondary maximum contaminant levels (40 CFR Part 143) are set by the U.S. Environmental Protection Agency to protect the public welfare. The secondary drinking water regulations control substances in drinking water that primarily affect aesthetic qualities (such as taste, odor, and color) relating to the public acceptance of water. These regulations are not federally enforceable, but are intended as guidelines for the States.

megajoule—A unit of heat, work, or energy equal to 1 million joules. (See *joule*.)

megawatt—A unit of power equal to one million watts. Megawatt-thermal is commonly used to define heat produced, while megawatt-electric defines electricity produced.

meteorology—The science dealing with the atmosphere and its phenomena, especially as relating to weather.

micron—One-millionth of one meter.

migration—The natural movement of a material through the air, soil, or groundwater; also, seasonal movement of animals from one area to another.

Migratory Bird Treaty Act—This Act states that it is unlawful to pursue, take, attempt to take, capture, possess, or kill any migratory bird, or any part, nest, or egg of any such bird other than permitted activities.

million electron volts (MeV)—A unit used to quantify energy. In this EIS, it describes a particle's kinetic energy, which is an indicator of particle speed.

millirem—One-thousandth of one rem.

minority population—Minority populations exist where either: 1) The minority population of the affected area exceeds 50 percent; or 2) The minority population percentage of the affected area is meaningfully greater than in the general population or other appropriate unit of geographic

analysis (such as a governing body's jurisdiction, a neighborhood, census tract, or other similar unit). "Minority" refers to individuals who are members of the following population groups: American Indian or Alaska Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic. "Minority populations" include either a single minority group or the total of all minority persons in the affected area. They may consist of groups of individuals living in geographic proximity to one another or a geographically dispersed/transient set of individuals (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect. (See *environmental justice* and *low-income population*.)

Miocene—An epoch of the upper Tertiary Period, spanning between approximately 24 and 5 million years ago.

mitigate—Mitigation includes: 1) Avoiding an impact altogether by not taking a certain action or parts of an action; 2) Minimizing impacts by limiting the degree or magnitude of an action and its implementation; 3) Rectifying an impact by repairing, rehabilitating, or restoring the affected environment; 4) Reducing or eliminating the impact over time by preservation and maintenance operations during the life of an action; or 5) Compensating for an impact by replacing or providing substitute resources or environments.

mixed waste—Waste that contains both nonradioactive hazardous waste and radioactive waste, as defined in this glossary.

Modified Mercalli Intensity—A level on the modified Mercalli scale. A measure of the perceived intensity of earthquake ground shaking with 12 divisions, from I (not felt by people) to XII (nearly total damage). It is a unitless expression of observed effects.

National Ambient Air Quality Standards—Air quality standards established by the *Clean Air Act*, as amended. The primary National Ambient Air Quality Standards are intended to protect the public health with an adequate margin of safety, and the secondary National Ambient Air Quality Standards are intended to protect the public welfare from any known or anticipated adverse effect of a pollutant.

National Emission Standards for Hazardous Air Pollutants—Standards set by the U.S. Environmental Protection Agency for air pollutants which are not covered by National Ambient Air Quality Standards and which may, at sufficiently high levels, cause increased fatalities, irreversible health effects, or incapacitating illness. These standards are given in 40 CFR Part 61 and 63. National Emission Standards for Hazardous Air Pollutants are given for many specific categories of sources (e.g., equipment leaks, industrial process cooling towers, dry-cleaning facilities, petroleum refineries). (See *hazardous air pollutants*.)

National Environmental Policy Act of 1969—This Act is the basic national charter for the protection of the environment. It requires the preparation of an environmental impact statement for every major Federal action that may significantly affect the quality of the human environment. Its main purpose is to provide environmental information to decision makers and

the public so that actions are based on an understanding of the potential environmental consequences of a proposed action and its reasonable alternatives.

National Environmental Research Park—An outdoor laboratory set aside for ecological research to study the environmental impacts of energy developments. National environmental research parks were established by the Department of Energy to provide protected land areas for research and education in the environmental sciences and to demonstrate the environmental compatibility of energy technology development and use.

National Historic Preservation Act of 1966, as amended—This Act provides that property resources with significant national historic value be placed on the National Register of Historic Places. It does not require any permits but, pursuant to Federal code, if a proposed action might impact an historic property resource, it mandates consultation with the proper agencies.

National Pollutant Discharge Elimination System—A provision of the *Clean Water Act* which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by the U.S. Environmental Protection Agency, a State, or, where delegated, a tribal government. The National Pollutant Discharge Elimination System permit lists either permissible discharges, the level of cleanup technology required for wastewater, or both.

National Register of Historic Places—The official list of the Nation's cultural resources that are worthy of preservation. The National Park Service maintains the list under direction of the Secretary of the Interior. Buildings, structures, objects, sites, and districts are included in the National Register for their importance in American history, architecture, archeology, culture, or engineering. Properties included on the National Register range from large-scale, monumentally proportioned buildings to smaller-scale, regionally distinctive buildings. The listed properties are not just of nationwide importance; most are significant primarily at the State or local level. Procedures for listing properties on the National Register are found in 36 CFR Part 60.

natural uranium—Uranium with the naturally occurring distribution of uranium isotopes (approximately 0.7-weight percent uranium-235 with the remainder essentially uranium-238). (See *uranium*, *depleted uranium*, and *enriched uranium*.)

neutron—An uncharged elementary particle with a mass slightly greater than that of the proton. Neutrons are found in the nucleus of every atom heavier than hydrogen-1.

neutron flux—The product of neutron number density and velocity (energy), giving an apparent number of neutrons flowing through a unit area per unit time.

nitrogen—A natural element with the atomic number 7. It is diatomic in nature and is a colorless and odorless gas that constitutes about four-fifths of the volume of the atmosphere.

nitrogen oxides—The oxides of nitrogen, primarily nitrogen oxide and nitrogen dioxide. These are produced in the combustion of fossil fuels and can constitute an air pollution problem. Nitrogen dioxide emissions contribute to acid deposition and the formation of atmospheric ozone.

noise—Undesirable sound that interferes or interacts negatively with the human or natural environment. Noise may disrupt normal activities (e.g., hearing, sleep), damage hearing, or diminish the quality of the environment.

nonattainment area—An area that the U.S. Environmental Protection Agency has designated as not meeting (i.e., not being in attainment of) one or more of the National Ambient Air Quality Standards for sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and particulate matter. An area may be in attainment for some pollutants, but not for others.

nonproliferation—Preventing the spread of nuclear weapons, nuclear weapon materials, and nuclear weapon technology.

normal operations—All normal (incident-free) conditions and those abnormal conditions that frequency estimation techniques indicate occur with a frequency greater than 0.1 events per year.

Notice of Intent—Announces an agency's intent to prepare an EIS and describes the proposed action and possible alternatives and the scoping process. The scoping process includes holding at least one public meeting and requesting written comments on issues and environmental concerns that an EIS should address.

nuclear assembly—Collective term for the primary, secondary, and radiation case.

nuclear component—Part of a nuclear weapon that contains fissionable or fusionable material.

nuclear criticality—See *criticality*.

nuclear excursion—A very short time period (in milliseconds) during which the fission rate of a supercritical system increases, peaks, and then decreases to a low value.

nuclear explosive—Any assembly containing fissionable and/or fusionable materials and maincharge high-explosive parts or propellants capable of producing a nuclear detonation.

nuclear facility—A facility subject to requirements intended to control potential nuclear hazards. Defined in DOE directives as any nuclear reactor or any other facility whose operations involve radioactive materials in such form and quantity that a significant nuclear hazard potentially exists to the employees or the general public.

nuclear grade—Material of a quality adequate for use in a nuclear application.

nuclear material—Composite term applied to: 1) Special nuclear material; 2) Source material such as uranium, thorium, or ores containing uranium or thorium; and 3) Byproduct material, which is any radioactive material that is made radioactive by exposure to the radiation incident or to the process of producing or using special nuclear material.

Nuclear Nonproliferation Treaty—A treaty with the aim of controlling the spread of nuclear weapons technologies, limiting the number of nuclear weapons states and pursuing, in good faith, effective measures relating to the cessation for the nuclear arms race.

Nuclear Posture Review—A report, led by the Department of Defense, which addresses possible changes in U.S. nuclear policy.

nuclear production—Production operations for components of nuclear weapons that are fabricated from nuclear materials, including plutonium and uranium.

nuclear radiation—Particles (alpha, beta, neutrons) or photons (gamma) emitted from the nucleus of unstable radioactive atoms as a result of radioactive decay.

Nuclear Regulatory Commission—The Federal agency that regulates the civilian nuclear power industry in the United States.

nuclear warhead—A warhead that contains fissionable and fusionable material, the nuclear assembly, and nonnuclear components packaged as a deliverable weapon.

nuclear weapon—The general name given to any weapon in which the explosion results from the energy released by reactions involving atomic nuclei, either fission, fusion, or both.

Nuclear Weapons Complex—The sites supporting the research, development, design, manufacture, testing, assessment, certification, and maintenance of the Nation's nuclear weapons and the subsequent dismantlement of retired weapons.

nuclide—A species of atom characterized by the constitution of its nucleus and hence by the number of protons, the number of neutrons, and the energy content.

Occupational Safety and Health Administration—The U.S. Federal Government agency which oversees and regulates workplace health and safety; created by the *Occupational Safety and Health Act* of 1970.

offsite—Denotes a location, facility, or activity occurring outside of the boundary of a DOE Complex site.

onsite—Denotes a location or activity occurring within the boundary of a DOE Complex site.

onsite population—Department of Energy and contractor employees who are on duty, and badged onsite visitors.

outfall—The discharge point of a drain, sewer, or pipe as it empties into a body of water.

ozone—The tri-atomic form of oxygen; in the stratosphere, ozone protects Earth from the Sun's ultraviolet rays, but in lower levels of the atmosphere, ozone is considered an air pollutant.

package—For radioactive materials, the packaging, together with its radioactive contents, as presented for transport (the packaging plus the radioactive contents equals the package).

packaging—The assembly of components necessary to ensure compliance with Federal transportation regulations. It may consist of one or more receptacles, absorbent materials, spacing structures, thermal insulation, radiation shielding, and devices for cooling or absorbing mechanical shocks. The vehicle tie-down system and auxiliary equipment may be designated as part of the packaging.

palentological resources—The physical remains, impressions, or traces of plants or animals from a former geologic age; may be sources of information on ancient environments and the evolutionary development of plants and animals.

Paleozoic—Geologic time dating from 50 million to 245 million years ago when seed-bearing plants, amphibians, and reptiles first appeared.

palustrine wetland—Nontidal wetlands dominated by trees, shrubs, and emergent vegetation.

particulate matter (PM)—Any finely divided solid or liquid material, other than uncombined (i.e., pure) water. A subscript denotes the upper limit of the diameter of particles included. Thus, P₁₀ includes only those particles equal to or less than 10 micrometers (0.0004 inch) in diameter; P_{2.5} includes only those particles equal to or less than 2.5 micrometers (0.0001 inch) in diameter.

peak ground acceleration—A measure of the maximum horizontal acceleration (as a percentage of the acceleration due to the Earth's gravity) experienced by a particle on the surface of the Earth during the course of earthquake motion.

Pennsylvanian—A geologic time period of the Paleozoic era, spanning between about 320 and 286 million years ago.

perched aquifer/groundwater—A body of groundwater of small lateral dimensions separated from an underlying body of groundwater by an unsaturated zone.

perchlorate—Perchlorate originates as a contaminant in the environment from the solid salts of ammonium, potassium, or sodium perchlorate. It can persist for many decades under typical groundwater and surface water conditions. Ammonium perchlorate is manufactured for use as the oxidizer component and primary ingredient in solid propellant for rockets, missiles, and fireworks. Other uses of perchlorate salts include their use in nuclear reactors and electronic tubes, as additives in lubricating oils, and in aluminum refining.

perennial stream—A stream that flows throughout the year.

Perimeter Intrusion Detection and Assessment System (PIDAS)—A mutually supporting combination of barriers, clear zones, lighting, and electronic intrusion detection, assessment, and access control systems constituting the perimeter of a Complex protected area and designed to detect, impede, control, or deny access to the protected area.

permeability—In geology, the ability of rock or soil to transmit a fluid.

Permian—The final geologic time period of the Paleozoic Era, spanning between about 286 and 245 million years ago.

person-rem—The unit of collective radiation dose commitment to a given population; the sum of the individual doses received by a population segment.

pit—The central core of a nuclear weapon containing plutonium-239 and/or highly enriched uranium that undergoes fission when compressed by high explosives. The pit and the high explosive are known as the “primary” of a nuclear weapon.

placer—A surficial mineral deposit formed by mechanical concentration of valuable minerals from weathered debris, usually through the action of stream currents or waves.

playa—A dry lake bed in a desert basin or a closed depression that contains water on a seasonal basis.

Pleistocene—The geologic time period of the earliest epoch of the Quaternary period, spanning between about 1.6 million years ago and the beginning of the Holocene epoch at 10,000 years ago. It is characterized by the succession of northern glaciations, also called the “ice age.”

plume—The elongated pattern of contaminated air or water originating at a source, such as a smokestack or a hazardous waste disposal site.

plutonium—A heavy, radioactive, metallic element with the atomic number 94. It is produced artificially by neutron bombardment of uranium. Plutonium has 15 isotopes with atomic masses ranging from 232 to 246 and half-lives from 20 minutes to 76 million years.

plutonium-239—An isotope of plutonium with a half-life of 24,110 years which is the primary radionuclide in weapons-grade plutonium. When plutonium-239 decays, it emits alpha particles.

population dose—See *collective dose*.

Precambrian—All geologic time before the beginning of the Paleozoic era. This includes about 90 percent of all geologic time and spans the time from the beginning of the Earth, about 4.5 billion years ago, to about 570 million years ago.

prehistoric resources—The physical remains of human activities that predate written records; they generally consist of artifacts that may alone or collectively yield otherwise inaccessible information about the past.

prevention of significant deterioration—Regulations required by the 1977 *Clean Air Act* amendments to limit increases in criteria air pollutant concentrations above baseline in areas that already meet the National Ambient Air Quality Standards. Cumulative increases in pollutant levels after specified baseline dates must not exceed specified maximum allowable amounts.

These allowable increases, also known as increments, are especially stringent in areas designated as Class I areas (e.g., national parks, wilderness areas) where the preservation of clean air is particularly important. All areas not designated as Class I are currently designated as Class II. Maximum increments in pollutant levels are also given in 40 CFR 51.166 for Class III areas, if any such areas should be so designated by the U.S. Environmental Protection Agency. Class III increments are less stringent than those for Class I or Class II areas. (See *National Ambient Air Quality Standards*.)

prime farmland—Land that has the best combination of physical and chemical characteristics for producing food, feed, fiber, forage, oil seed, and other agricultural crops with minimum inputs of fuel, fertilizer, pesticides, and labor, without intolerable soil erosion, as determined by the Secretary of Agriculture (*Farmland Protection Act* of 1981, 7 CFR Part 7, paragraph 658).

probabilistic risk assessment—A comprehensive, logical, and structured methodology that accounts for population dynamics and human activity patterns at various levels of sophistication, considering time-space distributions and sensitive subpopulations. The probabilistic method results in a more complete characterization of the exposure information available, which is defined by probability distribution functions. This approach offers the possibility of an associated quantitative measure of the uncertainty around the value of interest.

probable maximum flood—Flood levels predicted for a scenario having hydrological conditions that maximize the flow of surface waters.

process—Any method or technique designed to change the physical or chemical character of the product.

proliferation—The spread of nuclear weapons and the materials and technologies used to produce them.

prompt critical device—A critical assembly designed to reach the condition of prompt criticality. Prompt criticality is the nuclear physics supercriticality condition, due to neutrons released immediately during the fission process, in which a mass and geometric configuration of fissile material (uranium-233, uranium-235, plutonium-239, or plutonium-241) results in an extremely rapid increase in the number of fissions from one neutron generation to the next. Prompt criticality does not rely on the releases of delayed neutrons, which are not released immediately, but rather over a period of about one minute after fission. Prompt criticality describes the condition in which the nuclear fission reaction is not only self-sustaining, but also increasing at a very rapid rate.

protected area—A type of security area defined by physical barriers (i.e., walls or fences), to which access is controlled, used for protection of security Category II special nuclear materials and classified matter and/or to provide a concentric security zone surrounding a material access area (security Category I nuclear materials) or a vital area. (See *material access area* and *vital area*.)

proton—An elementary nuclear particle with a positive charge equal in magnitude to the negative charge of the electron; it is a constituent of all atomic nuclei, and the atomic number of an element indicates the number of protons in the nucleus of each atom of that element.

pulsed assemblies—A critical assembly designed to produce a brief emission of neutrons and gamma radiation associated with a critical condition which lasts a fraction of a second.

Quaternary—The second geologic time period of the Cenozoic era, dating from about 1.6 million years ago to the present. It contains two epochs: the Pleistocene and the Holocene. It is characterized by the first appearance of human beings on Earth.

rad—The English unit of absorbed dose, a rad is 0.01 joule of energy deposited per kilogram of absorbing material. A joule is a very small amount of energy. For example, a 60-watt light bulb on for about 0.02 seconds would use one joule of energy. It is historically derived from “radiation absorbed dose.”

radiation (ionizing)—See *ionizing radiation*.

radioactive waste—In general, waste that is managed for its radioactive content. Waste material that contains source, special nuclear, or byproduct material is subject to regulation as radioactive waste under the *Atomic Energy Act*. Also, waste material that contains accelerator-produced radioactive material or a high concentration of naturally occurring radioactive material may be considered radioactive waste.

radioactivity—*Defined as a process:* The spontaneous transformation of unstable atomic nuclei, usually accompanied by the emission of ionizing radiation. *Defined as a property:* The property of unstable nuclei in certain atoms to spontaneously emit ionizing radiation during nuclear transformations.

radioisotope or radionuclide—An unstable isotope that undergoes spontaneous transformation, emitting radiation. (See *isotope*.)

radon—A radioactive noble gas with the atomic number 86, resulting from the radioactive decay of radium. Radon occurs naturally in the environment and can collect in unventilated enclosed areas, such as basements. Large concentrations of radon can result in the accumulation of radioactive radon progeny which can cause lung cancer in humans.

RADTRAN—A computer code combining user-determined meteorological, demographic, transportation, packaging, and material factors with health physics data to calculate the expected radiological consequences and accident risk of transporting radioactive material.

Reasonably Available Control Technology (RACT)—The lowest emissions limit that a particular source is capable of meeting by the application of control technology that is reasonably available as well as technologically and economically feasible.

receiving waters—Rivers, lakes, oceans, or other bodies of water into which wastewaters are discharged.

recharge—Replenishment of water to an aquifer.

Record of Decision (ROD)—A document prepared in accordance with the requirements of 40 CFR 1505.2 and 10 CFR 1021.315 that provides a concise public record of DOE's decision on a proposed action for which an EIS was prepared. A ROD identifies the alternatives considered in reaching the decision; the environmentally preferable alternative; factors balanced by DOE in making the decision, and whether all practicable means to avoid or minimize environmental harm have been adopted, and, if not, the reasons they were not.

reference concentration—An estimate of a toxic chemical daily inhalation of the human population (including sensitive subgroups) likely to be without an appreciable risk of harmful effects during a lifetime. Those effects are both to the respiratory system (portal-of-entry) and the peripheral to the respiratory system (extra-respiratory effects). It is expressed in units of micrograms per cubic meter.

region of influence—A site-specific geographic area in which the principal direct and indirect effects of actions are likely to occur and expected to be of consequence for local jurisdictions.

regional economic area—A geographic area consisting of an economic node and the surrounding counties that are economically related and include the places of work and residences of the labor force. Each regional economic area is defined by the U.S. Bureau of Economic Analysis.

regulated substance—A general term used to refer to materials other than radionuclides that may be regulated by other applicable Federal, State, or local requirements.

reliability—The ability of a nuclear weapon, weapon system, or weapon component to perform its required function under stated conditions for a specified period of time. (Essentially equivalent to performance.)

rem—The English unit of dose equivalent. The dose equivalent in rem equals the absorbed dose in rad in tissue multiplied by the appropriate quality factor and possibly other modifying factors. Historically derived from "roentgen equivalent man," referring to the dosage of ionizing radiation that will cause the same biological effect as 1 roentgen of x-ray or gamma ray exposure. (See *absorbed dose* and *dose equivalent*.)

remediation—The process, or a phase in the process, of rendering radioactive, hazardous, or mixed waste environmentally safe, whether through processing, entombment, or other methods.

remote-handled waste—In general, refers to radioactive waste that must be handled at a distance to protect workers from unnecessary exposure (e.g., waste with a dose rate of 200 millirem per hour or more at the surface of the waste package). (See *contact-handled waste*.)

replacement pit fabrication—This function includes the fabrication, surveillance, and storage of the primary high explosive and plutonium core of a nuclear weapon.

Resource Conservation and Recovery Act—This Act gives EPA the authority to control hazardous waste from the "cradle-to-grave." This includes the generation, transportation, treatment, storage, and disposal of hazardous waste. RCRA also set forth a framework for the management of nonhazardous wastes.

retrofit—To furnish (e.g., a weapon) with new parts, equipment, or features not available at the time of manufacture.

rhyolite—A fine-grained, silica-rich igneous rock, the extrusive equivalent of granite.

riparian—Of, on, or relating to the banks of a natural course of water.

risk—The probability of a detrimental effect from exposure to a hazard. Risk is often expressed quantitatively as the probability of an adverse event occurring multiplied by the consequence of that event (i.e., the product of these two factors).

risk assessment (chemical or radiological)—The qualitative and quantitative evaluation performed in an effort to define the risk posed to human health and/or the environment by the presence or potential presence and/or use of specific chemical or radiological materials.

roentgen—A unit of exposure to ionizing x-ray or gamma radiation equal to or producing one electrostatic unit of charge per cubic centimeter of air. It is approximately equal to 1 rad.

runoff—The portion of rainfall, melted snow, or irrigation water that flows across the ground surface and eventually enters streams.

Safe Drinking Water Act, as amended—This Act protects the quality of public water supplies, water supply and distribution systems, and all sources of drinking water.

safe secure trailer—A specially modified semitrailer, pulled by an armored tractor truck, which DOE uses to transport nuclear weapons, nuclear weapons components, or special nuclear material over public highways.

safeguard—An integrated system of physical protection, material accounting, and material control measures designed to deter, prevent, detect, and respond to unauthorized access, possession, use, or sabotage of nuclear materials.

safety analysis report—A report that systematically identifies potential hazards within a nuclear facility, describes and analyzes the adequacy of measures to eliminate or control identified hazards, and analyzes potential accidents and their associated risks. Safety analysis reports are used to ensure that a nuclear facility can be constructed, operated, maintained, shut down, and decommissioned safely and in compliance with applicable laws and regulations. Safety analysis reports are required for DOE nuclear facilities and as a part of applications for U.S. Nuclear

Regulatory Commission licenses. The U.S. Nuclear Regulatory Commission regulations or DOE orders and technical standards that apply to the facility type provide specific requirements for the content of safety analysis reports. (See *nuclear facility*.)

sandstone—A sedimentary rock composed mostly of sand-size particles cemented usually by calcite, silica, or iron oxide.

sanitary waste—Waste generated by normal housekeeping activities, liquid or solid (includes sludge), which is not hazardous or radioactive.

sanitization—An irreversible modification or destruction of a component or part of a component to the extent required to prevent revealing classified or otherwise controlled information.

scope—In a document prepared pursuant to the *National Environmental Policy Act* of 1969, the range of actions, alternatives, and impacts to be considered.

scoping—An early and open process for determining the scope of issues to be addressed in an EIS and for identifying the significant issues related to a Proposed Action. The scoping period begins after publication in the *Federal Register* of a Notice of Intent to prepare an EIS. The public scoping process is that portion of the process where the public is invited to participate. DOE also conducts an early internal scoping process for environmental assessments or EISs. For EISs, this internal scoping process precedes the public scoping process. DOE's scoping procedures are found in 10 CFR 1021.311.

scrubber—An air pollution control device that uses a spray of water or reactant or a dry process to trap pollutants in emissions.

sealed pit—A nuclear weapon pit that is hermetically closed to protect nuclear material from the environment.

secondary—See *weapon secondary*.

security—An integrated system of activities, systems, programs, facilities, and policies for the protection of restricted data and other classified information or matter, nuclear materials, nuclear weapons and nuclear weapons components, and/or DOE contractor facilities, property, and equipment.

sedimentation—The settling out of soil and mineral solids from suspension in water.

seismic—Earth vibration caused by an earthquake or an explosion.

seismicity—The relative frequency and distribution of earthquakes.

severe accident—An accident with a frequency of less than 10^{-6} per year that would have more severe consequences than a design-basis accident in terms of damage to the facility, offsite consequences, or both.

sewage—The total organic waste and wastewater generated by an industrial establishment or a community.

shielding—In regard to radiation, any material of obstruction (e.g., bulkheads, walls, or other construction) that absorbs radiation to protect personnel or equipment.

short-lived activation product—An element formed from neutron interaction that has a relatively short half-life that is not produced from the fission reaction (e.g., a cobalt isotope formed from impurities in the metal of the reactor piping).

short-lived nuclides—Radioactive isotopes with half-lives no greater than about 30 years.

shrink-well potential—The potential for soils to contract while drying and expand after wetting.

sievert—The International System of Units (SI) unit of radiation dose equivalent. The dose equivalent in sieverts equals the absorbed dose in grays multiplied by the appropriate quality factor (1 sievert is equal to 100 rem). (See *gray*.)

silica gel—An amorphous, highly adsorbent form of silicon dioxide.

silt—A sedimentary material consisting of fine mineral particles intermediate in size between sand and clay.

siltstone—A sedimentary rock composed of fine textured materials.

soils—All unconsolidated materials above bedrock. Natural earthy materials on the Earth's surface, in places modified or even made by human activity, containing living matter, and supporting or capable of supporting plants out of doors.

somatic effect—Any effect that may manifest in the body of the exposed individual over his or her lifetime.

source material—Depleted uranium, normal uranium, thorium, or any other nuclear material determined, pursuant to Section 61 of the *Atomic Energy Act* of 1954, as amended, to be source material, or ores containing one or more of the foregoing materials in such concentration as may be determined by regulation.

source term—The amount of a specific pollutant (e.g., chemical, radionuclide) emitted or discharged to a particular environmental medium (e.g., air, water) from a source or group of sources. It is usually expressed as a rate (i.e., amount per unit time).

special nuclear materials—As defined in Section 11 of the *Atomic Energy Act* of 1954, special nuclear material means: 1) Plutonium, uranium enriched in the isotope 233 or in the isotope 235, and any other material which the U.S. Nuclear Regulatory Commission determines to be special nuclear material; or 2) Any material artificially enriched by any of the above.

spectral (response) acceleration—An approximate measure of the acceleration (as a percentage of the acceleration due to Earth’s gravity) experienced by a building, as modeled by a particle on a massless vertical rod having the same natural period of vibration as the building.

spectral characteristics—The natural property of a structure as it relates to the multidimensional temporal accelerations.

staging—The process of using two layers to achieve a combined effect greater than that of one layer.

START I and II—Terms which refer to negotiations between the United States and Russia (formerly the Soviet Union) during *Strategic Arms Reduction Treaty* (START) I negotiations aimed at limiting and reducing nuclear arms. START I discussions began in 1982 and eventually led to a ratified treaty in 1988. START II protocol, which has not been fully ratified, will attempt to further reduce the acceptable levels of nuclear weapons ratified in START I.

steppe—A semi-arid, grass-covered, and generally treeless plain.

stockpile—The inventory of active nuclear weapons for strategic defense of the United States.

stockpile stewardship program—A program that ensures the operational readiness (i.e., safety and reliability) of the U.S. nuclear weapons stockpile by the appropriate balance of surveillance, experiments, and simulations.

Stockpile surveillance—Routine and periodic examination, evaluation, and testing of stockpile weapons and weapon components to ensure that they conform to performance specifications and to identify and evaluate the effect of unexpected or age-related requirements.

strategic reserve—That quantity of plutonium and highly enriched uranium reserved for future weapons use. For the purposes of this SPEIS, strategic reserves of plutonium will be in the form of pits, and strategic reserves of highly enriched uranium will be in the form of canned secondary assemblies. Strategic reserves also include limited quantities of plutonium and highly enriched uranium metal maintained as working inventory at DOE laboratories.

stratigraphy—Division of geology dealing with the definition and description of rocks and soils, especially sedimentary rocks.

sulfur oxides—Common air pollutants, primarily sulfur dioxide, a heavy, pungent, colorless gas (formed in the combustion of fossil fuels, considered a major air pollutant), and sulfur trioxide. Sulfur dioxide is involved in the formation of acid rain. It can also irritate the upper respiratory tract and cause lung damage.

Superfund Amendments and Reauthorization Act (SARA) of 1986—Public Law 99-499 which amends the *Comprehensive Environmental Response, Compensation and Liability Act* (CERCLA) of 1980. SARA more stringently defines hazardous waste cleanup standards and emphasizes remedies that permanently and significantly reduce the mobility, toxicity, or volume of wastes. Title III of SARA, the *Emergency Planning and Community Right-to-Know Act*,

mandates establishment of community emergency planning programs, emergency notification, reporting of chemicals, and emission inventories.

surface water—All bodies of water on the surface of the earth and open to the atmosphere, such as rivers, lakes, reservoirs, ponds, seas, and estuaries.

Tertiary—The first geologic time period of the Cenozoic era (after the Mesozoic era and before the Quaternary period), spanning between about 66 and 1.6 million years ago. During this period, mammals became the dominant life form on Earth.

thermonuclear—The process by which very high temperatures are used to bring about the fusion of light nuclei, such as deuterium and tritium, with the accompanying release of energy.

Third Third wastes—The Environmental Protection Agency proposed the Third Thirds Rule, as required by the Hazardous and Solid Waste Amendments of 1984, to establish treatment standards and effective dates for all wastes (including characteristic wastes) for which treatment standards had not yet been promulgated (40 CFR 268.12), including derived-from wastes (i.e., multi-storage leachage), and for mixed radioactive/hazardous wastes.

threat—1) A person, group, or movement with intentions to use extant or attainable capabilities to undertake malevolent actions against DOE interests; 2) The capability of an adversary coupled with his intentions to undertake any actions detrimental to the success of DOE program activities or operation.

threatened species—Any plants or animals likely to become endangered species within the foreseeable future throughout all or a significant portion of their ranges and which have been listed as threatened by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures set in the *Endangered Species Act* and its implementing regulations (50 CFR Part 424). (See *endangered species*.)

threshold limit values—The recommended highest concentrations of contaminants to which workers may be exposed according to the American Conference of Governmental Industrial Hygienists.

total effective dose equivalent—The sum of the effective dose equivalent from external exposures and the committed effective dose equivalent from internal exposures.

Toxic Substances Control Act of 1976—This Act authorizes the Environmental Protection Agency to secure information on all new existing chemical substances and to control any of these substances determined to cause an unreasonable risk to public health or the environment. This law requires that the health and environmental effects of all new chemicals be reviewed by the Environmental Protection Agency before they are manufactured for commercial purposes.

Transuranic (TRU)—Any element whose atomic number is higher than that of uranium (atomic number 92), including neptunium, plutonium, americium, and curium. All transuranic elements are produced artificially and are radioactive.

Transuranic Package Transporter Model 2 (TRUPACT 2)—A version of Type B transportation container (see *Type B packaging*) used for transporting transuranic waste. It is made of stainless steel, approximately 8 feet in diameter, 10 feet high, and constructed with leak-tight inner and outer containment vessels. TRUPACT 2 can hold up to 14 55-gallon waste drums, 2 standard waste boxes, or 1 10-drum over-pack (a container designed to provide additional protection for older, deteriorating drums).

transuranic waste—Radioactive waste not classified as high-level radioactive waste and that contains more than 100 nanocuries (3,700 becquerels) per gram of alpha-emitting transuranic isotopes with half-lives greater than 20 years.

tritium—A radioactive isotope of the element hydrogen with two neutrons and one proton. Common symbols for the isotope are H-3 and T.

tuff—A fine-grained rock composed of ash or other material formed by volcanic explosion or aerial expulsion from a volcanic vent.

Type B packaging—A regulatory category of packaging for transportation of radioactive material. The U.S. Department of Transportation and U.S. Nuclear Regulatory Commission require Type B packaging for shipping highly radioactive material. Type B packages must be designed and demonstrated to retain their containment and shielding integrity under severe accident conditions, as well as under the normal conditions of transport. The current U.S. Nuclear Regulatory Commission testing criteria for Type B package designs (10 CFR Part 71) are intended to simulate severe accident conditions, including impact, puncture, fire, and immersion in water. The most widely recognized Type B packages are the massive casks used for transporting spent nuclear fuel. Large-capacity cranes and mechanical lifting equipment are usually needed to handle Type B packages.

Type B shipping cask—A U.S. Nuclear Regulatory Commission-certified cask with a protective covering that contains and shields radioactive materials, dissipates heat, prevents damage to the contents, and prevents criticality during normal shipment and accident conditions. It is used for transport of highly radioactive materials and is tested under severe, hypothetical accident conditions that demonstrate resistance to impact, puncture, fire, and submersion in water.

unconfined aquifer—A permeable geological unit having the following properties: a water-filled pore space (saturated), the capability to transmit significant quantities of water under ordinary differences in pressure, and an upper water boundary that is at atmospheric pressure.

unsaturated zone (vadose)—A region in a porous medium in which the pore space is not filled with water.

uranium—A radioactive, metallic element with the atomic number 92; one of the heaviest naturally occurring elements. Uranium has 14 known isotopes, of which uranium-238 is the most abundant in nature. Uranium-235 is commonly used as a fuel for nuclear fission. (See *natural uranium, enriched uranium, and depleted uranium*.)

vault (special nuclear material [SNM])—A penetration-resistant, windowless enclosure having an intrusion alarm system activated by opening the door and which also has: 1) Walls, floor, and ceiling substantially constructed of materials which afford forced-penetration resistance at least equivalent to that of 20.32-centimeter (8-inch) thick reinforced concrete; and 2) A builtin combination-locked steel door which, for existing structures, is at least 2.54-centimeter (1-inch) thick exclusive of bolt work and locking devices and which, for new structures, meets standards set forth in Federal specifications and standards.

viewshed—The extent of an area that may be viewed from a particular location. Viewsheds are generally bounded by topographic features such as hills or mountains.

vital area—A type of DOE security area that is located within the Protected Area and that has a separate perimeter and access controls to afford layered protection, including intrusion detection, for vital equipment.

Visual Resource Management Class—Any of the classifications of visual resources established through application of the Visual Resources Management process of the Bureau of Land Management. Four classifications are employed to describe different degrees of modification to landscape elements: ***Class I***—areas where the natural landscape is preserved, including national wilderness areas and the wild sections of national wild and scenic rivers; ***Class II***—areas with very limited land development activity, resulting in visual contrasts that are seen but do not attract attention; ***Class III***—areas in which development may attract attention, but the natural landscape still dominates; and ***Class IV***—areas in which development activities may dominate the view and may be the major focus in the landscape.

vitrification—A waste treatment process that uses glass (e.g., borosilicate glass) to encapsulate or immobilize radioactive wastes to prevent them from reacting with the surroundings in disposal sites.

volatile organic compounds (VOC)—A broad range of organic compounds, often halogenated, that vaporize at ambient or relatively low temperatures, such as benzene, chloroform, and methyl alcohol. In regard to air pollution, any organic compound that participates in atmospheric photochemical reaction, except for those designated by the U.S. Environmental Protection Agency Administrator as having negligible photochemical reactivity.

warhead—Collective term for the package of nuclear assembly and non-nuclear components that can be mated with a delivery vehicle or carrier to produce a deliverable nuclear weapon.

waste classification—Waste classified according to DOE Order 435.1, Radioactive Waste Management, including high-level radioactive, transuranic, and low-level radioactive waste.

Waste Isolation Pilot Plant—A facility in southeastern New Mexico developed as the disposal site for transuranic waste (not in operation prior to publication).

waste management—The planning, coordination, and direction of those functions related to the generation, handling, treatment, storage, transportation, and disposal of waste, as well as associated surveillance and maintenance activities.

waste minimization and pollution prevention—An action that economically avoids or reduces the generation of waste and pollution by source reduction, reducing the toxicity of hazardous waste and pollution, improving energy use, or recycling. These actions will be consistent with the general goal of minimizing present and future threats to human health, safety, and the environment.

water table—Water under the surface of the ground occurs in two zones: an upper unsaturated zone and the deeper saturated zone. The boundary between the two zones is the water table.

watt —A unit of power equal to 1 joule per second. (See *joule*.)

weapon primary—The crucial subsystem for weapon reliability and safety; the primary contains the main high explosive and the plutonium that comprise the principal safety concerns. Without proper primary-stage function, the secondary will not work.

weapon secondary—Provides additional explosive energy release; composed of lithium deuterium, and other materials. As the secondary implodes, the lithium in the isotopy forms lithium-6, is converted to tritium by neutron interactions, and the tritium product in turn undergoes fusion with the deuterium to create the thermonuclear explosion.

weapons-grade—Fissionable material in which the abundance of fissionable isotopes is high enough that the material is suitable for use in thermonuclear weapons.

weapons assembly/disassembly (A/D)—Assembly operations assembles piece parts into subassemblies using joining techniques such as welding, adhesive bonding, and mechanical joining. Disassembly takes retired weapons apart and recycles all materials of value.

weighting factor—Generally, a method of attaching different importance values to different items or characteristics. In the context of radiation protection, the proportion of the risk of effects resulting from irradiation of a particular organ or tissue to the total risk of effects when the whole body is irradiated uniformly (e.g., the organ dose weighting factor for the lung is 0.12, compared to 1.0 for the whole body). Weighting factors are used for calculating the effective dose equivalent.

wetland—“[T]hose areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas” (33 CFR 328.3).

whole-body dose—In regard to radiation, dose resulting from the uniform exposure of all organs and tissues in a human body. (See *effective dose equivalent*.)

wind rose—A circular diagram showing, for a specific location, the percentage of the time the wind is from each compass direction. A wind rose for use in assessing consequences of airborne releases also shows the frequency of different wind speeds for each compass direction.

worker year—Measurement of labor requirement equal to one full-time worker employed for one year.

X/Q (*Chi/Q*)—The relative calculated air concentration due to a specific air release; units are seconds per cubic meter (sec/m^3).

yield—The force in tons of TNT of a nuclear or thermonuclear explosion.

zero-based stockpile—A nuclear weapons stockpile with zero nuclear weapons and therefore requiring no stockpile management effort.

LIST OF PREPARERS

Chapter 14 LIST OF PREPARERS

Allen, George C., Jr., U.S. DOE/NNSA

PhD, Nuclear Engineering, Massachusetts Institute of Technology, 1976

M.B.A., Management, University of New Mexico, 1983

M.S., Nuclear Engineering, Massachusetts Institute of Technology, 1971

B.S., Civil Engineering, Massachusetts Institute of Technology, 1971

Year of Experience: 35

Bailey, C. Lawson, Radiation and Hazardous Chemical Environment, Tetra Tech, Inc.

B.S., Biology, Virginia Polytechnic Institute & State University, 1979

Years of Experience: 26

Barnhill, Angela, M., General Engineer, Pantex Site Office

M.S. Nuclear Engineering, University of Maryland, 1986

Years of Experience: 15

Begley, Loida, General Engineer, U.S. DOE/NNSA

M.P.P., University of California, Berkeley, 2007

M.S., Civil Engineering, University of California, Los Angeles, 2002

B.S., Civil Engineering, University of California, Los Angeles, 2000

Years of Experience: 8

Bird, Diane, Lead Weapons Program Manager, Livermore Site Office

B.S., Engineering, University of Pittsburgh, 1986

B.S., Mechanical Engineering, Worcester Polytechnic Institute, 1979

Years of Experience: 29

Boltz, Jacqueline K., Public Outreach Manager, Tetra Tech, Inc.

M.B.A., General Business, Boston University, 1991

B.A., French Language and Literature, Boston University, 1991

Years of Experience: 17

Browne, Karen, Tetra Tech, Inc.

M.E.P.M., Environmental Policy and Management, University of Denver, 2005

B.S., Environmental Science, New Mexico State University, 2000

Years of Experience: 8

Buenaflor, Delight, Deputy Project Manager/Senior Technical Editor, Tetra Tech, Inc.

B.A., Biology, McDaniel College (formerly Western Maryland College), 1996

Years of Experience: 10

Buenaflor, Justin, Document Production, Tetra Tech, Inc.

B.S., Information Systems Management, University of Maryland Baltimore County, 2002

Years of Experience: 5

Cox, Andrew B., Sandia National Laboratories

PhD, Applied Mechanics, Stanford University, 1979
Master of Mechanical Engineering, Rice University, 1973
B.A., Mechanical Engineering, Rice University, 1972
Years of Experience: 34

Dimsha, Mark, Radiological Transportation, Epsilon Systems, Inc.

B.S., Biology, University of New Mexico, 1992
M.S., Civil Engineering (Environmental), University of New Mexico, 2000
M.S., Nuclear Engineering (Radiation Protection), University of New Mexico, In Progress
Years of Experience: 12

Dubuque, William, R.,

MBA, University of New Mexico, 1995
M.S., Industrial Engineering, Texas A&M, 1975
B.S., Industrial Management, University of North Dakota, 1973
B.S., Chemical Engineering, University of North Dakota, 1968
Years of Experience: 37

Edgeworth, Jay, Acting Director, Pit Project Office, Office of Pit Projects, U.S. DOE/NNSA

M.S., Reliability Engineering, University of Maryland, 1999
M.S., Bioengineering, University of Michigan, 1991
B.S., Electrical Engineering, Michigan State University, 1986
Years of Experience: 21

Feldt, Al, Programmatic Assessment, Tetra Tech, Inc.

B.A., Economics, American University, 1971
Years of Experience: 36

Founds, Nanette, Director, Office of Stockpile Technology and Special Materials, U.S. DOE/NNSA

B.S., Chemistry, University of Nebraska
B.S., Aeronautical Engineering, Air Force Institute of Technology
Years of Experience: 25

Garson, Henry, Quality Assurance, Tetra Tech, Inc.

J.D., State University of New York at Buffalo, 1967
B.S., Finance, State University of New York at Buffalo, 1964
Years of Experience: 40

Guidice, Steve, Tetra Tech, Inc.

M.S., Management, Rensselaer Polytechnic Institute, Troy, NY, 1972
B.S., Engineering, Rensselaer Polytechnic Institute, Troy, NY, 1968
Years of Experience: 38

Gullett, Harry W., Sandia National Laboratories

M.B.A., Finance, Webster University, 1992

M.S., Industrial Engineering, Air Force Institute of Technology, 1980

B.A., History, University of California, San Diego, 1973

Year of Experience: 21

Gutierrez, Ralph, T., General Engineer, Office of Program Management and Evaluation, U.S. DOE/NNSA

M.S., Systems Management, University of Southern California, 1975

B.S., U.S. Naval Academy

Years of Experience: 37

Hardy, Geoff, Document Production, Tetra Tech, Inc.

B.B.A, Averett University, 2005

A.D., Applied Science, 1994

Years of Experience: 17

Higgins, Patrick, J., Supervisory General Engineer, Office of Program Management and Evaluation, U.S. DOE/NNSA

M.S., Business Administration, University of New Mexico, 1983

M.S., Nuclear Engineering, University of New Mexico, 1980

B.S, Electrical Engineering, University of Texas, El Paso, 1976

Years of Experience: 37

Livesay, Mark, A., Senior Program Manager, U.S. DOE/NNSA

M.B.A, Auburn University, 2001

B.S.M.E, University of Tennessee, 1980

Years of Experience: 27

McMahan, Erin, K., Socioeconomics and Environmental Justice, Tetra Tech, Inc.

M.S., Environmental Science and Policy, University of South Florida, 2006

B.A., Environmental Studies, Washington College, 2004

Years of Experience: 4

Madore, Catherine, Regulatory Compliance and Document Integration, Epsilon Systems, Inc.

J.D., Law, George Mason University School of Law, 1990

M.R.P, Environmental Planning, University of Massachusetts, 1981

M.S., Health Physics, Georgia Institute of Technology, 1989

B.S., Radiation Health (Health Physics), Oregon State University, 1988

Years of Experience: 17

Chapter 15
DISTRIBUTION LIST

Chapter 15 DISTRIBUTION LIST

The U.S. Department of Energy provided copies of the *Complex Transformation Supplemental Programmatic Environmental Impact Statement* (SPEIS) or the Summary to Federal, state and local elected and appointed government officials and agencies; Native American representatives; national, state, and local environmental and public interest groups; and other organizations and individuals listed in this chapter. Approximately 600 copies of the Final Complex Transformation SPEIS, 3,150 copies of the Summary and CD-ROM, and 1,500 CD-ROMs of the SPEIS were sent to interested parties. Copies will be provided to others upon request.

Appendix A
ALTERNATIVES

Appendix A

ALTERNATIVES

A.1 CONSOLIDATED PLUTONIUM CENTER (CPC)

CPC Requirements

- A CPC would consolidate all Category I/II security and hazard class defense programs mission activities requiring the use and handling of plutonium material. It would provide the facilities and equipment to perform pit manufacturing, pit surveillance, plutonium research and development, manufacturing process development, manufacture of parts for pit certification testing, and training of manufacturing and research and development personnel. A CPC would also consolidate and store all plutonium metal and other materials and parts required in support of these activities, and have supporting analytical chemistry and metallurgical capability.
- Stockpile requirements are based on national security requirements directed by the President based upon strategy and agreements between the Department of Energy (DOE) DOE and Department of Defense (DoD). CPC capacity and production output would be designed to meet the Reliable Replacement Warhead (RRW) requirements. Legacy pits would be supported as required through the use of contingency floor space, additions of required specific pit equipment, and development of specific procedures in handling required material. The facility would not be designed specifically to support all legacy pit types, but would accommodate any requirement for legacy pits as an adjustment to the equipment and facility capability designed for RRW pits with the use of contingency floor space and module flexibility.
- A CPC would provide the facilities and equipment to perform pit manufacturing, pit surveillance, and plutonium research and development.
- Stockpile requirements are based on national security requirements directed by the President and the Congress based on joint recommendations from DOE and DoD. CPC capacity and production output would be designed to meet national security requirements, which could include production of new pits for maintenance of the legacy stockpile or replacement weapons (e.g., RRWs).
- As described in Chapter 2, this SPEIS assumes that a CPC would provide a manufacturing capacity of 125 pits per year (ppy) using a single shift, with a contingency of 200 pits through multiple shifts. A CPC would be capable of supporting the surveillance program at a rate of one pit being destructively evaluated per pit type in the stockpile per year. For Los Alamos, this SPEIS also assesses an alternative that would result in a smaller pit production capacity (80 ppy), based on the use of the existing and planned infrastructure at that site.
- A newly constructed CPC would be constructed and started up over a six year period, and would be fully operational by approximately 2022. A CPC would be designed for a service life of at least 50 years.
- The sites being considered as potential locations for a CPC and consolidation of Category

I/II quantities of special nuclear material (SNM) include: Los Alamos, NTS, Pantex, SRS, and Y-12.

- A newly constructed CPC would consist of a central core area surrounded by a Perimeter Intrusion Detection and Assessment System (PIDAS), which would enclose all operations involving Category I/II quantities of SNM. The enclosed area would be approximately 40 acres. A buffer area would provide unobstructed view of the area surrounding the PIDAS. All administrative and non-SNM support buildings would be located outside the edge of the buffer area. Once operational, approximately 110 acres would be required for a new CPC (Table A.1-1). As shown in Table A.1-1, two CPC alternatives at Los Alamos (Upgrade Alternative and 50/80 Alternative) could reduce land area requirements by the use of existing and planned facilities and infrastructure.

Table A.1-1—Land Requirements for CPC Alternatives

Greenfield Alternative	Construction (acres)	Operation (acres)	
	140	110*	
		PIDAS	Non-PIDAS
Upgrade Alternative	13	40	70
50/80 Alternative	6.5	6.5 (All within PIDAS)	
		2.5 (All within PIDAS)	

* Includes a buffer area that would provide unobstructed view of the area surrounding the PIDAS.

- It is assumed that CPC facilities would be constructed above ground. During design activities, studies would be performed on worker safety, security enhancements, and costs. Examining whether the site of the CPC facilities above or below ground is an example of such a study. All five sites are assumed to be able to support a buried or partially buried/bermed facility. This SPEIS includes a discussion of the potential differences among the sites in supporting a buried or bermed facility (see Section A.1.5).
- If Los Alamos is not selected for the CPC mission, it is assumed that plutonium facilities at that site would be reduced to Category III or IV nuclear facilities for R&D purposes, or closure, after the CPC begins operations. Any residual non-Defense Program (DP) missions (i.e. Pu-238) would be responsible for funding to meet safety/security requirements. However, as explained in Section 3.4.1.6, facilities at Los Alamos are also being considered for upgrade to meet CPC requirements.
- SNM storage at the CPC would be based on the need to support a 3 month production period. Approximately 3 metric tons of storage is anticipated.
- Any transuranic (TRU) waste from a CPC is assumed to be disposed of at the Waste Isolation Pilot Plant (WIPP) (see Section 10.5.5).

A.1.1 CPC Operations

The following section discusses the operations for the CPC. The section begins with a summary of the pit production process that would occur in a CPC. The overall process would involve three main areas: 1) Material Receipt, Unpacking, and Storage; 2) Feed Preparation; and 3) Manufacturing.

A.1.1.1 *Material Receipt, Unpacking, and Storage*

Plutonium feedstock material would be delivered from offsite sources in DOE/Department of Transportation (DOT) approved shipping containers. The shipping containers would be held in Cargo Restraint Transporters (CRT) and hauled by Safeguards Transporters (SGTs). The bulk of the feedstock material would come from Pantex, in the form of pits from retired weapons. Additionally, small amounts of plutonium metal from LANL and SRS could be used. The CRTs would be unloaded from the truck and the shipping packages unpacked from the CRT. Each shipment would be measured to confirm the plutonium content, entered into the facility's Material Control & Accountability (MC&A) database, and placed into temporary storage. The shipping packages would later be removed from storage and opened to remove the inner containment vessel. Containment vessels with the feedstock material would then be measured for purposes of and transferred to the Receipt Storage Vault pending transfer to the Feed Preparation Area.

A.1.1.2 *Feed Preparation*

The containers would then be transferred through a secure transfer corridor to an adjacent Feed Preparation Area where plutonium metal is prepared for manufacturing. For pits to be recycled, the pit is first cut in half and all nonplutonium components are removed. Notable among these non-plutonium components is enriched uranium (EU), which would be decontaminated and then shipped to Y-12 for recycling. All of the other disassembled components would be decontaminated, to the maximum extent possible, and then disposed of as either low-level waste (LLW) or TRU waste, as appropriate.

There are two baseline processes currently being evaluated for the purification of the plutonium metal. One process relies more heavily on aqueous chemistry (aqueous process) and the other on pyrochemical reactions (pyrochemical process). The primary difference between the two processes is that the aqueous process does not employ chloride containing aqueous solutions, which means conventional stainless steels can readily be used to contain all of its processes. On the other hand, the pyrochemical process requires specialized materials to contain the corrosive chloride bearing solutions that it employs.

The primary process evaluated in this SPEIS is the aqueous process. This is a well known process, which has been successfully used at DOE sites for many years. It is comparatively simple and experiences few, but well controlled corrosion problems. This process requires more space than the pyrochemical process and does not produce as pure a product metal as the pyrochemical process. This lower purity requires additional processing runs and therefore produces significantly more waste than the pyrochemical process. The aqueous process provides a bounding analysis of the waste impacts from a CPC.

The pyrochemical process is more complex than the aqueous process, employing seven versus four major processing steps. However, this can be done in less space with more processing flexibility. It also produces very pure metal and a lower volume of waste. The purity of metal allows the pyrochemical process to have the option of only partially processing metallic plutonium to obtain adequate production purity. The pyrochemical process, however, requires special materials to contain the corrosive chloride solutions. Based on results from ongoing

technology development, the pyrochemical process appears to have the greatest potential for improvements in efficiencies and in waste stream reductions. The pyrochemical process has been successfully used for many years at LANL.

The pyrochemical process has the potential to be environmentally more benign, thus having less environmental impact than the aqueous process. As the design of a CPC develops and a final purification process is selected, the site-specific, tiered EIS would evaluate in more detail the impact of the actual process to be used. Additionally, for a CPC that might be constructed at SRS, this SPEIS includes consideration of using facilities and infrastructure that are being constructed in support of the Materials Disposition Program. One particular facility, the Pit Disassembly and Conversion Facility (PDCF), could provide the capability to disassemble pits and convert the plutonium to a form suitable for producing new pits. The PDCF would include a hardened plutonium processing building, conventional buildings and structures housing support personnel, systems, and equipment (see Section 3.4.1.2).

A.1.1.3 *Manufacturing*

The pit manufacturing work includes the fabrication of the plutonium components for pits and the assembly of pits. A pit in this context is the assembly of all components into the full pit that is shipped to Pantex. Typically, non-plutonium parts would be government-furnished equipment and fabricated elsewhere. Non-plutonium components would be shipped to the CPC to be assembled along with the plutonium components into pits. A quality assurance acceptance program would be required to receive and accept non-plutonium parts. In addition, a bonded stores capability must be provided for interim storage of government-furnished equipment and other parts/materials for war reserve (WR) production. The CPC would require the capability to perform SNM shipping, receiving, and storage; pit disassembly and feedstock sampling; metal preparation, recovery, and refining; product forming, machining, welding, cleaning, and assembly; and product inspection (including radiography), process qualification, production surveillance, and analytical chemistry support. Supporting and ancillary functions (waste handling, security operations, training, maintenance, administration, process development, and testing) required to perform pit manufacturing are also included in the CPC. These capabilities would be applied to both WR production and production of parts/samples in support of certification and new production surveillance activities.

The CPC would deploy manufacturing processes that would enable the production of RRW pits as components for replacement of warheads in the enduring stockpile. The facility would be designed based on an agile facility concept, whereby processes could be changed out as new technologies are developed and limited additional capacity created as contingency for unforeseen requirements. Feedstock for the fabrication of the plutonium components would consist primarily of site-return pits requiring disassembly and reprocessing, but would also include purified metal from the CPC processing line. The capability to manufacture legacy pits would be retained through the agility and flexibility aspects of design with the manufacturing modules and floor space within the facility.

New pits would be inspected and prepared for storage and eventual shipment to Pantex. The majority of the waste from this process would be plutonium shavings that would be recycled within a CPC.

A.1.1.3.1 Manufacturing Process Development

During the projected lifetime of the facility, there would be changes in technology and changes in design of warheads where new processes and equipment would need to be developed and tested before they enter the production line. Process development requires both cold and hot space. Examples currently underway are foundry development where a new casting process is being developed to increase capacity and efficiency; metal purification where a new piece of equipment would accelerate activities, reduce radiation exposure, and reduce waste; machining where multi-functional equipment can replace the need for 3 or 4 separate pieces of equipment; new dimensional analysis to reduce time and improve accuracy of measurement; and module development to locate multiple pieces of equipment in a manner that increases efficiency within a set of operations. This area also provides capability for training new personnel, developing processes, and evaluating new equipment without unnecessary exposure to radiation.

A.1.1.3.2 Manufacture of Certification Parts

Besides the manufacture of pits for the stockpile, the manufacture of pits or parts of pits would be required for support of physics and engineering certification testing. In most instances, such pits or parts may be manufactured on the production line. Their production, however, must be considered in design of the floor space and equipment to ensure the production line is not interrupted in achieving its required capacity and output.

A.1.1.4 *Plutonium Research and Development*

The CPC would also conduct plutonium research and development. Plutonium research and development seeks to understand the properties and performance characteristics of plutonium, including fundamental thermodynamic, shock-induced deformation, intermediate strain-rate elastic-plastic behavior, spall, and surface ejecta. Understanding of the properties and performance characteristics supports modeling of weapon performance and provides assurance of stockpile reliability. Samples are prepared to support tests, such as those using the JASPER gas-gun facility at NTS. Parts are manufactured to support subcritical experiments to study specific fundamental plutonium properties. R&D also supports studies on plutonium aging to measure and understand weapon characteristics as the material ages. Sample fabrication requires the use of lathes, drill presses, tomography, metallographic equipment, polishing, precision machining and inspection, and rolling mill equipment. This research and development resource would also constantly assess the activities required for pit processing and work to develop new more efficient and environmentally preferred methods.

A.1.1.5 *Plutonium Pit Surveillance*

Pit surveillance is the periodic disassembly and inspection of pits removed from the active stockpile to help identify any defects or degradation and assure that nuclear weapons in the enduring stockpile are safe and reliable. Evaluations include leak testing, weighing, dimensional inspection, dye penetration inspection, ultrasonic inspection, radiographic inspection, metallographic analysis, chemical analysis, pressure tests, and mechanical properties testing.

A.1.2 CPC Facility Requirements

In order to allow for the pit production process, as described above, the CPC would require the design of facilities to allow for its operation. Although the overall specific requirements are still in the design stage, the general needs are clearly known and are as follows:

Security. The majority of CPC would be located within a PIDAS. The PIDAS would be a multiple-sensor system within a 30-foot wide zone enclosed by two fences that surround the entire Security Protection Area. There would be an Entry Control Facility (ECF) at the entrance to the Security Protection Area.

Process and R&D buildings. A proposed concept being evaluated for a CPC divides the major plant components into four separate buildings identified as Material Receipt, Unpacking, and Storage; Feed Preparation; Manufacturing; and R&D to perform the functions described in Section 3.1.1. The process buildings would be two-story reinforced concrete structures located aboveground at grade. The exterior walls and roofs would be designed to resist all credible man-made and natural phenomena hazards and comply with all NNSA security requirements.

The first story of each building would include plutonium processing areas, manufacturing support areas, waste handling, control rooms, and support facilities for operations personnel. The second story of each of the three process buildings would include the heating, ventilating, and air conditioning (HVAC) supply fans, exhaust fans and high-efficiency particulate air (HEPA) filters, breathing/plant/instrument air compressor rooms, electrical rooms, process support equipment rooms, and miscellaneous support space. Interior walls are typically reinforced concrete to provide personnel shielding and durability for the 50-year facility design life. Each of these processing buildings would have its own ECF, truck loading docks, operations support facility, and safe havens designed in accordance with applicable safety and security requirements. The three processing buildings would be connected by secure transfer corridors.

Support Buildings within the PIDAS. The major support structures located within the PIDAS would include an Analytical Support Building and a Production Support Building. The Analytical Support Building would contain the laboratory equipment and instrumentation required to provide analytical chemistry and metallurgical support for the CPC processes, including radiological analyses. The Production Support Building would provide the capability for performing nonradiological classified work related to the development, testing, staging and trouble-shooting of CPC processes and equipment. A number of other smaller structures also supporting a CPC would include standby generator buildings, fuel and liquid gas storage tanks, an HVAC chiller building, cooling towers, and an HVAC exhaust stack.

Support buildings outside the PIDAS. The major structures located outside the PIDAS would include an Engineering Support Building, a Commodities Warehouse, and a Waste Staging/TRU Packaging Building. This Waste Staging/TRU Packaging Building would be used for characterizing and certifying the TRU waste prior to packaging and short-term lag storage prior to ship-ment to the TRU waste disposal site. Parking areas and storm water detention basins would also be located outside the PIDAS. In addition, a temporary concrete batch plant and construction laydown area would be required during construction. A generic layout showing the major buildings and their relationship to each other is shown in Figure A.1.2-1. Table A.1.2-1

shows the dimension estimates. The overall plant layout in this generic representation is a greenfield campus type layout, and would be adapted to each site, as necessary. The actual footprint of all of the buildings, as shown in the table, is considerably less than the “developed” area from the generic layout. Thus, the actual developed site layout could be much less than that shown in Table A.1.2-2, and could fit any site with enough space for buildings footprint and adequate security standoff distances.

Table A.1.2-1—Dimensions for the CPC

	Dimension
Processing Facilities Footprint (ft ²)	308,000
Support Facilities Footprint (ft ²)	280,000
Research and Development (ft ²)	57,000
Total Facilities Footprint (ft ²)	645,000
Area Developed During Construction (acres)	140
Post Construction Developed Area (acres)	110

Source: NNSA 2007.

A.1.3 CPC Transportation Requirements

The CPC would require transportation activities as described in this section. Plutonium pit assemblies would be shipped from Pantex to the CPC site. During startup, and potentially at other infrequent times, additional plutonium metal could be required. This additional plutonium could be shipped to the CPC from SRS. Additionally, as discussed in Section 3.4.1.4, once the CPC becomes operational, LANL would transfer its Category I/II plutonium to the CPC if LANL is not selected as the CPC site.

Both TRU waste and LLW would be generated at the CPC site. DOE’s WIPP near Carlsbad, New Mexico, or a WIPP-like facility would be the destination for TRU waste from all CPC alternative sites. Three CPC site alternatives (LANL, NTS, and SRS) have low level waste (LLW) disposal facilities and would dispose of LLW onsite. Although Y-12 has some LLW disposal capability, it currently ships its LLW to NTS for disposal. Pantex does not have any LLW disposal capacity and would have to ship LLW to the NTS, if Pantex is selected as the CPC site. A matrix depicting the origins, destinations, and materials shipped is provided in Table A.1.3-1. The matrix also includes shipments under the No Action Alternative and LANL Upgrade Alternative (see Section 3.4.1.2). The number of shipments per year is presented in Table A.1.3-2.

Source: NNSA 2007.

Figure A.1.2-1—Generic Layout of a CPC

Table A.1.3-1—Origins, Destinations, and Material Shipped to Support the CPC

Shipment Type	CPC at SRS	CPC at Pantex	CPC at LANL	CPC at NTS	CPC at Y-12
LANL Plutonium in	LANL ⇒ SRS	LANL ⇒ Pantex	None	LANL ⇒ NTS	LANL ⇒ Y-12
Pits in	Pantex ⇒ SRS	None	Pantex ⇒ LANL	Pantex ⇒ NTS	Pantex ⇒ Y-12
EU in	Y-12 ⇒ SRS	Y-12 ⇒ Pantex	Y-12 ⇒ LANL	Y-12 ⇒ NTS	None
EU out	SRS ⇒ Y-12	Pantex ⇒ Y-12	LANL ⇒ Y-12	NTS ⇒ Y-12	None
Pits out	SRS ⇒ Pantex	None	LANL ⇒ Pantex	NTS ⇒ Pantex	Y-12 ⇒ Pantex
TRU waste out	SRS ⇒ WIPP	Pantex ⇒ WIPP	LANL ⇒ WIPP	NTS ⇒ WIPP	Y-12 ⇒ WIPP
LLW out	Onsite Disposal	Pantex ⇒ NTS	Onsite Disposal	Onsite Disposal	Y-12 ⇒ NTS

Materials Shipped. The materials which would require shipping are described as follows:

- **SRS plutonium/LANL plutonium.** This material is plutonium metal that is primarily plutonium-239, but contains other plutonium isotopes in small amounts. It would be used for start-up testing and once the CPC becomes operational could be infrequently shipped. Additionally, once the CPC becomes operational, LANL would transfer its Category I/II plutonium to the CPC if LANL is not selected as the CPC site (see Section 3.4.1.4).
- **Pits.** Pits would be the feed and product stream for the CPC. A pit is actually an assembly of plutonium metal. The plutonium is primarily plutonium-239, and the uranium is primarily uranium-235. A single shipment of pits would contain several hundred pounds of plutonium and uranium. In order to produce 125 ppy it is estimated that 7 annual round trips (or 14 total) would be required.
- **EU.** The EU parts from disassembled pits would be shipped to Y-12 for processing and returned to the CPC. A single shipment of EU contains more than a thousand pounds of uranium.
- **TRU waste.** Processing of plutonium pits would produce contact-handled TRU waste, primarily americium-241. It is estimated that this would require about 74 shipments per year to the WIPP in New Mexico or a WIPP-like facility
- **LLW.** This waste would consist of job control waste and decontamination wastes. The radioisotopes would primarily be TRUs, but their concentrations would be sufficiently low to classify the waste as LLW. Approximately 0.1 percent of the volume analyzed for shipping LLW would be mixed (MLLW). Waste generation is expected to sufficiently low to allow for disposal onsite for all candidate sites, except for Y-12 and Pantex, which would ship its LLW either to NTS or a commercial LLW disposal facility. It is estimated that this would require up to 10 shipments per year.

Table A.1.3-2—Numbers of Shipments per Year for the CPC

Transported Materials	200 ppy
Pits	22
TRU waste	118
Total	156

Source: NNSA 2007.

A.1.4 Differences Between a CPC and the Rocky Flats Plant

A CPC would be designed and operated to minimize risk to both workers and the general public during normal operations and in the event of an accident. Benefiting from decades of experience, a CPC would employ modern processes and manufacturing technologies and would utilize an oversight structure for safety, environmental protection, and management oversight that has been established since the closure of the Rocky Flats Plant.

A.1.4.1 *Building Design*

Modern safety and security design standards of today require substantially different structures from the earlier pit manufacturing facilities at the Rocky Flats Plant, near Golden, Colorado. The buildings at the Rocky Flats Plant were constructed in the 1950s with metal roof sheeting covered by a builtup weather seal. In contrast, the exterior walls and roof of PF-4 (the current interim production plutonium machining facility at LANL) are constructed of reinforced concrete greater than a foot thick. Internal walls at PF-4 provide multiple-hour fire barriers between wings. A CPC would be designed with similar improvements.

A.1.4.2 *Fire Control*

Although DOE experienced accidents associated with the manufacture of plutonium pits, most of these accidents occurred in a relatively short time period (from 1966 to 1969) at the Rocky Flats Plant. The majority of these accidents involved plutonium metal and chips undergoing spontaneous ignition. Such events can occur when the environment they are in allows for the rapid oxidation of plutonium, often in association with a moist air environment. Efforts at Rocky Flats concentrated on the elimination of such fires. It is now recognized that potential for fire initiation cannot be totally eliminated. Although the frequency and severity of fires can be reduced through the management of combustible materials and facility design, such events are now anticipated and planned for in the structural and process design and operational procedures. Engineering monitoring systems would be activated if a fire were to occur. These systems would activate controls and procedures to control, quickly suppress, and contain fires within the specific originating glovebox, minimizing the risk to workers and the general public.

Today, plutonium machining activities are conducted in gloveboxes supplied with an inert gas. Furthermore, gloveboxes are now equipped with exhaust filter systems. All working areas are separately vented with systems containing HEPA filters. These HEPA filters are fabricated of special nonflammable bonded material. Filter plenums are equipped with an automatic cooling system to reduce the temperature of the air reaching the final stages of HEPA filters. Unlike Rocky Flats, a CPC would have an automatic fire detection and suppression system designed to meet the latest National Fire Protection Association life safety codes and standards for manufacturing facilities. The design features would include multiple zones for both fire detection and suppression to assure that any fire which may occur would be isolated in small, separated areas of the facility and thereby preclude the spread of fire to other separated areas or the entire building.

A.1.4.3 *Waste Management and Material Control*

A CPC would have a dedicated waste handling area capable of preparing waste for transport in accordance with established procedures and waste acceptance requirements. In addition, all waste streams to be generated by the CPC would have an established disposition path for each alternative being considered. Since the CPC SEIS analyzes operations over a 50-year period, it is reasonable to expect that some disposition paths may change. A CPC would utilize a stringent MC&A system to accurately account for all SNM.

A.1.5 *Above Ground Versus Below-Grade or Bermed CPC*

An above ground facility is the basic preconceptual design configuration for a CPC. During conceptual design, a below grade facility configuration would be considered during the conduct of alternative studies. Although an above-grade facility can be designed to meet required security from the present design basis threat, a below-grade facility provides for a more passive security design with less reliance on active security systems and can provide additional physical security protection. However, a below grade facility poses additional life-safety considerations to protect personnel in an emergency and for them to be able to egress the facility in a timely manner. These issues together with physical security would be explored during a conceptual design period.

With regard to environmental considerations, a preconceptual design representation of a below grade production building, bermed with a concrete overcap, would require 25–50 percent more acreage than an above grade facility due to the extension of the berm to the physical structure. This soil overburden has the potential to reduce challenges to the building confinement system from events such as external fires and tornados. As much as 100 percent more concrete in volume is estimated to be necessary for support structures and an overcap, together with a 100–200 percent increase in the volume of material excavated, backfilled, and compacted. A 25 percent increase in asphalt paving is also estimated to take place.

There are additional costs and schedule increases estimated for a below-grade facility. Additional project costs are estimated to be between \$100 million to \$500 million depending upon both the design and the soil characterization. For example, a below-grade facility with soft soil and some involvement of groundwater might only add as little as two to three months to the project schedule. However, a 100 percent solid bedrock earthwork could take an additional two-and-a-half to three years for excavation. Both examples provide bounding estimates with no site expected to be 100 percent solid bedrock.

As part of a preliminary business case analysis for this SPEIS, NNSA has evaluated the issues, challenges, advantages and disadvantages of underground facilities. The information in this section is summarized from that report.¹ For each of the five sites considered in this SPEIS (Los Alamos, NTS, Pantex, SRS, and Y-12), two “cut-and-fill” options were assessed: 1) A buried facility with about 5 feet of soil cover; and 2) A facility buried at 20 feet below grade (i.e., 20 feet of soil cover). With any cut-and-fill option, a relatively shallow depression is excavated in the earth, the facility is built, followed by back-filling to bury the structure. The 5-foot

¹Independent Business Case Analysis of Consolidated Options for the Defense Programs SNM and Weapons Production Mission, September 2007, Preliminary Draft, Prepared.

underground option was evaluated because this depth provides the equivalent overpressure protection as hardening gives an above-ground building. The 20-foot underground option was evaluated because a concrete breaker slab over this earth cover would protect the facility from the impact of a fully loaded airliner. Modeling of the effects of the impact of an aircraft show that, for the worst case, nine feet of earth cover will prevent penetration of aircraft parts, and a design for a 50 psi overpressure will protect from the blast from the detonation of the aircraft fuel. The building designed for the 35 psi overpressure buried 20 feet deep is capable of withstanding the 50 psi surface blast.

Building underground would require increased excavation and the need to construct the roof slab and roof slab support system to support the pressure from the earth cover. Conversely, the walls underground do not need to be as robust as the equivalent above ground structure. Underground buildings could use earth to shield between structures and to contain migration of materials in an accident. Underground facilities could be constructed in stages or modules connected to one another via underground passages after the construction is completed. This would allow facility expansion in stages and consolidation of activities at a single site.

The results from this feasibility study show putting nuclear facilities underground is not a significant discriminator among the proposed five sites as all five sites can employ underground construction. All of the proposed sites for the CPC/Consolidated Nuclear Center (CNC)/Consolidated Nuclear Production Center (CNPC) were assessed to be capable of using underground construction. For sites where the water table is high or the earth is less amenable to excavation, most of the cover for the building can be bermed by bringing in fill material. In addition, the underground options are more robust in meeting the DBT and will likely be capable of adapting to changes in the DBT in the future. Proper planning of the underground facilities can allow expansion without a significant change in the PIDAS or the protective force. This could lead to a consolidation strategy which could occur in stages over a number of years.

Modeling showed that the underground facility (5 or 20, no difference) could be protected with 85 less security guards than the same structure above ground. In addition, this modeling showed that the reduced guard force required two hardened fighting positions versus the five hardened fighting positions required for the above ground construction. Seismic resistance is improved slightly for both the structure and sensitive equipment underground. However, worker safety and construction would be much more complex for the underground option.

A.2 URANIUM PROCESSING FACILITY (UPF) AT Y-12

The UPF would replace multiple existing enriched uranium (EU) and other processing facilities. The current operating and support areas occupy approximately 633,000 square feet in multiple buildings, while the consolidated UPF would result in approximately a 33 percent reduction, to approximately 400,000 square feet in one building. Once the UPF becomes operational, some of those existing facilities would be available for decontamination and decommissioning (D&D), while other facilities could be used for non-EU processes. Figure A.2-1 shows an artist's rendering of the proposed UPF. Figure A.2-2 shows the location of the UPF relative to other buildings at Y-12.

Source: NNSA 2005c.

Figure A.2-1—Artist's Rendering of the UPF Adjacent to the HEUMF

A.2.1 UPF Construction

The new structures and support facilities that would comprise the UPF complex include the following:

- UPF building;
- UPF electrical switching center;
- Chiller building and chiller building switch center; cooling tower;
- Aboveground water tank for a seismic-qualified firewater system with a firewater pumping facility;
- Electrical generators; and
- Modified PIDAS to encompass the UPF complex.

The design service life of the UPF would be 50 years. The UPF would be equipped with safety support systems to protect workers, the public, and the environment. The UPF would be housed in a multistory, reinforced concrete building designed and built for security. The main building would be a reinforced concrete structure with reinforced concrete exterior walls, floor slabs, and roof. The roof and exterior walls would be sized to protect the interior from tornado- and wind-borne missiles and blast effects.

Conventional construction techniques would be used to build the UPF. The preliminary schedule for the project indicates that site preparation would begin in approximately 2011, with completion by approximately 2016, and operations beginning by approximately 2018. Construction activities would be performed in a manner that assures protection of the environment during the construction phase. Disposal of construction debris would be made in accordance with waste management requirements in properly permitted disposal facilities. Throughout the construction process, storm water management techniques, such as silt fences and runoff diversion ditches, would be used to prevent erosion and potential water pollutants from being washed from the construction site during rainfall events.

As shown on Figure A.2-2, construction of the UPF would require approximately 35 acres of land, which includes land for a construction laydown area and temporary parking. Once constructed, the UPF facilities would take up approximately eight acres. The construction laydown area for the UPF would be developed on the west side of the proposed UPF site. This area would be finished with an eight-inch thick compacted, stabilized base for the construction phase. Interim employee parking lots would be developed west of the proposed construction laydown area. The site would be sufficiently graded and developed to accommodate a number of temporary construction trailers, storage buildings, and materials storage yards. After construction of the UPF is complete, it may be feasible to rework the laydown area to provide for additional parking.

A.2.2 Traffic Planning and Parking

The entrance road to the existing Polaris parking lot would be relocated to facilitate site work. Up to 1,200 car spaces may be built to replace the parking spaces lost when the proposed UPF is constructed. Further PIDAS modifications would be constructed to encompass the Highly Enriched Uranium Materials Facility (HEUMF) (under construction) and the proposed UPF.

A.2.3 Site Preparation and Facility Construction

Site preparation would include any excavation, filling, and grading needed to meet design requirements for an on-grade, reinforced concrete structure. Detailed testing would be conducted to fully characterize site geology, hydrology, and soil compaction, as well as to sample for radioactive contamination, mercury, and other materials of concern before construction.

The structure's foundation would be concrete piers that are drilled down into the bedrock of the site, or a thick concrete slab. To reduce the overall footprint of the structure, a precast-concrete crib retaining wall would be constructed on the north and west sides of the UPF would be constructed with the same rigorous natural phenomena (NP) resistance design as the HEUMF, which is defined as Performance Category² (PC) 3.

² Performance Categories classify the performance goals of a facility in terms of facility's structural ability to withstand natural phenomena hazards (i.e., earthquakes, winds, and floods). In general, facilities that are classified as: PC 0 do not consider safety, mission, or cost considerations; PC 1 must maintain occupant safety; PC 2 must maintain occupant safety and continued operations with minimum interruption; PC 3 must maintain occupant safety, continued operations, and hazard materials confinement; and PC 4 must meet occupant safety, continued operations, and confidence of hazard confinement.

A.2.4 Security Considerations

Upon completion of construction, both the UPF and the HEUMF (which is already under construction and will have its full PIDAS in place) would be surrounded by a PIDAS security barrier. The PIDAS would be a multiple-sensor system within a 30-foot wide zone enclosed by two fences that surround the entire Security Protection Area.

A.2.5 UPF Operations

The core operations of the new consolidated UPF would be assembly, disassembly, Quality Evaluation, specialized chemical and metallurgical operations of EU processing, and product certification/inspection. The full range of operations would include:

- Assembly of subassemblies from refurbished and new components;
- Disassembly or dismantlement of returned weapons subassemblies resulting in recycle;
- Refurbishment, surplus generation, and disposal of components;
- Product certification through dimensional inspection, physical testing, and radiography;
- Quality evaluation (specially designed tests and inspections to collect data and determine the condition of units and components to assess the future reliability of the weapons systems in the stockpile);
- Metallurgical operations, including EU metal casting, rolling, forming, and machining;
- Analytical services for uranium; and
- Chemical processing, including conversion to uranium compounds and metal from salvage scrap and oxides. Chemical processing streams would be provided to process high enrichment, mixed enrichment, and special EU materials.

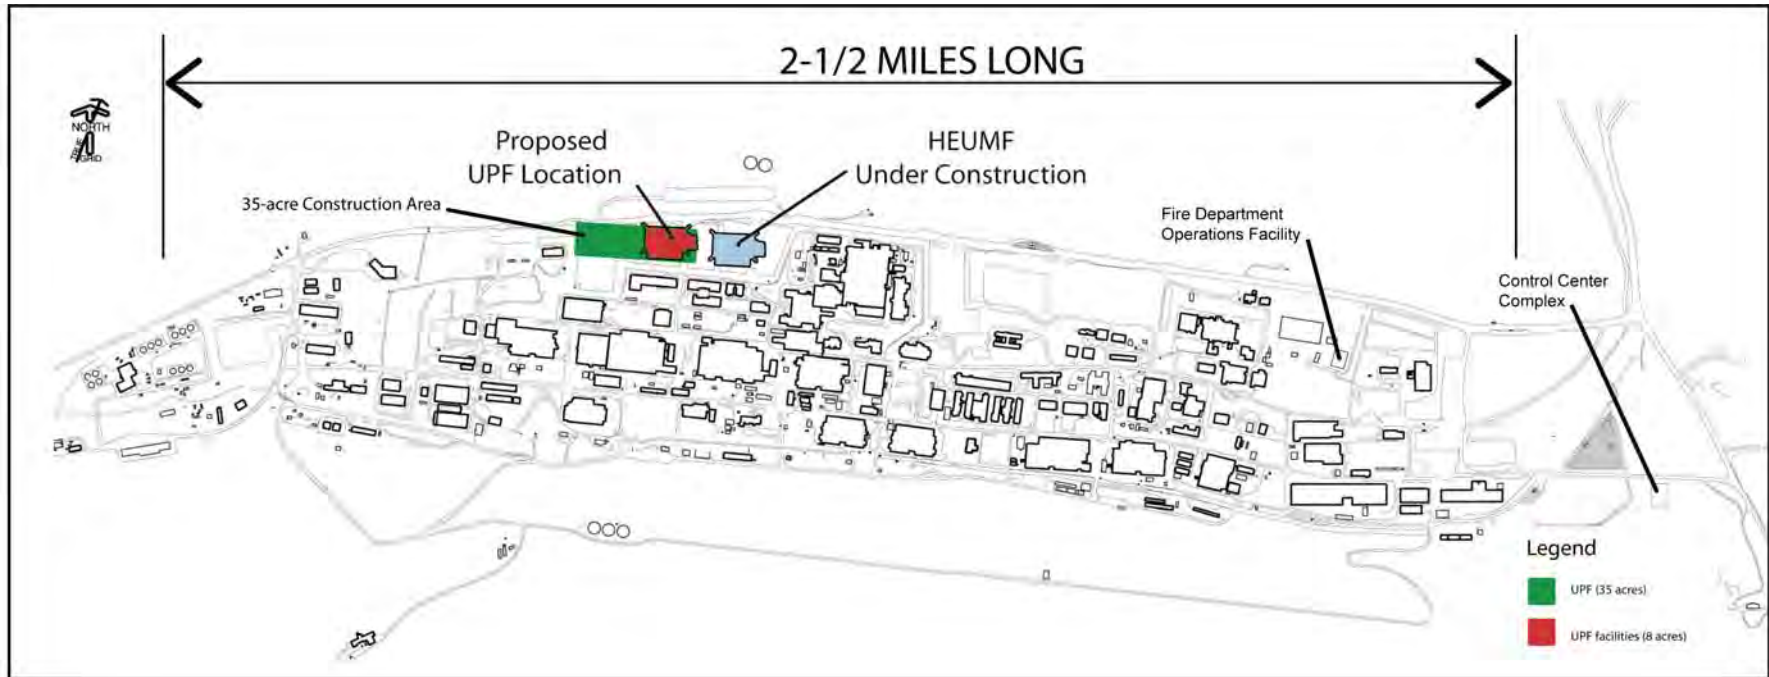

Figure A.2-2—Location of the UPF Relative to Other Buildings at Y-12

A.2.6 Utility and Safety Support Systems

The material processing areas within the UPF would incorporate the appropriate use of gloveboxes, inert atmosphere, negative air pressure, and other engineered controls, supported by administrative controls, to protect workers and the public from exposure to radiological and hazardous materials. Exhaust emissions for the facility would comply with the applicable Federal and State requirements. In conjunction with other engineered containment measures, the ventilation system barriers would provide a layered system of protection.

Other systems that would be included in the new UPF for facility operation and ES&H protection include:

- Criticality accident alarm system;
- Emergency notification system;
- Alarm system;
- Fire suppression alarm systems;
- Telephone and public address system;
- Classified and unclassified computer network;
- Personnel monitoring system;
- Security-related sensors; and
- Automated inventory system with continuous real-time monitoring.

The UPF would use a three-level negative air pressure approach to maintaining containment of particulate- and vapor-contaminated air, with the area having the lowest air pressure (i.e., highest negative air pressure) being primary containment. Secondary containment would be maintained at a lesser negative pressure, while the office and administrative areas would be maintained at a positive pressure with respect to the secondary containment areas. The primary containment ventilation system would consist of fans and collection ducts, scrubbers, mist eliminators, instrumentation, and HEPA filter banks. A secondary containment ventilation system would provide containment, negative pressure confinement, monitoring, and treatment for exhaust air from secondary containment areas frequented or occupied by operating personnel as well as other areas subject to contamination.

HEPA filters would be used in all process exhaust air streams to limit releases of EU. HEPA filters installed for this purpose would be performance qualified to limit offsite exposures to the public and releases to the environment. Current plans have a single exhaust stack being used as a central air emission point from the facility. All UPF process and exhaust air streams would be discharged from this stack, which would be located and designed to optimize the effects of plume dilution from the prevailing winds as well as to minimize the possibility of cross-contamination through the UPF and other Y-12 facility ventilation air intakes. The UPF discharge stack would be equipped with continuous emissions monitors for radiological emissions to meet Y-12 requirements to comply with environmental laws and reporting required data to the State of Tennessee as evidence of meeting those requirements.

Potable water, process water, and safety shower water would be supplied through the utility access corridors. The potable water would be used for sanitary purposes. Process water would be

provided by a dedicated system. Safety shower water also would be provided by a dedicated system.

A dedicated breathing air system would be installed within the UPF and would consist of dedicated compressors, receivers, filters, dryers, monitoring instrumentation and alarms, distribution piping, and breathing air stations at multiple points of use throughout the facility.

Liquid effluent monitors would be installed in all discharge lines from processes handling uranium metal or uranium compounds. Systems would be designed to detect and record concentrations in parts per million of uranium in solution. Discharge streams exceeding established limits for concentrations of uranium would be automatically diverted to geometrically safe holdup tanks.

A defense-in-depth approach would be used in the UPF to prevent the occurrence of a fire and ensure that sufficient means are provided to detect and suppress fires. The facility would be fully sprinklered (except for X-ray vaults), which would enable the performance of process operations except where the presence of water is a criticality safety concern. All systems, equipment, and processes would be designed in accordance with appropriate fire protection codes, building codes, and other available safety documentation. In addition to the water suppression capabilities, fire extinguishers would be installed throughout the facility.

The UPF would be built of noncombustible materials so that the building structure would not contribute to the fire loading. The process building would be separated from all other significant facilities. Roadways serving the UPF would provide access, from either direction, to any point on the exterior of the building and would be configured to allow emergency vehicles to maintain a standoff distance of 50 feet. Fire hydrants would be located 50 feet from the building with the pumper connection pointing to an accessible paved area.

Extension of the current fire alarm system would support UPF fire alarm needs. All water flow, smoke, and heat detection would be alarmed. Fire hazards and potential losses inside the UPF would be controlled. Storage for combustibles would be minimized in processing areas and would be properly stored in areas established for such materials. Use of flammable liquids and gases would be minimized to the extent practical. Bulk storage of flammable gases would be located outside the building, and appropriate excess flow valves would be installed in gas supply systems to stop flow in the event of a line break.

Two new 161- 13.8- kilovolt substations north of the UPF would provide electrical power to the UPF. For the purposes of this SPEIS, underground electric utility construction would be utilized. Auxiliary electrical power would be provided for safety and operational support utilizing hydrocarbon burning engine/generator sets.

A.2.7 Upgrades to Existing Enriched Uranium Facilities at Y-12

The upgrade projects proposed would be internal modifications to the existing facilities and would improve worker health and safety, enable the conversion of legacy SNM to long-term storage forms, and extend the life of existing facilities. For continued operations in the existing

facilities, major investments will be required for roof replacements; structural upgrades; HVAC replacements; and fire protection system replacement/upgrades. The projects would improve airflow controls between clean, buffer, and contamination zones; upgrade internal electrical distribution systems; and upgrade a number of building structures to comply with current NP criteria (BWXT 2004a).

For the purpose of this analysis, it is assumed that the upgrades would be performed over a 10-year construction period, following issuance of this SPEIS Record of Decision (ROD). This would enable the National Nuclear Security Administration (NNSA) to spread out the capital costs associated with the upgrades, and minimize disruption of operations.

Conventional construction techniques would be used for upgrade projects. Under this alternative, a preliminary schedule for the project indicates that site preparation would begin in 2008, with upgrades complete in approximately 2018. Upgrade activities would be performed in a manner that assures protection of the environment during the construction phase. Techniques would be used to minimize the generation of debris that would require disposal. Disposal of debris would be made in accordance with waste management requirements in properly permitted disposal facilities. Throughout the upgrade construction process storm water management techniques, such as silt fences and runoff diversion ditches, would be used to prevent erosion and potential water pollutants from being washed from the construction site during rainfall events.

NP: structural. The current authorization basis for many of the EU buildings has been designated as PC 2, which means these buildings must maintain occupant safety and continued operations with minimum interruption. An assessment of the structural adequacy of the buildings indicates they do not meet current codes and standards related to NP events (e.g., tornados and earthquakes) required for a PC 2 designation. If the buildings are intended to operate an additional 50 years, they would require structural upgrades to bring the buildings into compliance (BWXT 2004a).

Fire protection. The existing fire protection systems for many of the EU buildings are primarily piping systems operating under the Code of Record in effect at the time of installation. These codes have changed significantly over the years, and if the life of facility is intended to be extended any significant length of time, the systems may need to be upgraded to meet current codes and standards if exemptions for continued operations are denied. Upgrades would likely require total replacement of the current systems. Replacements would be required for sprinkler systems, riser replacements, and underground supply line upgrades (BWXT 2004a).

Utilities replacement/upgrades: mechanical systems. HVAC systems have an expected life in the range of 25–30 years. Many of the systems serving the EU building are beyond or are approaching the end of their useful life and are in need of replacement. The majority of the HEPA filters are located in antiquated systems. These systems also do not include test sections that allow the systems to be tested without removal of the prefilters. This arrangement subjects the filter change crews to added exposures compared to currently available filters with test sections. The continued long-term operations of existing facilities would require these filter systems to be replaced (BWXT 2004a).

Roofing. Most existing roofs for the EU buildings would need replacing (BWXT 2004a).

A.3 CONSOLIDATED NUCLEAR PRODUCTION CENTER

Program Requirements

- The CNPC would be sized and configured to support the U.S. nuclear weapons stockpile projected to exist after full implementation of the *Moscow Treaty*. The CNPC capacity would be sized to support delivery of 125 weapon assemblies per year in five-day, single shift operations. Multiple shift operation would yield up to 200 weapon assemblies per year.
- Sufficient capacity would be provided at the CNPC to support 75 weapon surveillance units per year. A capacity to perform up to 15 destructive nuclear component surveillances per year would be constructed.
- Weapon dismantlement sufficient to achieve the *Moscow Treaty*-accountable stockpile level of 1,700–2,200 operationally deployed strategic nuclear weapons is assumed to occur at Pantex in existing facilities. Because it is likely that further stockpile reductions and associated weapon dismantlements would occur during the operating life of the CNPC, a baseline dismantlement capacity of 400 units per year in five-day, single shift operations is assumed.
- The future U.S. nuclear weapons stockpile is assumed to consist of the same number of weapon types as exist today. The U.S. national security and political leadership are currently considering the authorization of a new weapon type, the RRW, to replace over the next several decades the weapon types in the existing nuclear weapons stockpile. Because a multi-decade series of decisions can not be forecast with confidence at this time, the CNPC would be equipped to allow the future production of both legacy type replacement weapons and the new RRW weapons.
- Plutonium and HEU (together referred to as SNM) would be stored at the CNPC to support future NNSA needs.

Required CNPC Capabilities

- The CNPC would include capabilities for HEU processing and weapon component production as currently performed at Y-12, and plutonium processing and weapon component production as currently performed on a limited capacity basis at LANL. In addition, R&D in support of LANL and LLNL programs requiring the use of Category I or II quantities of SNM would be performed at the CNPC.
- In addition, the CNPC would include facilities for the assembly/disassembly (A/D) mission currently performed at the Pantex Plant. In all cases, the HE processing and fabrication mission is assumed to be an integral part of the weapons A/D mission. As explained in Section 3.5.2, there is an option to separate the weapon A/D mission to allow decision-makers to consider an alternative that locates the nuclear production facilities portion of the CNPC at a different site than the weapons A/D mission.
- Fabrication, inspection, and assembly equipment at the CNPC must support the fabrication of new RRW weapons or replacement legacy weapons. In general, the ability

to produce legacy weapons would also provide RRW production capability. RRW concepts use fewer hazardous materials (than found in most legacy weapons) and require production tolerances within the range of those required for legacy weapons production.

- The assembly of plutonium and HEU nuclear weapons components also requires the production of several unique nonnuclear components. For plutonium components, it is assumed that the stainless steel and other unique metallic parts would be fabricated at or procured by Kansas City Plant (KCP). Legacy weapon plutonium components also require the production of beryllium components. It is assumed that the limited beryllium component production capability at LANL would be sufficient to support any required legacy plutonium component production.
- For HEU secondaries, it is assumed that non-nuclear components currently produced at Y-12 would be produced at the CNPC.
- The CNPC would be designed to provide best reasonably achievable levels of security to protect SNM and complete nuclear weapons. Current classified 2005 Design Basis Threat requirements from NNSA are to be used for the CNPC design. Trade studies would be performed to seek to balance worker safety, security enhancements, and costs for the CNPC. The siting of the CNPC facilities above or below ground is a major example of such a trade study. For initial planning purposes, it is assumed that CNPC facilities would be constructed above ground.
- The CNPC would be designed to have a useful operating life of at least 50 years without major facility renovation beyond normal preventive and corrective maintenance.
- The CNPC would be designed and operated to meet all existing applicable federal, state, and local laws and regulations.

CNPC Facility and Siting Requirements

- The CNPC would be considered for location at one of the following NNSA sites: Los Alamos, Pantex, Nevada Test Site (NTS), Savannah River Site (SRS), and Y-12. Should a site not have adequate space for the full CNPC mission, an option that locates only the plutonium and HEU missions at the site would be evaluated, with the weapons A/D mission remaining at Pantex or relocated to the NTS.
- Beneficial use would be sought from existing and planned assets and capabilities at each site that are expected to have a reasonable remaining useful life at the time of CNPC occupancy. For example, the new HEUMF being constructed at Y-12 is assumed to provide storage for planned inventories of DOE and NNSA highly enriched uranium (HEU) at least until the CNPC is operational. Should the CNPC be constructed at Y-12, the HEUMF would continue to support DOE and NNSA needs, and the Y-12-specific CNPC design would not require new HEU storage facilities.
- A modular arrangement of facilities (campus) is assumed for the CCE options rather than separate operational wings of a single large facility under one roof. The facilities making up the CCE campus would be configured so that they can be constructed sequentially. A single building to house the CCE functions was not considered to be reasonable due to

the need to bring facilities online in sequence and the fundamental differences in uranium, plutonium, and A/D operations.³ The assumed schedule for the CCE facilities is:

Facility	Start Detailed Facility Design	Begin Operations
CUC	2009	2018
CPC	2012	2022
A/D/HE Center	2015	2025

- It is assumed that facilities at Y-12 and Pantex, whose missions would be included in the CCE alternative, would be brought to a safe shutdown condition as soon as possible if these sites were not selected for a CCE.
- A CNPC or CNC would consist of a central area that includes all operations involving Category I/II quantities of SNM that would be surrounded by a PIDAS. A buffer area would provide unobstructed view of the area surrounding the PIDAS. Support facilities requiring lower levels of security protection would be outside the PIDAS. The land requirements for operation of a CNPC and CNC are shown in Tables A.3-1 and A.3-2 respectively.

Table A.3-1—Land Requirements to Operate a CNPC*

Operation (acres)	Total Area: 445 Acres**	
	PIDAS	Non-PIDAS
Total: 235	Total: 210	
<ul style="list-style-type: none"> • CPC: 40 • CUC: 15 • A/D/Pu Storage: 180 	<ul style="list-style-type: none"> • Non-SNM component production: 20 • Administrative Support: 70 • Explosives Area: 120 	

*Total land area for CNPC at Y-12 would be reduced by approximately 27 acres due to existing uranium production facilities.
 ** Includes a buffer area that would provide unobstructed view of the area surrounding the PIDAS.

Table A.3-2—Land Requirements to Operate a CNC*

Operation (acres)	Total Area: 145**	
	PIDAS	Non-PIDAS
Total: 55	Total: 90	
<ul style="list-style-type: none"> • CPC: 40 • CUC: 15 	<ul style="list-style-type: none"> • Non-SNM component production: 20 • Administrative Support: 70 	

*Total land area for CNC at Y-12 would be reduced by approximately 27 acres due to existing uranium production facilities.
 ** Includes a buffer area that would provide unobstructed view of the area surrounding the PIDAS.

A generic layout of the CNPC is shown in Figure A.3-1.

³ The facilities that would constitute a CCE would be separate buildings in a campus because they have different safety and operational requirements, and it would not be technically feasible to put them in a single large facility without having separate systems for the operation of the three facilities and other physical features (blast wall separation, etc.) to keep them separate. They would be built in sequence because they are very complex facilities and the realities of construction logistics, cash flow, and start-up management would not support a single facility. Building them in sequence reduces the construction management risk and allows lessons learned from one to benefit the others. The CUC would be first because the existing uranium facilities at Y-12 are very old. The CPC would be built second because the LANL facilities can handle the immediate need for pits. The weapons A/D/HE facilities would be last because there is the least programmatic urgency for them.

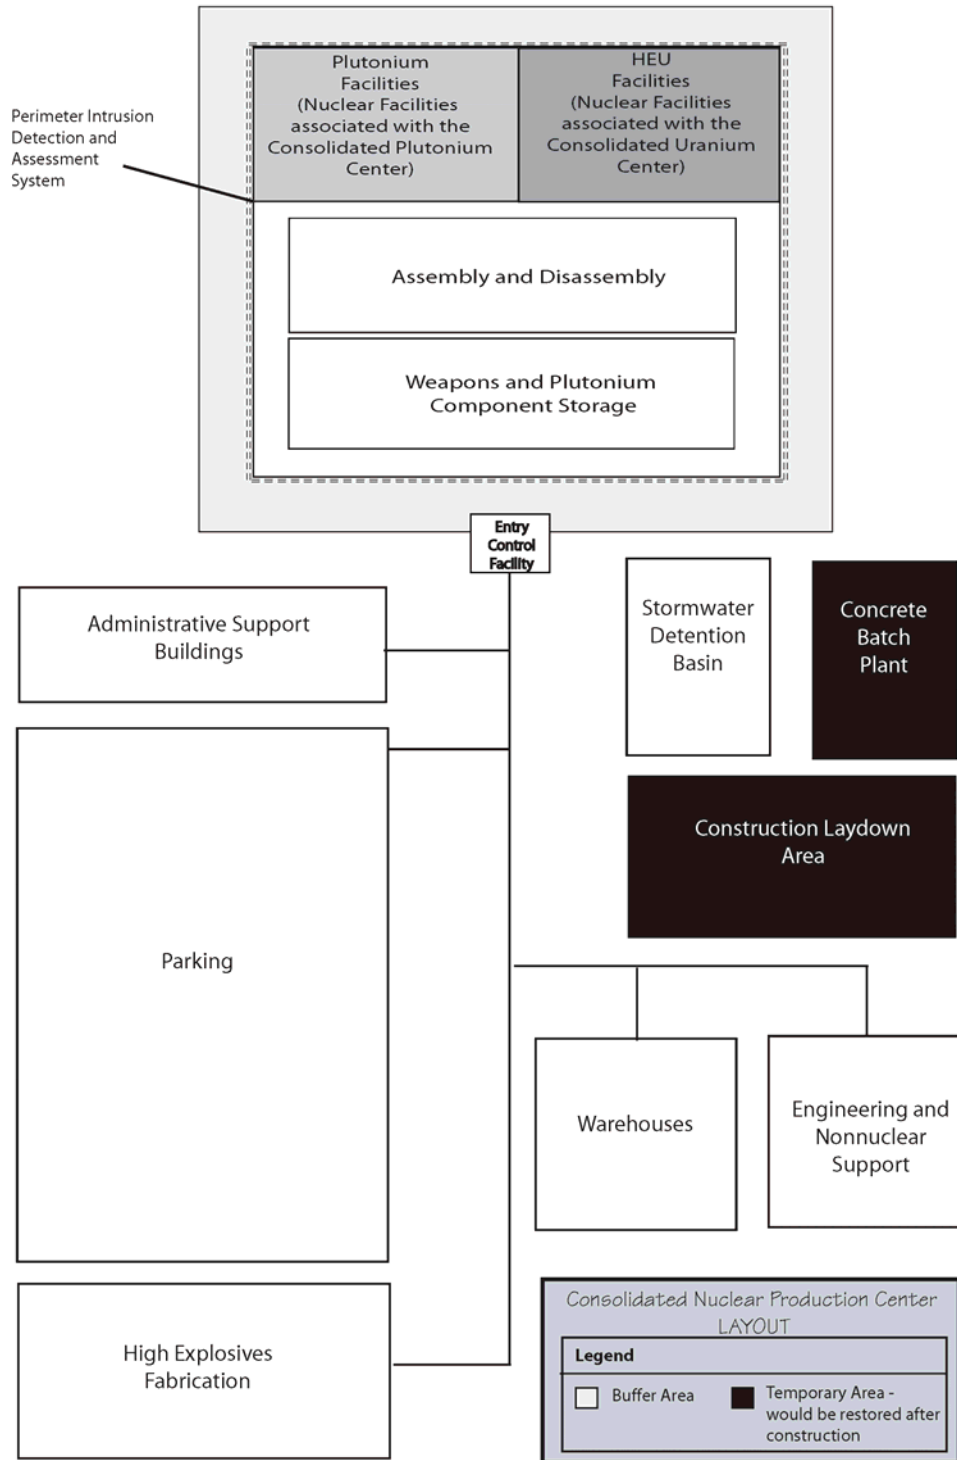

Figure A.3-1—Generic Layout of the CNPC

A.3.1 Consolidated Uranium Center (CUC)

The CUC would primarily be made up of a nuclear facility⁴ located within the PIDAS, and non-nuclear support facilities outside the PIDAS. The nuclear facility would process HEU, produce nuclear weapon secondary components, and provide the capability to perform HEU R&D in support of Los Alamos National Laboratory (LANL) and Lawrence Livermore National Laboratory (LLNL). The nuclear facility would also store HEU. The non-nuclear facilities would contain the necessary and support operations associated with additional weapon materials, such as depleted uranium (DU) alloys; lithium hydride and lithium deuteride; stainless steel, and other general manufacturing materials.

The CUC would be constructed over a six-year period, beginning in approximately 2011, with completion by approximately 2016, and operations beginning by approximately 2018. The design service life of the CUC would be 50 years.

This section presents major differences between the UPF described in Section 3.4.2 and the CUC that could be built at sites other than Y-12. The major difference involves the addition of HEU storage and the non-nuclear support facilities outside the PIDAS. Construction of the CUC at sites other than Y-12 would require approximately 50 acres of land.

The nuclear portion of the CUC would contain approximately 500,000 square feet in one building. Of this, storage would account for approximately 100,000 square feet, and would be used for long-term storage of Categories I/II HEU. A capacity to store approximately 10,500 cans and 10,500 drums (55-gallon equivalents) of HEU, a surge capacity area for an additional 3,000 drums, and a storage area for material currently under international safeguards would be provided. The non-nuclear support facilities outside the PIDAS would contain approximately 150,000 square feet.

The CUC would provide secure docking for safeguard transports (SGTs) to ensure the secure, safe transfer of secondaries and other materials containing HEU. The shipping and receiving docks at the CUC would accommodate the simultaneous loading and unloading of three Safeguards Transporters (SGTs) or Safe Secure Trailers (SSTs). The main operational steps that would be involved in handling containers with HEU materials are presented below:

- SGT arrives at the loading dock.
- Shipping containers are offloaded and moved to the nondestructive assay (NDA) and recontainerization area.
- A transfer check is performed.
- Containers undergo NDA.
- HEU materials are placed in new containers if required.
- Each container entered into the computerized tracking system and is assigned a rack location.

⁴ For purposes of this SPEIS, this nuclear facility will be referred to as the Uranium Processing Facility (UPF), as generally described in Section 3.4.2. However, the UPF at Y-12 would not require HEU storage within the UPF, as an existing HEU Materials Facility (HEUMF) exists at that site. The UPF for all other site alternatives would include HEU storage integral to the UPF. The UPF described in this section includes such integral HEU storage.

- Each container is moved by forklift to its assigned location in the storage area.
- Each container is connected to the automated inventory system

A.3.2 Assembly/Disassembly/High Explosives Center (A/D/HE Center)

The A/D/HE Center would carry out the following major missions:

- Assemble warheads;
- Dismantle weapons that are surplus to the strategic stockpile and sanitize or dispose of components from dismantled weapons;
- Develop and fabricate explosive components; and
- Conduct surveillance related to certifying weapon safety and reliability.

The A/D/HE Center would be made up nuclear facilities located within the PIDAS and non-nuclear facilities outside the PIDAS. In support of this mission, approximately 300 acres would be required for the A/D/HE Center. The nuclear facilities would contain the cells and bays in which maintenance, modification, and A/D operations are conducted. The facilities would be designed to mitigate the effects of the unlikely accidental detonation of the weapon's explosive components. Bays differ from cells in that bays are designed to vent an explosion to the atmosphere while protecting adjacent facilities from the blast, while cells are designed to filter the explosion products while also protecting the adjacent facilities from the blast.

An area of 180 acres would be provided in the PIDAS for the weapons A/D facilities and the associated weapons and plutonium component storage. Located outside the PIDAS area would be a buffer zone and non-nuclear facilities for HE fabrication, administrative support, and disposal of explosive materials. This area would be approximately 120 acres. The A/D/HE Center would be constructed over a six-year period, beginning in approximately 2021, with completion by approximately 2026, and operations beginning by approximately 2027. The design service life of the A/D/HE Center would be 50 years.

A.3.2.1 Operations Conducted at the A/D/HE Center

Assembly. Weapons assembly requires written, prescribed steps to combine separate parts to form a new weapon. Complete weapons assembly would be accomplished in the following stages:

- Physics package assembly;
- Mechanical and electronic components assembly; and
- Final package or ultimate user package assembly.

The physics package is a subassembly combining HE components (to be produced at the A/D/HE Center) and nuclear components (to be manufactured at the CPC and Consolidated Uranium Center [CUC]) within a protective shell. Physics package assembly entails bonding or mating the main charge subassemblies to a nuclear pit and then inserting this subassembly into a case along with other components. Mechanical and electronic components assembly entails placing the physics package in a warhead case and then installing the components for the arming,

fusing, and firing systems; the neutron generator; and the gas transfer system. The final package assembly involves installing additional components and packaging the weapon for shipment.

Dismantlement. Dismantlement consists of disassembly and disposal or sanitization of weapon components. The dismantlement process begins with the arrival of the weapon at the A/D/HE Center. Disassembly would include the following:

- Weapons staging, which includes inspection and verification after receipt from DoD;
- A variety of specialty operations (e.g., X-ray examinations, leak testing, coding, packaging, painting, verification, etc.) in special purpose bays;
- Mechanical disassembly operations in bays;
- Nuclear disassembly operations in cells;
- Demilitarization and sanitization of weapon components, which includes grinding, crushing, and open-air burning;
- Packaging and shipping HEU to the CUC and tritium components to the SRS;
- Packaging and shipping pits to the CPC; and
- Segregation of waste products into nonhazardous, hazardous, low-level radioactive, and low-level mixed waste categories.

High explosives fabrication. The A/D/HE Center would manufacture the main charge HE and other small explosive components. The fabrication process for explosives involves synthesizing energetic materials (explosives) and then formulating the energetic materials with other materials as appropriate. Some of the energetic materials are manufactured at the plant, while others are procured commercially. The explosive powder is then pressed into the configurations needed and machined for use in nuclear weapons. The products of manufacturing operations are explosive main charges, small explosive components, and other highly specialized explosive materials. Main charge subassemblies are emplaced in the physics package of a nuclear explosive during the weapon assembly process. Various small explosive subassemblies and pellets are produced from explosives, metal or plastic components, electrical components, hardware, assembly materials, and small explosive components that are manufactured offsite.

Surveillance. To maintain the reliability of the Nation's nuclear weapons, a certain number of randomly selected weapons from all active systems would be annually removed from the stockpile and returned to the A/D/HE Center. The weapons are disassembled, tested, and evaluated to ensure the operability of the weapons components. Most testing is done onsite, but tests associated with component aging are performed at other laboratories and production agencies. Some weapons are configured as Joint Test Assemblies (JTAs) and provided to the military for flight testing. Main charge explosive components and SNM are removed from weapons before this testing. Certain components are physically removed from the weapon, assembled into test configurations, and subjected to electrical and/or explosives testing. Components not destroyed during the testing process can be recycled and made available for use in other weapon system assemblies.

Security at the A/D/HE Center. Security at the A/D/HE Center would be charged with protecting plant personnel, facilities, materials, and information from intrusion. Protective forces guard against any events that may cause adverse impacts on national security, the environment or

the health and safety of the public or employees. Special response security team members prepare for any situation that may arise. Specially equipped and trained, these individuals face a range of events that may develop as a result of the constantly changing world situation or local events. State-of-the-art technologies would augment security forces to provide early detection, warning and deterrence.

A.4 A/D/HE CENTER AT NTS

At NTS, the A/D/HE Center would make use of the existing capabilities at NTS such that construction requirements would be reduced compared to the generic A/D/HE Center described above. The A/D/HE Center at NTS would maximize use of existing facilities at the Device Assembly Facility (DAF), the underground complex of tunnels at U1a, the Big Explosive Experiment Facility (BEEF), the Explosives Ordnance Disposal Unit (EODU), existing NTS site infra-structure, and the support areas of Mercury, the Control Point, and Area 6 construction (Figure A.4-1). By utilizing each of these unique existing assets, the need for additional construction is minimized and the existing benefits of each site are maximized.

The existing DAF would form the cornerstone of the A/D/HE Center at NTS. The NTS alternative would utilize the DAF for disassembly operations. DAF can fully support disassembly operations and continue to support the existing criticality experiment missions that were recently added to the DAF. Disassembly operations in the DAF would not require additional construction within the PIDAS or additions to the existing PIDAS. In the non-PIDAS area of the DAF and outside the buffer zones, an administrative facility and parking area would be constructed to support the increased personnel processing requirement for disassembly. The available space in DAF consists of the following:

- 3 Assembly cells (8,510 square feet);
- 2 Radiography bays (6,351 square feet);
- 1 Downdraft table bay (1,681 square feet);
- 1 Assembly bay (1,681 square feet);
- 2 Bunkers (1,872 square feet);
- 2 limited use vaults (180 square feet);
- 1 High bay (1,790 square feet);
- 1 Bunker (936 square feet);
- 1 MC&A measurement building (2,142 square feet);
- 1 shipping/receive bay (2,012 square feet);
- Administrative space (3,700 square feet);
- 1 Glovebox bay (1,681 square feet); and
- Corridors (20,000 square feet).

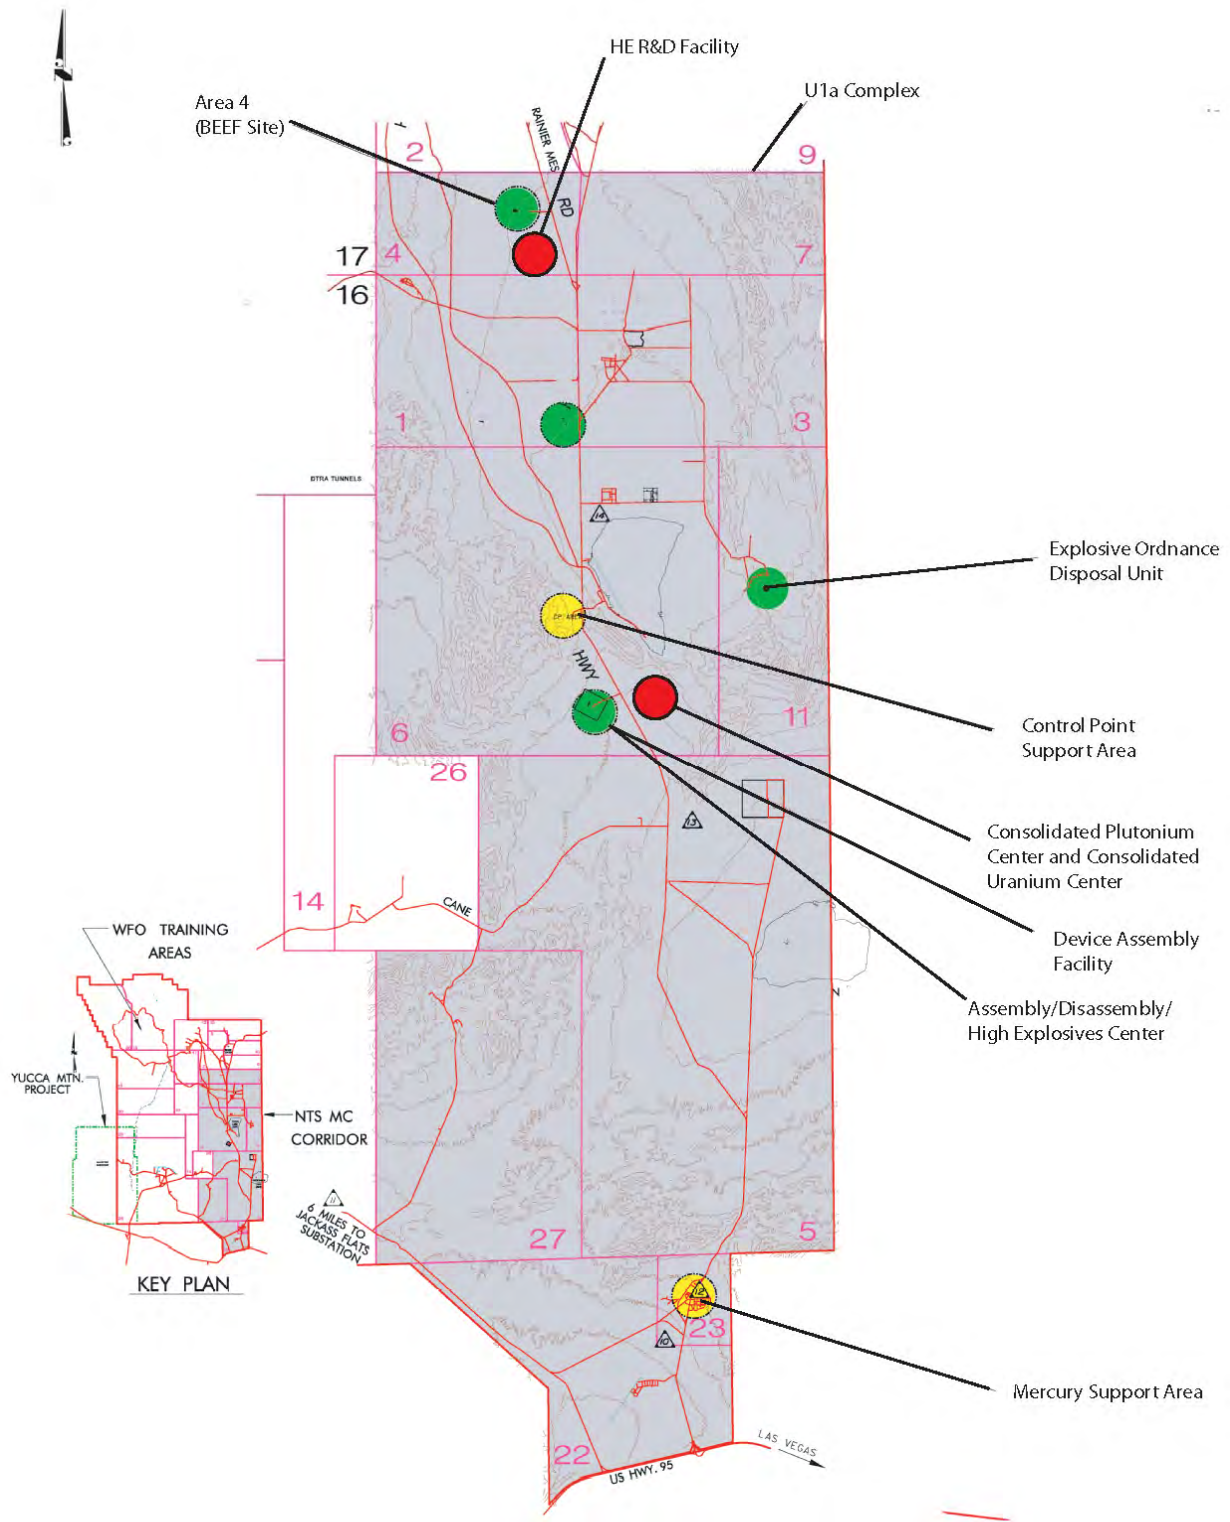

Figure A.4-1—NTS CNPC Reference Location

The remaining operations of assembly, longer-term storage for nuclear and non-nuclear components that are generated by DAF disassembly activities, weapon surveillance, and strategic reserve storage of plutonium would be located 900 feet underground in the tunnel complex at U1a. This alternative would include construction of new tunnels and alcoves in accordance with nuclear explosive requirements for assembly and storage operations. At the U1a Complex, access to the tunnel network is limited to two vertical access/egress shafts that would require construction of a small PIDAS around the surface footprint of each shaft.

A.5 CONSOLIDATION OF CATEGORY I/II SNM

A.5.1 No Action Alternative

A.5.1.1 *Lawrence Livermore National Laboratory*

LLNL uses radioactive materials in a wide variety of operations including scientific and weapons R&D, diagnostic research, research on the properties of materials, and isotope separation. Based on facility design and operation, LLNL establishes administrative limits for fissile, special use, radioactive, and sealed materials. An administrative limit is the total amount of certain materials allowed in a specific building at LLNL. These limits are used in determining potential risks associated with accidents. Actual inventories may be classified. Nonwaste management facilities at LLNL authorized to have Category I/II SNM quantities are Building 332, Building 334, and Building 239. However, only Building 332 stores such material, and both Building 334 and Building 239 have no materials stored in them. As such, only Building 332 is germane to the discussion below. With respect to waste management facilities with Category I/II SNM, the Decontamination and Waste Treatment Facility (DWTF) (Figure A.5.1-1) manages TRU waste that would be shipped to WIPP.

The Building 332 Plutonium Facility is part of the Superblock, a protected area located in the southwest quadrant of the Livermore Site (see Figure A.5.1-2). This building has a total area of 104,687 gross square feet, including radioactive materials laboratories, mechanical shops, change rooms, storage vaults, a fan loft, basement, equipment rooms, and offices. There are currently 24 laboratories in which radioactive materials can be handled within the radioactive material areas (RMAs) of the facility (LLNL 2005).

The mission of Building 332 includes R&D in the physical, chemical, and metallurgical properties of plutonium and uranium isotopes, compounds and alloys, and certain actinide elements. Operations within Building 332 include melting, casting, welding, and machining; developing alloys and heat treating; testing torsion, tensile, and compression; measuring density and heat capacity; machining, inspecting, and testing components; using chemical processes to purify, separate, or convert actinide materials; pressure testing and gas filling operations; and assembling components. Chemical analyses can also be conducted on gram-sized samples in support of these activities.

The Materials Management Division is responsible for all shipments of radioactive and other controlled materials to and from Building 332, as well as movement within the building. This division also controls storage of these materials in the building vaults. The vaults are equipped to

safely store fissile, radioactive, and certain other SNM required for programmatic operations. Criticality safety controls for the vaults include specially designed storage racks and containers to control the spacing of stored fissile materials and mass limits for each storage location or rack cell within a storage vault. LLNL criticality safety controls also specify mass limits for each workstation (LLNL 2005). Legacy and new TRU waste is temporarily stored in the basement, and the individual waste drums are scanned by a segmented gamma scanner to verify radionuclide and curie content. Although actual quantities of Category I/II SNM in Building 332 are classified, the administrative limits are as follows:

Plutonium	1,400 kg
Enriched uranium	500 kg

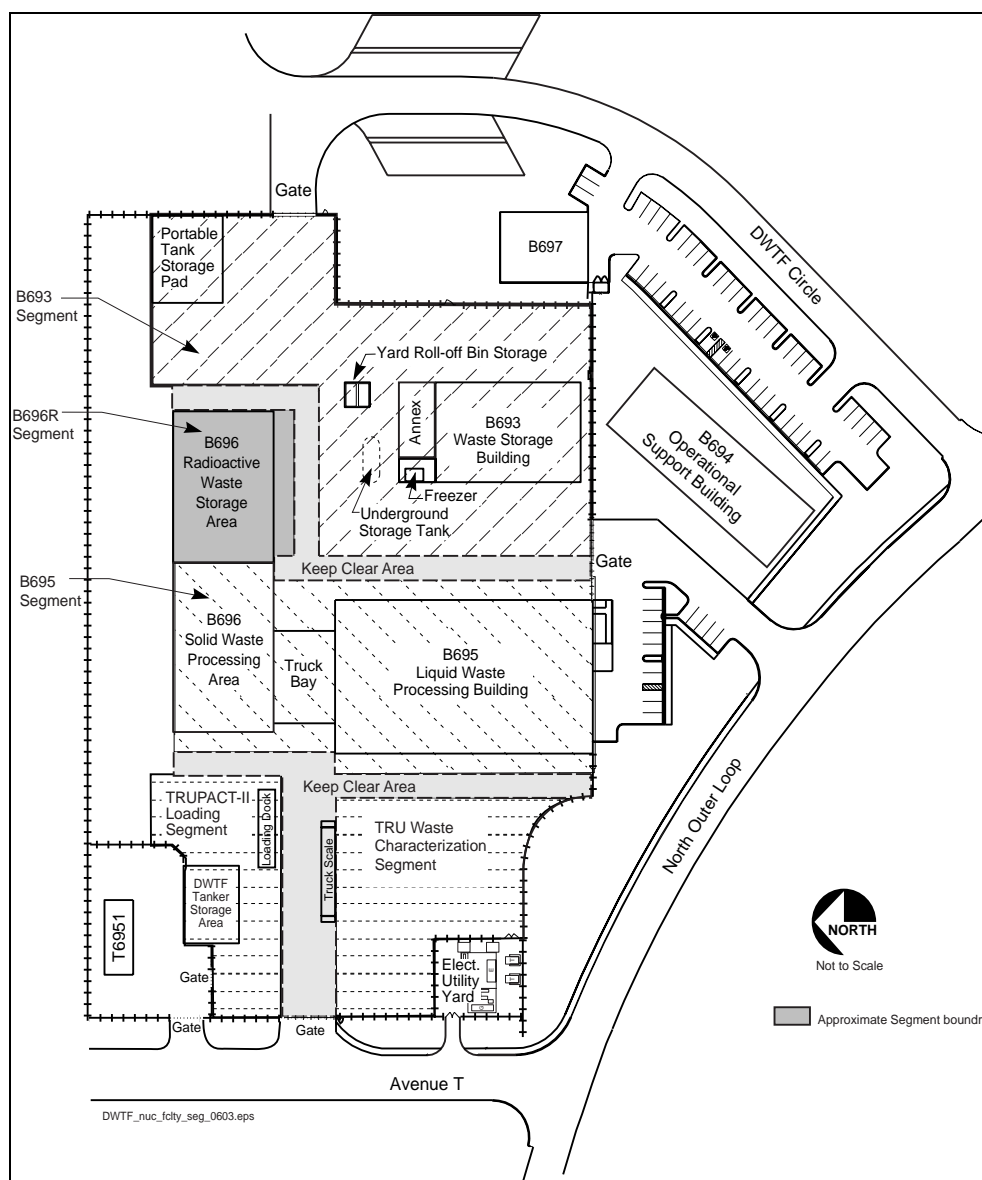

Figure A.5.1-1—Decontamination and Waste Treatment Facility at LLNL

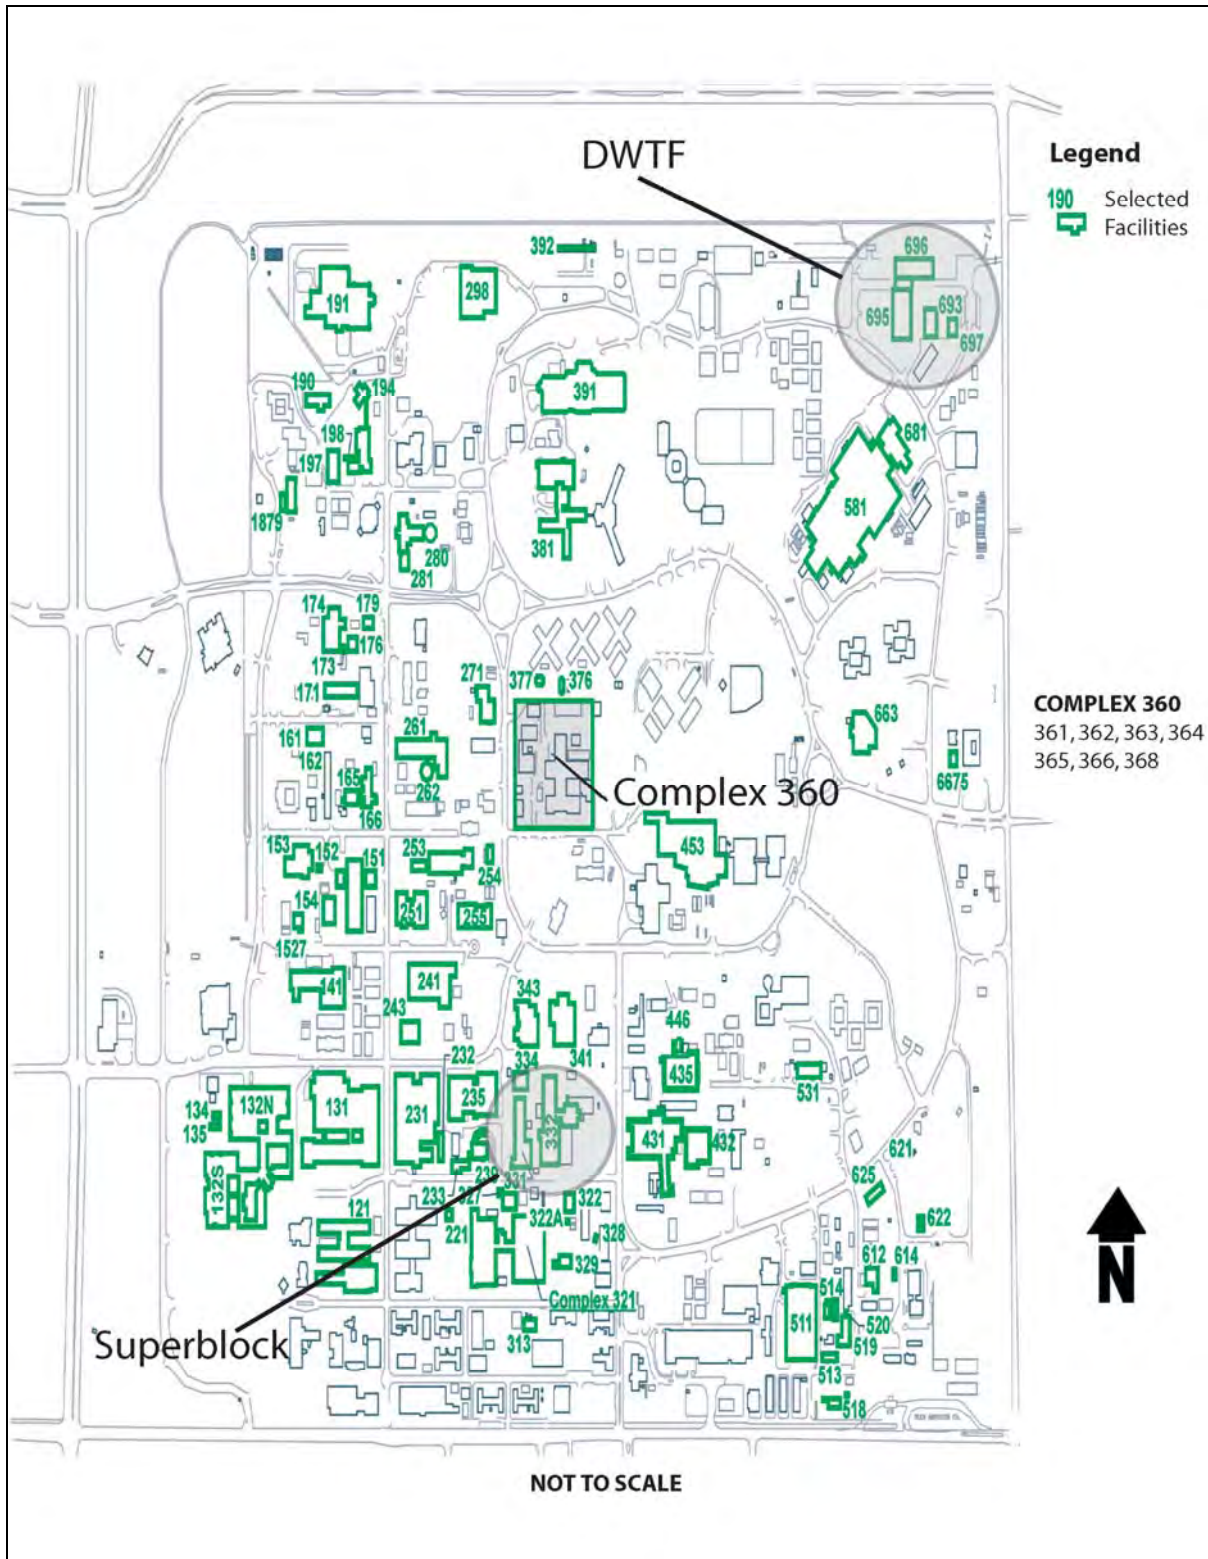

Figure A.5.1-2—Location of Building 332 and the DWTF at LLNL

In 1996, construction of a new consolidated waste treatment facility, the DWTF, began in the northwest corner of the Livermore Site (see Figure A.5.1-1). The DWTF construction has been completed and currently consists of Buildings 6951, 693, 694, 695, 696, and 697 and associated yard areas. The DWTF replaces waste management operations in Area 514 and Building 233 and consolidates other waste management activities into one facility (Figure A.5.1-3).

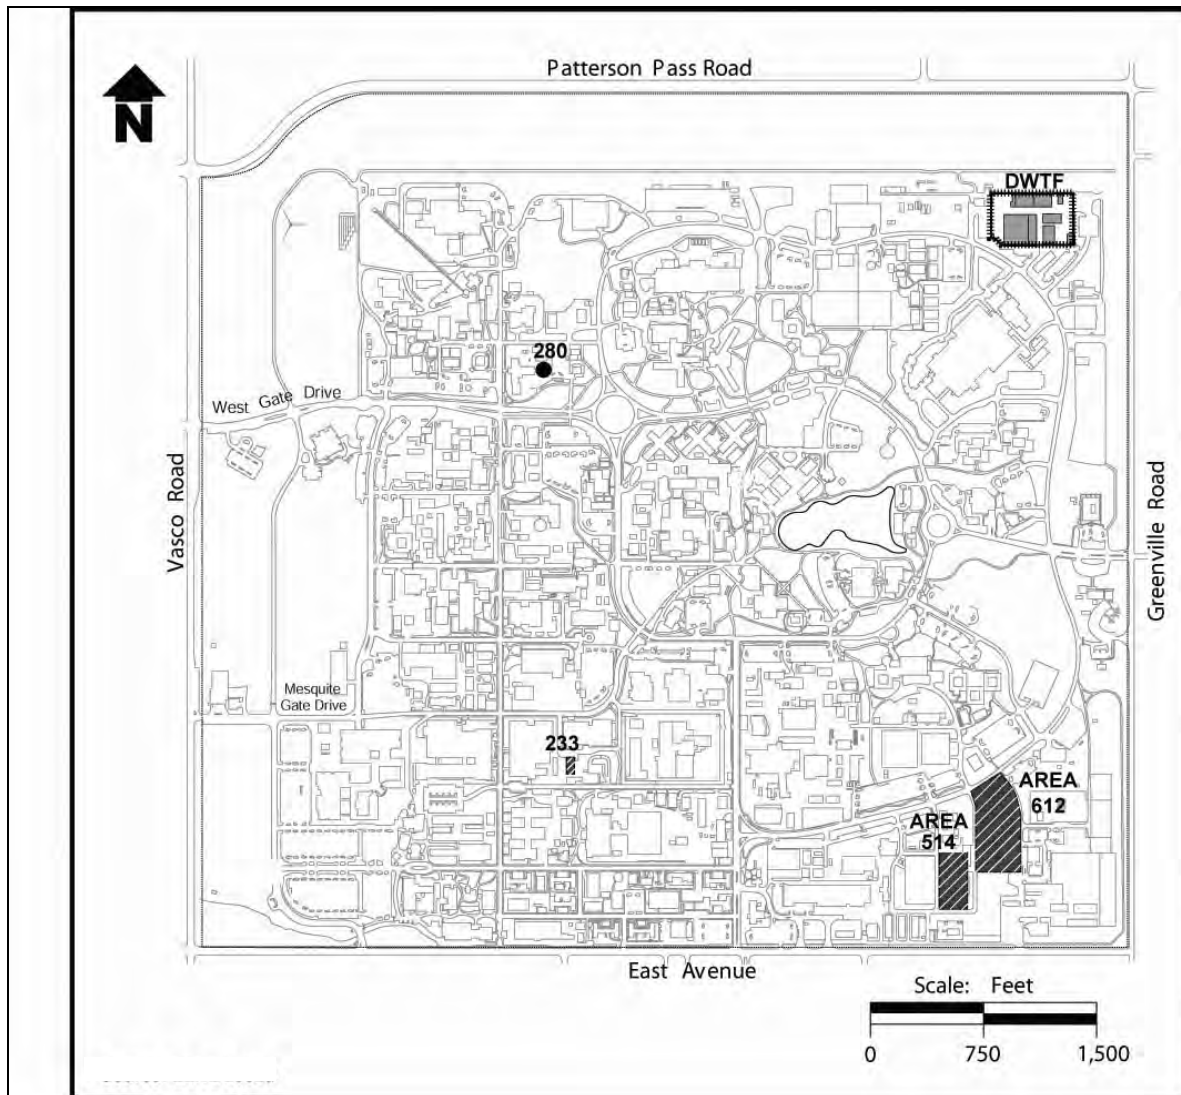

Figure A.5.1-3—Location of Waste Management Areas at LLNL

The DWTF is a hazardous, radioactive, and mixed waste treatment and storage facility located in the northeast corner of the Livermore Site. Hazardous and mixed waste management activities involve five individual facilities: Buildings 693, 694, 695, 696, and 697, and associated yard areas (see Figure A.5.1-3). Building 693 is a container storage unit and activities include waste packaging and storage. Building 695 provides storage and waste treatment capabilities including bulking and blending of wastes into treatment tanks; treating liquid and solid hazardous, mixed, and low-level radioactive wastes; storing; container rinsing; and waste transfer. Building 694 is the operational support facility and Building 697 is a Chemical Exchange Warehouse used for

chemical exchange operations. Building 696 provides radioactive waste storage and solid waste receiving and processing capabilities. Building 695 includes a maintenance shop. Areas within the DWTF yard include a rainwater management area, a tanker storage area, a covered truck bay, and truck scales. Yard areas are used by mobile vendors to certify TRU waste and load it for shipment to WIPP.

Building 696R is designed for the storage of solid TRU waste, solid and liquid LLW, and combined waste (i.e., radioactive and California-regulated hazardous waste). Operations in the Building 696R segment include loading, unloading, staging, storage, over packing, LLW sampling, and periodic visual inspections of waste containers. Building 635 also stores TRU waste.

The mission performed in the TRU waste segments is to characterize LLNL TRU waste, repackage it as necessary, and load the waste drums into Transuranic Package Transporter-II (TRUPAC-II) casks for offsite shipment. The waste needs to meet both the DOT shipping requirements and the waste acceptance criteria for the receiving facility, which will be the WIPP. The amount of TRU managed at DWTF is approximately 110 cubic meters per year (LLNL 2005).

A.5.1.2 *Los Alamos National Laboratory*

LANL uses radioactive materials in a wide variety of operations including scientific and weapons R&D, diagnostic research, research on the properties of materials, and plutonium pit production. The technical area (TA)-55 Plutonium Facility Complex (TA-55 Complex) encompasses about 40 acres and is located about one mile southeast of TA-3 (Figure A.5.1-4). The Plutonium Facility Complex has the capability to process and perform research on actinide materials, although plutonium is the principal actinide used in the facility. Most of TA-55 is situated inside a restricted area surrounded by a double security fence. The main complex has five connected buildings: the Administration Building, Support Office Building, Support Building, Plutonium Facility, and Warehouse.

The Plutonium Facility, a two-story laboratory of approximately 151,000 square feet, is the major R&D facility in the complex (Figure A.5.1-5). The Plutonium Facility provides storage, shipping, and receiving activities for the majority of the LANL SNM inventory, mainly plutonium. This includes temporary storage of Security Category I/II materials removed from TA-18 in support of TA-18 closure until these materials are shipped to NTS and other DOE sites. All materials from TA-18 are scheduled to be moved to final disposition locations by March 2008. In addition, sealed sources collected under DOE's Off-Site Source Recovery Project are stored at TA-55 or sent to other LANL locations for storage pending final disposition. When appropriate, mixed-oxide fuel materials stored at TA-55 would be transported to other DOE sites. TA-55 provides interim storage of up to 7.3 tons of the LANL SNM inventory, mainly plutonium.

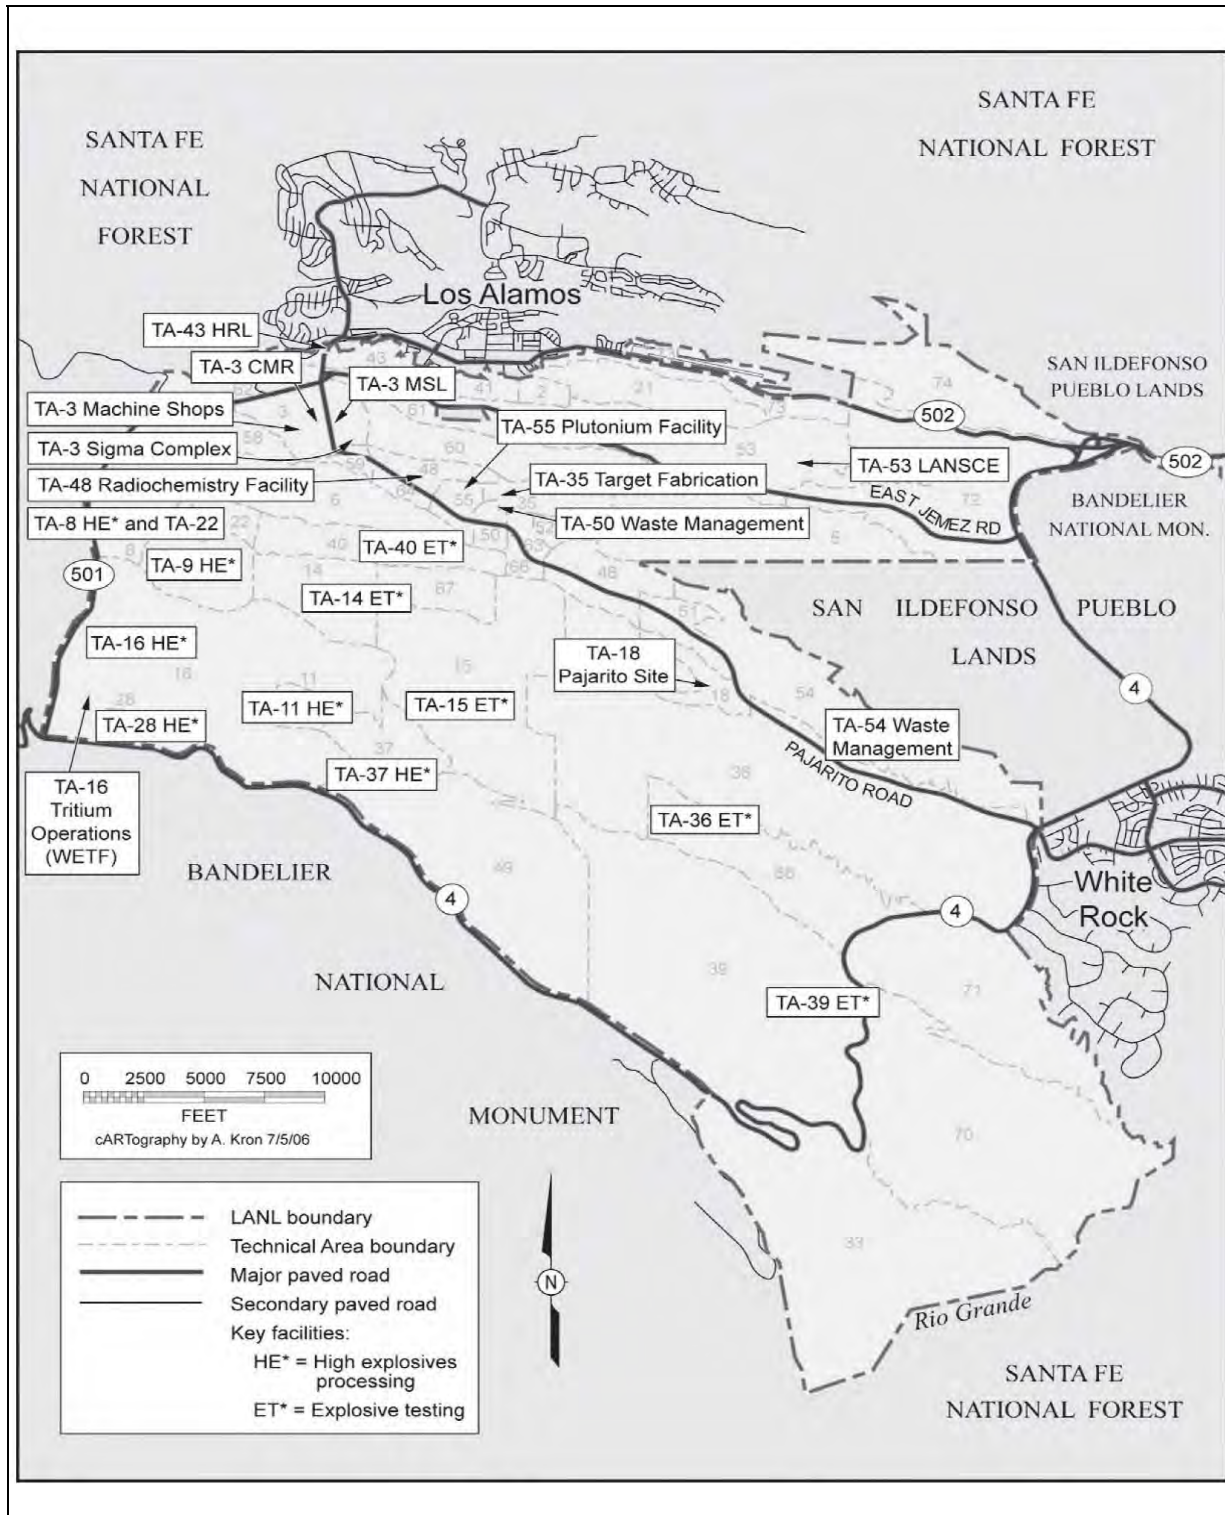

Figure A.5.1-4—Major Technical Areas at LANL, including TA-55 Plutonium Facility Complex

Figure A.5.1-5—Plutonium Facility at TA-55

PROJECT-SPECIFIC ALTERNATIVES

A.6 HIGH EXPLOSIVES R&D

A.6.1 No Action Alternative

This section describes the HE R&D facilities and missions currently conducted at weapons complex sites.

A.6.1.1 *Lawrence Livermore National Laboratory*

HE R&D at LLNL is carried out primarily in two facilities—the HEAF at the main Livermore site, and the Chemistry, Materials and Life Sciences Facility at Site 300. A basic description of each of these facilities is given below.

The High Explosives Application Facility (HEAF) is a full-spectrum R&D facility which performs the following missions:

- Explosive characterization and lab-scale development;
- Performance and safety testing; and
- Modeling and simulation of explosive properties and reactions.

The HEAF includes laboratory areas approved for handling explosives in quantities up to 10 kilograms, and office space for the research and support staff. The net usable area of the facility is approximately 65,000 square feet. An aerial view of the HEAF is shown in Figure A.6.1-1.

Note: The facility section at the bottom of the image is the office area; the area behind that houses the laboratory areas including firing tanks

Figure A.6.1-1—The LLNL HEAF

The Chemistry, Materials and Life Sciences Facility at Site 300 provides the capability for larger scale synthesis and formulation, HE R&D part fabrication (e.g. pressing radiography, machining and assembly), and explosives waste packaging, storage and treatment. These capabilities are provided by the Chemistry Area, the Process Area, the Explosive Waste Storage Facility, and the Explosive Waste Treatment Facility. The net usable space is approximately 35,000 square feet. Figures A.6.1-2 and A.6.1-3 show the Chemistry, Materials and Life Sciences Facility at Site 300.

Figure A.6.1-2—Chemistry Area at Site 300, providing scale up of formulation and synthesis of HE

Note: Shown are B.806 (foreground), B807 directly behind B806 to the left, B805 behind B806 to the right, and the EWSF at the top of the photo

Figure A.6.1-3—A portion of the Process Area at Site 300

There are approximately 175 scientists, engineers, and technicians associated with the HE R&D mission at LLNL.

A.6.1.2 *Los Alamos National Laboratory*

LANL conducts HE R&D activities in nine technical areas, as discussed below. While the LANL HE R&D facilities share some common spaces with the hydrodynamic program, for purposes of

this SPEIS, the current HE R&D activities at LANL are considered to be housed in approximately 250,000 square feet, managed as three facilities (HE Science, HE Fabrication, and HE Firing Sites) in 31 buildings (>1000 square feet), which includes magazines and firing points. Major TAs with HE R&D facilities are discussed below and shown on Figure A.6.1-4.

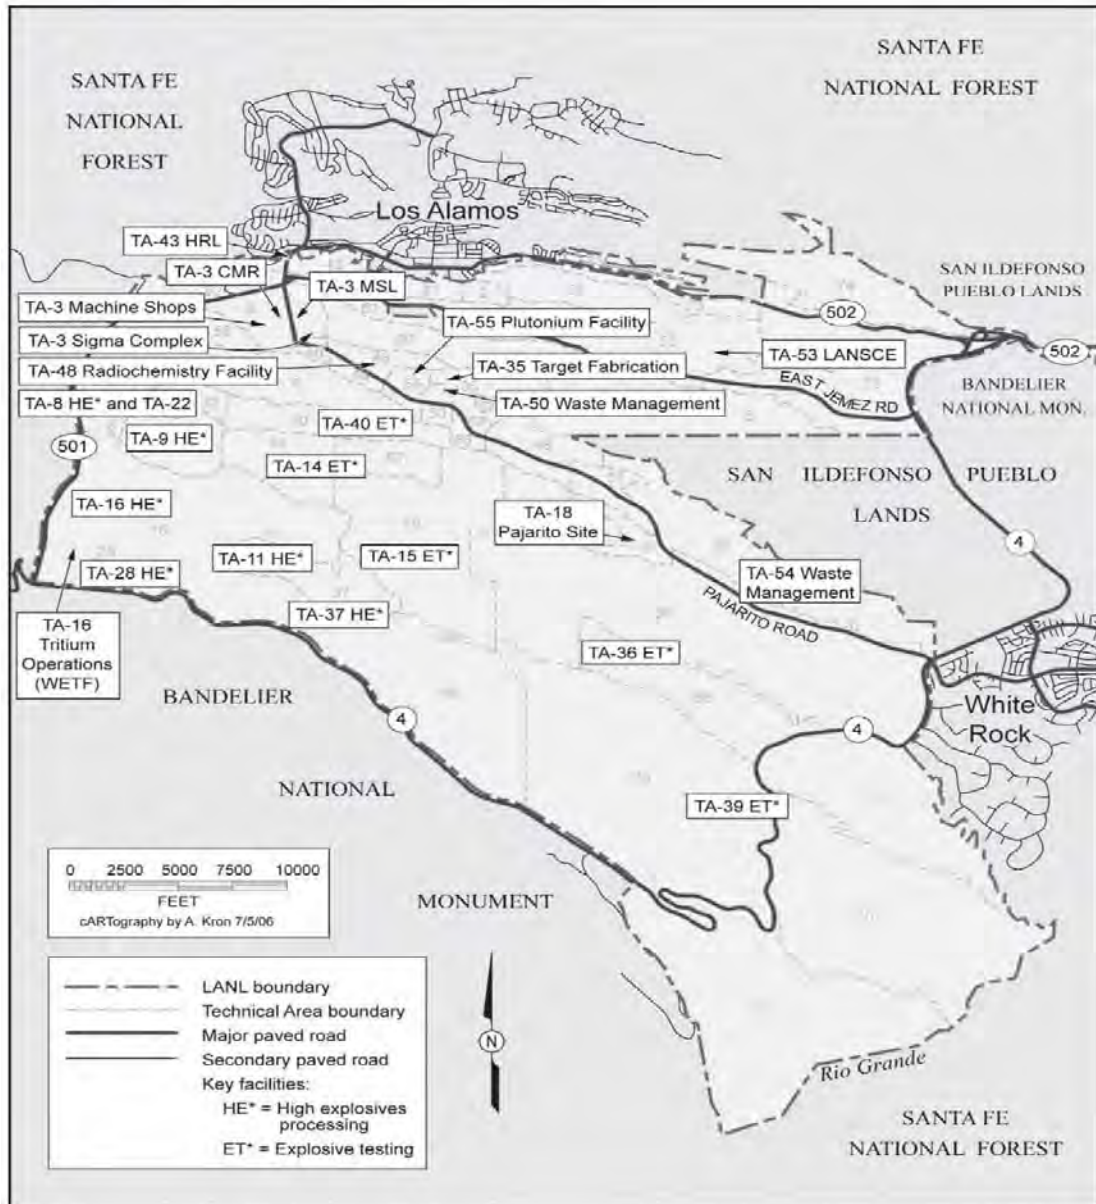

Figure A.6.1-4—LANL Technical Areas

- TA-9** This TA is located on the western edge of LANL. Fabrication feasibility and the physical properties of explosives are explored at this site, and new organic compounds are investigated for possible use as explosives. Storage and stability problems are also studied.
- TA-14** Located in the northwestern part of LANL, this TA is one of 14 firing areas. Most operations are remotely controlled and involve detonations, certain types of high explosives machining, and permitted burning. Tests are conducted on explosives charges to investigate fragmentation impact, explosives sensitivity, and thermal responses of new high explosives. This site is currently permitted to treat waste through open detonation or open burning under the *RCRA*.
- TA-16** Fabrication of precision explosive assemblies, from powder pressing to machining and inspection, occurs at TA-16 to support HE R&D experimentation. LANL owns and maintains the only capability for fabrication of plane wave lenses used throughout the nation, at this facility.
- TA-22** This TA, located in the northwestern portion of LANL, houses the Los Alamos Detonator Facility. Construction of a new Detonator Production Facility began in 2003. R&D and fabrication of high-energy detonators and related devices are conducted at this facility.
- TA-36** TA-36 is in a remotely located area in the eastern portion of LANL that is fenced and patrolled. It has two active firing sites that support the HE R&D mission (it has two other firing sites that support the hydrotesting mission). The sites are used for a wide variety of nonnuclear ordnance tests pertaining to warhead designs, armor and armor-defeating mechanisms, explosive vulnerability to projectile and shaped-charge attack, warhead lethality, and determining the effects of shock waves on explosives and propellants. Diagnostics include optical photography, multiple beam laser velocimetry, high speed electrical signal recording, and pulsed X-ray techniques.
- TA-39** TA-39 is located at the bottom of Ancho Canyon. The behavior of nonnuclear weapons is studied here, primarily by photographic techniques. Also studied are the various phenomenological aspects of explosives, interactions of explosives, explosions involving other materials, shock wave physics, equation-of-state measurements, and pulsed-power systems design and experimentation.
- TA-40** TA-40, centrally located within LANL, is used for studies of explosive initiation, detonation, and shock wave response of other materials related to weapon systems. Both fundamental and applied research investigating phenomena associated with the physics of high explosives and shock-induced chemical reactions are conducted. In addition, surveillance and qualification studies of War Reserve (WR) detonators are conducted.

- TA-46** TA-46, located between Pajarito Road and the San Ildefonso Pueblo, is one of LANL's basic research sites. Activities have focused on applied photochemistry operations and have included development of technologies for laser isotope separation and laser enhancement of chemical processes. Current operations include studies of the response of small quantities of explosives to thermal and mechanical stimuli, with the experiments housed in boomboxes.
- TA 53** At Area C of LANSCE, located at TA-53, LANL has developed Proton Radiography, a unique national resource. Proton radiography (800 megaelectron volts [MeV]) has the ability to capture a sequence of images, creating a movie of an explosive event (up to 33 frames, currently). Protons have approximately 100 micrometers spatial resolution for HE systems, with high contrast over a wide range of areal densities. Protons are different from X-rays in that there is no background or detector scatter, so quantitative density measurements are possible. Proton radiography shots are currently limited to 10 pounds Trinitrotoluene (TNT) equivalent in a containment vessel.

The general HE R&D activities at LANL can be broken down into the following missions:

- HE synthesis and formulation R&D;
- Physics and engineering performance, and safety models;
- Thermal response of HE;
- HE characterization;
- Characterization of HE-driven materials;
- Detonator technology R&D;
- HE test fire capabilities; and
- Military and commercial applications of HE.

A.6.1.3 *Pantex Plant*

The Pantex Plant researches the physical and chemical characteristics of the parts used in nuclear weapons. Highly specialized explosive main charges and initiation systems are required for a weapon to produce a nuclear explosion. Research at Pantex includes the use of insensitive HE for increased safety as well as refinement of HE manufacturing methods and safety procedures. Pantex performs HE synthesis, formulation, machining, extrusion, testing, process development, and analytical operations in performing its HE research and development and production missions. These operations are performed in Zone 11 or Zone 12 using HE materials stored in Zone 4 East remote firing sites (see Figure A.6.1-5). HE R&D activities and HE production mission work at Pantex occur in common facilities and work areas. As a result, R&D and production missions are not segregated in terms of facilities, infrastructure or work force. In general, less than 10 percent of the annual HE-related budget at Pantex is associated with HE R&D activities.

R&D activities at Pantex, not related specifically to production process improvement, primarily involve stockpile-related surveillance and periodic reimbursable work typically with technical direction from the national laboratories. This work is traditionally concentrated within the testing

mission categories. There are currently no Pantex facilities dedicated entirely to HE R&D work. By conducting HE R&D efforts in the production facilities, NNSA is able to leverage the infrastructure investment to accomplish both objectives.

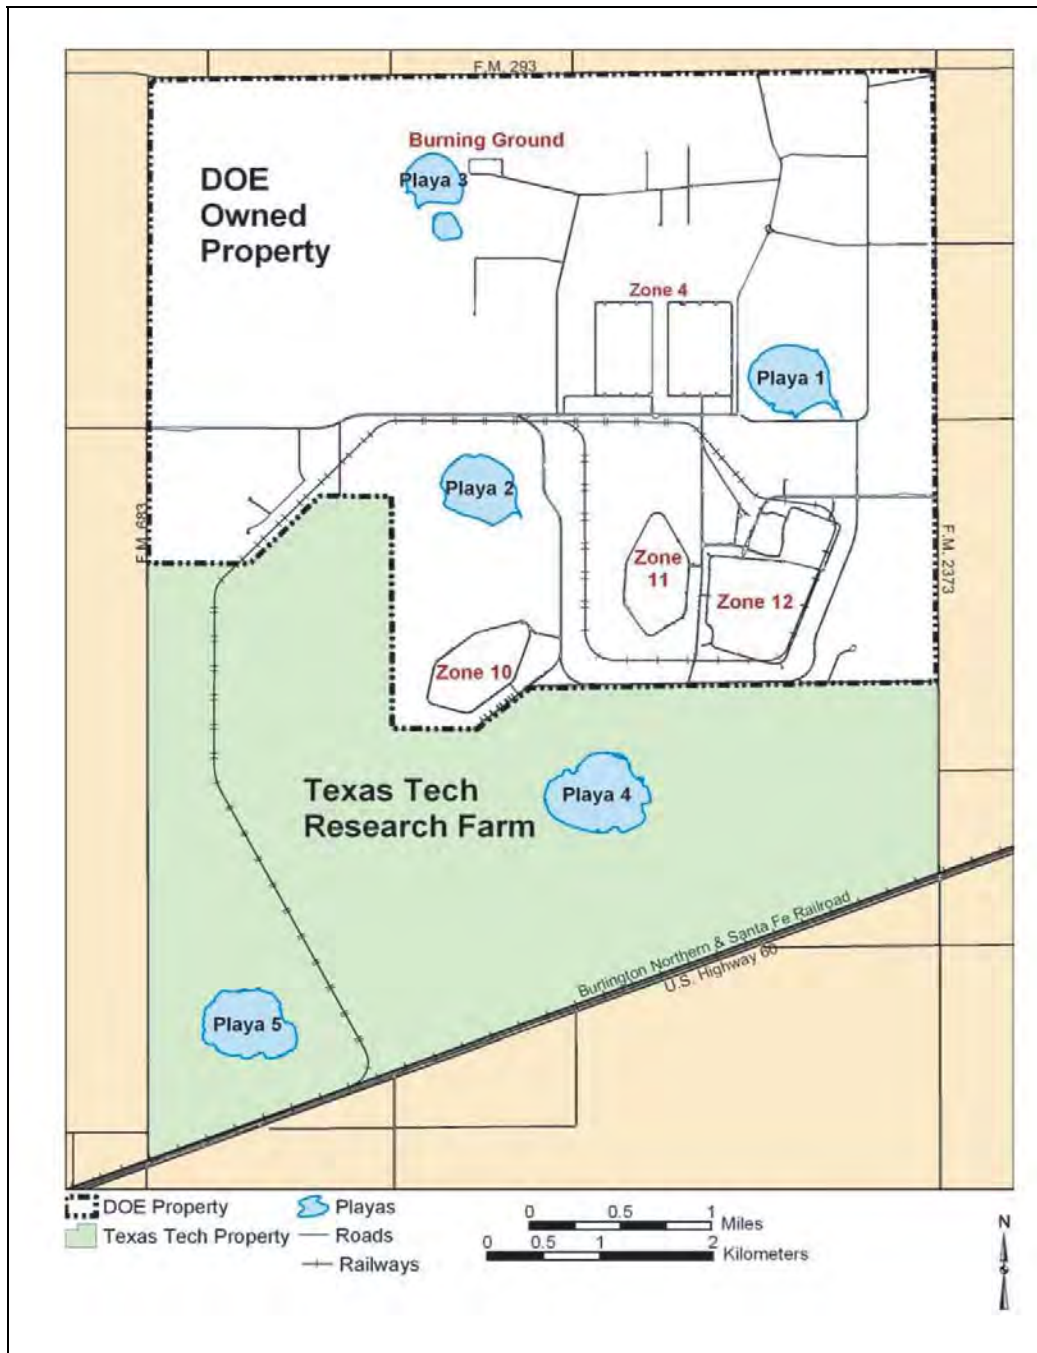

Figure A.6.1-5—Relevant Zones at Pantex for HE R&D

A.6.1.4 *Sandia National Laboratories/New Mexico (SNL/NM)*

SNL/NM has mission responsibility for the nonnuclear components, which comprise approximately 95 percent of the components in a weapons system, and for assuring the safety and reliability of the complete, integrated nuclear weapon system. The major SNL/NM facilities and labs that conduct HE R&D are described below.

The Explosive Component Facility (ECF), shown in Figure A.6.1-6, was built specifically to conduct the SNL/NM work on explosive components. The ECF includes over 100,000 square feet of laboratories, diagnostic centers and performance facilities for the research and development of advanced explosive technology and sits on 22 acres on Tech Area II (see Figure A.6.1-7). Unique facility features include explosives labs qualified for all types of explosives, HE chambers and firing pads, explosive component disassembly area, explosives receiving area, and explosives storage. The ECF includes the ability to handle, store, test and model all types of explosive materials, conduct performance testing and material compatibility studies, and surety assessments related to safety and reliability. Approximately 80 people work at the ECF.

Figure A.6.1-6—Explosive Component Facility (ECF); SNL/NM Bldg 905

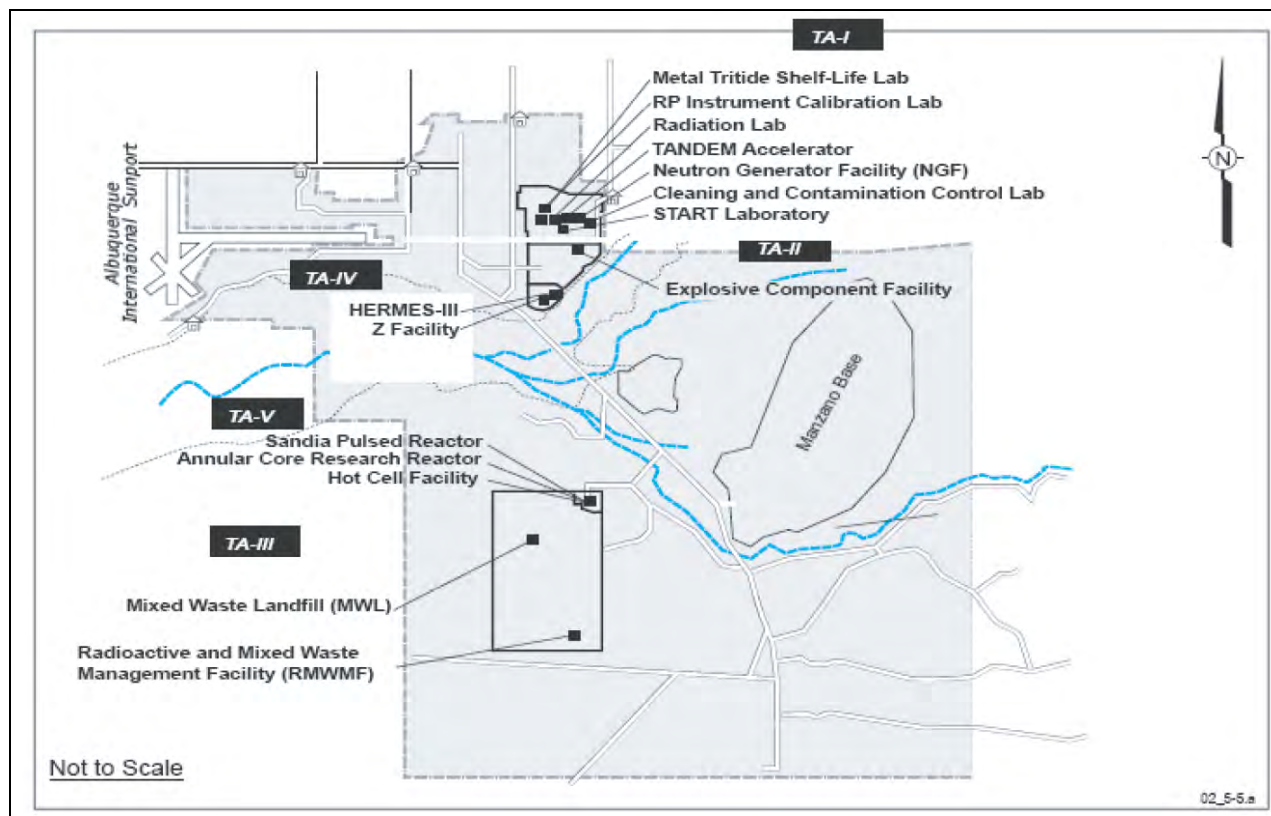

Figure A.6.1-7—SNL/NM Technical Areas

The Terminal Ballistics Facility (TBF) includes a 1,000 square-foot indoor and a 100-acre outdoor firing range that accommodate live testing and firing of guns ranging in size from 0.17 caliber to 8-inch. The facility retains the world's fastest launch capability for masses of 300–2000 grams. The site also conducts static firings of solid fuel rocket motors of up to 100,000 pounds thrust. The firing site can accommodate explosive detonation tests up to 50-pound TNT equivalent. Up to 12 people work at the TBF depending upon the test being supported. These staff are part of the approximately 80 people who work at the ECF.

Currently, there are two facility infrastructures used for explosive storage: the “6000 Igloos” and Manzano. Both storage infrastructures and the facilities are owned by Kirtland AFB. The 6000 Igloo storage area has a total of 21,000 square feet and includes 21 facilities (10 of 21 are for classified storage). The Manzano storage area includes 43 facilities, of which 13 are used for explosive storage. Approximately 18 people maintain the storage facilities.

Sandia utilizes facilities in 9930, 9939, 9920 to conduct research, design, development, manufacture and testing of explosive components, explosive systems, and arming and firing system hardware. The department also operates laboratories in Tech Area IV and the Explosives Applications Laboratory (Site 9930) in Coyote Canyon. Approximately 36 people support this mission.

The DETS Complex utilizes facility 9940 and is located on the Coyote Test Field. Current work at the facility involves arming and firing of explosives and the testing of explosive systems components in both terrestrial and aquatic settings. The site can fire up to 50 pounds TNT equivalent. These facilities are used to serve the needs of the Joint Tactical Operations Teams (JTOT) nuclear emergency response program and to meet the energetics technology needs of the DoDSpecial Forces and the Intelligence Community. There are three lines of business: energetics research, emergency response training, and threat assessments. This now includes a firing site on Thunder Range, which is 523 acres and can fire up to 500 pounds TNT equivalent. Staffing at these two sites is approximately 30–60 people.

A.7 TRITIUM R&D

A.7.1 Tritium R&D No Action Alternative

Under the No Action Alternative, NNSA would continue the ongoing tritium mission at current sites. This would entail the following tritium operations at the sites described below.

A.7.1.1 *Lawrence Livermore National Laboratory*

The LLNL Tritium Facility is a Hazard Category 3 (HC-3) nuclear facility supporting a variety of NNSA, DoD, Department of Homeland Security, and work-for-others programs using tritium, plutonium, uranium, and other radionuclides. It is located within the Superblock limited security area (see Figure A.7.1-1) at LLNL's main Livermore site. The primary tritium mission of the LLNL Tritium Facility is NIF target R&D with NIF production target filling to be added in support of the NIF Ignition Campaign beginning in 2009. As a result, per the LLNL SWEIS ROD, LLNL has received NNSA approval to increase its tritium inventory to 35 grams. The facility also hosts Gas Transfer System Research and Development experiments conducted by Sandia National Laboratory/California (SNL/CA) researchers, which is engaged in neutron generator development and provides maintenance and recertification services for the UC-609 Type B tritium shipping package.

Figure A.7.1-1—LLNL Tritium Facility within Superblock

A.7.1.2 *Los Alamos National Laboratory*

The LANL WETF is a Hazard Category 2 nuclear facility located at TA-16, which also is referred to as S-Site. TA-16 is in a remote area with controlled access (that is, a limited security area) (Figure A.7.1-2). The Weapons Engineering Tritium Facility (WETF) is in the early stages of its anticipated operational life of 30–40 years. The WETF mission is to perform tritium R&D in support of LANL’s stockpile stewardship mission, primarily the gas transfer system (GTS) design agency (DA) mission. Support of the GTS DA mission requires the flexibility to quickly react to any issue that is discovered in the stockpile. The primary use of tritium in the stockpile is in GTS, which requires that large quantities of tritium be processed and handled. Typical WETF tritium processing activities include: 1) Loading and unloading; 2) Removing tritium decay products and other impurities from gaseous tritium; 3) Mixing tritium with other gases; 4) Analyzing tritium as mixtures; 5) Loading tritium onto various metals and metal alloys; 6) Repackaging tritium and other gases to user specifications; 7) Environmental storage and conditioning of GTS components; 8) Performing various user-defined experiments with tritium; 9) Unloading (depressurizing) containers of tritium; and 10) Functionally testing R&D GTS.

A number of WETF systems support tritium processing, experiments, containment, confinement, gaseous tritium cleanup, analysis, and tritium monitoring. WETF’s inventory is limited to a total of 1000 grams of tritium. With some physical modifications to the facility, the current Documented Safety Analysis (DSA) would support a tritium inventory as high as 2,000 grams. A portion of the WETF is dedicated to shipping and receiving tritium, which is usually received from SRS in PV-18 primary containers inside UC-609 DOT Type B containers.

Figure A.7.1-2—Aerial Photo of the WETF

All tritium R&D at LANL is performed by approximately 25 people. The number of programmatic R&D researchers is approximately 10 full-time employee (FTEs), with portions of R&D support people making up the remaining 15 FTEs (performing gas analysis, gas mixing, R&D material preparation, R&D apparatus construction/maintenance, etc.).

A.7.1.3 *Savannah River Site*

The SRS Tritium Facilities consist of six HC-2 facilities and two HC-3 facilities which support the NNSA Stockpile Stewardship missions for tritium target extraction; tritium unloading, purification and enrichment; tritium and nontritium reservoir loading; reservoir reclamation; and GTS surveillance. These are collectively referred to as the "tritium production" missions, although the actual production of new tritium is carried out in a Tennessee Valley Authority reactor, with extraction taking place at SRS in the Tritium Extraction Facility (TEF). The TEF includes two of the HC-2 facilities and became operational in late 2006. This facility was designed for a 40-year service life. Final processing of new tritium gas from TEF, as well as all other tritium gas processing, is carried out in the H-Area New Manufacturing Facility (HANMF). This facility became operational in 1994 and was also designed for a 40 year service life. The Tritium Facility Modernization & Consolidation Project, completed in 2004, significantly expanded the tritium gas processing capabilities in the HANMF and added surveillance capabilities in a new 234-7H facility.

The SRS Tritium Facilities, shown in Figure A.7.1-3, are located adjacent to H-Area near the center of the site and about seven miles from the nearest site boundary. The bounding safety basis tritium inventory for the SRS Tritium Facilities is 75,520 grams. All tritium gas processing is done within secondary containment gloveboxes or modules which have either nitrogen or argon atmospheres. The glovebox and module atmospheres are continuously recirculated through stripper systems to recover any tritium which may leak out of piping or components. All gas streams released to the environment are processed through a recovery system to reduce tritium levels to as low as reasonable achievable.

Figure A.7.1-3—Aerial Photo of SRS Tritium Facilities

A.7.1.4 *Sandia National Laboratories/New Mexico (SNL/NM)*

Tritium Operations at SNL/NM are primarily associated with the Neutron Generator Production Facility (NGPF) (Figure A.7.1-4). The primary responsibility of the NGPF is to produce and manufacture neutron generators, which fuse deuterium and tritium to produce neutrons used to initiate the fission reaction in nuclear weapons. The neutron generator is a “limited-life” component of a nuclear weapon that uses tritium and must be replaced periodically due to the relatively short half-life of tritium. Neutron generators were produced at the Pinellas Peninsula Plant in Florida starting in the late 1950s. In 1993, as part of the Non-nuclear Reconfiguration Program, Sandia was given the mission assignment for production of various nuclear weapons components, including neutron generators.

SNL/NM also performs weapons research qualification and testing on neutron tube and generator materials, process and lot samples, subcomponents, and post-mortem examinations on final product. The department also performs technical studies that characterize processes and products in collaboration with production and development and design organizations. The site-wide reporting issue for tritium at SNL/NM is about 65,000 curies. The NGPF has a maximum inventory level of 12,000 curies and has the ability to increase to 15,999 curies if required. Presently, the inventory on site at the NGPF is about 3,500 curies.

Figure A.7.1-4—Neutron Generator Production Facility at SNL/NM

A.8 NNSA FLIGHT TEST OPERATIONS

Introduction. NNSA flight test operations is an SNL-managed program to assure compatibility of the hardware necessary to interface between the NNSA weapons and the DoD delivery systems and to assess weapon system functions in realistic delivery conditions. The actual flight tests are conducted with both the B83 and B61 weapons, which are pulled from the stockpile and

are converted into JTA units. In addition, development tests of gravity bomb and short-range systems are conducted at Tonopah Test Range (TTR). These flight tests are presently conducted at the TTR, a 280 square-mile site, located about 140 air-miles northwest of Las Vegas, Nevada. TTR activities include: stockpile reliability testing; structural development R&D; arming, fuzing, and firing testing; testing delivery systems; and environmental restoration. NNSA operates this facility under the terms of a land use agreement with the United States Air Force (USAF) entitled “Department of the Air Force Permit to the NNSA To Use Property Located On The Nevada Test and Training Range, Nevada.”. Figure A.8-1 shows the location of TTR and its proximity to NTS.

Figure A.8-1—Location of TTR and its proximity to NTS

Conversion of nuclear weapons into JTAs is a multi-step operation. Pantex denuclearizes selected nuclear weapon that become JTAs. These JTAs are not capable of producing nuclear yield. These JTAs may then be further modified at SNL. These JTAs are then dropped from nuclear certified aircraft at various altitudes and velocities. Depleted uranium usually remains in all JTAs but because there is no explosive event, the depleted uranium is contained within the weapon case and fully recovered after each flight test experiment. There is no contamination of the soil as the result of a JTA flight test. In some cases, JTAs are flown at velocities and altitudes of interest and not dropped at TTR. In such cases, the aircraft returns to its base with the JTA onboard. In an average year, 10 JTAs are tested at TTR. Historically, JTAs included SNM, but NNSA does not plan to use SNM in JTAs after 2008. Therefore, all alternatives assume that SNM would not be present in future JTAs.

In addition to analyzing the impacts associated with the No Action Alternative, four additional alternatives are evaluated in the Complex Transformation SPEIS for conducting NNSA Flight Test Operations. These alternatives are as follows: 1) (1) upgrade the Flight Test Program at TTR; (2) operate the program at TTR in a “campaign” mode; (3) transfer the program to White Sands Missile Range (WSMR) in New Mexico; and (4) transfer the program to NTS. Specific locations within WSMR and NTS are being evaluated to assure that the required geological conditions exist to successfully support all flight testing requirements. Specific locations within WSMR and NTS are being evaluated to assure that the required geological conditions exist to successfully support all flight testing requirements. The locations are also being evaluated for the sufficiency of flight corridors for ingress and egress of test aircraft to the target areas. Infrastructure such as power and roads would also be needed at these new locations or they would have to be constructed to support flight testing activities. NNSA has conducted flight tests at facilities other than TTR, on occasion, when specific test requirements could not be met by TTR assets. Under any of the alternatives considered in this SPEIS, NNSA may continue to conduct one or more flight tests at a different facility, consistent with environmental reviews for that site.

Section A.8.1 describes the No Action Alternative, Section A.8.2 describes the alternative to upgrade TTR, Section A.8.3 describes the alternative to operate TTR in a campaign mode, Section A.8.4 describes the alternative to transfer NNSA’s flight testing mission to WSMR, and Section A.8.5 describes the alternative to transfer the mission to NTS. Analysis of the environmental impacts of the alternatives is contained in Section 5.15. The analysis of alternatives does not affect NNSA’s responsibilities at TTR relating to post-weapons testing by the Atomic Energy Commission, a predecessor agency of DOE (See Section 4.4.6.2.1). Any remediation related to such post-weapons testing is independent of decisions to be made as a result of this SPEIS.

NNSA Flight Test Operations Alternatives

- **No Action.** Continue operations at TTR
- **Upgrade Alternative.** Continue operations at TTR and upgrade equipment with state-of-the-art mobile technology
- **Campaign Mode Operations.** Continue operations at TTR but reduce permanent staff and conduct tests with DOE employees from other sites. Three options are assessed:
 - Option 1—Campaign from NTS: Reduce mission staff and relocate remaining Sandia staff to NTS; O&M and Security taken over by NTS. Additional contract for technical support of equipment is needed for maintenance and upgrade.
 - Option 2—Campaign Under Existing Permit: Reduce mission staff at TTR; campaign additional staff for each test series; SNL to retain O&M responsibilities at TTR; permit would be retained in current form; security responsibilities would be transferred to the Air Force.
 - Option 3—Campaign Under Reduced Footprint Permit: Reduce mission staff at TTR; campaign additional staff for each test series; SNL to retain O&M responsibilities at TTR; permit would be reduced to less than 1 square mile; security, emergency services, power line and road maintenance responsibilities transferred to the Air Force.
- **Transfer to WSMR.** Move NNSA Flight Testing from TTR to WSMR
- **Transfer to NTS.** Move NNSA Flight Testing from TTR to NTS

A.8.1 No Action Alternative

Under the No Action Alternative, NNSA would continue to conduct the flight test mission at TTR. This section describes the NNSA Flight Test Operations Program currently being conducted at the TTR. Figure A.8-1 shows the location of TTR. There would be no construction required at TTR for the No Action Alternative. The current facilities would continue to remain serviceable, assuming adequate funding is provided for the normal maintenance of existing facilities and equipment. Table A.8-1 shows operational requirements for this alternative.

It is noted that the No Action Alternative includes minimal investments to maintain current operations capabilities and to enable a commensurate level of Flight Tests in the future. This investment would maintain the existing TTR capabilities through the year 2030. The TTR can be sustained to meet its present mission requirements only with such minimal reasonable investments in technology and infrastructure. The investment required covers the following areas, the details for each area are described below:

Radar. This includes a transformation of one radar from a maintenance intensive unit to a modern fully functional unit, eliminating the prone to failure systems/parts; a future depot-level maintenance effort for a second radar; and the acquisition of an Identification, Friend or Foe (IFF) system. The acquisition of this IFF system would allow for the elimination of two existing maintenance intensive radar systems.

Optics. The optics group upgrade under this option would consist of three distinct functions: 1) Addition of a Time Space Positioning Information (TSPI) section to collect precise positional data; 2) Addition of an event optics section using telescope tracking mounts to record event data for documentary purposes; and 3) Addition of a photometrics section utilizing both high speed fixed camera arrays to augment the existing still photography capability.

Facilities. TTR will continue to use the existing facilities and maintain them within the normal budget process. A new HVAC system for the control facility and a roof and siding repair on one building would be required under this minimal investment option. Repair to the electrical grid and road surfaces would also be required under this alternative. In addition to these repairs, there are several structures that must undergo D&D in order to continue ongoing operations at TTR.

Table A.8-1—TTR No Action Annual Operational Requirements

Operation Requirements	Consumption/Use
Annual electrical energy (megawatt-hours [MWh])	595
Peak electrical demand (MWe)	812
Other process gas (N, Ar, etc.)	480 ft ³
Diesel generators	44 (about 20 per test)
Water (Yearly for entire range including AF)	6 million gallons
Steam (tons)	0
Range area (sq. miles)	280
Employment (workers)	135
Number of radiation workers	25
Average annual dose	<10 Mrem
Radionuclide emissions and effluents—nuclides and curies	0
NAAQS emissions (tons/yr)	13.32
Hazardous Air Pollutants and Effluents (tons/yr)	3.7 x 10 ⁻⁶
Chemical use	0
Maximum inventory of fissile material/throughput	0
Waste Category	Volume
Hazardous	
Liquid (gal.)	150
Solid (yds ³)	3
Low-Level	
Liquid (gal.)	0
Solid (yds ³)	0
Mixed Low-Level	
Liquid (gal.)	0
Solid (yds ³)	0
Nonhazardous (sanitary)	
Liquid (gal.)	0
Solid (yds ³)	63
Nonhazardous (Other)	
Liquid (gal.)	700
Solid (yds ³)	15

Source: NNSA 2007

Past weapons destruction tests, unrelated to the Flight Test Program, have contaminated soil at TTR in three distinct areas. These sites have been characterized, and remediation is ongoing. Additional details on this can be found in Section 4.4.6.2.1 of this document. In addition to these remediation projects, there are several structures which must undergo D&D in order to continue

ongoing operations at TTR. It is estimated that the soil and structure remediation activities would entail a two-year project involving 80,000 worker hours, and the requirements listed in Table A.8-2. The soil remediation activities are only the petroleum-contaminated areas under the buildings which are scheduled for demolition. The small quantities of LLW and hazardous wastes generated by this effort would be transported to NTS, or a commercial facility, for treatment and disposal. Nonhazardous waste would be disposed of onsite.

Table A.8-2—D&D Associated with TTR Operations—No Action Alternative

D&D Ongoing at TTR	D&D Amounts
Soil D&D (yd ³)	0
LLW generated (yd ³)	20
Non-Hazardous waste (yd ³)	8000
Hazardous waste (yd ³)	3703
Debris/Earth moving equip.(dozers/trucks)	2/3
D&D Related employment	
Peak	20
Total worker hours	80000

A.8.2 Upgrade of Tonopah Test Range Alternative

This alternative would use High-Tech Mobile (HTM) equipment to reduce the operational costs at TTR through the introduction of newer, more efficient, and more technologically advanced equipment. This alternative would lower manpower test operational needs and keep all test equipment highly reliable and operational between test dates, thereby reducing recalibration and startup requirements and costs. Under this alternative, additional range campaign activities could be considered and conducted with minimal additional costs.

A vision of the HTM at TTR is shown in Figure A.8-2. It includes the acquisition of modern, digital equipment that is compatible with other national test range standards. The emphasis is on highly mobile command, telemetry, communications, and radar units which could be readily moved to the different testing locations at TTR. This would not only eliminate duplicative permanent structures, but would also eliminate costly, startup calibration.

The actions required for the HTM option are as follows:

Documentary/TSPI optics. This action would include an additional five combined mount [TSPI and documentary telescopes] units with a separate optics Control Trailer for remote control operations. Encryption capability would be included.

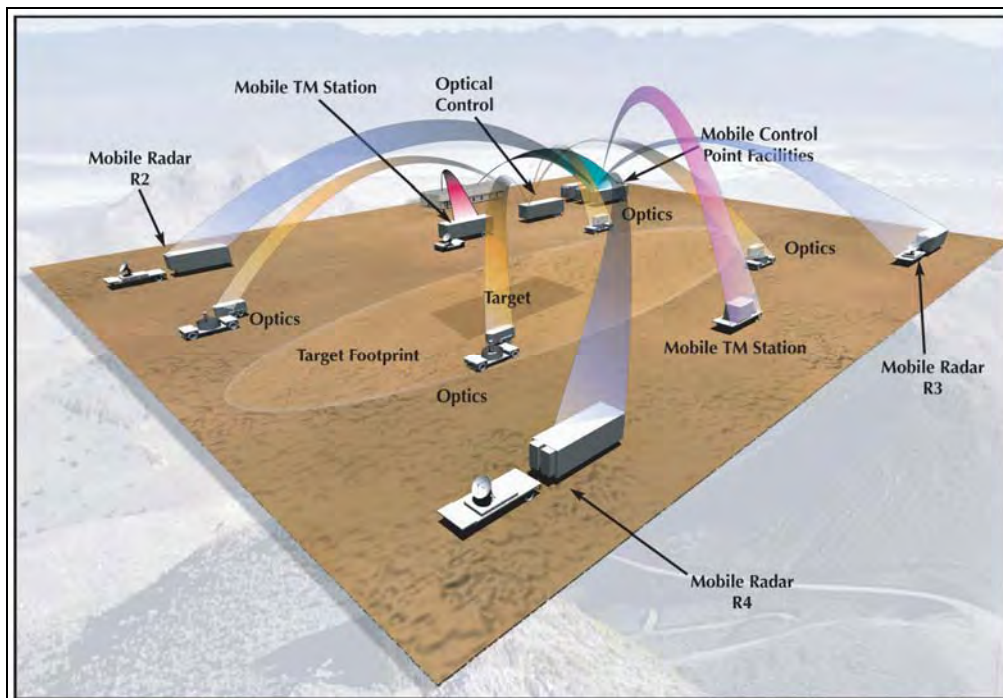

Figure A.8-2—HTM Upgrade Alternative

Radar. The proposal is identical to that proposed above for the minimum investment option.

Telemetry. New telemetry trailers, fully equipped, and antennas would be purchased and all trailers would be DOT-certified. This would allow the telemetry equipment and the antennas to be fully mobile.

Operations control equipment. Two operational control trailers, fully equipped, would be acquired to replace the operations that currently take place in the operational control tower at TTR. Test coordination, communications, and safety would all be housed in these trailers. Operation displays would provide continuous coverage of the test in progress.

Facilities. The proposal is identical to that proposed above for the minimum investment option.

There would be no construction required for the HTM Upgrade Alternative. The HTM Upgrade Alternative would rely on trailer and vehicular modules which would not require any construction. Since this alternative would use existing infrastructure and personnel, without any increases in the number or intensity of tests, the operational resource requirements would be about the same as for the No Action Alternative. TTR would continue to use the existing facilities and maintain them within the normal budget process. A new HVAC system for the control facility and a roof and siding repair on one building would be required under this alternative. Repair to the electrical grid and road surfaces would also be required. In addition to these repairs, there are several structures that must undergo D&D in order to continue ongoing operations at TTR. The requirements for this D&D are listed in Table A.8-2.

A.8.3 Campaign Mode Operation of TTR

An alternative to immediately relocating the entire TTR to another site would be to conduct the JTA tests at TTR on a campaign basis, bringing in employees from other NNSA sites to conduct tests, while doing Work for Others (WFO) as schedule permits. SNL would continue to be the program manager for this operation. Under this alternative, three options are addressed, as described in Table A.8-3.

Table A.8-3—Options for the Campaign Mode Operation of TTR

	Option 1—Campaign from NTS	Option 2—Campaign under existing permit	Option 3—Campaign under reduced footprint permit
Sandia Staff	Approximately ½ of current TTR staff work from NTS	Approximately ½ of current staff stay at TTR	Approximately ½ of current staff stay at TTR
Campaign Staff	Up to 20 test support personnel campaigned from NTS, Sandia NM & CA	Up to 20 test support personnel campaigned from NTS, Sandia NM & CA	Up to 20 test support personnel campaigned from NTS, Sandia NM & CA
Campaign Period	Each mission would require two week assignment	Each mission would require two week assignment	Each mission would require two week assignment
Campaign Frequency	Up to approximately 12 deployments per year + 1 training period per year	Up to Approximately 12 deployments per year + 1 training period per year	Up to Approximately 12 deployments per year + 1 training period per year
Land Use	180 sq miles	180 sq miles	< 1 sq mile
Technical Contract	New contract required to maintain equipment at TTR during year	None required	None required
O&M Contract	Contractor Managed by NTS	Contractor managed by Sandia	Contractor managed by Sandia
Security	Provided by NTS	Provided by the USAF	Provided by the USAF
Medical and Emergency Services	Provided by NTS	Downsized -Occupational Medicine and Rescue retained	Downsized -Occupational Medicine and Rescue retained
Infrastructure Maintenance	Provided by NTS	Provided through Sandia contract	Provided by the USAF
Road and Power Line Maintenance	Provided by NTS	Provided through Sandia contract	Provided by the USAF
Deep Recovery of JTAs	Provided by NTS	Provided through Sandia contract	Provided through Sandia contract

Table A.8-3—Options for the Campaign Mode Operation of TTR (continued)

	Option 1—Campaign from NTS	Option 2—Campaign under existing permit	Option 3—Campaign under reduced footprint permit
Equipment investment –	New mobile and transportable equipment	Upgrades to existing equipment	Upgrades to existing equipment

USAF = U.S. Air Force
 Source: NNSA 2008a.

Campaign from NTS—additional details:

1. Equipment investment:
 - Radar: Convert one fixed radar to mobile radar and completely refurbish pedestal;
 - Optics: Purchase 3 new documentary telescopes and upgrade 7 cinetheodolites (highly sophisticated optical tracking devices);
 - Telemetry: Replace equipment at risk and refurbish telemetry dish and mounts;
 - Communication Infrastructure: Create Ethernet cell configuration along lake beds and connect Ethernet cells using new fiber optic cable.
2. By the end of 2015, NNSA might decide to:
 - Discontinue NNSA Flight Testing at TTR in approximately 2019 and use the interim period to transition equipment and establish needed infrastructure at NTS or WSMR; or
 - Renew the USAF – DOE permit at TTR (which expires in 2019) and continue work at that site, managed by the Nevada Site Office and SNL.

Campaign Under Existing Permit or Reduced Footprint Permit—additional details:

1. Equipment investment:
 - Radar: Replace electronics in one fixed radar and perform depot level maintenance on pedestal;
 - Optics: Replace all film still and video cameras with modern high frame rate digital units and replace control and pedestal discrete electronics with modern personal computer based commercial-off-the-shelf equipment;
 - Telemetry: Replace equipment at risk and refurbish telemetry dish and mounts;
 - Communication Infrastructure: Use existing radio frequency and fiber backbone and convert custom communications interface to modern commercial-off-the-shelf Ethernet backbone.

This alternative would reduce the number of full-time employees to the level necessary to maintain facilities and equipment; employees from other facilities would complement resident staff in performing the actual tests. The operational requirements for all three options of this alternative are about the same as for the No Action Alternative and are shown in Table A.8-4.

Table A.8-4—TTR Annual Operational Requirements—Campaign Mode

Operation Requirements	Consumption/Use
Annual electrical energy (megawatt-hours [MWh])	595MWh
Peak electrical demand (MWe)	812MWe
Fuel usage (gal or cubic yd)	
Other process gas (N, Ar, etc.)	480 ft ³
Diesel generators	44
Water (Yearly for entire range including AF)	6 million gallons
Steam (tons)	0
Range size (square miles)	280
Employment (workers)	135 ¹
Number of radiation workers	25
Average annual dose	<10 mrem
Radionuclide emissions and effluents—nuclides and curies	0
NAAQS emissions (tons/yr)	13.32
Hazardous Air Pollutants and Effluents (tons/yr)	3.7 x 10 ⁻⁶
Chemical use	0
Waste Category	Volume
Hazardous	
Liquid (gal.)	150
Solid (yds ³)	3
Low-Level	
Liquid (gal.)	0
Solid (yds ³)	0
Mixed Low-Level	
Liquid (gal.)	0
Solid (yds ³)	0
Nonhazardous (sanitary)	
Liquid (gal.)	0
Solid (yds ³)	63
Nonhazardous (Other)	
Liquid (gal.)	700
Solid (yds ³)	15

Source: NNSA 2007.

¹Total employment – would be split between TTR, AF and SNL employees, as detailed below

For option 1 (Campaign from NTS), this alternative would result in the loss of approximately 92 full-time jobs at TTR through the downsizing of the permanent workforce from 135 to 43. This level of job reductions is different from the two alternatives that terminate all permanent TTR employment through the transfer of flight test operations to another facility. A discussion of the impacts associated with such a reduction in a community where supporting TTR is the primary employer is detailed in the next section. Other impacts, such as fuel, electricity and water usage and waste generation would remain about the same as the no-action alternative, since there would be no change in the number of tests performed. A reduction in employment of this level would have secondary impacts on the service sector and commercial establishments of the area.

For option 2 (campaign under existing permit), this alternative would result in the loss of approximately 57 jobs, but would create approximately 20 jobs for security guards as the AF takes over security responsibilities. The 14 full time Sandia staff is the minimum required to maintain and refurbish equipment to ensure operational readiness.

For option 3 (Campaign under reduced footprint permit), this alternative would result in the loss of approximately 70 jobs, but would create 20 jobs for security guards as the AF takes over security responsibilities. The 14 full time Sandia staff is the minimum required to maintain and refurbish equipment to ensure operational readiness.

Under this alternative, the JTA tests would be conducted on a campaign basis at TTR with support from the NTS, Sandia/NM and Sandia/CA. The remaining staff at TTR would also perform Work for Others (WFO) as time and workload permits. There would be no construction required as the existing facilities at TTR would be used and upgraded to sustain reliable test support.

A.8.4 Transfer to WSMR Alternative

This section describes the alternative for transferring the NNSA Flight Test Operations activities, presently being conducted at the TTR, to the WSMR, near White Sands, New Mexico. Figure A.8-3 shows the location of WSMR. Located in south central New Mexico, WSMR is the largest installation in the DoD. WSMR is a Major Range and Test Facility Base (MRTFB) under the Department of the Army Test and Evaluation Command, Developmental Test Command WSMR possesses extensive capabilities and infrastructure used by the Army, Navy, Air Force, NNSA and other government agencies as well as universities, private industry and foreign militaries. No NNSA activities currently take place on the WSMR. The Range spans 3,420 square miles of land space and 10,026 square miles of contiguous restricted airspace fully managed, scheduled and controlled by the WSMR. Holloman Air Force Base is located within and contiguous to the range east boundary with capabilities for air-craft support and staging.

Figure A.8-3—Location of WSMR

WSMR has a full suite of flight test instrumentation including radar, telemetry and optical equipment, which allows complete coverage of NNSA gravity weapons flight testing. As a major range and test facility base, the range infrastructure and instrumentation modernization and maintenance is funded under the DoD Test Resource Management Center and Army Test and Evaluation Command including additional investments made for Air Force, Navy and JTAs. WSMR has extensive experience conducting flight tests with requirements and flight test scenarios similar to the NNSA flight test program to include penetrating weapons, weapons recovery, and handling classified and special materials.

A.8.4.1 Existing WSMR Capabilities

Command and Control. The WSMR range control center is a state-of-the-art facility with real-time graphics and telemetry displays, an air traffic control center meteorological data displays, as well as communications centrally connected through the range network infrastructure for data acquisition and distribution across the entire test range.

Optical/video. WSMR has a complete range of optical tracking and video capabilities for event detection, documentation and Time Space and Positioning Information (TSPI) data including position, altitude, aspect angle, and roll rate. WSMR's optical tracking capabilities include mobile and fixed tracking mounts capable of multiple visible, near IR and far IR sensors.

Tracking Radars. The radar suite at WSMR consists mostly of C-band, gated continuous wave (CW), metric radars capable of tracking in skin or beacon mode. There are ten Single Object Tracking radars, of which eight are mobile. In addition, WSMR has two mobile Multiple Object Tracking radars. WSMR also has one mobile Weibel radar Doppler radar.

Telemetry. WSMR has an array of fixed telemetry sites to provide coverage of flight tests across the range and a set of mobile telemetry stations for receiving, recording, and relaying telemetry information at custom locations to meet test requirements. Telemetry data acquisition capabilities include fixed and mobile local and long range secure, multi-stream, and high data rate (excess of 20 megabites per second) telemetry, FM, PCM, PAM, 1553, RS232, 422, IRIG 106, JTIDS/Link 16, and other standard analog and digital data protocols and formats.

Operations Control Center. The Range Control Center (RCC) is a state-of-the-art digital data facility central to test operations, data collection and distribution. The center houses the operations control and data facility, telemetry data center, air traffic control radar facility, network operations center, flight safety engineering, real-time data display and reduction facility, instrumentation controllers, meteorological data center, and test customer and analyst cells.

Photometrics and photography. WSMR has an extensive capability to provide photographic data acquisition, editing, and production for ondemand and planned documentary photo of the test setup and any incidents of interest. Photographic support includes still photography, closed circuit video surveillance, and nontrack optical data video in the visible, image intensification, and IR bands at frame rates up to 2,000 digital and over 20,000 frames per second film.

Communications. WSMR range communications operates the main switch for all telecommunications and network operations including fiber, RF, and hardwire networks. The range utilizes a radio system with repeater systems to provide test conduct and local radio communication service.

Aircraft flight safety. WSMR has a renowned capability and experience in flight safety systems to include modeling and measuring instantaneous impact predictions design, and certification of flight termination systems (FTS), and safe test operations for aircraft and weapons systems. WSMR conducts mission analysis and real-time control and decision making for mission operations including meteorological data considerations, flight profile and instrumentation information for flight safety operations. Aircraft and test operations safety is highly afforded by the control, management and vast restricted air and land space.

Airspace. WSMR controls and manages over 10,000 square miles of restricted airspace with the full authority of the Federal Aviation Administration (FAA). Thus, WSMR is not required to call

up or schedule airspace operations or receive FAA approval for operations within the restricted airspace.

Explosive Ordnance Disposal/Recovery. WSMR has trained explosive ordnance disposal and recovery operations personnel for recovery and disposal of explosive ordnance that are utilized either on call or on standby for test operations as required by the test plan and safety operations.

Meteorology. WSMR has a meteorology section that provides a wide range of technical meteorological support including forecasts, warnings, and atmospheric observations and measurements for test data and control.

Trajectory plotting. The graphics facility provides the operational and display environment for the aircraft control operator and the radar director. The displays and the facility are located in the RCC. The trajectory is projected in the RCC operations center for the TD and other test personnel on the same plot as the planned trajectory, allowing the test team to evaluate the aircraft and test unit flight safety.

Security. WSMR has an integral security workforce for operations security, evacuation, and roadblock services across the range. In association with the operation of the nuclear test reactor, WSMR has personnel programs and special security training suitable for NNSA test operation requirements.

Radiological technician. Provided by SNL/NM from Albuquerque. For any tests that require post-test radiography, the equipment and specialists are provided by one of the physics laboratories.

Emergency services. A medical aid station with an ambulance, staffed by highly qualified medical technicians, is located at the Stallion range center within 10 minutes of the planned NNSA test area. Modern full service hospitals are located in the towns of Socorro and Alamogordo, about 20 and 45 miles respectively, from the proposed test location on the range. Additionally, a full-service fire station and Emergency Medical Services (EMS) unit is located at the Stallion range camp.

Shipping and receiving. WSMR performs all requirements to handle, classify, package, and ship hazardous and nonhazardous post-test assets and material off range.

Working space. Workspace for NNSA test operations could be provided by mobile facilities, at the Stallion range camp or at the defense.

Targets. WSMR has a wide variety of targets located throughout the range. Targets similar to those presently used by NNSA at TTR are located in the northern section of WSMR. The final determination of the specific target areas which would be used will be determined by the geological study. Potentially, a concrete target would be constructed in the general area of the penetration target to facilitate all missions in the same location.

Computer facility. The WSMR computer facility is located inside the RCC. This facility provides support to all facets of the test, from safety calculations and basic communications support, to the coordinated real-time radar and video picture so the test team can make instantaneous decisions about range safety and test execution.

A.8.4.2 *Siting Locations*

The northwest area of the WSMR would provide several target area options for flight testing. An Environmental Assessment (EA) is currently being prepared to support core sampling that is Preliminary drilling was conducted at several specific locations within WSMR to determine that the required geological conditions exist to successfully support all flight testing requirements. The locations are being evaluated to assure that the geology would support penetrator testing as well as the sufficient flight corridors for ingress and egress of test aircraft to target areas. Infrastructure such as power and roads would also need to exist or would need to be constructed to support flight testing activities. A review of the preliminary data indicates that this area of the WSMR could accommodate the safety footprints of all current flight test scenarios. Appropriate NEPA analysis would be required, by WSMR, prior to any detailed drilling of any of the candidate sites in order to assess the environmental impacts associated with the required construction of pads and a target and the operations associated with flight testing.

The only construction that would be required to support the JTA flight test operations at the WSMR would be the installation of a circular concrete target. The target aids in recovery of the JTAs used in flight test drops. The concrete target would be constructed of non-reinforced concrete, 500 feet in diameter, with a depth of 12 inches.

Under this alternative, NNSA Flight Testing at TTR would be discontinued. The environmental impacts of discontinuing flight testing at TTR are addressed in Section 5.15.4.2. Table A.8-5 and A.8-4 show the construction and operational requirements for this alternative.

Table A.8-5—WSMR Construction Requirements

Construction Requirements	Consumption/Use
Peak Electrical Energy Use (KW-hr)	40,000
Diesel Generators (Yes or No)	Yes
Concrete (yd ³)	800
Steel (t)	1
Liquid fuel and lube oil (gal)	32,000

Source: NNSA 2007

The only construction that would be required to support the JTA flight test operations at the WSMR would be the installation of a circular concrete target and associated pads. The target would be used to aid in recovery efforts. It would also be used for free-fall test units. The concrete target would be constructed of 4000 psi non-reinforced concrete, 500 feet in diameter with a depth of 12 inches. Tables A.8-1 and A.8-2 provide the construction and operational requirements associated with relocating NNSA flight test operations to the WSMR.

The required construction is a small project and it is not anticipated that the employment of 30 construction personnel over a 15-month period would have a significant impact on the existing labor pool of the area.

During flight test operations, the primary noise would be generated by aircraft flying over the WSMR drop areas. The noise would be sporadic and would be mitigated by the distance of the tests to the nearest public receptors. The effects of these operational activities would be primarily limited to those employed by WSMR. They would not likely result in any adverse effect on

sensitive wildlife species or their habitats, and would be similar to the effects discussed under the No Action Alternative.

Similarly, workers, the public, and sensitive wildlife receptors are unlikely to be adversely impacted by increased flights at WSMR as a result of NNSA conducting flight test operations. Workers are allowed to experience impulsive/impact noise events up to a maximum of 140 dBC and are remotely located from the flight-path of the aircraft. The public is not allowed on WSMR and noise levels produced by the aircraft are sufficiently reduced at locations where the public would be present to preclude hearing damage.

Sensitive wildlife species are unlikely to be adversely affected by the aircraft noise. WSMR has conducted such tests on a weekly basis over a number of years with no apparent adverse impacts to any species.

It is assumed that operational impacts, as shown in Table A.8-8 would be the same as the operational requirements for the No Action Alternative operation at TTR. Although they will certainly be different, current operational requirements are the best estimate, as there is no reason to believe the actual operation of JTA tests would be sufficiently different from the existing operation.

A.8.5 Transfer to NTS Alternative

This section describes the alternative for transferring the NNSA flight test operations activities, presently being conducted at the TTR, to the NTS. Figure A.8-1 shows the location of TTR and its proximity to NTS. This alternative involves transferring NNSA Flight Test Operations to NTS (Figure 3.10-4). It is estimated that a site of about two acres would be required. A review of three possible Areas at NTS (five separate sites) was conducted (see Figure 3.10-4). NNSA evaluated these locations at NTS to determine if flight testing could be conducted safely with the appropriate ingress and egress corridors for flight test aircraft and if the soil geology was suitable for testing requirements. Preliminary drilling was conducted to assure that the location would have the required soil geology. Appropriate NEPA analysis would be required prior to any detailed drilling of any of the candidate sites in order to assess the environmental impacts associated with the required construction of pads and a target and the operations associated with flight testing. Although the isolation of the NTS is a benefit for security and flight path purposes, the remoteness of these site locations could require an investment in road and utility infrastructure. A preliminary assessment indicates that these sites meet the necessary safety criteria for flight paths and target location to permit the program to use these areas of NTS. Other sites may be available at NTS, but these three sites meet the mission needs and provide a reasonable number of site alternatives for consideration.

If this alternative were to be selected, transition from TTR to NTS could occur as early as the latter part of 2009 and the beginning of 2010. Upgrades would only begin after the construction of the needed facilities was completed and transition of personnel and equipment completed. NNSA would need to construct pads and a target and possibly some road and utility infrastructure. [a1]Flight Test Program system upgrades would only begin after completion of the required NEPA analysis, construction of required infrastructure and facilities, and the completion of transition. The JTA Flight Test Program staff would be housed in CP-40, an existing NTS

facility that includes office space and an available high-bay area, which could accommodate high-tech mobile equipment. Minor building preparation could be required. The concrete target would be constructed of non-reinforced concrete, 500 feet in diameter with a depth of 12 inches.

Under this alternative, NNSA flight testing would be discontinued at TTR. The environmental impacts of discontinuing NNSA flight testing at TTR are addressed in Section 5.15.4.2.

Figure A.8-4—Potential Flight Test Sites at NTS

Figure A.8-5—CP-40 includes administrative areas and a high bay that would be useful for personnel and assembling test hardware

Figure A.8-6—CP-20 is an ideal facility for housing the electronics for the Flight Test Program

Existing communications capabilities between the CP facilities located in the southeast portion of Area 6, include a fiber optic link between the CP microwave towers and CP-1, 20, and 40. Microwave data communications are available for connecting data and video requirements from the target area to the CP complex. Setup of the microwave data/video links is a routine test requirement on the NTS. These same communications infrastructure elements can readily be applied to other locations on the site should the JTA Flight Test Program desire to test in different geological regimes.

A.8.5.1 Construction Requirements

As mentioned in the sections above, a target area would have to be constructed and a few enhancements to Building CP-40 would have to be made. The following tables give the impacts associated with the required construction and for the operation of the Flight Test Operations Program at NTS. Table A.8-6 and A.8-7 show the construction and operational requirements for the Relocation of Flight Test Operations to NTS Alternative.

Table A.8-6—Construction Requirements for NTS Alternative

Construction Requirements	Consumption/Use
Peak Electrical Energy (MWh)	40,000
Diesel Generators (Yes or No)	Yes
Concrete (yd ³)	800
Steel (t)	1
Liquid fuel and lube oil (gal)	32,000

A.8.6 Transportation

All post-test transportation from the NTS to Pantex would be identical to the transportation requirements of the current TTR process. New agreements replacing NTS as the originating site would replace the TTR agreements. NTS has a long history including formal agreements with Albuquerque for the shipment of SNM and classified components to and from major DOE/NNSA sites and is therefore thoroughly familiar with the processes and procedures for these shipments.

Due to the proximity of all alternative sites, the transportation requirements are similar for all three alternatives. All transportation of nuclear weapons, as well as JTAs, is conducted in DOE safe secure trailers by the DOE Office of Secure Transport, based in Albuquerque, New Mexico. Vehicles are state of the art, and all personnel associated with such shipments are highly trained both initially and on an ongoing basis. Although routes have been determined and environmental impacts evaluated for such transport, specifics of this information are not available to the public.

A.8.6.1 *Removal of Weapons From the Stockpile*

Under the existing operation at TTR, weapons are removed from the stockpile at various locations across the U.S. and abroad and are transported to Pantex. The specific locations are not for public release. Once the weapon has been inspected, the SNM removed from the weapon, and instrumentation added to the weapon, the weapon is considered a JTA. Transportation required to support this activity would be the same as for existing operations and would be the same for all alternatives.

A.8.6.2 *Transport of JTAs to Air Force Installations To Be Loaded Onto Test Aircraft*

Once the JTAs have been inspected and certified at Pantex, they are transported to USAF installations on DOE's fleet of SST vehicles to be loaded onto test aircraft. Transportation required to support this activity would be the same as for existing operations and would be about the same for all alternatives.

A.8.6.3 *Transport of JTAs From Test Site to Pantex*

Once the JTA test has been completed, the JTA is returned to Pantex for post testing analysis and disposition. For flyover tests, this transportation route would be from the Air Force installation from which the aircraft originated to Pantex. Transportation required to support this activity would be the same for existing operations as it would be for all alternatives. Dropped JTAs would be transported from the test facility to Pantex. Transportation required to support this activity would be site specific and vary for each alternative site. The No Action Alternative, the two TTR Upgrade Alternative, and the relocation to NTS would all be similar, since the distances and routes to Pantex are about the same for TTR and NTS. The transportation route from the relocation to the WSMR Alternative is less than half of the other two alternatives.

A.9 HYDRODYNAMIC TESTING

Hydrodynamic testing (hydrotesting) is the execution of high explosive (HE)-driven experiments

to assess the performance and safety of nuclear weapons. Data from experiments including hydrotesting, coupled with modeling and simulation using high performance computers, is used to certify the safety, reliability, and performance of the nuclear physics package of nuclear weapons without underground nuclear testing.

The alternatives for meeting the goal of the National Hydrotest Plan (NHP) are explained in the sections that follow. Section A.9.1 discusses the No Action Alternative, which would continue operations at the existing facilities of LANL, LLNL, NTS, SNL, and Pantex. Section A.9.2.1 discusses an alternative which would downsize the number of hydrotesting facilities at LANL, LLNL, NTS, SNL, and Pantex. Section A.9.2.2 discusses an alternative that would consolidate nonfissile hydrotesting activities at LANL. Section A.9.2.3 discusses a next generation alternative which would consolidate all hydrotesting activities at the NTS.

Hydrodynamic Testing Alternatives

- **No Action.** Continue hydrotesting at LLNL, LANL, NTS, Pantex, and SNL/NM
- **Downsize in Place**
 - Consolidate LLNL hydrotesting at Contained Firing Facility (CFF)
 - Consolidate LANL hydrotesting at Dual Axis Radiographic Hydrodynamic Test (DARHT) facility
 - Consolidate NTS hydrotesting to single confined and single open-air sites
 - Discontinue hydrotesting at Pantex and SNL/NM
- **Consolidation at LANL**
 - Integrate hydrotesting program at LANL
 - Construct new CFF-like facility at LANL
 - Discontinue hydrotesting at LLNL once CFF-like facility is operational
 - Maintain BEEF at NTS
 - Discontinue hydrotesting at Pantex and SNL/NM
- **Consolidation at NTS¹**
 - Integrate hydrotesting program at NTS
 - Construct new DARHT-like facility at NTS
 - Construct new CFF-like facility at NTS
 - Discontinue hydrotesting at LLNL, LANL, Pantex, and SNL/NM

¹The NTS Alternative is considered a “next generation” alternative because NNSA is not proposing these changes at this time.

Hydrotesting coupled with high performance computer modeling and simulation and data from data processing equipment (DPE), is used to certify the safety, reliability, and performance of the nuclear physics package of nuclear weapons without underground nuclear testing. Radiographic images and other data from hydrotesting help to ensure continued confidence in NNSA’s assessments of nuclear weapons by providing critical experimental data for representative nuclear weapons geometries, fine tuning computer modeling of nuclear weapons performance and behavior, evaluating effects of aging on materials, and evaluating performance of remanufactured or new materials and components.

As described in Section A.9.1, the majority of stockpile stewardship hydrotesting is conducted at LLNL in the Contained Firing Facility (CFF) at Site 300 and at LANL at the Dual Axis Radiographic Hydrodynamic Test Facility (DARHT). The diagnostic capabilities have been developed at these two facilities to meet specific nuclear weapons design and agency needs. Hydrotesting is also conducted at Pantex, SNL/NM, and NTS to support surveillance, production and fundamental equation of state (EOS) research on shock-driven plutonium. No single existing NNSA hydrotest facility offers all of the diagnostic capabilities or capacity necessary to meet the entire hydrotesting requirements for certifying the safety and reliability of the nuclear weapons stockpile.

The goal of NNSA's NHP is to meet the hydrotest requirements for certifying the safety and reliability of the nuclear weapons stockpile. This will require a wide range of facility capabilities to enable scientists from around the Complex to deal with differing issues. In addition, since the large hydrotesting experiments involve the development and detonation of state-of-the-art HE, many of the hydrotesting facilities are well suited for other uses and are therefore used for experiments which fall outside the scope of large-scale hydrotesting. Conversely, many of the HE R&D facilities are able to support hydrotesting experiments.

A.9.1 No Action Alternative

This section describes the hydrotesting facilities and missions currently being conducted at weapons complex sites. A summary of this information may be found in Section 3.11.

A.9.1.1 *Hydrotesting Facilities at LLNL*

LLNL's Site 300 has been used since 1955 to perform experiments that measure variables important to nuclear weapon safety, conventional ordnance designs, and possible accidents (such as fires) involving explosives. The facilities used for Site 300 firing activities consist of four firing point complexes and associated support facilities. The locations of the four firing complexes are indicated in Figure A.9-1.

The Building 801 Complex comprises Buildings 801A, 801B, and 801D, and encompasses approximately 51,000 square feet. The Building 801 Complex is in the northeast quadrant of the site, called the east firing area.

Figure A.9-2—The Contained Firing Facility at the Building 801 Complex

CFF is a permanent, state-of-the-art firing chamber constructed on the site of Building 801's previous open-air firing table. The CFF additions consisted of four components: a firing chamber, a support area, a diagnostic equipment area, and an office/conference module. The heart of the CFF is the firing chamber. Slightly larger than half a small gymnasium (52 by 60 feet and 32 feet high), the firing chamber contains the blast overpressure and debris from detonations of up to 60 kilograms of cased explosive charges. The inside surfaces of the chamber are protected from shrapnel traveling as fast as 1.5 kilometers per second with 38-millimeter-thick mild steel plates. To permit repetitive firings, all main structural elements of the firing chamber are required to remain elastic when subjected to blast. Detonations will be conducted above a 150-millimeter-thick steel firing surface (the shot anvil) embedded in the floor.

All main structural elements of the firing chamber must be able to withstand repetitive firing as well as meet design safety standards. These criteria require the structure to withstand a 94-kilograms TNT blast, which is the equivalent to 60 kilograms of HE. During the testing phase of the project, "overtests" were run using 75 kilograms of HE to assure that the building can withstand planned 60- kilograms detonations.

A key aspect of the new facility is that the rectangular concrete firing chamber was made with low-cost, conventional reinforcement, as opposed to the labor-intensive, laced reinforcement commonly found in many blast-resistant structures. From a materials standpoint, a spherical chamber shape would have been more blast efficient, but a slightly heavier, rectangular shape was cheaper to construct, provides easier and more desirable setup and working surfaces, and encompasses existing diagnostic systems. The thickness of the reinforced concrete walls, ceiling, and floor of the chamber are 3.9, 4.6, and 5.9 feet, respectively. The support area, which

measures about 16,000 square feet, is for preparing the nonexplosive components of an experiment and also for equipment and materials storage, personnel locker rooms, rest rooms, and decontamination showers. It also houses filters, scrubbers, and a temporary waste-accumulation area for the waste products from testing.

In addition to the CFF, Building 801 Complex is designed to obtain explosives test data through the use of the flash x-ray accelerator, designed to accelerate charged particles and generate x-rays; a high-speed camera; and a laser-doppler interferometry operation. About 26,000 additional square feet were recently added to Building 801, also the site of LLNL's recently upgraded 18-megaelectron-volt flash x-ray (FXR) machine. Building 801 contains a variety of other advanced, high-speed optical and electronic diagnostic equipment that together constitute a unique capability to diagnose the behavior of HE-driven assemblies. This equipment measures the velocity of explosively driven surfaces. Other electronic and mechanical systems capable of diagnosing various aspects of the high explosives tests are housed in Building 801 Complex facilities.

A.9.1.1.1 Building 812 Complex

The Building 812 Complex is an active open-air explosives firing facility. The complex includes five buildings (Buildings 812A, 812B, and 812C, 812D [currently inactive], and 812E), two magazines, and an open-air firing table. Building 812E is currently used to repair and test portable x-ray equipment. The current total operational building area is 5,532 square feet.

A.9.1.1.2 Building 850 Complex

The Building 850 Complex is an explosives testing facility. This 5,840 square-foot complex consists of Bunker 850 and a magazine in the northwest quadrant of the site (called the west firing area) and comprises an active firing, explosives test, and high-speed camera repair and test facility. The multidagnostic facility includes a permanently mounted, smooth-bore, 155-millimeter gun for conducting impact experiments, high-speed rotating-mirror cameras, specialized light sources, portable flash x-ray sources, and various other diagnostic equipment.

This facility has an outdoor detonation firing table with gravel-covered pads for stands of concrete, wood, or steel. During an experiment, the explosive is placed on the test stand and fired. The firing debris may consist of wood, plastic, wiring, and gravel. This debris is potentially contaminated with high explosives, beryllium, and depleted uranium.

A.9.1.1.3 Building 851 Complex

The Building 851 Complex is part of the explosive test facility operations. This 13,681 square-foot complex is in the northwest quadrant of the site and houses specialized laser equipment in a laser room, several laboratories, a portable x-ray room, several shop areas, and offices.

Building 851 Complex includes an open-air firing table of gravel-covered pads with stands of concrete, wood, or steel. During an experiment, an explosive device is placed on the test stand and fired. The firing debris may consist of wood, plastic, wiring, and gravel. The debris is potentially contaminated with unexpended explosives, beryllium, and depleted uranium.

Building 851 Complex is equipped for the radiography of explosives devices during detonation testing, including high-speed rotating-mirror cameras; optical interferometry for precise, free-surface velocity measurements; electronic pin timing diagnostics; and various other photo processing operations that involve both manual and automatic film and paper developing.

A.9.1.2 *Associated Support Facilities*

The following list includes facilities that are necessary support facilities for hydrotesting or facilities that are necessary to the operation of Site 300 as a hydrotesting facility:

- Site 300 HE casting and machining facilities (covered under HE R&D);
- Site 300 Shaker and Environmental test facilities (covered under Environmental Testing); and
- Site 300 supporting magazines, shops, offices, observation posts, guard stations, and materials management

Four other facilities which do not conduct hydrotesting experiments, but are necessary for supporting the hydrotest facilities are not addressed here, since they are addressed in the HE R&D or Environmental Testing Sections. These four facilities are as follows:

A.9.1.2.1 Building 806 Complex

The Building 806 Complex is located in the process area in the southeast quadrant of Site 300 and consists of Buildings 806A and 806B. This 8,314 square foot complex is used for machining and inspecting explosive parts. Explosives are also temporarily stored at the complex.

A.9.1.2.2 Building 810 Complex

The 5,079 square-foot Building 810 Complex is located in the process area, in the southeast quadrant of Site 300, and consists of Buildings 810A, 810B, and 810C. Building 810A and 810B are used to assemble explosives parts into test components. Building 810A is also used for the temporary storage of explosives components. Building 810C is used for storing nonexplosive parts for test components. The test components may also include beryllium, lithium, tritium, thorium, or depleted uranium.

A.9.1.2.3 Building 823 Complex

The 2,748 square-foot Building 823 is in the southeast quadrant of Site 300 and consists of two buildings. Building 823A contains office space, a darkroom with a radiographic film processor, and control panels for three real-time imaging systems housed in Building 823B. These units include a transportable 9-million-electron-volt (MeV), a 2-MeV, and 120-thousand-electron-volt (KeV) x-ray machines. Building 823B contains staging and real-time imaging systems, and a doubly encapsulated cobalt-60 isotope source in a lead-shielded radiographic projector. The isotope source is no longer operational and is being stored in Building 823 until it is sent back to the manufacturer for disposal. This complex provides the means for radiographic inspection of pressed explosives parts and weapon test components. After x-ray film has been exposed in

Building 823B, it is processed through the automatic film processor in Building 823A.

Building 823B has an earthen berm on two sides that provides radiation shielding for the office/control building located east of the berm. The Varian 9-million-electron-volt LINAC is used in Building 823B to beam into the open space directly to the west.

A.9.1.2.4 Building 845, Explosive Waste Treatment Facility (EWTF)

The EWTF is a 666 square-foot facility located in the north-central section of Site 300. The EWTF replaced Building 829, which had been closed. The EWTF consists of an earth-covered control room, Building 845A; an inert storage area, Building 845B; a thermal treatment unit (burn cage), an open burn unit (burn pad), and an open detonation unit (detonation pad). The EWTF is permitted under a hazardous waste permit issued by the California Department of Toxic Substance Control for the treatment of explosives waste. Treatment of other hazardous, radioactive, or mixed waste materials is prohibited.

A.9.1.3 *Hydrotesting Facilities at LANL*

The Hydrotesting Facilities at LANL are located within one of the five TAs that contain HE R&D facilities. TA-15, located approximately 2.6 miles from the main administrative area, in the central portion of LANL, is the location of two firing sites: the DARHT, which has an intense high-resolution, dual-machine radiographic capability, and Building 306 (R306), a multipurpose facility where primary diagnostics are performed (see Figure A.9-3). Currently, there exists no permanent radiographic capability at R306. Figure A.5.1-4 shows the location of TA-15 at LANL. The Pulsed High Energy Radiation Machine Emitting X-Rays (PHERMEX) Facility, a multiple-cavity electron accelerator capable of producing a very large flux of x-rays, was disabled in 2004. D&D of this facility has not yet been completed. LANL conducts about 100 hydrotest experiments a year.

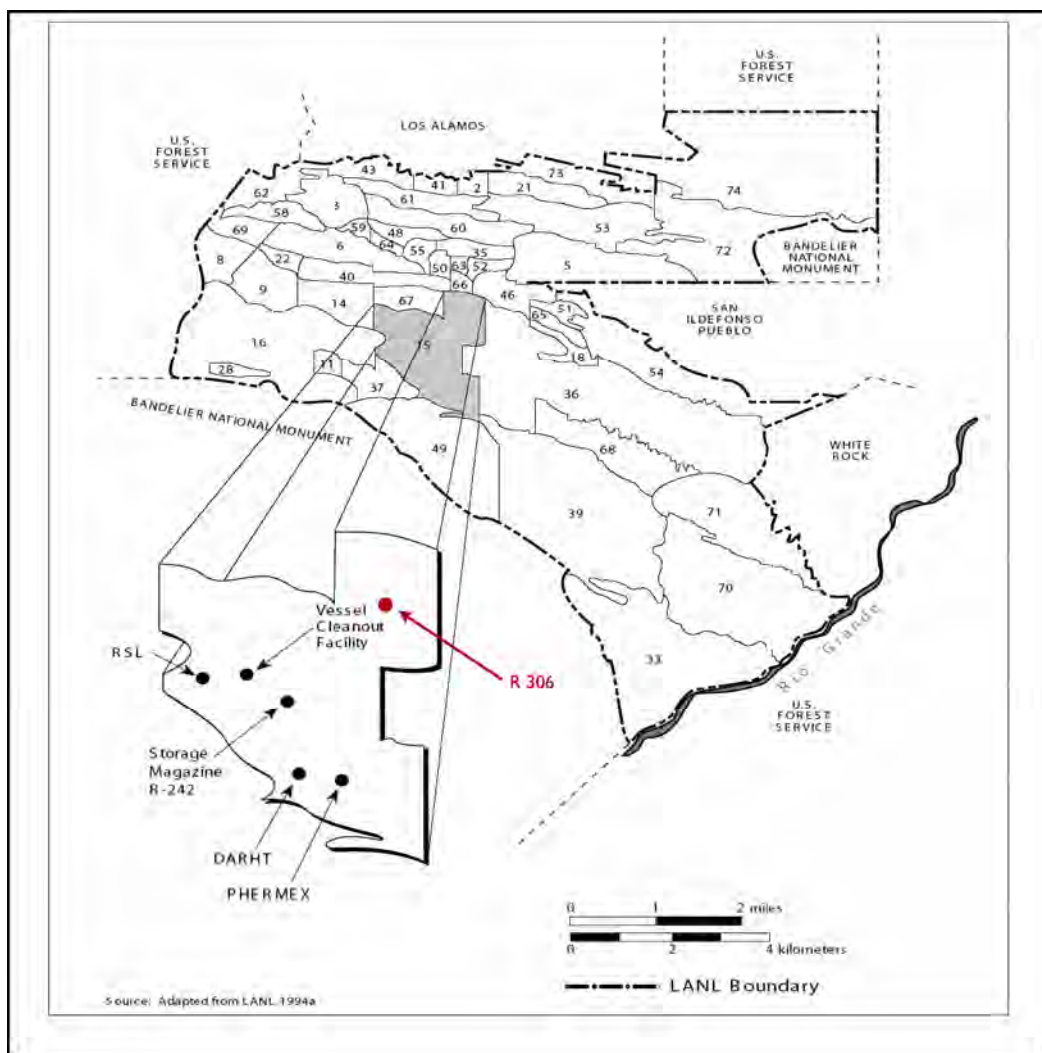

Figure A.9-3—TA-15 at LANL

DARHT is a state-of-the-art, full scale radiography facility and is used to investigate weapons functioning and systems behavior in nonnuclear testing. DARHT is designed to include two high intensity x-ray machines whose beams cross at right angles. Each machine has been designed to generate radiographs of far higher resolution than anything previously obtainable—the resolution required for stockpile stewardship without underground nuclear testing. The first axis became operational in 1999, and the second axis was tested in late 2002. In 2003, LANL began refurbishing failing accelerator cells Facility Axis II in order to bring them up to design specifications. The injector for the second axis of DARHT is now being “tuned” in preparation for undergoing commissioning tests. When DARHT becomes fully operational, its multi-axis large scale hydrodynamic tests will allow researchers to obtain three-dimensional as well as time-resolved radiographic information. Figure A.9-4 shows the DARHT facility.

The DARHT x-ray machines are based on linear induction accelerators, a technology derived from that of the Fusion Energy Research Program at Lawrence Berkeley Laboratory. An intense pulsed electron beam strikes an x-ray target, creating x-rays. The first machine provides a pulse 60 nanoseconds long. In the second machine, a “macropulse” 1.6 microseconds long will be

chopped into four shorter pulses, providing four snapshots in quick succession. One of the pulses from the second axis will be able to be synchronized with that of the first axis so that three-dimensional information can be reconstructed..

Figure A.9-4—The DARHT at LANL

TA-15 also includes office space for approximately 100 staff in buildings 494, 484, and 183. The DARHT uses office space at Building R306. Also in TA-15, is the Vessel Preparation Building that serves as a facility to clean out the steel vessels used in hydrodynamic testing. The Vessel Preparation Area also includes a low-energy x-ray calibration facility, a carpenter shop, and a warehouse.

Additional facilities required to support hydrotesting are located in six other TAs, at LANL. The Test Device Assembly Building is one such facility. The Test Device Assembly Building provides the capacity to assemble test devices ranging from full-scale nuclear-explosive-like assemblies (where fissile material has been replaced by inert material) to materials characterization tests. In addition to assembly operations, other facilities conduct explosives testing support and radiography examinations of the final assemblies. Other activities conducted at these support facilities support HE R&D. LANL also performs R&D and fabrication of high-power detonators at these facilities.

A.9.1.4 *Hydrotesting Facilities at Pantex, SNL/NM, and NTS*

Smaller hydrotest facilities, which are not capable of dynamic weapons radiography, are also located at Pantex, SNL/NM, and NTS. Both Pantex and SNL/NM have several outside blasting table facilities which are primarily used for HE R&D activities and can only handle small hydrotesting experiments. NTS has several facilities which are utilized for very large explosion-type experiments. The BEEF is one such facility at NTS, which is the only NNSA facility where some experiments, due to the amount of HE utilized, can be conducted. Three additional and similar facilities at Pantex conduct both HE R&D and hydrotesting experiments. All three will require upgrades within the next several years. The upgrades will include two open-air firing sites with bunkers and one facility containing indoor firing chambers. SNL/NM has several small HE R&D firing sites and the Explosives Component Facility and ancillary facilities, which have been used for hydrodynamic tests. Because none of SNL/NM's facilities are used primarily for hydrotesting, they are described more completely in the No Action Option for HE R&D in Section 3.7.2.1. The Explosives Component Facility and its ancillary locations support the design, development, and life cycle management of all explosive components outside the nuclear package.

A.9.2 **Action Alternatives**

A.9.2.1 *Downsize in Place Alternative*

This option would continue hydrotesting activities by consolidating LANL activities at the DARHT, consolidating LLNL activities at Building Complex 801 and the CFF, closing some of the smaller facilities at both of these sites, and moving tests requiring larger amounts of HE to the BEEF at NTS and LANL. Although outside the scope of large-scale hydrotesting, six firing sites at Pantex, used for HE production, development, and surveillance, and also previously used on an intermittent basis for hydrotesting experiments, will be decommissioned and decontaminated. SNL/NM would continue to operate several small HE R&D firing sites and the ECF and its ancillary locations, which would be available for hydrodynamic tests.

This alternative would entail the closure of a number of facilities both at LLNL and LANL. It could also entail the closure of facilities at Pantex and SNL/NM. At LLNL, this would entail the closing of at least Building 812 Complex, Building 850 Complex and Building 851 Complex. The associated support facilities probably would not be impacted by this alternative. At LANL, this would entail the closing of all hydrotesting facilities except those located on TA-15. At TA-15, several of the support facilities would be consolidated into one facility and closure of the idle PHERMEX would continue. At Pantex, at least six outdoor burn areas would be closed. At SNL/NM, at least three outdoor burn areas could be closed if their joint sponsor program, HE R&D, were to concur with a decision from the Hydrotesting Program that these facilities were no longer needed. NTS would maintain operations at BEEF and continue DPE operations at U1a.

Closure of over a dozen facilities would entail a substantial cleanup and D&D effort. Although not heavily contaminated, these facilities all have a substantial amount of reinforced concrete and steel structures designed to withstand sizeable HE explosions. It is estimated that at least 100,000 square feet of hardened concrete and steel structures would have to be dismantled, razed and disposed of.

A.9.2.2 *Consolidation at LANL*

This option integrates all large-scale hydrotesting at the single location of LANL. Since LLNL and NTS both have required capabilities not presently at LANL, this alternative would entail maintaining those facilities presently at LLNL until such time that a new facility which has the capabilities presently at the CFF and Building 801 Complex at LLNL could be constructed. For a description of what such a new facility entails, see Section 3.5.7.1, Building 801 Complex. There are three potential sites at LANL where such a “CFF-like” facility could be constructed. Figure A.9-5 shows these three alternative locations at LANL.

Until such time as these capabilities could be established at LANL, the CFF capabilities at LLNL would have to remain in operation. In addition, it is not anticipated that it would be possible to transfer the capability to conduct experiments requiring very large amounts of HE, presently being conducted at the BEEF, to LANL. Accordingly, under a consolidation of hydrotest capabilities at LANL, the BEEF would still be required to maintain its operational status at NTS and continue DPE operations at U1a.

This alternative would entail a large amount of cleanup and D&D associated with the closure of all hydrotest facilities at LLNL, SNL/NM (based on a joint agreement of the HE R&D Program and the Hydrotesting Program), and Pantex and a substantial number of facilities at LANL. It is estimated that this alternative would entail the closure and clean-up of close to 170,000 gross square feet of hardened concrete and steel structures designed to withstand very large HE explosions.

In this process it would make sense to collocate distant support facilities (storage, staging, and assembly) during the construction of such a facility. The construction of such a facility would involve a two- to three-year process resulting in an 8,000–12,000-square-foot primary structure with two to three smaller support buildings situated on a five to seven acre site.

Figure A.9-5—Potential Locations of “CFF-Like” Replacement Facility at LANL

A.9.2.3 *Consolidation at NTS—A Next Generation Alternative*

The next generation hydrodynamic experimental facility would be an improved SNM-capable radiographic facility that would provide for imaging on two or more axes, each with multiple time frame capability, though the number of axes and time frames is still subject to requirements definition and design evolution. The facility would be used to better reveal the evolution of weapon primaries implosion symmetry and boost-cavity formation under normal conditions and in accident scenarios. Due to the nature of the dynamic plutonium experiments and hydrodynamic testing with SNM to be conducted at the facility, the next generation hydrodynamic experimental facility would probably be considered for location at NTS only.

A next generation hydrodynamic experimental facility, either aboveground or underground, would require new building construction and considerable infrastructure (i.e., facilities, equipment, and personnel) in support of test events. Existing infrastructure at NTS might be used to the extent practical. The construction and operational requirements for the next generation hydrodynamic test facility might be greater than that of the DARHT Facility. The impacts associated with construction and operation of facilities based on the different technology approaches could be significantly different. For example, the acreage required could be comparable to or somewhat larger than the nine acres of land resources required for DARHT, but use of proton radiography could require an accelerator comparable in scale to the kilometer-long Los Alamos Neutron Science Center (LANSCE) or to other large accelerators operated by DOE. Based on information on the DARHT Facility, it is estimated that over 250 additional workers would be required for construction and operation of the next generation hydrodynamic test facility. Construction and operation of the next generation hydrodynamic test facility is not anticipated to use large quantities of water. New construction activities would be expected to result in an increase in short-term air emissions. Operation of the next generation hydrodynamic test facility would be expected to have a minimal impact on the air quality considering the impacts projected for DARHT operations. The next generation hydrodynamic test facility would not be expected to impact existing community infrastructure or services in the area; however, depending on the specific design, a proton accelerator could require significant electrical power resources. Waste volumes would not be expected to increase substantially over existing operations at NTS, and waste management associated with dynamic experiments with plutonium at NTS could require additional infrastructure.

In addition to the next generation facility which would be constructed for the consolidation at NTS Alternative, an alternative to also construct a new CFF-like facility at NTS in the 2040 timeframe is also being considered. This facility would be similar to the facility described in the LANL Consolidation Alternative (see Section 3.11.2.2).

A.10 **MAJOR ENVIRONMENTAL TEST FACILITIES**

Environmental testing supports a primary DOE/NNSA mission of maintaining and demonstrating the safety, reliability and performance of the nation's nuclear weapons systems. The ETFs to support environmental testing are divided into two categories—base ETFs and system ETFs. The base ETFs are those facilities and laboratory scale (or “table-top”) items used to evaluate components or subassemblies in the environments defined by the Stockpile-to-Target

Sequence (STS) and the military characteristics requirements for each nuclear weapon in the enduring stockpile. Every laboratory within the DOE/NNSA Complex has some base capability essential for day-to-day operations. The system ETFs are those facilities used to test full-scale weapons systems (with or without SNM or A/D) or those unique major facilities that are applied to development and certification of components, cases, accessories, subsystems, and systems. This SPEIS is focused on the subset of base and system environmental testing facilities, referred to as “major” ETFs that are costly to maintain or have potentially significant environmental impacts. Major ETFs are located at SNL, LANL, LLNL, and NTS.

Section A.10.1 discusses the No Action Alternative, which would continue operations at the existing facilities at SNL, LANL, LLNL, and NTS. Section 3.12.2 discusses an alternative which would downsize facilities in-place. Section 3.12.3 discusses an alternative that would consolidate major ETFs at one site (NTS or SNL), with an option to move the LLNL Building 334 ETF capabilities to Pantex. The analysis of the environmental impacts of the alternatives is contained in Section 5.17.

Major ETF Alternatives
<ul style="list-style-type: none"> • No Action. Maintain status quo at each site. All facilities would be maintained, or upgraded to meet safety and security standards. • Reduce-in-place. No duplication of capability within a given site, but there may be duplication from site to site—phase out aging and unused facilities. • Consolidate ETF capabilities at one site (NTS or SNL/NM). Would entail closings at sites not selected and construction of new facilities if NTS were selected. This alternative also includes an option to move the LLNL Building 334 ETF capabilities and the LLNL Site 300 Building 834 Complex to Pantex.

A.10.1 No Action Alternative

Under the No-Action Alternative, DOE/NNSA would continue to operate the existing ETFs at the current levels of activity. Only those upgrades and maintenance required to allow for the current activities would take place. ETFs are located at three national laboratories (SNL/NM, LANL, and LLNL) and the NTS. It should be noted that ETF laboratories and capabilities also exist at Pantex and SRS. These facilities, however, are not involved in the R&D or weapon system/component design and qualification process, but instead, utilizes ETF capabilities as an integral part of the production/certification process. Without these ETF capabilities, these sites could not complete their mission. Accordingly, they have not been included in this analysis. Table A.10-1 lists the existing ETF facilities at the three DOE/NNSA laboratories and the NTS.

Table A.10-1—ETFs at LANL, LLNL, Sandia, and NTS

Facility	Size (ft ²)
LANL	
K Site Environmental Test Facility	8,452
Weapons Component Test Facility	22,075
Thermo-Conditioning Facility	6,795
PIXY	6,245
Total	43,567 ft²
SNL	
Simulation Tech Lab	56,886
PBFA Saturn and Sphinx	42,052
ACRR and Sandia Pulsed Reactor Facility ¹	13,793
Radiation Metrology Lab`	1,774
Gamma Irradiation Facility	12,514
Low Dose Rate Gamma Irradiation Facility	206
Auxiliary Hot Cell Facility	13,358
Model Validation and System Certification Test Center	18,842
Centrifuge Complex (including outdoor centrifuge)	15,360
Complex Wave Test Facility	3,459
Sled Track Facility	9,368
Light Initiated HE Test Facility	4,138
Aerial Cable Facility and Control Building	6,808
Radiography Building and Nondestructive Test Facility	6,397
Photometrics/Data Acquisition Complex	13,079
Mechanical Shock Facility	6,600
Mobile Guns Complex	2,400
Thermal Test Complex	15,712
Vibration Acoustics and Mass Properties Lab	8,950
Engineered Sciences Experimental Facility	19,416
Component Environmental Test & Advanced Diagnostic Facility	44,091
Electromagnetic/Environmental/Light Strategic Defense Facility	103,185
SNL/CA Environmental Test Complex	65,964
Total	484,352 ft²
LLNL	
Dynamic Testing Facility (836 Complex)	12,913
Building 834 Complex	4,289
Building 834	6,300
Total	23,502 ft²
NTS	
Device Assembly Facility Area (DAF)	4,790
U1a Complex	2,100
Total	6,890 ft²
Complex Total	558,311 ft²

¹The reactor itself has been moved to NTS

A.10.1.1 Environmental Test Facilities at LANL

LANL has four primary ETFs located within three different Tech Areas: 1) The K Site Environmental Test Facility; 2) The Weapons Component Test Facility; 3) The Thermo-conditioning Facility; and 4) The Pulsed Intensive X-Ray Facility with sled track (PIXY) X-Ray

Building with sled track. The K Site is a large complex consisting of 11 major structures and is located on TA-11. The total size of all facilities at the K Site is 8,452 square feet. Both the Weapons Component Test Facility and the Thermo-Conditioning Rest House are located at TA-16. Together, these two facilities total 28,870 square feet. The PIXY facility is a 6,245 square foot facility located on 194 acres at TA-36. In all, the ETF structures at LANL total 43,567 square feet and are operated by a staff of about 30. Figure A.10-1 shows the location of the LANL ETF facilities. A more detailed description of this facility is as follows:

K Site Environmental Test Facility. The K Site Environmental Test Facility consists of 11 separate structures and is located at TA-11. In all, these 11 structures consist of a total of about 8,452 square feet and occupy a total area of about 10 acres. LANL also has a substantial number of closed ETF facilities which are a function of old age and past downsizing programs. These facilities occupy an area of about 50 acres and are in the process of undergoing D&D and being cleaned up. The following is a description of the 11 existing ETF facilities presently operating at the K Site Environmental Test Facility at LANL:

11-0001 Storage Building. This building was built in 1945 and is used for storage of test equipment that is used to support many of the laboratory and field testing done by LANL/ WT-4.

11-0002 Test Building. TA-11-0002 was built in 1945 and is being used for the angular acceleration test apparatus. It contains various data acquisition systems used to support the angular acceleration testing, as well as other various tests that are conducted in building 11-0002. It has been used in the past for the air-bearing currently housed in TA-16-207, as well as other various tests. It is one of three—11-0002, -0003, and -0004—approved bunkers for personnel protection during high hazard test operations.

11-0003 Control Building. TA-11-0003 was built in 1945 and is currently used as the control room for the TA-11 firing site. It was also used as the control room for the drop tower and burn pit described below. There are various data acquisition systems used to support tests conducted at the drop tower, firing site and burn pit. It is one of three—11-0002, -0003, and -0004—approved bunkers for personnel protection during high hazard test operations.

11-0004 Control Room. TA-11-0004 was built in 1945 and is currently used as the control room for the shock and vibration testing conducted in 11-0030. It contains various data acquisition systems used to support shock and vibration testing, as well as other various tests that are conducted in the building 11-0030. There are capabilities in 11-0030 for remote control of shock and vibration testing in 11-0030. It is one of three—11-0002, -0003 and -0004—approved bunkers for personnel protection during high hazard test operations.

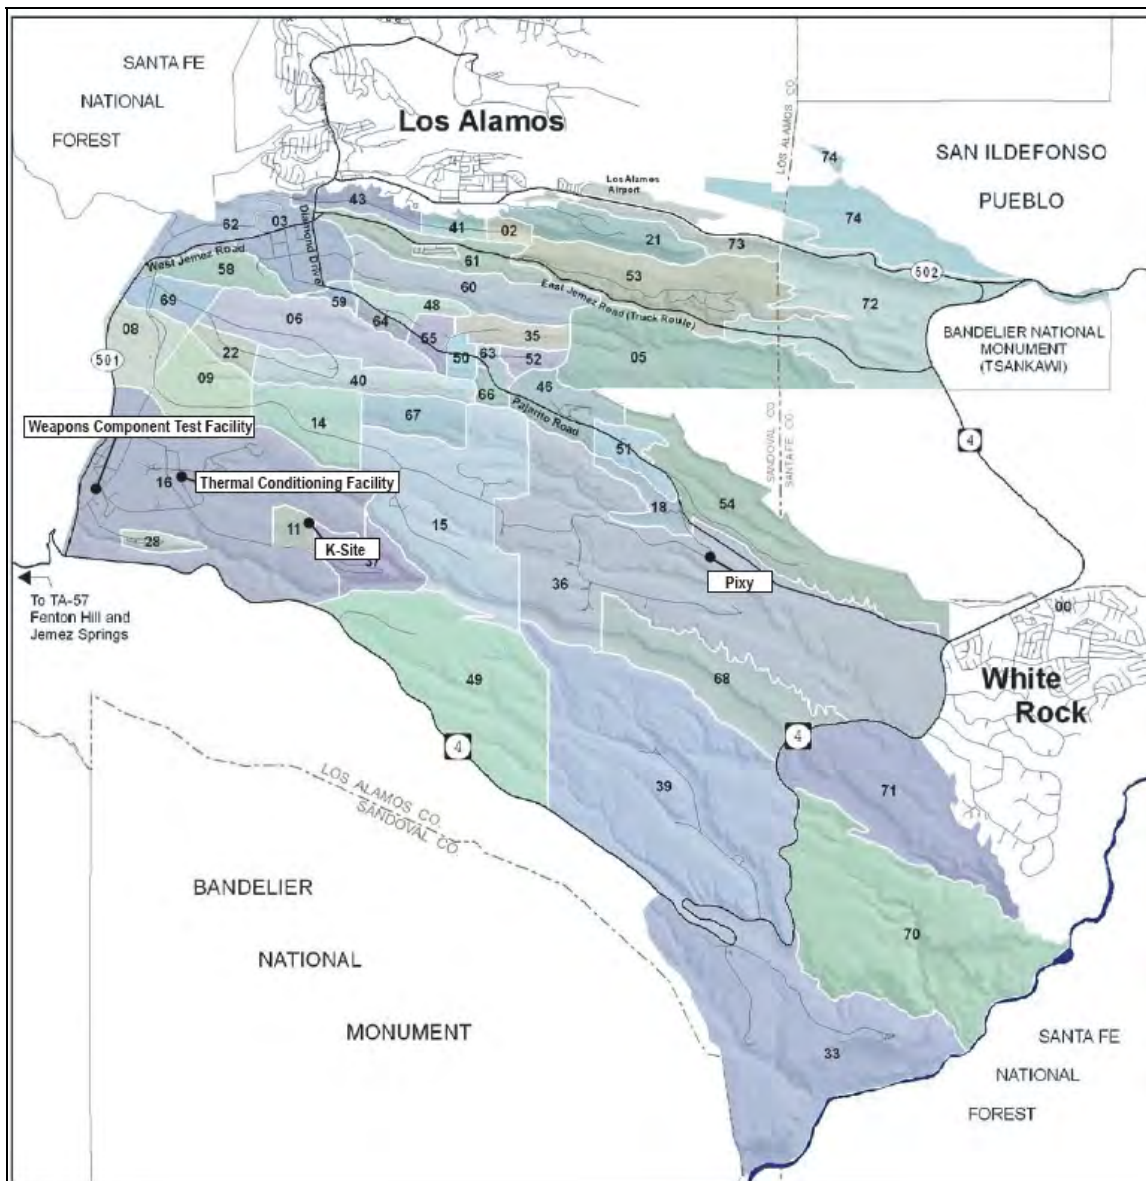

Figure A.10-1—Location of LANL ETFs

11-0024 Office/Shop/Assembly Building. TA-11-0024 was built in 1957 and is currently used as an office space for five ETFs, and has housed as many as eight. It is also used as a staging and preparation area for nonhazardous tests. It contains data acquisition systems used to support many tests that are performed by LANL/WT-4. It contains a small staff shop used for basic fixture manufacture and modification.

11-0025 Drop Tower. TA-11-0025 is a 165-foot drop tower and was built in the early 1960s. It was used to drop test units from as high as 150 feet. Typical test units included full-up weapons systems, shipping containers as well as other DOE and DoD test units. The drop tower was also used for HE sensitivity tests, where HE was dropped from ever-increasing heights until detonation occurred. Acceleration, strain, overpressure and various other data were acquired during testing activities. The drop tower was decommissioned in 2005.

11-0030 Shock and Vibration Test Facility. TA-11-0030 was built in 1957 and now houses the shock and vibration facilities. There are two vibration exciters, an Unholtz-Dickie T-1000 and an Unholtz-Dickie T-4000. These vibration exciters are controlled remotely from 11-0004. Ambient, hot or cold tests can be performed; either alone or in conjunction with shock or vibration on the vibration exciters. 11-0030 also houses a high-g drop machine. This drop machine is approximately 22 feet tall, with a capable drop height of 20 feet. Ambient, hot or cold shock tests can also be performed. TA-11-0030 is also used for free-fall drop testing. Testing with up to 100 pounds of HE can be performed in TA-11-0030

11-0030A Shock and Vibration Amplifier Room. TA-11-0030A houses the power amplifiers used for the Unholtz-Dickie vibration exciters detailed above.

11-0033 Equipment Room. TA-11-33 was built in 1962 and houses an air compressor that supplies house air to TA-11-0030 and TA-11-0030A.

11-0036 HE Magazine. TA-11-0036 was built in 1966 and is a transient HE magazine used for short term storage of HE prior to being used for testing at TA-11-0025.

11-0076. TA-11-0076 was built in about 2004 and is an awning that covers a 2,500-gallon liquid nitrogen Dewar used for thermal testing in TA-11-0030.

Weapons Component Test Facility. The Weapons Component Test Facility is located at TA-16. Originally built in the 1950s, this 22,075 square foot building was completely refurbished in the early 1990s. The facility is located on about an acre and a quarter site and supports nuclear weapons stockpile surveillance by providing high-fidelity testing for explosive valves, the portable high-speed data acquisition systems and test instrumentation, and QC-1 R10 compliant testing. An Advanced Diagnostics capability is housed in 16-0207 to develop, design, fabricate, qualify, field, and analyze new measurement applications. These systems include HE Radio Telemetry and fiber optic sensors. A main focus of this capability is not only flight testing of our

weapon systems, but the development of new fiber based measurements for a broader customer base. The measurements capabilities include quasi-static component and miscellaneous laboratory and field testing and data analysis on many different systems and components. The data acquisition systems used are NIST-traceable and meet A2LA requirements and are capable of up to 120 channels of long-term logging and high-speed data collection of up to 1 sample per microsecond.

Thermo-Conditioning Facility. Also located at TA-16 is the Thermo-Conditioning Facility. This 6,795 square foot facility, consisting of five structures, is located on about a three-quarter acre site, and houses the thermal conditioning capabilities. The facility consists of a walk-in thermal chamber and a small stand alone thermal chamber. HE and non-HE tests can be performed with up to 500 pounds of HE. There are also tensile test machines that can be used in conjunction with thermal testing.

Pulsed Intense X-Ray (PIXY) Facility with sled track. The PIXY is a world class radiographic facility with a combined sled track and gun range capability. This 6,245 square foot facility, located on a large site of about 194 acres. The x-ray capability of the facility is less than 100-nanosecond pulse and stops all motion, even at hypersonic speeds. The X-Ray penetrates 6 inches of steel and the timing of PIXY and other diagnostics to 3 nanoseconds. The facility is capable of high speed photograph to 2,000,000 frames per second. There are oil storage tanks that support PIXY at this site.

A.10.1.2 Environmental Test Facilities at LLNL

As a nuclear weapons design facility, LLNL has been involved with weapons testing virtually since its inception in 1952. However, the construction of large scale environmental testing facilities didn't begin until the late 1950s and early 1960s. By 1970 there were a total of 37 buildings associated with weapons testing with approximately 48 people assigned to weapons testing activities. Weapons testing at LLNL was at its peak in 1985 with 46 buildings and roughly 55 people working on testing related activities. Today, LLNL's ETF program consists of seven people operating three facilities consisting of nine operational buildings. These three facilities consist of a total area of 23,502 square feet occupying a total site area of 17.75 acres. There is not a specific and dedicated crew of test technicians or engineers assigned to any of the individual test facilities listed below. Rather, the Weapons Test Group (WTG) that operates the ETF facilities has stewardship to maintain all the facilities and provide support staff to the appropriate building in order to conduct and complete the necessary testing. The WTG has a total of six workers, which provide support over all the facilities listed below. Specifically there are three test technicians and three test engineers. The technicians and engineers rove to each of the buildings on an as-needed basis to perform the required testing. The following is a description of the three LLNL ETF facilities:

Building 334 (Hardened Engineering Test Building). Building 334 is a 6,300 square foot facility located on a 2.5-acre site in the Superblock section of the LLNL main site. This facility is often referred to as the Hardened Engineering Test Building (HETB). The building is primarily used for environmental testing of SNM. One half of the building is the Radiation Measurement Facility, including the Intrinsic Radiation (INRAD) Bay, and the other half is the ETF, consisting of the Engineering Test Bay (ETB). The two bays are separated from each other by a thick concrete wall. The HETB is a unique facility within the Nuclear Weapons Complex (NWC). With regard to INRAD measurement testing, it is currently the only building within the NWC that allows intrinsic radiation detection of SNM on configured assemblies (outside of drums or containers) and without significant background radiation present. The INRAD facility supports measurement operations for Nonproliferation, Homeland and International Security Division (NHI), the Accident Response Group (ARG), the Joint Technical Operations Team (JTOT), and radiation detector development work. With regard to environmental testing, Building 334 is currently the only building within the NWC that can facilitate environmental testing of SNM (i.e., pits and secondary assemblies containing SNM). Environmental testing includes vibration, shock, thermal conditioning, or combinations of these environments. Figure A.10-2 shows the location of Building 334 in Superblock, at LLNL.

Figure A.10-3—Build. 834 Complex and Build. 836 Complex at Site 300

Building 834 Complex at Site 300. The 834 Complex is comprised of four buildings totaling 4,289 square feet located on an 11.5 acre site in the Site 300 area of LLNL. The facilities located at this complex are used for thermal and humidity testing of weapons components and systems. The original layout had a total of 12 buildings, but through downsizing efforts now only four are used for thermal testing (one control room, two test cells, and one temporary storage magazine). The strength of the test facilities at the 834 Complex is the ability to test large weapon assemblies with large quantities of HE. In addition to testing of HE, the 834 Complex has the authorization basis to test other hazardous materials commonly found in legacy weapon assemblies. Figure A.10-3 shows the location of Building 834 Complex, at Site 300, at LLNL.

Building 836 Complex at Site 300. The Building 836 Complex consists of four buildings, with a total size of 12,913 square feet, located on a 3.75-acre site in the Site 300 Area of LLNL. This facility is used for dynamic testing of full-up weapon assemblies containing high explosives or other hazardous materials. The four buildings include: one control room, two test cells, and one storage building. The strength of the test facilities at the 836 Complex is the ability to test large weapon assemblies with large quantities of live HE. The authorization basis also allows for testing of other hazardous materials commonly found in Legacy systems. The types of testing performed in the complex are vibration, shock, spin, jerk, and some impact. The test cells are also capable of providing simultaneous thermal conditioning during testing. Figure A.10-4 shows the location of Building 836 at Site 300, at LLNL.

A.10.1.3 Environmental Test Facilities at Sandia National Laboratory

SNL/NM has 19 major ETF complexes, each with multi-operational capability. These facilities

have a combined footprint of 462,390 square feet. These facilities as shown in Figure A.10-5 are briefly described below.

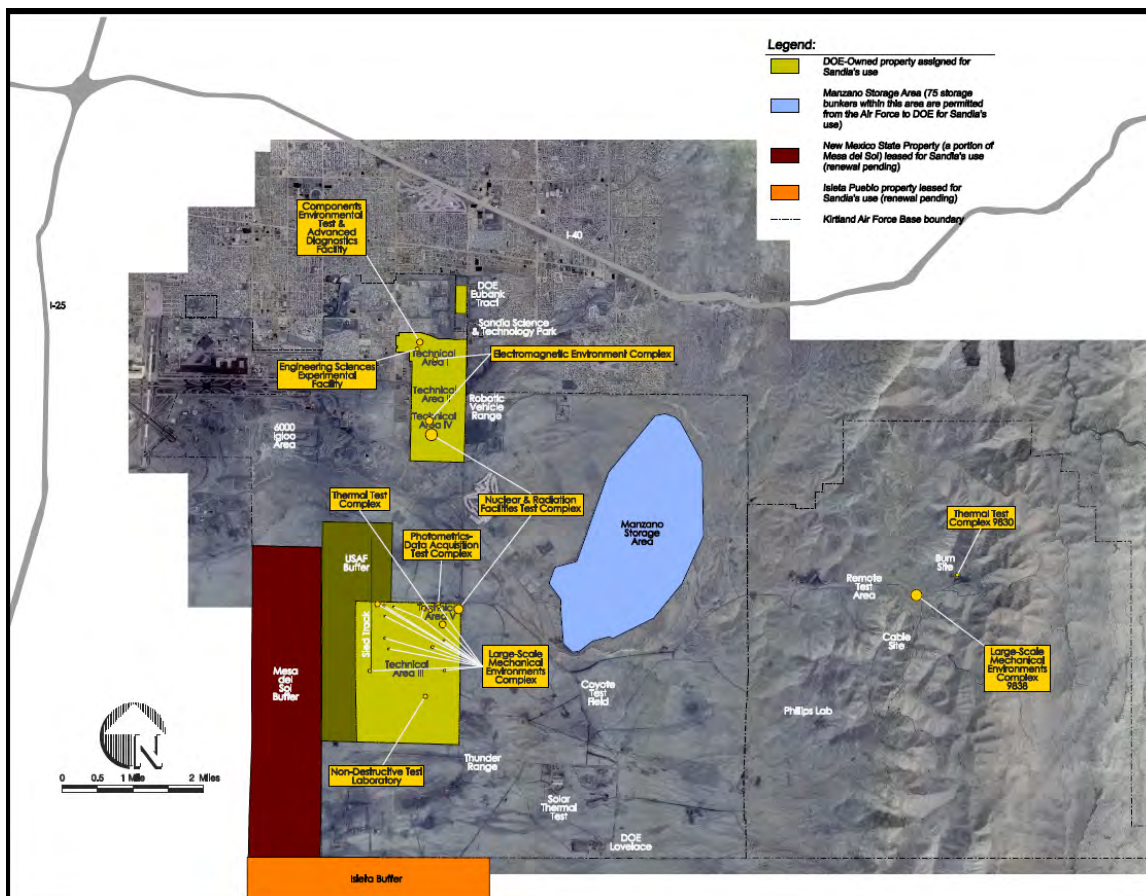

Figure A.10-5—ETF Facilities at SNL/NM

Simulation Tech Lab Hermes III and Repetitive High Energy Pulsed Power. HERMES III is a 56,886 square foot FXR facility located on about 14.5 acres. HERMES III produces high-energy x rays (up to ~20 MeV) by the bremsstrahlung process, providing high spectral and temporal fidelity environments for physical simulation testing to STS prompt gamma radiation requirements. No other U.S. facility can provide these testing capabilities at the subsystem level. Without HERMES III, reentry systems cannot be qualified to STS prompt gamma requirements. The capability is critical for qualifying electronic subsystems. In the large test cell, these bremsstrahlung sources can also stimulate high-fidelity source region electromagnetic pulse (SREMP) environments for nuclear weapon as well as other military system testing. In addition, physical simulation modes utilizing direct deposition of the accelerator's electron beam in experiment objects have been developed and utilized for structural response model development and validation. There are no high-fidelity testing facilities for these responses, and validated models are critical for adequate system qualification.

HERMES III operations are conducted by a crew of 23 that maintains and operates the Saturn, HERMES III, and SPHINX facilities, with certain specialized skills shared amongst the set.

Eight full-time equivalent positions from this crew are associated with HERMES III, with various mechanical and electrical engineering and technician positions along with administrative and ES&H personnel. In addition, the facility relies upon the corporate infrastructure to provide the various areas of ES&H support and Facility Maintenance and Operations Committee (FMOC) maintenance of real property.

PFBA Heavy Lab Saturn and Sphinx. Saturn is designed to produce intense x-ray pulses, providing physical simulation for STS hot and cold x-ray requirements. Saturn can be configured for either bremsstrahlung x-ray sources or plasma radiating sources (PRS).

In bremsstrahlung mode, Saturn simulates hot x-ray environments, producing a broad spectrum of x rays peaking near 50 keV energy, extending up to nearly 2 MeV. The x rays are generated in a 17-nanosecond full width at half maximum (FWHM) pulse providing high spectral and temporal physical simulation (testing) fidelity for hot x-ray requirements for heavily shielded full subsystems such as an arming, fuzing and firing (AF&F) subsystem. No other U.S. facility can provide adequate x-ray environments. Without Saturn, reentry systems cannot be qualified to STS x-ray requirements. Physical simulation (testing) at Saturn is required for system

qualification to hot x-ray requirements. In bremsstrahlung mode, Saturn also provides critical physics discovery and model validation data for microelectronics and circuit x-ray response.

In PRS mode, Saturn provides atomic line or combined atomic line/continuum x-ray sources up to 3 keV in energy. There are no U.S. facilities to provide adequate cold or warm x-ray testing environments. Therefore, the PRS sources on Saturn are used to acquire material property data for model development and model validation, including support for system qualification computational simulations.

Saturn operations are conducted by a crew of 23 that maintains and operates the Saturn, HERMES III, and SPHINX facilities, with certain specialized skills shared amongst the set. Fourteen FTE positions from this crew are associated with Saturn, with various mechanical and electrical engineering and technician positions, along with administrative and ES&H personnel. In addition, the facility relies upon the corporate infrastructure to provide the various areas of ES&H utilities, and maintenance of real support.

SPHINX has both bremsstrahlung and direct electron beam deposition modes of operation. Accelerator power is approximately a factor of 250 below that of Saturn. SPHINX provides fast turnaround capability (cycle time, five minutes) for dose-rate studies of microelectronic devices as well as material response research in direct electron beam mode. SPHINX has supported qualification of the W76-1 electronic subsystems as well as the W76-0, W76-1, and W78 neutron generators. SPHINX provides a cost-effective capability for a large volume of experiments that would otherwise be done at significantly more expensive facilities (on a per test item-shot basis) such as Saturn.

SPHINX operations are conducted by a crew of 23 that maintains and operates the Saturn, HERMES III, and SPHINX facilities, with certain specialized skills shared amongst the set. One FTE position from this crew is associated with SPHINX (primarily an electrical/mechanical technician with some administrative and ES&H support). In addition, the facility relies upon the corporate infrastructure to provide the various areas of ES&H support and FMOC maintenance of real property.

Annular Core Research Reactor (ACCR) and Sandia Pulsed Reactor. The ACCR is a 13,793 square foot facility, which is a critical element in the neutron vulnerability and hardness testing and certification of stockpile weapon systems electronic components (e.g., transistors, integrated circuits), subsystems (e.g., fire sets, neutron generators), and systems (e.g., AF&F system). The ACRR is also a critical element in the hostile environment testing of weapon system physics packages (both primary and secondary) at the full-up system level, as well as material sample tests. In addition, the ACRR performs neutron radiographic nondestructive examinations of weapons systems components (e.g., neutron generators). The Complex Transformation strategy includes the need for a responsive infrastructure to design, develop, and field new weapon systems if needed, and/or repackage current systems. As noted above, the ACRR would be critical to the neutron vulnerability and hardness testing and certification in such cases. Also, the ACRR would be critical to the neutron vulnerability and hardness testing and certification of primary and secondary components and systems for the RRW program.

The ACRR directly subjects the part/device being tested to a neutron (and gamma) irradiation environment that simulates the neutron spectrum anticipated from an endo-atmospheric threat. The environment can be produced over long periods of time (e.g., minutes to hours) in a steady-state operation mode or very short periods of time (10–100 milliseconds) in a pulse-operation mode. The irradiation location is accessible for cables that transmit power/signals to the device being tested, and/or receive operational and diagnostic signals from the device being tested. Under appropriate work controls, the device being tested can even include components which contain explosives that can be detonated while being irradiated. These testing capabilities allow for a customer to determine and/or assess the function, failure, and recovery characteristics of the device being tested within neutron-gamma irradiation test environments that simulate STS threat levels. In addition, the ACRR also has a neutron radiography capability to allow customers to perform nondestructive examination of components to search for small defects or other conditions not otherwise detectable.

The ACRR facility includes a relatively modern control room panel with computer-aided control and diagnostic systems, and a newly installed (2005–2006) heat rejection system for long duration steady-state operations. Aging reactor power monitoring devices are being replaced as time and funding allow.

The Sandia Pulsed Reactor (SPR) Facility shown in Figure A.10-6 is a 6,099 square foot facility located on about two tenths of an acre, in conjunction with the ACRR. The SPR was a fast-burst reactor used for neutron testing. The SPR directly subjected the part or device being tested to a neutron (and gamma) irradiation environment which simulated the neutron spectrum anticipated from an exo-atmospheric threat. The reactor, itself, as well and the SNM from the SPR, has already been moved to NTS and the facility is not presently in operation.

Radiation Metrology Laboratory (RML). The RML is a 1,774 square foot facility, which provides measurement of dosimetry for high-dose applications of exposure to neutron and gamma environments (Table A.10-13). This critical capability provides the underpinning for the SNL/NM radiation effects experimental facilities for dose and dose rate measurements. Dosimeter measurements for neutron environments specifically include the fast burst reactors (SNL/NM-SPR, WSMR-FBR), epithermal reactors (ACRR), gamma irradiation environments (Gamma Irradiation Facility [GIF], Low Dose Rate GIF [LDRGIF], HERMES), along with other NNSA test facilities as requested (LANSCE). The RML includes a wide variety of radiation measurement tools, dosimetry, and equipment, including alanine, sulfur, thermoluminescent dosimeter (TLD), alpha spectroscopy, and germanium detectors. The main RML facility is located at SNL/NM TA V, with a satellite laboratory in TA IV to support the pulsed power facilities. All system calibrations are traceable to the National Institute of Standards and Technology (NIST), and measurement procedures follow American Society for Testing Materials (ASTM) international consensus standards.

Along with radiation effects facility experiment support, the RML provides numerous radiation interrogation techniques for a variety of experiments including: specialty R&D projects in the field of radiation testing and measurements, fuel enrichment confirmations, and flux profile mapping of subcritical experiments. The laboratory also has supported environmental analyses for underground storage, such as confirmation of actinide migration through salt columns and other geologic strata. In past operations, the facility has provided direct support to NTS for underground testing as well as mobile testing support for other NNSA laboratories and universities.

Gamma Irradiation Facility (GIF). The GIF is housed in a 12,514 square foot building. The GIF provides for testing, experimentation and system/component performance when exposed to Co-60 gamma environments. The GIF provides extensive flexibility in both high dose rate and total dose testing to support a wide array of radiation effects and experimental needs. Activities include electronic component hardness, survivability, and certification tests for military and commercial applications, weapon component degradation, radiation effects on material properties, and experiments containing radioactive and strategic nuclear materials testing. Typical experimental customers include radiation damage computer modeling testing, support of Qualification Alternatives to Sandia Pulsed Reactor (QASPR) modeling, and National Aeronautics and Space Administration (NASA) and SNL/NM radiation hardnesstesting for space communications, lasers, and satellite systems. The GIF complements the ACRR facility in that it allows for gamma exposure discrimination to better understand both neutron and gamma damage in radiation environments. The GIF is used to precondition neutron dosimeter transistors used for experimental applications in neutron environments, and organic materials R&D testing in nuclear environment applications.

The facility supports calibration of TLD measurement systems used in support of reactor and pulsed-power machine dose measurements. It has also been utilized for the radiation hardness testing for robotic systems used in nuclear material retrieval devices (i.e., “dirty bombs”). The facility is working with LLNL to determine feasibility of relocating the instrumentation calibration capability from NTS to SNL/NM in support of underground testing, should it be required in the future.

The GIF provides three concrete, dry test cells and a 5.5 meters (approximately 18 feet) deep pool for a variety of gamma irradiation experiments with different test configurations, dose rates, and dose levels. To accommodate these specific irradiation needs for experiments, custom features have been incorporated into the GIF design as follows:

- Configurable radiation sources provide different geometries for the source array (e.g., point, planar, circular).
- Shielded windows allow for experiment observation during irradiation.
- Remote manipulators available to facilitate experiment or source handling.

The in-cell facilities are dry, shielded rooms where irradiations are performed with a high-intensity gamma ray source. Typical irradiations performed in the dry cells are at high dose rates (typically on the order of 3 mrem/hr at >1 m [approximately 3.3 ft] from the source) and for short to intermediate durations lasting up to a few days. The facility also provides for future experimental and testing capabilities that would require the radiation shielding provided by the facility experimental test cells.

For the in-pool testing, radioactive sources are held in a submerged irradiation fixture near the bottom of the 5.5-meter (approximately 18 ft) deep pool of demineralized water. Typical irradiations performed in the pool are at moderate and low dose rates and for long durations lasting days, weeks, or months. Dry experiment canisters, which contain test units, are immersed in the pool and positioned in preset locations in the irradiation fixtures. The fixtures are voided of water to provide an unshielded path between the source and the test unit. The pool can store up to 1.5 mega curies of cobalt-60 (⁶⁰Co). The sources are in the form of pins and can be shared between the in-cell irradiation facilities and the in-pool irradiation facilities.

This Hazard Category 3 facility is operated by a facility supervisor and a facility operator as dedicated staff, as well as system engineers, safety basis analysts, facility maintenance technicians, a radiological control technician, and department management.

Low Dose Rate Gamma Irradiation Facility (LDRGIF). The LDRGIF is a 206 square foot facility. The LDRGIF provides the ability to perform Enhanced Low Dose Rate Sensitivity (ELDRS) effect testing to a large number of piece parts for extended periods of time (several years in many cases). The program personnel supported in this application are weapons systems component developers responsible for certifying the reliability of their designs maintained in storage configurations over decades. Additionally, satellite piece parts have been tested to predict device degradation over the lifespan of the program mission. A separate exposure room is equipped with a combination of temperature-controlled ovens and radioactive sources that permit the simultaneous exposure to thermal and gamma radiation environments. Finally, WFO customers, in support of DoD missions, use the facility.

Attractive features of the facility are simplicity of operation, adequate shielding for personnel working in manned spaces, the use of special form sources, low inventories of source materials, security controls for classified components, an existing infrastructure of radiation protection, industrial hygiene (IH), training, maintenance, administrative, and security support.

The facility is operated by a single operator [1 FTE] with approximately 10 percent of an FTE for supervision and management. This radiological facility is supported by approximately 7.5 percent of an FTE.

Auxiliary Hot Cell Facility (AHCF). The AHCF is a 13,358 square foot facility. The AHCF is used for characterizing and repackaging nuclear materials, radioactive materials, and mixed waste materials. The AHCF is designed to allow SNL/NM to safely characterize, treat, and repack radioactive material for reuse, recycling, or ultimate disposal. It is designed to be operated as either a radiological or Hazard Category 3 nuclear facility, depending on material at risk quantities campaigned within the facility. The facility's main purpose is to support the de-inventory of security category 3 and 4 nuclear materials from SNL/NM. The facility systems provide for remote handling capabilities for existing and future items. SNL/NM has an inventory of legacy nuclear materials that are excess to SNL/NM but not necessarily excess to the DOE Complex. Some of these materials have been designated as "no defined use" (NDU). Current disposition plans specify that some of the materials will ultimately be sent to DOE disposal facilities.

The AHCF also provides short-term storage for radioactive materials and wastes. In addition to handling low-level radioactive material, the AHCF has remote-handling capabilities to allow for the characterization and repackaging of high-level radioactive materials and waste. The AHCF is located in the high-bay area of Building 6597 at SNL/NM. The AHCF consists of three parts: 1) A hot cell with two storage silos in the floor (inside the cell) and access ports in the roof; 2) A work area next to the hot cell with a permanent shield wall, a fume hood, and six storage silos in the floor; and 3) Space for material storage. The building contains remotely operated bridge cranes, hot cell manipulators, and video capability. Six-inch floor silos are available for short-term storage of materials during material campaign processing. The silos are 15 feet deep; four are 9-inch diameter and two are 30-inch diameter. A remote electric chain hoist is used in conjunction with the bridge cranes to introduce material into the hot cell. The hot cell is a 10 feet by 10 feet square, it is lined with stainless steel for ease of decontamination, and it contains a one-ton jib crane.

The AHCF is currently not operational. DOE has not granted authorization for operation because of limitations and concerns in the DSA for the facility. The facility is being planned for use as a radiological facility to handle low quantities of nuclear materials for disposal processing.

Many of the Legacy material packages will require repackaging at the AHCF because of their Hazard Category quantities or because their form requires remote-handling capabilities. These packages contain uranium oxide in various forms, miscellaneous radioactive materials, depleted uranium, experiment packages and scrap parts, metallographic samples, a small quantity of thorium, and several Americium Beryllium sources.

During operations, the facility is staffed with one facility supervisor, two facility technicians, a radiological control technician, and department management. As a Hazard Category 3 nuclear facility, additional support staff include system engineers, safety basis analysts, and facility maintenance technicians.

The AHCF is a temporary life facility and is intended to support material removal. Its project length of operation is approximately eight years from initial startup.

Large Scale Mechanical Environments Complex. The Large Scale Mechanical Environments Complex is a collection of test facilities used to simulate a wide variety of mechanical environments that a weapon system or subsystem might experience as specified by the STS document. These facilities support development, qualification, and acceptance testing; model validation experiments; and other weapon systems evaluations. The facilities included in this complex for purposes of this EIS are: the Model Validation and System Certification Test Center, Centrifuge Complex, Complex Wave Test Facility, Sled Track Facility, Aerial Cable Test Facility, Radiography Building and NDT Test Facility, Photometrics/Data Acquisition Test

Complex, Mechanical Shock Facility, and Vibration-Acoustics and Mass Properties Facility. In addition to the tests that utilize facilities, open air firing of explosives (>1 Kg) are used to expose nuclear weapon systems and subsystems to shock environments as part of the qualification process for abnormal or hostile environments. These impulses provide loadings to drive structural responses that can be measured and analyzed in conjunction with computational results. These detonations can be used to drive planar pressure waves using blast tubes, spherical pressure waves using a free charge, or high velocity flyer plates for impact studies. These tests are typically conducted in the open area at the sled track facility, but can also be conducted in open areas at other approved facilities in the Large Scale Mechanical Environments Complex such as the aerial cable and burn site facilities. The complex also includes advanced diagnostic capabilities which are used to analyze system response, interpret hardware failures, and to support model validation efforts. The core of this complex is the Model Validation and System Certification Test Center, which supports all of the centrifuge, mechanical shock, rocket sled tracks, radiant heat (part of the thermal test complex), vibration, and complex wave facilities that are remotely located to allow for testing of hazardous items.

Model Validation and System Certification Test Center (MVSCTC). The MVSCTC is located in TA-III and housed in Building 6584. This 18,842 square foot building, located on a 3.5-acre site, supports development, qualification, and acceptance testing; model validation experiments; and evaluation of weapon components and other hardware. In addition to providing an office complex for staff, it contains laboratories that support the development and fielding of advanced diagnostics. The MVSCTC contains a small chemical inventory, but no radioactive materials. The chemicals used are typical cleaners, lubricants, solvents, paints, and adhesives that could typically be found in a light lab setting. The building also houses classified and unclassified computing capabilities, a visualization complex for the interpretation of experimental data, and control capabilities to allow for the remote control of seven experimental capabilities in TA-III. characteristics and site infrastructure requirements of the MVSCTC and are shown in Table A.10-17.

The 29-foot centrifuge supports both the vibrafuge and the superfuge capabilities. These are unique capabilities developed at SNL/NM that allow additional environments (vibration and vibration/spin) to be applied to systems while being spun by the centrifuge.

Centrifuge Complex. Located in TA III, the Centrifuge Complex consists of an outdoor 35-foot centrifuge with five support buildings and an indoor 29-foot centrifuge with three support buildings. The complex encompasses a total floor space of 15,360 square feet, situated on a site of about four and a half acres. The two centrifuges in this TA III facility generate high-acceleration environments to certify weapons components and systems, satellite systems, guidance systems, and transportation containers. Both the 35-foot (outdoor) and 29-foot (indoor) centrifuges simulate Reentry Vehicle (RV) launch and reentry environments, aircraft maneuvering accelerations, crash and impact decelerations, and other acceleration environments within the STS envelope, and support environmental sensing device testing on bomb and missile systems. The 29-foot centrifuge supports both the vibrafuge and superfuge capabilities. These are unique capabilities developed at SNL/NM that allow additional environments (vibration and vibration/spin) to be applied to systems while being spun by a centrifuge. Four technical personnel operate both centrifuges.

The Centrifuge Complex contains a small chemical inventory but no radioactive materials as shown in Table A.10-19. Cleaners, lubricants, solvents, paints, and agents are used in small quantities. Compressed gases used in the assembly areas include acetylene and oxygen, argon, and helium. Chemical emissions, including alcohols, ketones, and other solvents, are associated with various aspects of surface preparation, cleaning, and material processing, including quality control. Small amounts of airborne emissions, including carbon monoxide and lead, are released during explosives tests. Radioactive air emissions are not produced at this facility. Noise from centrifuge operation, collision impacts, and explosive testing does occur. Fragments resulting from centrifuge-launched explosives are recovered shortly after test events.

Complex Wave Test Facility. The Complex Wave Facility, located in Building 6610 in TA-III, is a 3,459 square foot facility located on a little more than a half acre site. This facility supports development, qualification, and acceptance testing of weapon systems for normal shock and vibration environments. The facility can be operated remotely, which enables testing of systems that include hazardous and explosives materials. The electrodynamics shakers, control systems, and data acquisition systems are located within a vault-type room (VTR), which simplifies logistics associated with testing of classified articles. Characteristics and site infrastructure requirements of the Complex Wave Test Facility are shown in Table A.10-20.

Building 6610 has the highest force-rated shakers at SNL/NM and is used extensively for system-level tests of full-scale assemblies or items requiring high vibration levels. For fast and efficient setup, two UD T4000 electrodynamic shakers have been dedicated for vertical and horizontal testing, respectively. The facility has state-of-the-art control and data acquisition systems, allowing for up to 200 channels of data sampled at 102 kilohertz.

Controlled dynamic simulations are performed on test articles ranging from small subsystem components to full-scale assemblies. Tests include random vibration, shock on shakers, sinusoidal vibration, mixed-mode vibration, tracked resonant dwells, and combined temperature and vibration. Recent testing has included weapons, satellite subsystems, rockets and payloads, reentry vehicles, and shipping configurations.

Light Initiated High Explosive (LIHE) Facility. The LIHE Facility is a 4,138 square foot facility located on a little more than a two acre site. The primary purpose of the SNL/NM LIHE facility is to simulate cold x-ray-induced shock loading from an exo-atmospheric nuclear blast, primarily investigating structural response. This one-of-a-kind facility and technique can induce load levels in varying distribution (such as cosine distributions), including load discontinuities. The facility accomplishes this testing by the remote-controlled spray application of a sensitive primary explosive onto the surface of complex structural shapes. The explosive is simultaneously detonated over the sprayed surface by exposing it to an intense flash of light generated by 40 kilovolts to 208 kiloJoules capacitor bank. An emerging technology at the LIHE facility is to drive a thin metallic flyer plate with the silver acetylide-silver nitrate (SASN) explosive. Targets of various geometries, such as flats, rings, cylinders, cones, and RVs can be impacted with representative impulse distributions as well as varying pressure pulse profiles. The LIHE facility is chartered by SNL/NM in concurrence with DOE/NNSA to: 1) Establish and maintain the LIHE impulse testing capability at SNL/NM; 2) Maintain the LIHE facility to modern operating standards; 3) Support the development and qualification testing of nuclear weapons for DOE/NNSA; and 4) Provide test data for use in validation of computer models developed for the Stockpile Stewardship Program.

The LIHE facility operated continually from 1971 to 1992, when it was mothballed at the end of the Cold War. In 2001, a decision was made to reconstitute the cold x-ray impulse test capability at SNL/NM by restoring the facility to its prior capabilities. Because of the onsite New Mexico Environmental Department permitted Thermal Treatment Facility, where excess explosive and explosive contaminated materials are treated, the restoration of the LIHE facility was constrained to its original location at Building 6715 in TA-III. During the time between mothball and restart, the physical condition of 6715 deteriorated to the point that a full renovation of the building was required. Characteristics and site infrastructure requirements of the LIHE Facility are shown in Table A.10-21.

Sled Track Facility. The 10,000-foot sled track is on a 1,941 acre site consisting of 16 support buildings located in TA-III. The support buildings include observation towers, storage sheds, transformer pads, a total of about 9,368 square feet of buildings. This facility supports weapons system qualification testing and weapons development efforts that must simulate penetration, flight, high-acceleration, and high-shock environments. The simulated environment may be provided through impact, reverse ballistic, or ejection testing. This testing includes shock/laydown tests for bombs, sled ejection tests to verify parachute and laydown performance, impact tests on transportation and container systems, impact fuze tests for reentry vehicles, and a variety of other DOE and DoD system tests that require high-speed impacts.

In addition to tests using the sled track, open air explosive firings greater than one kilogram are used to expose nuclear weapon systems and subsystems to shock environments as part of the qualification process for abnormal or hostile environments. These impulses provide loadings to drive structural responses which can be measured and analyzed in conjunction with computational results. These detonations can be used to drive planar pressure waves using blast tubes, spherical pressure waves using a free charge, or high velocity flyer plates for impact studies. These tests are typically conducted in the open area at the sled track facility, but can also be conducted at other approved facilities in the Large Scale Mechanical Environments Complex such as the aerial cable and burn site facilities.

Small amounts of chemicals are maintained for use in assembling rocket sleds and test payloads in buildings 6741, 6743, and 6736. These include various adhesives and epoxies used to fasten transducers and similar items. Cleaners, lubricants, solvents, paints, and other such agents may also be used in small quantities. Compressed gases are used in the assembly areas, including acetylene and oxygen (for welding), argon, and helium; and dry nitrogen and carbon dioxide are used for pneumatic actuators. Characteristics and site infrastructure requirements of the Sled Track Facility are shown in Table A.10-22.

Aerial Cable Test Facility. The Aerial Cable Test Facility, located in the Coyote Test Field, is a 5,022 square foot facility, consisting of three structures located on about a 2.5-acre site. This facility performs gravity drop and accelerated pull-down tests in support of bomb qualification tests and weapons development activities. This test capability provides controlled simulations of the worst-case impact environments experienced by weapons systems and shipping containers. Gravity drop tests are performed from a cable suspended between two peaks, giving up to a 600-foot vertical distance for acceleration. A rocket-assisted (320-foot sled track) pull-down technique is used to provide higher impact velocities when gravity tests are not adequate. Characteristics and site infrastructure requirements of the Aerial Cable Test Facility are shown in Table A.10-23.

Operations require the use of a variety of chemicals (corrosives, solvents, organics, and inorganics) in gaseous, liquid, and solid forms, in relatively small quantities. No radioactive emissions are routinely produced at this facility. Compressed gases used in the assembly areas

include acetylene and oxygen, argon, and helium. There are some chemical emissions, including alcohols, ketones, and other solvents. Small amounts of airborne emissions, including carbon monoxide and lead, are released during explosives tests. Operations associated with preparation of test payloads, fixtures, and rocket sleds involve machining that generates residues, bonding of parts with epoxies, cleaning of parts, and wiping of excess materials.

Radiography Building and Non-Destructive Test Facility. The Non-Destructive Test Laboratory is a two-building facility, 6635 and 6639, with a total floor space of 6,397 square feet, located on about a 7.5-acre site. The purpose of this facility is to allow the radiographic inspection of full weapon systems that contain HE and/or rad materials. These inspections are often necessary to determine the state of the weapon prior to testing in the large-scale facilities in TA-III. After testing, it is required to inspect the system prior to shipping to assure that the mechanisms have remained in a safe position. The high-energy capabilities of the facility allow for imaging through numerous layers of materials or thick sections. In addition to its primary function, the facility has also been used to evaluate other items such as solid rocket motors and recovered waste drums to quantify the contents to determine if the drums can be processed without further evaluation. Characteristics and site infrastructure requirements of the Radiography Building and Non-Destructive Test Facility are shown in Table A.10-24.

Photometrics/Data Acquisition Test Complex. The Photometrics/Data Acquisition Test Complex, consists of a 1.2-acre site, a 13,079 square foot building which houses photometric cameras, a collection of mobile data acquisition systems, and two mobile laser trackers. Personnel use high speed digital and film cameras to quantify the performance of test articles subjected to a range of test environments. Typical measurements include velocity, acceleration, angle of attack, and impact angle. The photo results are used to verify the applied boundary and initial conditions in a test, to quantify the response of the test unit to the applied stimulus, and to assist in the development and validation of models for use in our computational simulation tools. At the end of the day, the core of any major experiment is the quality of the data obtained. The capability to obtain time-accurate and spatially resolved information is critical to the qualification of weapon systems and for the development of mathematical models.

Laser Tracker II and III represent unique national assets that provide TSPI and photographic coverage currently unavailable by other means. Historically, the trackers (and slaved video data acquisition) have been used to collect data during rocket sled tests, missile firings, weapon development tests and aerial cable pull-downs. The trackers have supported every major Sandia weapon development program, along with significant work for the DoD. The laser trackers routinely track missiles, rocket sleds, smart munitions, parachute systems, aircraft, and other test items. Test-item ranges up to 25,000 feet and velocities up to 20,000 feet per second can be accommodated with a single tracker system. For trajectories that range beyond 25,000 feet, both trackers can be used in tandem. Under good atmospheric conditions, test ranges up to 50,000 feet can be provided. Targets with speeds up to 6,000 feet per second can be acquired on the fly. Current laser tracker capabilities include:

- Azimuth and elevation pointing accuracy of +/-13 microradians;
- Maximum slew rates of 10 radians/second;
- Maximum accelerations of 150 radians/second/second; and
- Trajectory data rate of 1,000 Hz real-time data to disk.

The mobile instrument unit (MIU) and the mobile instrumentation data acquisition system (MIDAS) are used to record accelerations, pressures, and temperatures with transducers that are hardwired to a test unit that may be positioned in a remote location.

SNL has a host of cameras to choose from to capture photometric information. These capabilities are essential given the variety and types of experiments performed in TA-III. These include infrared cameras, high-speed digital cameras (color and black-and-white), high-speed film, digital still cameras, and other specialized equipment such as streak and framing cameras.

Characteristics and site infrastructure requirements of the Photometrics/Data Acquisition Test Complex are shown in Table A.10-25.

Mechanical Shock Facility. The Mechanical Shock Facility, located in TA-III and housed in Building 6570, is a 6,600 square foot facility. The facility provides controlled impact and shock environments to support subsystem- and component-level development and qualification testing and to model development and validation activities. This facility houses two horizontal pneumatic actuators (18 inch and 12 inch) and their associated sled tracks (95 feet and 75 feet, respectively) (Figure A.10-12) and two bungee-assisted vertical shock machines. Each actuator can support sled and reverse ballistic speeds up to 250 feet per second. Characteristics and site infrastructure requirements of the Mechanical Shock Facility are shown in Table A.10-26.

Vibration-Acoustics and Mass Properties Facility. The Vibration-Acoustics and Mass Properties Facility, located in TA-III and housed in Building 6560, is an 8,950 square foot facility. The large-scale vibration-acoustics facility also houses mass properties operations, providing system-level vibration and shock environment testing capabilities to certify weapons systems (bombs, missile warheads, and reentry systems) to the normal STS environment specifications and to support model development and validation activities. These environmental requirements include transportation, launch, flight, and reentry shock and vibration simulations on full-scale weapons systems. The test capabilities include normal shock and vibration, combined vibration and acoustics, and combined thermal and vibration environments. The Mass Properties Facility provides capabilities to completely characterize the mass properties (weight, center of gravity, moments of inertia, and products of inertia) of full weapon systems.

All of the capabilities have the option of being operated and monitored remotely for tests involving HE or other hazardous materials. Recent improvements have included converting the building into a limited area and creating a VTR in the mass properties high bay.

Characteristics and site infrastructure requirements of the Mechanical Shock Facility are shown in Table A.10-27.

Mobile Guns Complex. The Mobile Gun Complex (Figure A.10-14) is a large multi-acre facility with no permanent buildings. The Mobile Gun Complex consists of three Davis guns and one gas gun. The Davis guns are smooth-bored guns in 8-, 12-, and 16-inch diameters, mounted on mobile carriers. These barrels are open at both ends and employ a moving mass recoil system. This recoil system allows the guns to be trailer mounted and mobile. The 8- and 12-inch barrels are interchangeable on the same trailer, while the 16-inch gun has a dedicated trailer. Each Davis gun trailer includes a hydraulic power unit, a winch for hoisting the load into the barrel, and the hydraulic cylinders necessary to elevate the barrel and operate the stabilizers. The gas gun is a six-inch diameter gun. It is also trailer mounted for mobility. It contains an onboard compressor and two air storage tanks with a capacity of 27 cubic feet each. These tanks are fed directly by the compressor and are capable of storing compressed air up to 5000 psi. These storage tanks feed the firing chamber, which is 7.2 cubic feet. All guns are hinged to allow firing angles from horizontal to vertical. Characteristics and site infrastructure requirements of the Mobile Guns Complex are shown in Table A.10-28.

The guns have limitations on the size and weight of the projectiles they can deliver. The 16-inch guns can achieve a launch velocity of approximately 1,200 feet per second for a 2,000-pound, 16-inch projectile, including sabot and pusher plate assemblies. The maximum weight of a gas gun projectile/sabot assembly is approximately 120 pounds for similar impact velocities.

These mobile guns are unique in that they provide a capability for component (fuze), subsystem, or full-scale penetration testing into in situ target materials (limestone, granite, layered geologies, etc.) in addition to engineered targets. The mobile guns provide a controlled environment for Hi-G impact conditions (velocity, angle of obliquity, angle of attack, etc.) along with high-fidelity photometric coverage or other off-board measurements. These unique capabilities provide cost-effective alternatives for risk mitigation, qualification, and failure investigations to sled or flight testing.

The mobile guns primarily provide support to penetrating weapons programs for DoD and DOE. The guns are also used in support of other Federal agencies, including the Japanese Lunar A space program. Recently, DoD has performed more full-scale testing with the Davis guns, while DOE programs have utilized the gas gun for component qualification and acceptance testing. SNL/NM maintains a capability for full-scale testing of its NW Penetrator, the B61-Mod11 test with the Davis guns. There are no permanent structures, and the guns are mobile. Seven staff are required to manage and operate this program.

Thermal Test Complex (TTC). The TTC is a four-building complex, with a total floor space of 15,712 square feet, located on a 10-acre facility in TA-III. This facility demonstrates through testing that the nuclear weapon stockpile is safe from inadvertent nuclear detonation in abnormal thermal environments. All weapons systems, as part of the weapons design, qualification, and initial certification process, have to demonstrate that they fail safely in fire environments. TTC contains the test facilities, diagnostics, and highly trained personnel to perform such qualification work. Characteristics and site infrastructure requirements of the TTC are shown in Table A.10-29.

Numerous risk assessments have demonstrated that fire, either alone or in combination with other environments, is a dominant contributor to risk. During accidents, fire occurs frequently when in the presence of fuels, such as are common in transportation modes. Further, fire presents a severe thermal threat to weapon systems. They are not intended to survive, but they must safely fail.

Computational advancements in the coming decades will improve ability to cost effectively test weapons systems as part of design, qualification, and certification but will not replace testing for at least another century. It must be shown that the weapon system maintains a positive safety margin throughout a failure transient so pervasive that the system is rendered irreversibly inoperable. Failure is atomistic in nature and the length scale range is beyond scientific prediction until computational machines become many orders of magnitude larger. On the other hand, engineering prediction has become an invaluable design-of-experiment tool and is considered an indispensable part of the testing process. Cost-effective testing is not possible without computational modeling.

Historically, it has not been necessary to conduct abnormal thermal environment testing with SNM. Acceptable measurement and computational methods exist for making the extrapolation from test articles without SNM. There is no evidence to suggest that the future will force a change in what has been accepted historically in this regard. If anything, it can be expected that advancements in computing will only solidify the testing basis without SNM.

Weapon system owners use the TTC during all phases of design and initial qualification. It is also used to address significant findings and for nonroutine testing to support the technical basis for annual assessments. Testing includes safety critical components such as capacitors, subsystems, fire sets, and full-up systems. The facility includes multiple environment capability. Examples include ovens and humidity chambers for prepping hardware, test bays for evaluating thermal properties of materials such as thermal diffusivity, and test chambers for fire environments. Fire environments can be cost effectively simulated electrically using radiant heat panels as is often done during the design phase. Fires can be created with gaseous or liquid fuels up to 20 MW.

The TTC consists of Fire Laboratory for the Accreditation of Models and Experiments (FLAME), Cross-wind Test Fire Facility (XTF), radiant heat cells, laboratories, and an outdoor test site in Lurance Canyon for larger, open fires. The FLAME and the XTF were designed with optical access for advanced optical diagnostics to further the multidisciplinary sciences underlying turbulent reacting flow as part of the goal to make fire models more predictive. In addition to weapon system owners, other nuclear weapons users include the computational model developers. The test facilities within the TTC are unique in the world in that they were specifically designed (by CFD fire models) to provide controlled, reproducible boundary conditions necessary to validate fire and thermal response models. The TTC is operated by a staff of twelve.

Electromagnetic/Environmental/Lighting, Strategic Defense Facility. The Electromagnetic Environs Complex consists of three buildings located on approximately 19.5 acres. This 103,185 total square foot facility consists of the following capabilities: Mode-Stirred and Anechoic Chambers—The Mode-Stirred and Anechoic Chambers are used alone or in combination for Radio Frequency (RF) measurements. The Mode-Stirred Chamber provides a reverberant environment in which electromagnetic fields are statistically uniform, providing 360-degree, homogeneous coverage of test items in a single test run regardless of test item orientation. The Anechoic Chamber simulates a free-field environment where test items are illuminated in a directional manner dependent on the source antenna. Both types of testing have their advantages and disadvantages, but the combination supports the strengths of both. In addition, testing in these chambers can be done at 220 megahertz (MHz) and above. The combination of these chambers with the Electromagnetic Environments Simulator (EMES) in TA-I (250 MHz and below) allows for electromagnetic characterization over a very broad frequency range.

Electromagnetic Environments Simulator (EMES). EMES is a building-sized Transverse Electromagnetic (TEM) cell, which supports electromagnetic plane wave illumination of test objects. Two electromagnetic (EM) sources are used at the facility, low-frequency Electromagnetic Radiation (EMR) and an Electromagnetic Pulse (EMP) simulator. The TEM cell structure can theoretically support frequencies as low as DC (or 0 hertz [Hz]); however, the current amplifier at the facility can be used from 100 kHz to 250 MHz. This gives good low-frequency coverage to support higher frequency measurements in the Mode-Stirred and Anechoic Chambers in TA-IV. The EMP simulator design is based on Mil-Std 2169B requirements and is unique in its fast-rise-time pulse combined with a large range of electric field amplitudes that can be generated.

EMES supports a portion of the frequency range of nuclear-weapon STS EMR environments as well as high-altitude EMP environments. Every weapon has these environmental requirements in most, if not all, weapon stages called out in their respective STSs. EMES was used during 2006 in the EMR mode to characterize electromagnetic leakage into the air-launch cruise missile (ALCM) and Advanced Cruise Missile as part of the W80-3 qualification effort. While the W80-3 program was cancelled, the cruise missile information is still useful for the W80-1 stockpile system, and it has been planned to include this information in the W80 STS. EMES was also used in 2003 and 2004 to conduct EMP testing of commercial items for the congressionally chartered EMP commission.

SNL/NM Lightning Simulator. The SNL/NM Lightning Simulator can replicate severe direct-strike lightning to meet stockpile needs for assuring nuclear safety in lightning environments. The Lightning Simulator can also be used to generate nearby lightning environments, which are a normal-environment concern for reliability of electronic systems. It can generate lightning-like pulses that meet the top one percent requirements for peak current, pulse width, and rise-time in nuclear weapon STS requirements documents. In the last two years, the Lightning Simulator has been used to characterize a variety of stockpile and new development Lightning Arrestor

Connectors and to qualify the nuclear safety of the W76-1 in lightning environments. The SNL/NM Lightning Simulator is housed in Building 888 on the east end of TA-I at SNL/NM. In the past, an F4 airplane was instrumented and tested at this facility. This part of TA-I has been significantly developed, virtually eliminating the opportunity to test large items outdoors.

SNL/CA Environmental Test Complex. The California Environmental Test Complex provides a number of table-top capabilities (shock, vibration, acceleration, climatic chambers, mass properties, radiography, etc.) used for proof and qualification of weapon systems, subsystems, and components. In addition to the ongoing weapon design activities between LLNL and SNL/CA, this complex also supports WFO (DoD, Department of Homeland Security, Engineering Campaign Six, Model Validation) projects. The shock, vibration, and climatic chambers have been used by the W80 Program for margin testing. They are also used for weapon JTA and GTS activities.

A.10.1.4 *Environmental Test Facilities at Nevada Test Site*

Two environmental testing facilities are located on NTS, the DAF and the U1a Facility. Both DAF and U1a are considered “user facilities,” operated by LLNL and LANL respectively on behalf of the NNSA Nevada Site Office with the site manage and operation providing support, primarily in the area of facility maintenance. Under this concept, the facility is maintained in a “warm standby” condition ready to accept programmatic work. The assigned personnel maintain the facility, its authorization basis, and ensure that programmatic work is properly authorized. The actual programmatic work is conducted by project teams that deploy to the facility to conduct their activities. Thus staffing levels would only reflect the personnel required to maintain the facility in a warm standby condition and not programmatic work. In general, waste streams are associated with project activity and not routine day-to-day activities. These facilities are described below:

Device Assembly Facility Area (DAF). The DAF (Figure A.10-15) is a collection of more than 30 individual steel-concrete buildings connected by a rectangular common corridor. The entire complex, covered by compacted earth, spans an area of 120,000 square feet. It is located within a 19-acre high security area. The operational buildings in the DAF include five assembly cells (Gravel Gerties); four high bays; three assembly bays, one of which houses a glovebox, and one of which houses a down draft table; and two radiography bays. Five staging bunkers provide space for staging nuclear components and high explosives. All material packages arrive or depart the DAF through either of two shipping or receiving bays. The support buildings include three small vaults for staging quantities of high explosives, or SNM; two decontamination areas; two buildings providing laboratory space; and an administration area. Supporting the DAF are an entry guard station and a mechanical/electrical building.

In support of the Critical Experiments Facility (CEF) project, a portion of the DAF (two assembly cells, two high bays, two staging bunkers, and one of the laboratory areas) is undergoing modifications to house the critical assembly machines being moved from Los Alamos TA-18. The nuclear material associated with CEF has been moved to the DAF. This material is being used by various programs to measure the radiation signature of the nuclear material in different configurations. The DAF also supports the assembly of subcritical experiment packages and has been designated as the site for receipt of a damaged nuclear weapon that can not be taken to Pantex. The Nevada Site Office has received direction from NNSA’s Principal Assistant Deputy Administrator for Operations to have the approved safety authorization basis for the DAF in place to support a September 2009 operational readiness date to perform specific weapons program work. DAF is being proposed as one siting option for the Engineering Test Bay (Building 334, LLNL), and the ACRR (SNL/NM) has one option within the DAF PIDAS (security area).

U1a Complex. The U1a Complex (Figure A.10-16) is a standard industrial hazard facility with demonstrated capabilities to safely conduct nuclear activities including dynamic experiments involving the combination of HE with SNMs. In its current configuration it consists of approximately 1.25 miles of underground drifts located approximately 1,000 feet beneath the surface. Three shafts connect the underground drifts with the surface and provide personnel access, extensive materials handling capabilities, numerous utility systems, and a large diagnostic cable inventory. Improved structures, aboveground, are small and sufficient to enter and exit the facility. Additional underground space can be mined out and tailored to meet experiment/facility requirements. Offices, shops, and diagnostic recording facilities, and parking are located on the surface.

Because of its unique location, 1,000 feet beneath the surface, U1a offers the potential for greatly reducing security costs associated with nuclear facilities and of mitigating any potential offsite exposure to radiation. It has been proposed as a potential site for ACRR (SNL/NM) and for the ETB (Building 334, LLNL).

Appendix B
ENVIRONMENTAL IMPACT METHODOLOGY

Appendix B

ENVIRONMENTAL IMPACT METHODOLOGY

This appendix briefly describes the methods used to assess the potential direct, indirect, and cumulative effects of the alternatives in the Complex Transformation Supplemental Programmatic Environmental Impact Statement (Complex Transformation SPEIS). Included are impact assessment methods for land use, visual resources, site infrastructure, air quality and noise, water resources, geology and soils, biological resources, cultural and archeological resources, socioeconomics, human health and safety, accidents, environmental justice, transportation, waste management, and cumulative impacts.

B.1 LAND RESOURCES

B.1.1 Description of Affected Resources and Region of Influence (ROI)

The analysis of impacts to land use considers land use plans and policies, zoning regulations, and existing land use as appropriate for each site analyzed. The potential impacts associated with changes to land use as a result of the alternatives are also discussed.

B.1.2 Description of Impact Assessment

Land use changes associated with the implementation of the Complex Transformation SPEIS could potentially affect both developed and undeveloped land at each site. Potential changes in land use, if any, would likely occur within the existing boundaries of the alternative sites. However, the use of lands adjacent to or in the vicinity of U.S. Department of Energy (DOE) sites (i.e., non-DOE land) could be affected by these changes, including new or expanded safety zones.

Land use changes associated with construction and operation of new facilities could potentially affect both developed and undeveloped land. Land use impacts were assessed based on the extent and type of land that would be affected. The land use analysis also considers potential direct impacts resulting from the conversion of, or the incompatibility of, land use changes with special status lands such as national parks/monuments or prime farmland, and other protected lands such as Federal- and State-controlled lands (e.g., public land administered by the Bureau of Land Management (BLM) or other Government agencies). DOE did not consider the indirect land use impacts that could result from construction and operation of new facilities. In assessing impacts to land, the programmatic and project-specific methodologies were the same.

B.2 VISUAL RESOURCES

B.2.1 Description of Affected Resources and Region of Influence

Visual resources include natural and man-made physical features that give a particular landscape its character and value. The feature categories that form the overall impression a viewer receives of an area include landform, vegetation, water, color, adjacent scenery, rarity, and manmade (cultural) modifications.

B.2.2 Description of Impact Assessment

Criteria used in the visual resources analysis include scenic quality, visual sensitivity, distance, and/or visibility zones from key public viewpoints. The analysis is comparative in nature and consists of a qualitative examination of potential changes in visual resources, scenic values (attractiveness), and view corridors (visibility). Aspects of visual modification examined include site development or modification activities that could alter the visibility of structures at each of the alternative sites or obscure views of the surrounding landscape, and changes in land cover that could make structures more visible. In assessing impacts to visual resources, the programmatic and project-specific methodologies were the same.

B.3 SITE INFRASTRUCTURE

B.3.1 Description of Affected Resources and Region of Influence

Potentially affected site infrastructure resources include ground transportation systems, electrical distribution systems, fuels (primarily natural gas), and water. The ROI is considered to be all the land area and resources within the site boundary

B.3.2 Description of Impact Assessment

The assessment of potential impacts to site infrastructure focuses on the ability of the sites to support any of the facilities assessed in the SPEIS. The programmatic analysis focuses on supporting electrical power requirements. Other infrastructure demands, such as fuels or industrial gases, are not expected to be major discriminators for the programmatic alternatives analyzed in this SPEIS. The analysis addresses whether there is sufficient available and peak capacity to support Complex Transformation. Projections of electricity availability, site development plans, and other DOE mid- and long-range planning documents are used to project site infrastructure conditions. The project-specific analyses identify any significant infrastructure demands. In general, the infrastructure demands of all the project-specific alternatives would be minor compared to the existing infrastructure that exists at the sites analyzed.

B.4 AIR QUALITY AND NOISE

B.4.1 Nonradiological Air Resources

B.4.1.1 *Description of Affected Resources and Region of Influence*

The air quality assessment evaluates the consequences of criteria and hazardous/toxic air pollutants associated with each alternative at each candidate site. The criteria pollutants are specified in 40 *Code of Federal Regulation* (CFR) Part 50, the U.S. Environmental Protection Agency (EPA) Regulations on National Primary and Secondary Ambient Air Quality Standards (NPSAAQS). The hazardous/toxic air pollutants are listed in Title III of the 1990 *Clean Air Act* (CAA) Amendments, the National Emissions Standards for Hazardous Air Pollutants (NESHAPs) (40 CFR Part 61), and standards or guidelines proposed or adopted by the respective States.

Current information on emissions from existing operations and ambient air concentrations have been obtained for each alternative site (e.g., site annual reports, recent Environmental Impact Statements [EISs]).

B.4.1.2 *Description of Impact Assessment*

Industrial Source Complex Model 3 (ISC3) is a steady-state Gaussian plume model which can be used to assess pollutant concentrations from a wide variety of sources associated with an industrial complex. This model can account for settling and dry deposition of particles; downwash; point, area, line, and volume sources; plume rise as a function of downwind distance; separation of point sources; and limited terrain adjustment. ISC3 operates in both long-term and short-term modes. The screening version of ISC3 is SCREEN3. The impacts of construction emissions are evaluated based on results of SCREEN3 dispersion model and Industrial Source Complex Short Term (ISCST) model. The SCREEN3 model estimates pollutant concentrations (in units of $\mu\text{g}/\text{m}^3$) as a function of distance from the source. EPA-approved conversions are applied to adjust the predicted concentrations for comparison to the ambient air quality standards (NRC 2005). Pollutant emissions that contribute to or cause a violation of air quality standards are considered to have a major impact. Mitigation measures are identified where appropriate.

For the programmatic alternatives, which have the potential to disturb significant land during construction, modeling was performed to determine if PM_{10} emissions (which were considered to be the most likely criteria pollutant to exceed regulatory limits) at the site boundary would exceed regulatory limits. Fugitive dust generated during the clearing, grading, and other earth-moving operations is dependent on a number of factors including silt and moisture content of the soil, wind speed, and area disturbed. Fugitive emissions were estimated based on the EPA emission factor of 1.20 tons per acre per month of activity (EPA 1995). This emission factor represents total suspended particulates (i.e., particles less than 30 microns in diameter). A multiplication factor of 0.75 was used to correct the emission rate to one for PM_{10} (EPA 1995). Also, it was assumed that water would be applied to disturbed areas. This would reduce emission rates by about 50 percent.

The impacts of nonradiological emissions from operations are evaluated based on results of the ISCST3 dispersion model. The predicted concentrations at the nearest site boundary are added to regional background concentrations for comparison with the ambient air quality standards to assess compliance. Additional qualitative evaluation is applied to describe potential adverse impacts for proposed sites that are located within 50 miles of a Federal Class I area. Pollutant emissions that contribute to or cause a violation of air quality standards are considered to have a major impact.

For the project-specific alternatives, increases in air emissions were compared to emissions from existing operations to determine if detailed modeling was necessary to demonstrate National Ambient Air Quality Standards (NAAQS) compliance. For minor increases and/or situations in which the ambient concentrations of pollutants are well below NAAQS standards, modeling was not necessary.

B.4.2 Radiological Air Resources

B.4.2.1 *Description of Affected Resources and Region of Influence*

Inhalation and ingestion are the two primary modes of exposure from radionuclide emissions. Inhalation occurs while the radionuclides are still airborne. The ROI for inhalation exposure is considered the DOE site boundary because Federal regulations limit the airborne dose exposures at the site boundary.

Radionuclide emissions will eventually settle back to the earth onto vegetation, soils, and waterbodies. Vegetation can then absorb radionuclides from the soils, and fish can absorb radionuclides from the water. When people and wildlife eat the plants or fish, they can potentially ingest radionuclides. Wildlife and waterbodies are generally not confined within the site boundary; therefore, ingestion impacts can extend to a larger region, but are generally bounded within 50 miles of the point of release.

Current information on dose to non-involved workers, maximally exposed individual (MEI), and collective dose to surrounding population due to radiological releases from existing operations has been obtained from each alternative site (e.g., site annual reports, recent EISs). Impacts from implementation of Complex Transformation programmatic alternatives were modeled at each potentially affected site using the CAP-88 computer model, version 3. The CAP-88 model was developed by EPA for assessments of both collective populations and MEIs.

B.4.2.2 *Description of Impact Assessment*

It is expected that radiological impacts from Complex Transformation to workers and surrounding population will be predominantly via the air pathway because no effluents are anticipated to be released. The impacts from implementation of Complex Transformation at each site are based on a combination of site-specific and technology-specific data. Site-specific data required for modeling include meteorology (e.g., wind speed, wind direction, precipitation), population distribution (for impacts on population), agricultural production (distribution about the release, types and quantity produced), and distances and directions to the fenceline (or other locations at which the public could be exposed; and for MEI calculations).

Operations data required for the calculations include release rates (i.e., curies per year by nuclide) and modes of release (e.g., stack height, stack velocity, diffuse release area). Doses have been calculated for the general population and for non-involved workers (i.e., onsite workers not directly involved in the pit manufacturing operations). Doses were converted to impacts as explained in Section B.11.2. For the project-specific tritium analysis, radiological emissions associated with tritium alternatives were used to estimate potential impacts based on comparisons to the impacts from other tritium emissions. There were no other radiological releases associated with other project-specific analyses.

B.4.3 Noise

B.4.3.1 *Description of Affected Resources and Region of Influence*

Current information on noise from existing operations has been obtained from each alternative site (e.g., site annual reports, recent EISs). Resources potentially affected by noise include wildlife and sensitive receptors in the vicinity of the project site. Construction noise levels would generally be higher than operation noise levels; therefore, the ROI is the radial area within 500–1,000 feet of the project site, depending on the specific conditions affected noise propagation that include topography and presence of large structures or dense vegetation.

B.4.3.2 *Description of Impact Assessment*

The methodology used to determine environmental impacts of Complex Transformation at each of the alternative sites with respect to noise involves a two-step analysis. The first step is to identify noise levels associated with implementation of Complex Transformation and determine if they are likely to exceed noise levels defining ambient background conditions. If these noise levels could exceed ambient conditions, the analysis determines whether the impacts are significant, using a qualitative assessment of the increase or decrease in noise level experienced by receptors near the source.

In the noise assessment, DOE included a description of the noise sources and noise levels anticipated for construction. Unmitigated logarithmic sound attenuation is assumed to estimate the distance needed for sound levels to achieve an acceptable level for both human and wildlife populations. It is anticipated that operational noise levels would be consistent with other noise sources at the site, and that they would not impose an appreciable change to the overall noise environment. In assessing noise impacts, the programmatic and project-specific methodologies were the same.

B.5 WATER RESOURCES

B.5.1 Surface Water

B.5.1.1 *Description of Affected Resources and Region of Influence*

Surface waters include rivers, streams, lakes, ponds, playas, and reservoirs. An inventory of surface water resources in the project ROI, a description of areas in the ROI currently using surface water, general flow characteristics, reservoirs, and an identification of classifications applicable to the surface water have been used to determine the affected environment at each alternative site. Emphasis has been placed on those waterbodies that have the potential to be impacted during the facility's operations over the timeframe analyzed. Current wastewater treatment facilities and discharges have also been described in the baseline.

The affected environment descriptions for water quality of potentially affected receiving waters for each site have been developed by reviewing current monitoring data to identify parameters that exceed water quality criteria. Monitoring reports for discharges permitted under the National

Pollutant Discharge Elimination System (NPDES) program and state regulations have been examined for exceeding permit limits or requirements. In addition, surface water quality has been evaluated in terms of whether the water body supports the designated use assigned by the individual states under the *Clean Water Act* (CWA).

B.5.1.2 *Description of Impact Assessment*

The assessment of potential water quality impacts includes evaluation of the type (wastewater effluent), rate, and potential discharge constituents. Environmental consequences may result if: 1) The surface water flow rate is decreased to the point where the capacity of the receiving waterbody to assimilate discharges is noticeably diminished; 2) The proposed increases in discharge cannot comply with NPDES permit limits on flow rates; 3) The proposed increases in discharges contribute to receiving waters already identified as exceeding applicable surface water quality criteria; or 4) The proposed increases in effluent cannot comply with pretreatment limits on flow rates or specific constituent contributions without additional treatment. In addition, any expected increases in surface water runoff are discussed along with the potential impact to surface water features at each site.

B.5.2 **Groundwater**

B.5.2.1 *Description of Affected Resources and Region of Influence*

As part of the affected environment section of the SPEIS, groundwater is described in terms of the local aquifers' extent and yield, thickness, EPA classification, and recharge and discharge areas for each site. Areas in the ROI currently experiencing groundwater overdraft and related problems, and areas that have experienced large water table declines are described if applicable. Current potable and process water supplies and systems, water rights agreements, and water allocation of the site areas are also described. The latest environmental data, including maps, reports, and other literature, are used to the maximum extent possible to evaluate these conditions.

The affected groundwater quality at the site was evaluated by reviewing current monitoring data and identifying any parameters that exceed State water quality standards, drinking water standards, and DOE derived concentration guides for radionuclides in water. Parameters that exceed water quality criteria are further described and contaminant plumes delineated, where possible.

B.5.2.2 *Description of Impact Assessment*

An assessment of potential groundwater quality environmental consequences associated with pollutant discharges during facility modification and operation phases (e.g., process wastes and sanitary wastes) is examined for each site to determine if a direct input to groundwater could occur. The results of the groundwater quality projections are then discussed relative to Federal and State groundwater quality standards, effluent limitations, and safe drinking water standards to assess the acceptability of each alternative. Operation parameters from the alternatives with the potential to further degrade existing groundwater quality have been identified.

The potential effects to groundwater availability are assessed for each alternative at each candidate site by evaluating whether the proposed project: 1) Increases groundwater withdrawals in areas already experiencing overdraft and other related problems (e.g., land subsidence); 2) Potentially decreases groundwater levels causing a substantial depletion of the resource; 3) Water requirements exceed the allotment, water rights, or available supply limits, if present; or 4) Reduces or ceases the flow of one or more major springs. Suitable mitigation measures to reduce impacts are identified and discussed. In assessing impacts to water resources, the programmatic and project-specific methodologies were the same.

B.5.3 Floodplains

Floodplains include any lowlands that border a water body and encompass areas that may be covered by overflow during flood stages. As part of the affected environment discussion at each site, floodplains are identified from maps and environmental documents. Any potential facility location within a 100-year floodplain or a critical action in a 500-year floodplain is assessed for environmental consequence. The 500-year floodplain evaluation is of concern for activities determined to be critical actions for which even a slight chance of flooding would be intolerable. Appropriate mitigation measures are identified to minimize potential floodplain impacts. In assessing impacts to floodplains for both the programmatic and project-specific alternatives, if any potential facility were located in a 100-year or 500-year floodplain, this was identified.

B.6 GEOLOGY AND SOILS

B.6.1 Description of Affected Resources and Region of Influence

The analysis of geology and soils examines the ROI, or lands occupied by and immediately surrounding each alternative site. Information on the regional structural geology, stratigraphy, and soils have been collated and summarized.

In addition, the seismicity of the region surrounding each site is evaluated to provide a perspective on the probability of earthquakes in the area and their likely severity. This information is used to provide input to the evaluation of accidents due to natural phenomena.

B.6.2 Description of Impact Assessment

The proposed project areas at each site are evaluated for the amount of disturbance that may affect the geology and/or soils of the areas under study. These impacts may include, among others, potential erosion impacts and impacts to potential geologic economic resources. Impacts, if any, have been evaluated and a determination made as to severity. Possible mitigation has also been identified for adverse impacts. In assessing impacts to geology/soils, the programmatic and project-specific methodologies were the same.

B.7 BIOLOGICAL RESOURCES

B.7.1 Description of Affected Resources and Region of Influence

The affected biological resources may include both terrestrial and aquatic plants and animals. Subsets of these categories include threatened and endangered (T&E) species, and specific protected habitats, such as wetlands. Biological resources have been described within the ROI, which is defined by the lands occupied by and immediately surrounding each alternative site. In the case of T&E species, and other special interest species, biotic information includes species distribution within the county of each alternative site location. Biological data from earlier projects, wetlands surveys, and plant and animal inventories of the proposed sites were reviewed to identify the locations of plant and animal species and wetlands and to identify the impact from physical, chemical, or radiological stressors. Descriptions are at a summary level and focus within four categories: terrestrial resources, wetlands, aquatic resources, and T&E species.

B.7.2 Description of Impact Assessment

During construction, impacts to biotic resources, including terrestrial resources, wetlands, aquatic resources, and T&E species, may result from land-clearing activities, erosion and sedimentation, and human disturbance and noise. Operations may affect biotic resources as a result of changes in land use, emission of radionuclides, water withdrawal, wastewater discharge, and human disturbance and noise. In general, potential impacts have been assessed based on the degree to which various habitats or species could be affected by an alternative. Where appropriate, impacts have been evaluated with respect to Federal and State protection regulations and standards.

The analysis of impacts of Complex Transformation programmatic alternatives to biological resources were addressed at a level that was appropriate to allow for a comparison of alternatives using the best information available. In general, the programmatic analysis of impacts to biological resources presented in the Complex Transformation SPEIS is qualitative rather than quantitative. Quantitative analyses would be performed in follow-on site- and project-specific *National Environmental Policy Act* (NEPA) documentation. For the project-specific analyses, the analysis evaluated the amount of land disturbed, and if any critical habitats or special status species could be affected, these were identified.

B.7.2.1 Terrestrial Resources

Impacts of the Complex Transformation proposed alternatives on terrestrial plant communities have been evaluated by comparing data on site vegetation communities to proposed land requirements for construction and operation. The analysis of impacts to wildlife is based to a large extent on plant community loss or modification, which directly affects animal habitat. The loss of important or sensitive habitats and species is considered more important than the loss of regionally abundant habitats or species. Impacts on biotic resources from the release of radionuclides were not evaluated because there are no data to suggest that biotic resources are more adversely affected than humans.

B.7.2.2 *Wetlands*

The potential direct loss of wetlands resulting from implementation of Complex Transformation have been addressed in a way similar to the evaluation of impacts on terrestrial plant communities; that is, by comparing data on site or area wetlands to proposed land requirements. Sedimentation impacts have been evaluated based on the proximity of wetlands to Complex Transformation project areas. Impacts resulting from wastewater discharge and other transport pathways (e.g. spills) into a wetland system have been evaluated, recognizing that effluents would be required to meet applicable Federal and State standards. In assessing impacts to wetlands, the programmatic and project-specific analyses identified whether any wetlands would likely be affected by new facilities.

B.7.2.3 *Aquatic Resources*

Impacts to aquatic resources resulting from sedimentation and wastewater discharge have been evaluated as described for wetlands. Potential impacts from radionuclides have not been addressed for the same reasons described for terrestrial resources.

B.7.2.4 *Threatened and Endangered Species*

Impacts on T&E species and other special interest species have been determined in a manner similar to that used to describe terrestrial and aquatic resources since the sources of potential impacts are similar. A list of species potentially present on each candidate site or in proximity to the candidate site or area has been developed using information obtained from the U.S. Fish and Wildlife Service (USFWS) and appropriate State agencies' databases. This list, along with consideration of site environmental and engineering data, and provisions of the *Endangered Species Act*, have been used to evaluate whether the various Complex Transformation siting alternatives could impact any threatened or endangered plant or animal (or its habitat). In assessing impacts to T&E species, the programmatic and project-specific analyses identified whether any T&E species would likely to be affected by new facilities.

B.8 **CULTURAL AND ARCHEOLOGICAL RESOURCES**

B.8.1 **Description of Affected Resources and Region of Influence**

Cultural resources are those aspects of the physical environment that relate to human culture and society, and those cultural institutions that hold communities together and link them to their surroundings. For this SPEIS, cultural resources are divided into three general categories: archeological resources, historic resources, and Native American resources. A cultural resource can fall into more than one of these categories due to use through a long period of time or multiple functions.

Archeological resources mean any material remains of past human life or activities which are of archeological interest (Public Law 96-95; 16 USC 470aa-mm). By definition, these resources predate written records. Historic resources include the material remains and landscape alterations that have occurred since the arrival of Europeans to the area. Due to the focus of this SPEIS on DOE facilities, historic resources often include resources associated with the Manhattan Project,

World War II, and the Cold War. Native American resources are material remains, locations, and natural materials important to Native Americans for traditional religious or heritage reasons (Public Law 101-601). These resources are rooted in the community's history or are important in maintaining cultural identity.

The ROI includes the area within which cultural and archeological resources could be physically impacted by construction and operation activities include the area in and around the footprint of the proposed facilities. The ROI for all alternatives also includes cultural resources nearby that could have their historic settings adversely affected by the introduction of the new facility into the viewshed.

B.8.2 Description of Impact Assessment

The analyses of potential impacts to cultural and archeological resources are very similar because the two types of resources can be affected by the alternatives in much the same manner. The analyses address potential direct and indirect impacts at each candidate site from construction activities and operation of the facility. Most potential impacts are those resulting from groundbreaking activities; however, other types of impacts are considered, such as reduced access by practitioners to resources, introduction of visual, audible, or atmospheric elements out of character with the resources, and increased visitation to sensitive areas. Analyses of impacts take into consideration the location of the reference site, the acreage required for the proposed facility, and the likelihood of resources being located in that area. In assessing potential impacts to cultural and archeological resources, the programmatic and project-specific methodologies were the same.

B.9 SOCIOECONOMICS

The analysis of socioeconomics describes impacts on local and regional socioeconomic conditions and factors including employment, economy, population, housing, and community services at each alternative site considered in the Complex Transformation SPEIS. The potential for socioeconomic impacts is greatest in those local jurisdictions immediately adjacent to each site. Therefore, potential socioeconomic impacts are assessed using a geographic ROI. ROIs are used to assess potential effects on the economy as well as effects that are more localized in political jurisdictions surrounding the sites.

For each site, socioeconomic impacts were estimated using two geographic areas. First, an ROI was identified based on the distribution of residences for current DOE and contractor employees. The ROI is defined as those counties where approximately 90 percent of the current DOE and contractor employees reside. The ROI for each candidate site is presented in Table B.9-1. This residential distribution reflects existing commuting patterns and attractiveness of area communities for people employed at each site and is used to estimate the future distribution of direct workers associated with the each alternative. The evaluation of impacts is based on the degree to which change in population affects the housing market and community services.

The ROI for each site encompasses an area that involves trade among and between regional industrial and service sectors. It is characterized by strong economic linkages between the

communities located in the region. These linkages determine the nature and magnitude of multiplier effects on economic activity (i.e., purchases, earnings, and employment) at each candidate site. Demographic characteristics included in the socioeconomic analysis within the ROI include population, housing, and community services.

The U.S. Bureau of Economic Analysis measures multiplier effects of interindustry linkages with the Regional Input-Output Modeling System (RIMS II). RIMS II is based on an accounting framework called an input-output table. An input-output table shows, for each industry, industrial distributions of input purchased and outputs sold. RIMS II Total Direct-Effect Multipliers has been used in the Complex Transformation SPEIS to estimate additional regional employment and income generated by employment and income directly associated with the Proposed Action. In assessing potential impacts to socioeconomics for the project-specific alternatives, the analysis focused on identifying jobs lost or added and compared these changes to the baseline. For the flight testing alternatives that would cease operations at the Tonopah Test Range (TTR), a more detailed socioeconomic analysis was performed, due to the potential to cause more significant impacts. That specific methodology is described in Section 5.15.4.2.1.

Table B.9-1—Candidate Sites’ Region of Influence

LANL	LLNL	NTS	TTR	Pantex	SNL	WSMR	SRS	Y-12
New Mexico	California	Nevada	Nevada	Texas	New Mexico	New Mexico	Georgia	Tennessee
Los Alamos	Alameda	Clark	Esmeralda	Armstrong	Bernalillo	Dona Ana	Columbia	Anderson
Rio Arriba	Contra Costa	Nye	Nye	Carson	Sandoval	Lincoln	Richmond	Knox
Santa Fe	San Joaquin	Lincoln	Lincoln	Potter	Torrance	Otero	South Carolina	Loudon
	Stanislaus			Randall	Valencia	Sierra Socorro	Aiken Barnwell	Roane

B.10 ENVIRONMENTAL JUSTICE

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, signed by President William J. Clinton in February 1994, requires each Federal agency to formulate a strategy for addressing environmental issues in human health and environment related programs, policies, planning and public participation processes, enforcement, and rulemaking. The White House memorandum accompanying the Executive Order directs Federal agencies to “analyze the environmental effects...of Federal actions, including effects on minority communities and low income communities when such analysis is required by NEPA.”

Any disproportionately high and adverse human health effects on minority populations or low-income populations that could result from Complex Transformation at any of the proposed alternative sites have been analyzed. The minority population and low-income population composition of the area surrounding the proposed alternative sites will be compared to that of a larger geographic area to determine whether possible impacts of siting Complex Transformation at a particular site will have a disproportionately high and adverse impact on minority or low-income populations. In assessing potential environmental justice impacts, the programmatic and

project-specific methodologies were the same. As a first step, the analysis focused on whether there would be any high and adverse human health effects. If none were determined, then there was no need to determine if these high and adverse human health effects were disproportionate. For this PEIS, none of the health effects were determined to be both high and adverse.

B.11 HEALTH AND SAFETY

Potential impacts of construction and operation of facilities on public and worker health and safety include cancer fatalities resulting from exposure to radionuclides, and occupational injuries and illnesses resulting from facility construction and operation. Included in this appendix is a brief discussion of the methodology for analysis of impacts to public and worker health and safety.

B.11.1 Description of Affected Resources and Region of Influence

Potential impacts to human health and safety posed by Complex Transformation include radiological and nonradiological exposure pathways and occupational injuries, illnesses, and fatalities resulting from construction activities and normal (accident-free) operations of the completed facility. Exposure pathways include inhalation, immersion, ingestion, and exposure to external sources. Occupational regions of influence include involved and uninvolved workers. Nonoccupational ROIs for the public include the MEI and the general population surrounding the candidate sites.

Because NNSA operations have the potential to release measurable quantities of radionuclides to the environment that result in exposure to the worker and the public, NNSA conducts environmental surveillance and monitoring activities at its sites. These activities provide data that are used to evaluate radiation exposures that contribute doses to the public. Each year, environmental data from the NNSA sites are collected and analyzed. The results of these environmental monitoring activities are summarized in an Annual Site Environmental Report (ASER). The environmental monitoring conducted at most NNSA sites consists of two major activities: effluent monitoring and environmental surveillance.

Effluent monitoring involves the collection and analysis of samples or measurements of liquid (waterborne) and gaseous (airborne) effluents prior to release into the environment. These analytical data provide the basis for the evaluation and official reporting of contaminants, assessment of radiation and chemical exposures to the public, and demonstration of compliance with applicable standards and permit requirements.

Environmental surveillance data provide a direct measurement of contaminants in air, water, groundwater, soil, food, biota, and other media subsequent to effluent release into the environment. These data verify the NNSA site's compliance status and, combined with data from effluent monitoring, allow the determination of chemical and radiation dose and exposure assessment of NNSA operations and effects, if any, on the local environment. The effluent and environmental surveillance data presented in the ASERs were used as the primary source of data for the analysis of radiation exposure to the public for the No Action Alternative.

The public health consequences of radionuclides released to the atmosphere from normal operations at NNSA sites are characterized and calculated in the applicable ASER. Radiation doses are calculated for the MEI and the entire population residing within 50 miles of the center of the site. In this SPEIS, dose calculations from normal operations were made using the CAP-88 package of computer codes, version 3 (EPA 2008), which was developed under EPA sponsorship to demonstrate compliance with 40 CFR Part 61, Subpart H, which governs the emissions of radionuclides other than radon from DOE facilities. This package implements a steady-state Gaussian plume atmospheric dispersion model to calculate concentrations of radionuclides in the air and on the ground and uses Regulatory Guide 1.109 (NRC 1977) food-chain models to calculate radionuclide concentrations in foodstuffs (vegetables, meat, and milk) and subsequent intakes by humans.

Meteorological data used in the calculations were in the form of joint frequency distributions of wind direction, wind speed class, and atmospheric stability category. For occupants of residences, the dose calculations assume that the occupant remained at home (actually, unprotected outside the house) during the entire year and obtained food according to the rural pattern defined in the NESHAP background documents (EPA 1989). This pattern specifies that 70 percent of the vegetables and produce, 44.2 percent of the meat, and 39.9 percent of the milk consumed are produced in the local area (e.g., a home garden). The remaining portion of each food is assumed to be produced within 50 miles of the site. The same assumptions are used for occupants of businesses, but the resulting doses are divided by two to compensate for the fact that businesses are occupied for less than one-half a year, and that less than one-half of a worker's food intake occurs at work. For collective effective dose equivalent (EDE) estimates, production of beef, milk, and crops within 50 miles of the site was calculated using production rates provided with CAP-88.

B.11.2 Description of Impact Assessment

Radiological impacts have been assessed for workers (both involved and non-involved in Complex Transformation operations) and for the public (MEI and population). Health impacts to involved workers from Complex Transformation operations are based on information from the Complex Transformation alternative data report [NNSA 2007]. NNSA converted radiological doses to health effects (latent cancer fatalities [LCF]) using a multiplier of 600 fatal cancers per 10^6 person-rem based on "Radiation Risk Estimation from Total Effective Dose Equivalents (TEDEs)," (Office of Environmental Policy and Guidance, Washington, DC. August 9.) Similarly, health impacts to the MEI and population are based on doses calculated by the radiological air analyses. Continuous exposure over the year is assumed. For worker exposures, impacts were estimated based on estimates of the number of radiation workers and the average radiological dose, based on information from the Complex Transformation alternative data report [NNSA 2007]. In assessing potential human health impacts, the programmatic and project-specific methodologies were the same.

B.11.3 Occupational Safety

Occupational injury, illness, and fatality estimates are evaluated using occupational incidence rates of major industry groups, DOE, and DOE contractors. When site-specific evaluations are performed, DOE Computerized Accident/Incident Reporting System (CAIRS) data is used. Since

activities similar to Complex Transformation operations or facility construction are not being performed at all of the potential Complex Transformation sites, U.S. Department of Labor, Bureau of Labor Statistics (BLS) injury, illness and fatality information for similar activities have been used. These rates are compared to person-hour estimates for the project. Occupational injury, illness, and fatality categories used in this analysis are in accordance with Occupational Safety and Health Administration (OSHA) definitions. Incident rates were developed for facility construction and facility operations.

Facility operations were evaluated to determine if any chemical-related health impacts would be associated with normal (accident-free) operations. Initial screens for the hazard analysis did not result in the identification of any controls necessary to protect the public or workers from direct chemical exposures. Facility design features that minimize the worker exposures during facility operations act as defense-in-depth controls. In addition to these controls, worker protection is augmented by facility safety programs such as Integrated Safety Management System (ISMS), work planning, chemical hygiene, industrial hygiene personnel monitoring, and emergency preparedness. In assessing potential human health impacts, the programmatic and project-specific methodologies were the same.

B.12 ACCIDENT ANALYSIS

B.12.1 Description of Affected Resources and Region of Influence

Potential impacts to human health and safety from postulated accidents include radiological and nonradiological exposures. For both radiological and chemical accidents associated with operations, the affected resources are the facility and site workers and the offsite population. Specifically, for radiological accidents, the impact is incremental adverse health effects (i.e., LCFs) for a noninvolved worker, the offsite MEI, and the offsite population within 50 miles of each alternative site. For nonradiological accidents, airborne concentrations and potential health effects have been calculated for the noninvolved worker and the offsite MEI.

B.12.2 Description of Impact Assessment

Postulated accidents can be initiated by internal operations (e.g., fire, spill, criticality), external events (e.g., airplane crash), or natural phenomena (e.g., earthquake, flood). The Complex Transformation SPEIS evaluates unmitigated accident scenarios chosen to reflect the range and kinds of accidents that are postulated. The range of accidents is from low frequency high consequence events (probabilities as low as approximately 10^{-6}) to high frequency-low consequence events (probabilities as high as approximately 10^{-2}) in order to assess potential risks. The spectrum of accidents and their calculated impacts should provide a baseline for each site that can be used to judge the environmental implications of locating particular facilities and missions at different sites. The accident analyses were performed in accordance with the *Recommendations for Analyzing Accidents Under the National Environmental Policy Act* (DOE 2002b). Appendix C provides additional information on the accident methodology.

For radiological accidents, point estimates of radiation dose and, for the offsite population, corresponding incremental LCFs were calculated for a hypothetical noninvolved worker from

release points at proposed sites, the offsite MEI, and the offsite population within 50 miles of each alternative site. For nonradiological accidents, estimates of airborne concentrations of chemical substances have been calculated for a hypothetical noninvolved worker and the offsite MEI.

It should be noted that the purpose of this SPEIS is to assist NNSA in making site selection decisions. Since nuclear weapons activities or facilities would be the same regardless of location, the risk to involved workers is independent of where the activity occurs or the facility is located and would not be a discriminating factor for programmatic siting decisions. For the project-specific analyses, potential impacts to involved workers were considered and discussed as appropriate.

For radiological and chemical accidents, the following general analytical steps were followed:

1. Screen operations at the facilities to identify those with the potential to contribute to offsite risk.
2. Identify and screen postulated accident scenarios associated with those operations.
3. Calculate source terms (release rates and frequencies) for these unmitigated scenarios assuming no mitigation of releases or frequencies.
4. Calculate onsite and offsite consequences (impacts to the health and safety of workers and the general public) of these scenarios.

The unmitigated consequences of accidental releases of radioactivity were calculated using the MELCOR Accident Consequence Code System Version 2 (MACCS2) with the radiological source term values described above. In addition to the source term data, the following input data for the MACCS2 code were obtained:

- Estimated location of specific facilities and their distance from the site boundary;
- Release heights (i.e., stack release, building release, or ground level release);
- Local meteorological conditions;
- Offsite population distribution (using the 2000 census data); and
- Offsite agricultural and economic data.

The consequences of accidental releases of hazardous chemicals were calculated using the Aerial Location of Hazardous Atmospheres (ALOHA) code based on information from the Complex Transformation alternative data report [NNSA 2007]. In addition to the source term data, input data for the ALOHA code is similar to that required for the radiological accident analysis, with the exception that offsite agricultural and economic data are not required.

For accident scenarios involving multiple operations within nuclear weapons facilities, such as those that might be caused by natural phenomena, estimates of radiation dose and corresponding incremental LCFs and estimates of airborne concentrations of chemical substances were calculated for the same receptors as described previously.

B.12.3 Terrorist Attacks

Analyses of the potential impacts of terrorist attacks are in a classified appendix to this SPEIS. The impacts of some terrorist attacks would be similar to the accident impacts described earlier in this section, while others would have more severe impacts. This section describes the methodology NNSA uses to assess the vulnerability of its sites to terrorist attacks and then designs its systems to prevent and deter those threats.

B.12.3.1 *Assessment of Vulnerability to Terrorist Threats*

In accordance with DOE Order 470.3A, Design Basis Threat Policy, and DOE Order 470.4, Safeguards and Security Program, NNSA conducts vulnerability assessments and risk analyses of its facilities and sites to determine the physical protection elements, technologies, and administrative controls NNSA should use to protect its assets, its workers, and the public. DOE Order 470.4 establishes the roles and responsibilities for the conduct of DOE's Safeguards and Security Program. DOE Order 470.3A establishes requirements designed to prevent unauthorized access, theft, diversion, or sabotage of nuclear weapons, components, and special nuclear material controlled by NNSA.

Among other things, DOE Order 470.3A: 1) Specifies those national security assets that require protection; 2) Outlines threat considerations for safeguards and security programs to provide a basis for planning, designing, and constructing new facilities; and 3) Requires the development of credible scenarios of threats that are used to design and test safeguards and security systems. NNSA must also protect against espionage, sabotage, and theft of materials, classified matter, and critical technologies.

NNSA's safeguards and security programs and systems employ state-of-the-art technologies to:

- Deny adversaries access to nuclear weapons, nuclear test devices, and completed nuclear assemblies;
- Deny adversaries the opportunity to steal special nuclear materials (SNM), sabotage weapons or facilities, or produce an unauthorized nuclear yield (criticality) of SNM;
- Protect the public and employees from harm resulting from an adversary's use of radiological, chemical, or biological materials; and
- Protect classified information, classified matter, and designated critical facilities or activities from sabotage, espionage, and theft.

NNSA's vulnerability assessments employ a rigorous methodology based on guidance from the DOE Vulnerability Assessment Process Guide (September 2004), and the Vulnerability Assessment Certification course. Typically, a vulnerability assessment involves analyses by subject matter experts to determine the effectiveness of a safeguard and security system used to protect against an adversary with certain capabilities. Vulnerability assessments generally include the following activities:

Characterizing the threat. Threat characterization provides a detailed description of a physical threat by a malevolent adversary to a site's physical protection systems. Usually the description

includes information about the types of potential adversaries, their motivations, objectives, actions, capabilities, and site-specific tactical considerations. Much of the information required to develop a threat characterization is described in DOE Order 470.3A and the Adversary Capabilities List. The Department also issues site-specific guidance, to assist in this process.

Determining the target. Target determination involves identifying, describing, and prioritizing potential targets among NNSA's security interests. Results of target determinations are used to help characterize potential threats and objectives, as well as, protective force and neutralization requirements.

Defining the scope. The scope of a vulnerability assessment is determined by subject matter experts and depends on the site vulnerabilities. In addition to defining the threat and possible terrorist objectives, the scope establishes the key assumptions and interpretations that will guide the analyses, as well as the objectives, methods, and format for documenting the results of the vulnerability assessment.

Characterizing the facility or site. This activity requires defining and documenting every aspect of the facility or site to be assessed, particularly existing security programs (personnel security, information security, physical security, material control and accountability, etc.), to assist in identifying strengths and weaknesses. Results are used as inputs to the pathway analyses, which DOE uses to develop representative scenarios for evaluating the security system. Facility and site characterization modeling tools include Analytical System and Software for Evaluating Safeguards and Security (ASSESS), Adversary Time-Line Analysis System (ATLAS), VISA, tabletop analysis, and others.

Characterizing the protective force. To assess a facility or site's vulnerability, analysts must accurately characterize protective force's capabilities against a defined threat and objective, particularly its ability to detect, assess, interrupt, and neutralize an adversary. Specific data used for this activity include special nuclear materials categorization; configuration, flow, and movement of special nuclear materials within or from a facility or site; defined threats; detection and assessment times; and adversary delay and task time. The protective force's equipment, weapons, size, and posts also are considered in the characterization. The characterization information is validated and verified via observation, alarm response assessments, performance tests, force-on-force exercises, joint conflict and tactical simulation (JCATS), and tabletop analyses. The JCATS software tool is used for training, analysis, planning, and mission rehearsal, as well as characterization of the protective force. It employs detailed graphics and models of buildings, natural terrain features, and roads to simulate realistic operations in urban and rural environments.

Analyzing adversary pathways. This activity identifies and analyzes adversary pathways based on the results of threat, target, facility, and protective force characterization, as well as ancillary analyses such as explosives analysis. ASSESS and ATLAS are two primary tools that are used in this analysis. Analysts also conduct insider analysis as part of this activity.

Developing credible scenarios. Credible scenarios are developed for use in performance testing and to determine the effectiveness of the security system in place against a potential adversary's

objectives. As part of this activity, data from the adversary pathways analyses are used to identify applicable threats, threat strategies, and objectives, and combined with protective force strategies and capabilities to develop scenarios that include specific adversary resources, capabilities, and projected task times to successfully achieve their objectives. Specialists also work with the vulnerability assessment team to develop realistic scenarios that provide a structured and informal analysis of the strengths and weaknesses of potential adversaries.

Determining the probability of neutralization. The probability of neutralization is the probability that a protective force can prevent an adversary from achieving its objectives. The probability is derived from more than one source, one of which must be based on Joint Tactical Simulation, JCATS analysis, or force-on-force exercises.

Determining system effectiveness. System effectiveness is determined by applying an equation that reflects the capabilities of a multi-layered protection system. Analysis data derived from the various vulnerability assessment activities are used to calculate this equation, which reflects the security system's effectiveness against each of the scenarios developed for the vulnerability assessment. If system effectiveness is unacceptable for a scenario, the root cause of the weakness must be analyzed and security upgrades must be identified. The scenarios are reanalyzed with the upgrades, and effective upgrades are documented in the vulnerability analysis report.

Implementation. The culmination of the vulnerability assessment is development of a report documenting the analyses and results and a plan for implementing any necessary changes to security systems. NNSA verifies the results of the vulnerability assessment report and the conclusions of the implementation plan. NNSA also oversees the implementation of security system upgrades.

B.12.3.2 *Terrorist Impacts Analysis*

Substantive details of the credible scenarios for terrorist attacks NNSA's countermeasures, and potential impacts of attacks are not released to the public because disclosure of this information could be exploited by terrorists and assist them in the planning of attacks. Depending on the intentionally destructive acts, impacts may be similar to or would exceed those of bounding accidents analyzed elsewhere in the SPEIS. A separate classified appendix to this SPEIS evaluates the impacts of an adversary achieving its objectives in one or more of the credible scenarios.

The classified appendix evaluates the potential impacts of the successful execution of credible scenarios for the alternatives at seven sites (LANL TA-16, LANL TA-55, LLNL, NTS, SRS, Pantex, and Y-12) and calculates consequences to a noninvolved worker, maximally exposed individual, and population in terms of direct effects, radiation dose, and LCFs. Risks are not calculated because the probability that an adversary could successfully execute the attack in a scenario cannot be quantified. The MACCS2 and RISKIND computer codes are used along with other manual methods to calculate human health effects of each credible scenario. The same site-specific meteorology and population distribution that is used in the accident analyses in SPEIS Appendix C are used in analyses of the impacts of an adversary achieving its objectives in the credible attack scenario.

B.12.3.3 *Mitigation of Impacts from Potential Terrorist Attacks*

The DOE strategy for the mitigation of environmental impacts resulting from a terrorist attack has three distinct components: 1) Prevent and deter terrorists from executing successful attacks; 2) Plan and provide timely and adequate response to emergency situations; and 3) Progressive recovery through long-term response in the form of monitoring, remediation, and support for affected communities and their environment.

B.12.3.3.1 *Actions to Prevent or Reduce the Probability of Successful Attacks*

NNSA employs a well-established system of engineered and administrative controls to prevent or reduce the probability of occurrence of extreme events and to limit their potential impacts on the environment. This system has evolved over time and will continue to evolve as new security requirements are identified, as new become available, and as new engineering standards or best practices are developed. The directing requirements and the framework for implementing this system of controls are embodied in the Code of Federal Regulations and in DOE Orders. These are imposed as contractual requirements for DOE management and operating (M&O) contractors. The NNSA system of safety requirements and quality assurance guidelines and controls covers all aspects of key nuclear and non-nuclear facilities including design requirements, construction practices, start-up and operational readiness reviews, and routine operations and maintenance. The contractor and federal staff at these facilities are evaluated for trustworthiness and reliability.

B.12.3.3.2 *Plan for and Respond to Emergency Situations*

While NNSA has comprehensive security measures to prevent terrorist attacks, it is also necessary to have the capability for timely and adequate response to emergency situations. Therefore, in addition to the systems of workplace hazard controls and safeguards and security measures, the NNSA emergency management system imposes additional protections over operations involving dispersible hazardous materials in quantities that could harm people outside the immediate workplace. NNSA's comprehensive all-hazards approach to emergency management is established in DOE Order 151.1C, Comprehensive Emergency Management System. This Order provides a general structure and framework for responding to any emergency at an NNSA facility or for an NNSA activity and specific requirements to address protection of workers, the public, and the environment from the release of hazardous materials.

NNSA's comprehensive emergency management system is based on a three-tiered structure consisting of facility, site, or activity management; the Cognizant Field Element; and Headquarters, with each tier having specific roles and responsibilities during an emergency. Each organizational tier provides management, direction, and support of emergency response activities. Management personnel of a facility, site, or activity manage the tactical response to the emergency by directing the mitigative actions necessary to resolve the problem, protect the workforce, the public, and the environment; and return the facility, site, or activity to a safe condition. The Cognizant Field Element oversees the facility/site response and provides local assistance, guidance, and operational direction to the facility/site management. The Cognizant Field Element also coordinates the tactical response to the event with tribal, state, and local

governments. NNSA Headquarters provides strategic direction to the response, provides assistance and guidance to the Cognizant Field Element, and evaluates the broad impacts of the emergency on the NNSA complex. Headquarters also coordinates with other Federal agencies on a national level, provides information to representatives of the executive and legislative branches of the Federal government, and responds to inquiries from the national media.

Each NNSA facility, site, or activity is required by DOE Order 151.1C to have an Operational Emergency Base Program, which provides the framework for responding to serious events or conditions that involve the health and safety of the workforce and the public, the environment, and safeguards and security. The objective of the Operational Emergency Base Program is to achieve an effective integration of emergency planning and preparedness requirements into an emergency management program that provides capabilities for all emergency responses through communication, coordination, and an efficient and effective use of resources, that is commensurate with the hazards present at that facility, site, or activity.

DOE Order 151.C requires that a Hazards Survey be prepared, maintained, and used for emergency planning purposes. The Order requires that emergency management efforts begin with the identification and qualitative assessment of the facility- or site-specific hazards and the associated emergency conditions that may require response, and that the scope and extent of emergency planning and preparedness reflect these facility-specific hazards. Hazards Surveys are used to:

- identify the generic emergency conditions that apply to each facility;
- qualitatively describe the potential health, safety, or environmental impacts of the applicable emergencies;
- identify the applicable planning and preparedness requirements; and
- indicate the need for further evaluation of hazardous materials in an Emergency Planning Hazards Assessment (EPHA).

Some facilities have been analyzed as stand-alone facilities; however, several structures or component units with common or related purposes have been combined into a facility- or complex-wide hazards survey. Each facility- or complex-specific hazards survey clearly identifies the facility and describes the facility's mission, operations, and physical characteristics.

Using the knowledge and insights gained through the Hazards Survey and EPHA processes, the emergency management organization at each NNSA site or facility develops detailed plans and procedures and trains the staff to carry out response actions to reduce the severity of hazardous material release events and to minimize health impacts.

The Response Activities of the Emergency Management Program that would come into play should an operational emergency occur would include many of the following elements, depending on the specific circumstances:

Emergency Response Organization (ERO). The ERO is structured to enable it to assume overall responsibility for initial and ongoing site actions associated with the emergency response and mitigation. The ERO establishes effective control at the event/incident scene and integrates local agencies and organizations providing onsite response services.

Offsite response interfaces. DOE Order 151.1C requires coordination with tribal, state, and local agencies and organizations responsible for offsite emergency response. Interrelationships and interfaces for fire, HAZMET, medical, and law enforcement and mutual assistance and support are pre-arranged and documented in various formal plans, agreements, and memoranda of understanding.

Emergency facilities and equipment. The EPHA is used to assist in determining the types and amounts of personal protective equipment, radiation monitoring, communications, and other equipment and supplies required to be maintained and operable for immediate use in responding to an operational emergency. Facilities established for either dedicated permanent use or on an ad hoc basis depending on the specific type and location of the operational emergency can include Emergency Operations Centers (EOCs), Command Centers, and Joint Information Centers. Departmental assets that may be required in the event of an operational emergency involving nuclear weapons, weapons components, or the dispersal of special nuclear materials include the Accident Response Group, Nuclear Emergency Search Team, Federal Radiological Monitoring and Assessment Center, Aerial Measuring System, Atmospheric Advisory Capability, Radiological Emergency Assistance Center/Training Site, and the Radiological Assistance Program.

Emergency categorization and classification. DOE Order 151.1C and the associated Emergency Management Guide (DOE G 151.1-1A) require a DOE site or facility to declare an operational emergency when unplanned or abnormal events or conditions require time-urgent response from outside the immediate affected site, facility, or area of the incident. Events or conditions meeting the criteria for categorization as operational emergencies are those events or conditions that have the potential to cause: serious health or safety impacts to workers or the public; serious detrimental effects on the environment; direct harm to people or the environment as a result of degradation of security or safeguards conditions; direct harm to people or the environment as a result of a major degradation of safety systems, protocols, or practices involving hazardous biological agents or toxins; or loss of control over hazardous materials (for example, toxic chemicals or radioactive materials). NNSA sites or facilities are also required to classify an operational emergency that involves the loss of control over hazardous materials resulting in an actual or potential airborne release to the environment (outside a structure or enclosure on an NNSA facility or site) as either an Alert, Site Area Emergency, or General Emergency, in order of increasing severity.

Notifications and communications. The accurate, timely, and useful exchange of information during an emergency response is a key factor in understanding the scope of an emergency and providing proper response to limit its impacts. Emergency reporting includes initial notifications to onsite personnel, emergency response personnel, and offsite authorities including applicable NNSA elements; other Federal Agencies; and local, state, and tribal government organizations, and follow-on emergency status updates.

Consequent assessment. Consequence assessment includes all processes utilized to perform data collection and analysis necessary to support critical initial assessments and the continuing processes of refining the assessments as more information and additional resources become available. These can involve monitoring for specific indicators or field measurements and the

integration of monitoring data with calculations and modeling capabilities. Consequence assessment is integrated with both event classification and protective action decision making and can include coordination with offsite entities including federal, state, local, and tribal organizations.

Protective actions and re-entry. Protective actions can be implemented either individually or in combination to reduce exposure of the workforce and the public to special nuclear materials or other hazardous materials. These can include:

- Controlling, monitoring, and maintaining records of personnel exposure to radiological and nonradiological hazardous materials;
- Sheltering or evaluation;
- Turning off heating, ventilation, and air conditioning systems during sheltering;
- Controlling access to contaminated areas and decontaminating personnel or equipment exiting the area;
- Controlling foodstuffs and water, or changing livestock and agricultural practices; and
- Developing and deploying for use in protective action decision making prepared Protective Action Guides and Emergency Response Planning Guidelines using DOE-approved guidance applicable to the actual or potential release of hazardous materials.

Planning and executing re-entry activities must include establishing adequate measures for the protection of response personnel from unnecessary exposure to hazardous materials or conditions either known or suspected to exist at the site of the accident or incident.

Emergency medical support. Emergency medical support includes providing various levels of treatment to those who may become injured or contaminated and arranging with offsite medical facilities to transport, accept, and treat contaminated, injured personnel. DOE Order 440.1A establishes requirements for facility and site medical programs required to meet the provisions of 10 CFR 851.210, *Occupational Medicine*, and addresses the medical organization, facilities and equipment, communications planning, and preparedness activities considered necessary for providing the medical treatment and access to medical services for mass casualty situations and medical response to an operational emergency involving contamination.

Emergency public information. The Emergency Public Information program plays a critical role in establishing and maintaining coordination with tribal, state, and local governments and the public. The program is expected to provide timely, candid, and accurate information to the workforce, the news media, and the public during an operational emergency. Providing accurate and factual health and safety information and security information helps to avoid and discourage speculation. The elements of an effective program can be pre-established by developing appropriate broadcast and print media interfaces, establishing a system for assembling and releasing emergency information that may include set-up of a Joint Information Center with representatives of offsite organizations, and conducting various drills and exercises that include exercising various Emergency Public Information program systems to educate the press and the public.

Termination and recovery. An operational emergency is terminated only after a predetermined set of criteria is met and in many scenarios, termination must be coordinated with various offsite

agencies. The various pathways and timelines for recovery and resumption of normal operations must be developed to ensure the health and safety of the work force and the public. Actions may include the creation of a recovery organization to manage the conduct of recovery operations and to maintain communication and coordination with local, state, and tribal organizations, and other federal agencies providing support at the site. Specific recovery procedures may include dissemination of information to federal, state, tribal, and local organizations regarding the emergency and conditions required for the relaxation of public protection measures; planning and conducting decontamination actions; development and compliance with reporting requirements; and the creation of processes and procedures to guide the resumption of normal operations. Recovery also specifically includes the evaluation of the accident or incident and the response to identify lessons learned and develop potential means to mitigate the effects of future operational emergencies.

B.12.3.3.3 Progressive Recovery Through Long-Term Response

The recovery phase of an operational emergency in which radioactive materials are dispersed over a wide area could require years to complete and might require an extended response by NNSA. The specific requirements for an extended response would be dictated by the circumstances. Requirements may include a continuing coordination with local authorities and various government agencies to continue protective actions and controls; long-term monitoring of the affected environment, population, or both for effects attributable to the operational emergency; providing medical support for affected individuals; maintaining public information and various technical and other response interfaces; and performing periodic reassessments and evaluations of progress in the recovery and return to more normal conditions.

B.13 TRANSPORTATION

B.13.1 Description of Affected Resources and Region of Influence

Transportation routes in the vicinity of the proposed Complex Transformation location have been identified, in text and on a map, to indicate which highways would be impacted by Complex Transformation traffic, including commuters and shipments. Traffic data, such as annual average daily traffic, is presented as a baseline for a subsequent qualitative analysis of increased traffic congestion. Traffic data has been derived from recent DOE environmental documentation or from state agencies.

B.13.2 Description of Impact Assessment

The Complex Transformation SPEIS assesses the impacts associated with the transportation of radiological materials and workers as described below. The methodology for both the programmatic alternatives and project-specific alternatives was the same.

B.13.2.1 *Incident-Free Transportation Impacts*

The amount of radiological material requiring transportation was first determined based on information from the Complex Transformation alternative data report [NNSA 2007]. Next, using

the RADTRAN 5 code, routes and routing characteristics were determined for the origin-destination pairs associated with the transportation of radiological material.

Radiological dose during normal, incident-free transportation of radioactive materials results from exposure to the external radiation field that surrounds the shipping containers. The dose is a function of the number of people exposed, their proximity to the containers, their length of time of exposure, and the intensity of the radiation field surrounding the containers. For the purpose of providing a conservative estimate of impacts, exposure rates assumed exposure rates of five millirem per hour. This assumption is much higher than assumptions utilized in the handling/loading analysis of pits and canned subassemblies (CSAs) provided in the *Final Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components*. In that FEIS, an external exposure rate of one millirem per hour was assumed (DOE 1996).

Loading operations typically represent the largest exposure impacts involved with the transportation of nuclear materials. NNSA assumed that loading operations would require one shift-day for each truck trailer loaded. A shift-day would represent a crew of five workers exposed to the load for eight hours. Estimation of loading operation impacts of other materials and waste products was based on the size and number of packages per load.

Radiological impacts were determined for crew workers and the general population during normal, incident-free transportation. For shipments, the crew was defined as the driver and passenger of the shipment vehicles. The general population was the individuals within 800 meters (2,625 feet) of the road, sharing the road, and at stops. Collective doses for the crew and general population were calculated using the RADTRAN 5.6/RadCat 2.3 computer codes (Weiner et al. 2006).

For the worker populations, DOE evaluated the following scenario:

- A truck driver and passenger, serving as an escort, that would be expected to drive radioactive shipments for 1,000 hours per year and unload shipments for 1,000 hour per year.

For shipments, the three scenarios for members of the public were:

- A person caught in traffic and located 1 meter (3 feet) away from the surface of the shipping container for 30 minutes;
- A service station worker working at a distance of 20 meters (66 feet) from the shipping container for 1 hour; and,
- A resident living 30 meters (98 feet) from the highway used to transport the shipping container.

The hypothetical maximum exposed individual doses were accumulated for all shipments over one year. For workers, it was assumed that they would be exposed to 23 percent of the shipments, based on working 2,000 hours per year. However, for the scenario involving an individual caught in traffic next to a truck, the radiological exposures were calculated for only

one event because it was considered unlikely that the same individual would be caught in traffic next to all containers for all shipments. The maximum exposed transportation worker is the driver who was assumed to drive shipments for up to 1,000 hours per year. In the maximum exposed individual scenarios, the exposure rate for the shipments depended on the type of material being transported. Also, the maximum exposure rate for the truck driver was two millirem per hour (10 CFR 71.47[b] [4]).

Incident-free nonradiological fatalities were estimated using unit risk factors. These fatalities would result from exhaust and fugitive dust emissions from highway and rail traffic and are associated with 10-micrometer particles. The nonradiological unit risk factors were adopted from the transportation analysis conducted for the Final West Valley Demonstration Waste Management EIS (DOE 2003). The unit risk factors used in this analysis was 1.5×10^{-11} fatalities per kilometer per persons per square kilometer for diesel truck transport.

B.13.2.2 *Transportation Accidents*

The offsite transportation accident analysis considers the impacts of accidents during the transportation of radiological materials. Under accident conditions, impacts to human health and the environment may result from the release and dispersal of radioactive material. Accidents that could potentially breach the shipping container are represented by a spectrum of accident severities and radioactive release conditions. Historically, most transportation accidents involving radioactive materials have resulted in little or no release of radioactive material from the shipping container. Consequently, the analysis of accident risks takes into account a spectrum of accidents ranging from high-probability accidents of low severity to hypothetical high-severity accidents that have a correspondingly low probability of occurrence. This accident analysis calculates the probabilities and consequences from this spectrum of accidents.

To provide NNSA and the public with a reasonable assessment of radioactive waste transportation accident impacts, two types of analyses were performed. An accident risk assessment was performed that takes into account the probabilities and consequences of a spectrum of potential accident severities using a methodology developed by the NRC (NRC 1977; Fischer et al. 1987; Sprung et al. 2000). For the spectrum of accidents considered in the analysis, accident consequences in terms of collective dose to the population within 80 kilometers (50 miles) were multiplied by the accident probabilities to yield collective dose risk using the RADTRAN 5.6/RadCat 2.3 computer code (Weiner 2006).

The impacts for specific alternatives were calculated in units of dose (rem or person-rem). Impacts are further expressed as health risks in terms of estimated latent cancer fatalities in exposed populations. The health risk conversion factor of 0.0006 LCF/person-rem was derived from the Interagency Steering Committee on Radiation Standards report (ISCOR 2002), A Method for Estimating Radiation Risk from Total Effective Dose Equivalent (TEDE).

The risk analyses consider a spectrum of accidents of varying severity. Each first determines the conditional probability that the accident will be of a specified severity. Then, based on the accident environment associated with each severe accident, each models the behavior of the

material being shipped and the response of the packaging. The models estimate the fraction of each species of radioactive material that might be released for each of the severe accidents being considered.

B.13.2.3 *Traffic Impacts*

Traffic flow has been analyzed to determine whether or not the flow would be adversely impacted by the addition of new commuters at each of the potential sites for both construction and operations phases. The number of new commuters has been determined based on construction and operations employment. The analysis determined the percent change in traffic as a result of the alternatives.

B.14 WASTE MANAGEMENT

B.14.1 Description of Affected Resources and Region of Influence

A key goal of Complex Transformation is to develop a safe, secure, environmentally compliant facilities based on modern manufacturing procedures. Waste minimization is a goal of Complex Transformation. The production of waste requiring offsite disposal will be reduced to as low as reasonably achievable (ALARA) consistent with cost-benefit analyses. Waste minimization and pollution prevention efforts and the management of Complex Transformation-related wastes have been analyzed for each alternative site. The impact assessment addresses the projected waste types and volumes from Complex Transformation facilities and operations at each site compared to the No Action Alternative. The methodology for both the programmatic alternatives and project-specific alternatives was the same.

Wastes generated during Complex Transformation operations would consist of five primary types: transuranic (TRU) waste, low-level waste (LLW), mixed LLW, hazardous waste, and nonhazardous waste. Waste management facilities supporting Complex Transformation operations would treat and package the waste into forms that would enable long-term storage or disposal. Other waste types generated by Complex Transformation facilities would be transferred to existing facilities and managed in accordance with current practices at the DOE site.

B.14.2 Description of Impact Assessment

To provide a framework for addressing the impacts of waste management for Complex Transformation facilities, descriptive information has been presented on each site's waste management capabilities. The volumes of each waste type generated are estimated. These estimates, obtained from the Complex Transformation data call, include consideration of concepts for waste minimization. Impacts have been assessed in the context of existing site practices for treatment, storage, and disposal including the applicable regulatory requirements. Permits, compliance agreements, and other site-specific practices have been reviewed and analyzed to assess the ability to conduct the Complex Transformation-related waste management activities.

DOE generates both "routine" waste (e.g., job control, maintenance) and waste associated with Environmental Restoration (ER) and Decontamination and Decommissioning (D&D) activities. The ER/D&D waste volumes can vary greatly from year to year and often exceed the routine

waste volumes. ER/D&D waste is fundamentally different (more volume, less contamination) from routine wastes and is frequently managed at separate facilities. The estimated waste volumes for Complex Transformation operations have been compared to the routine waste generation at each site to identify potential impacts to the site's waste management infrastructure.

For any alternatives that generate TRU waste, the number of additional shipments required to transport TRU waste to the Waste Isolation Pilot Plant (WIPP) was estimated and the impacts assessed as part of the transportation analysis. The SPEIS acknowledges that the total disposal capacity at WIPP is limited to 6,180,000 ft³ under the *WIPP Land Management Act*. However, DOE continues to recognize that the amount of TRU waste to be disposed of could exceed these volumes. In the future, if inventory projects show a need for additional disposal capacity for TRU waste, DOE would initiate the development of strategies for expanding such capacity at an appropriate time. However, because DOE has made no plans to date regarding the location or design of a waste disposal facility for TRU waste beyond WIPP's current capacity, this SPEIS assumed WIPP as the disposal location for TRU waste generated under each alternative, for the purposes of transportation analysis only.

For sites under consideration for Complex Transformation that do not have existing or planned onsite LLW disposal, the number of additional shipments required to transport LLW from the site to a DOE LLW disposal facility has been estimated. For example, for purposes of this analysis, it is assumed that the Pantex Plant would ship its LLW to the Nevada Test Site (NTS) as per current practice. The risks associated with additional LLW shipments have been addressed as part of the transportation impacts assessment.

B.15 CUMULATIVE IMPACTS

The Council on Environmental Quality (CEQ) regulations implementing NEPA define cumulative effects as "the impact on the environment which results from the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions" (40 CFR 1508.7). The regulations further explain "cumulative effects can result from individually minor but collectively significant actions taking place over a period of time." Other DOE programs and other Federal, State, and local development programs all have the potential to contribute to cumulative effects on DOE sites.

The methodology for the analysis of cumulative effects for the Complex Transformation SPEIS was developed from the guidelines and methodology in the CEQ's *Considering Cumulative Effects Under the National Environmental Policy Act*. The major components of the CEQ methodology include:

- Scoping, including identifying the significant potential cumulative effects issues associated with the proposed action, and identifying other actions affecting the resources;
- Describing the affected environment; and
- Determining the environmental consequences, including the impacts from the proposed action and other activities in the ROI, and the magnitude and significance of the cumulative effects

The cumulative effects of the Complex Transformation SPEIS alternatives have been analyzed for each alternative site by reviewing and analyzing data from existing NEPA documents and other DOE documents. To update the data and to supplement this information, Internet searches, literature reviews of environmental documents for the regions surrounding the proposed sites, and personal contacts with local government planning departments have been undertaken, as needed, to obtain information on the potential cumulative effects for each resource area. For some resource areas, the analysis includes the cumulative regional impacts. For example, the air analysis must examine air quality in the region for each potential site in order to assess the impacts of the proposed action.

Environmental impacts for other DOE programs and other Federal, State, and local development programs for each potential site have been reviewed and the cumulative impacts analyzed. The analysis includes impacts from previous actions at each of the sites and within the region of influence, current actions, and actions planned for reasonably foreseeable future actions. These impacts, combined with the impacts from the Complex Transformation SPEIS, form the basis of the analysis of cumulative effects. Where possible, quantifiable data is used. The level of analysis for each resource area is commensurate to the importance of the potential cumulative impacts on that resource. The data and analysis are then summarized and potential cumulative impacts for each site identified. For the project-specific analyses, because impacts were generally very small relative to existing operations at sites, the analysis of the additive project-specific impacts to the site baseline was tantamount to a cumulative assessment.

Appendix C
HUMAN HEALTH AND ACCIDENTS

Appendix C

HUMAN HEALTH, SAFETY, AND ACCIDENTS

This appendix to the Complex Transformation Supplemental Programmatic Environmental Impact Statement (SPEIS) provides supplemental information pertaining to potential human health impacts associated with radiation exposures, chemical exposures, accidents, and worker safety issues due to operations of the major facilities (as identified in Chapter 3) associated with the programmatic alternatives analyzed. Located at the end of this appendix is a separate reference section.

C.1 RADIOLOGICAL IMPACTS ON HUMAN HEALTH

C.1.1 Radiation and Radioactivity

Humans are constantly exposed to naturally occurring radiation through sources such as from the universe and from the Earth's rocks and soils. This type of radiation is referred to as *background radiation* and it is always around us. Background radiation remains relatively constant over time and is present in the environment today just as it was hundreds of years ago. In addition, humans are also exposed to manmade sources of radiation, including medical and dental x-rays, household smoke detectors, materials released from coal burning power plants, and nuclear facilities. The following sections describe some important principles concerning the nature, types, sources, and effects of radiation and radioactivity.

C.1.1.1 What Is Radiation?

Some atoms have large amounts of energy and are inherently unstable. They may reach a stable, less energetic state through the emission of subatomic particles or electromagnetic radiation, a process referred to as radioactivity. The main subatomic particles that comprise an atom are electrons, protons, and neutrons. *Electrons* are negatively charged particles that are principally responsible for chemical reactivity. *Protons* are positively charged particles, and *neutrons* are neutral. Protons and neutrons are located in the center of the atom, called the nucleus. Electrons reside in a designated space around the *nucleus*. The total number of protons in an atom is called its *atomic number*.

Atoms of different types are known as elements. There are more than 100 natural and manmade elements. Atoms of the same element always contain the same number of protons and electrons, but may differ by their number of constituent neutrons. Such atoms of elements having a different number of neutrons are called the *isotopes* of the element. The total number of protons and neutrons in the nucleus of an atom is called its *mass number*, which is used to identify the isotope. For example, the element uranium has 92 protons. Therefore, all isotopes of uranium have 92 protons. Each isotope of uranium is designated by its unique mass number: ^{238}U , the principal naturally occurring isotope of uranium, has 92 protons and 146 neutrons; ^{234}U has 92 protons and 142 neutrons; and ^{235}U has 92 protons and 143 neutrons. Atoms can lose or gain electrons in a process known as *ionization*.

Ionizing radiation has enough energy to free electrons from atoms, creating ions that can cause biological damage. Although it is potentially harmful to human health, ionizing radiation is used in a variety of ways, many of which are familiar to us in our everyday lives. An x-ray machine is one source of ionizing radiation. Likewise, most home smoke detectors use a small source of ionizing radiation to detect smoke particles in the room's air. The two most common mechanisms in which ionizing radiation is generated are the electrical acceleration of atomic particles such as electrons (as in x-ray machines) and the emission of energy from nuclear reactions in atoms. Examples of ionizing radiation include alpha, beta, and gamma radiation.

Alpha radiation occurs when a particle consisting of two protons and two neutrons is emitted from the nucleus of an unstable atom. Alpha particles, because of their relatively large size, do not travel very far and do not penetrate materials well. Alpha particles lose their energy almost as soon as they collide with anything, and therefore a sheet of notebook paper or the skin's surface can be used to block the penetration of most alpha particles. Alpha emitters only become a source of radiation dose after they are inhaled, ingested, or otherwise taken into the body.

Beta radiation occurs when an electron or positron is emitted from an atom. Beta particles are much lighter than alpha particles and therefore can travel faster and farther. Greater precautions must be taken to guard against beta radiation and some shielding is usually recommended to limit exposure to beta radiation. Beta particles can pass through a sheet of paper but can be stopped by a thin sheet of aluminum foil or glass. Most of the radiation dose from beta particles occurs in the first tissue they penetrate, such as the skin, or dose may occur as the result of internal deposition of beta emitters.

Gamma and x-ray radiation are known as electromagnetic radiation and are emitted as energy packets called *photons*, similar to light and radio waves, but from a different energy region of the electromagnetic spectrum. Gamma rays and x-rays are the most penetrating type of radiation. Gamma rays are emitted from the nucleus as waves of pure energy, whereas x-rays originate from the electron field surrounding the nucleus. Gamma rays travel at the speed of light, and because they are so penetrating, concrete, lead, or steel is required to shield them. The amount of shielding required, depends upon the energy and intensity of the gamma or x-radiation. For example, to absorb 95 percent of the gamma radiation from a ^{60}Co source, 6 centimeters of lead, 10 centimeters of iron, or 33 centimeters of concrete would be needed.

The neutron is another particle that contributes to radiation exposure, both directly and indirectly. Indirect exposure results from gamma rays and alpha particles that are emitted after neutrons are captured in matter. A neutron has about one quarter of the weight of an alpha particle and can travel 2.5 times faster than an alpha particle. Neutrons are less penetrating than gamma rays because they have mass, but neutrons are more penetrating than beta particles because they are uncharged. They can be shielded effectively by water, graphite, paraffin, or concrete.

Some elements, such as uranium, radium, plutonium, and thorium, share a common characteristic: they are unstable or radioactive. Such radioactive isotopes are called *radionuclides* or *radioisotopes*. As these elements attempt to change into more stable forms, they emit invisible rays of energy or particles at rates which decrease with time. This emission is known as

radioactive decay. The time it takes a material to lose half of its original radioactivity is referred to as its half-life. Each radioactive isotope has a characteristic half-life. The half-life may vary from a millionth of a second to millions of years, depending upon the radionuclide. Eventually, the radioactivity will essentially disappear.

As a radioactive element emits radioactivity, it often changes into an entirely different element that may or may not be radioactive. Eventually, however, a stable element is formed. This transformation may require several steps, known as a decay chain. Radium, for example, is a naturally occurring radioactive element with a half-life of 1,622 years. It emits an alpha particle and becomes radon, a radioactive gas with a half-life of only 3.8 days. Radon decays to polonium and, through a series of steps, to bismuth, and ultimately to lead.

Nonionizing radiation bounces off or passes through matter without displacing electrons. Examples include visible light and radio waves. At this time, scientists are unclear as to the effects of nonionizing radiation on human health. In this SPEIS, the term radiation is used to describe ionizing radiation.

C.1.1.2 *How Is Radiation Measured?*

Scientists and engineers use a variety of units to quantify the measurement of radiation. These different units can be used to determine the amount, and intensity of radiation. Radiation is usually measured in *curies*, *rads*, or *rems*. The *curie* describes the activity of radioactive material. One curie is equal to 3.7×10^{10} disintegrations (decays) per second.

Absorbed radiation dose is the amount of energy deposited in a unit mass of material, such as a gram of tissue. Radiation dose is expressed in units of *rad*. One rad is 0.01 joule of energy deposited per kilogram of absorbing material. A joule is a very small amount of energy. For example, a 60-watt light bulb on for about 0.02 seconds would use one joule of energy.

A *rem* is a unit of equivalent dose, which is the absorbed dose modified by a weighting factor to account for the relative biological effectiveness of different types of radiation. The rem is used to measure the effects of radiation on the body. As such, one rem of one type of radiation is presumed to have the same biological effects as one rem of any other type of radiation. This standard allows comparison of the biological effects of different types of radiation. Note that the term millirem (mrem) is also often used. A millirem is one one-thousandth (0.001) of a rem.

C.1.1.3 *How Does Radiation Affect the Human Body?*

Ionizing radiation affects the body through two basic mechanisms. The ionization of atoms can generate chemical changes in body fluids and cellular material. Also, in some cases the amount of energy transferred can be sufficient to actually knock an atom out of its chemical bonds, again resulting in chemical changes. These chemical changes can lead to alteration or disruption of the normal function of the affected area. At low levels of exposure, such as the levels experienced in an occupational or environmental setting, these chemical changes are very small and ineffective. The body has a wide variety of mechanisms that repair the damage induced. However, occasionally, these changes can cause irreparable damage that could ultimately lead to initiation

of a cancer, or change to genetic material that could be passed to the next generation. The probability for the occurrence of health effects of this nature depends upon the type and amount of radiation received, and the sensitivity of the part of the body receiving the dose.

At much higher levels of acute whole-body exposure, at least 10–20 times higher than the legal limits for occupational exposures (the limit for annual occupational exposures is 5 rem); damage is much more immediate, direct, and observable. Health effects range from reversible changes in the blood to vomiting, loss of hair, temporary or permanent sterility, and other changes leading ultimately to death at acute exposures (above about 100 times the regulatory limits). In these cases, the severity of the health effect is dependent upon the amount and type of radiation received. Exposures to radiation at these levels are quite rare.

For low levels of radiation exposure, the probabilities for induction of various cancers or genetic effects have been extensively studied by both national and international expert groups. The problem is that the potential for health effects at low levels is extremely difficult to determine without extremely large, well-characterized populations. For example, to get a statistically valid estimate of the number of cancers caused by an external dose equivalent of 1 rem, 10 million people would be required for the test group, with another 10 million for the control group. The risk factors for radiation-induced cancer at low levels of exposure are very small, and it is extremely important to account for the many nonradiation-related mechanisms for cancer induction, such as smoking, diet, lifestyle, chemical exposure, and genetic predisposition. Refer to the Glossary (Chapter 13) for the definition of risk. These multiple factors also make it difficult to establish cause-and-effect relationships that could attribute high or low cancer rates to specific initiators.

The most significant ill-health effects that result from environmental and occupational radiation exposure are cancer fatalities. These ill-health effects are referred to as “latent” cancer fatalities (LCFs) because the cancer may take many years to develop and for death to occur. Furthermore, when death does occur, these ill-health effects may not actually have been the cause of death.

Health impacts from radiation exposure, whether from sources external or internal to the body, generally are identified as somatic (affecting the individual exposed) or genetic (affecting descendants of the exposed individual). Radiation is more likely to produce somatic effects rather than genetic effects. The somatic risks of most importance are the induction of cancers.

For a uniform irradiation of the body, the incidence of cancer varies among organs and tissues. The thyroid and skin demonstrate a greater sensitivity than other organs; however, such cancers also produce relatively low mortality rates because they are relatively amenable to medical treatment.

C.1.1.4 *What Are Some Types of Radiation Dose Measurements?*

The amount of ionizing radiation that the individual receives during the exposure is referred to as *dose*. An external dose is delivered only during the actual time of exposure to the external radiation source. An internal dose, however, continues to be delivered as long as the radioactive material is in the body, although both radioactive decay and elimination of the radionuclide by

ordinary metabolic processes decrease the dose rate with the passage of time. The measurement of radiation dose is called *radiation dosimetry* and is completed by a variety of methods depending upon the characteristics of the incident radiation. External radiation is measured as a value called deep dose equivalent. Internal radiation is measured in terms of the committed effective dose equivalent (CEDE). The sum of the two contributions (deep dose equivalent and CEDE) provides the total dose to the individual, called the total effective dose equivalent (TEDE). Often the radiation dose to a selected group or population is of interest and is referred to as the collective dose equivalent, with the measurement units of *person-rem*.

C.1.1.5 *What Are Some Sources of Radiation?*

Several different sources of radiation have been identified. Most sources are naturally occurring, or background sources, which can be categorized as cosmic, terrestrial, or internal radiation sources. Manmade radiation sources include consumer products, medical sources, and other miscellaneous sources. The average American receives a total of about 360 millirem per year from all sources of radiation, both natural and manmade (ATSDR/CDC 2006).

Cosmic radiation is ionizing radiation resulting from energetically charged particles from space that continuously hit the Earth's atmosphere. These particles and the secondary particles and photons they create are referred to as cosmic radiation. Because the atmosphere provides some shielding against cosmic radiation, the intensity of this radiation increases with altitude above sea level. For example, a person in Denver, CO, is exposed to more cosmic radiation than a person in New Orleans, LA. The average annual dose from cosmic radiation to a person in the United States is about 27 millirem.

Terrestrial radiation is emitted from the radioactive materials in the Earth's rocks, soils, and minerals. Radon, radon progeny, potassium, isotopes of thorium, and isotopes of uranium are the elements responsible for most terrestrial radiation. The average annual dose from terrestrial radiation is about 28 millirem, but the dose varies geographically across the country. Typically, reported values are about 16 millirem on the Atlantic and Gulf coastal plains and about 63 millirem on the eastern slopes of the Rocky Mountains.

Internal radiation arises from the human body metabolizing natural radioactive material that has entered the body by inhalation, ingestion, or through an open wound. Natural radionuclides in the body include isotopes of uranium, thorium, radium, radon, bismuth, polonium, potassium, rubidium, and carbon. The major contributors to the annual dose equivalent for internal radioactivity are the short-lived decay products of radon which contribute about 200 millirem per year. The average dose from other internal radionuclides is about 39 millirem per year, most of which results from potassium-40 and polonium-210. Internal exposure can also come from manmade radiation; not only "natural." (Ingestion is primarily associated with natural radioactive materials [e.g., K-40]. Inhalation is associated with both natural and manmade radioactive materials with the dose delivered to the bronchii of the lungs—without the body metabolizing the material. Open wounds are primarily a concern for internal radiation exposure resulting from occupational settings.)

Consumer products also contain sources of ionizing radiation. In some products, like smoke detectors and airport x-ray machines, the radiation source is essential to the operation of the product. In other products, such as televisions and tobacco products, the radiation occurs incidentally to the product function. The average annual dose from consumer products is about 10 mrem.

Medical source radiation is an important diagnostic tool and is the main source of exposure to the public from manmade radiation. Exposure is deliberate and directly beneficial to the patient exposed. In general, medical exposures from diagnostic or therapeutic x-rays result from beams directed to specific areas of the body. Thus, all body organs generally are not irradiated uniformly. Nuclear medicine examinations and treatments involve the internal administration of radioactive compounds or radiopharmaceuticals by injection, inhalation, consumption, or insertion. Even then, radionuclides are not distributed uniformly throughout the body. Radiation and radioactive materials also are used in the preparation of medical instruments, including the sterilization of heat-sensitive products such as plastic heart valves. Diagnostic x-rays result in an average annual exposure of 39 millirem. Nuclear medical procedures result in an average annual exposure of 14 millirem. It is recognized that the averaging of medical doses over the entire population does not account for the potentially significant variations in annual dose among individuals, where greater doses are received by older or less healthy members of the population.

A few additional sources of radiation contribute minor doses to individuals in the United States. The doses from nuclear fuel cycle facilities, such as uranium mines, mills, and fuel processing plants, nuclear power plants, and transportation routes have been established to be less than 1 mrem per year. Radioactive fallout from atmospheric atomic bomb tests, emissions of radioactive material from U.S. Department of Energy (DOE) facilities, emissions from certain mineral extraction facilities, and transportation of radioactive materials contributes less than 1 mrem per year to the average individual dose. Air travel contributes approximately 1 mrem per year to the average dose.

C.1.2 Radioactive Materials in This SPEIS

The release of radiological contaminants into the environment at National Nuclear Security Administration (NNSA) sites occurs as a result of nuclear weapons production, research and development, maintenance, and waste management activities. This section describes the primary types of radioactive sources at NNSA sites, how DOE regulates radiation and radioactive materials, and the data sources and methodologies used to evaluate the potential health effects of radiation exposure to the worker and public.

C.1.2.1 *What Are Some Sources That May Lead to Radiation Exposure?*

Historically, NNSA has conducted many operations that involve the use of uranium, plutonium, tritium, and other radionuclides. These have included nuclear material production; recovery and recycle operations; purification processes; and metal forming, machining, and material handling operations. The releases from these operations consisted primarily of particulates, liquids, fumes, and vapors.

Airborne emissions contribute to the potential for radiation dose at, and around, NNSA sites with operations involving radioactive materials. National Emission Standards for Hazardous Air Pollutants (NESHAP) regulations specify that any source that potentially can contribute greater than 0.1 mrem per year TEDE to an offsite individual is to be considered a “major source” and emissions from that source must be continuously sampled. As such, there are a number of process exhaust stacks at NNSA sites that are considered major sources.

In addition to major sources, there are a number of minor sources that have the potential to emit radionuclides to the atmosphere. Minor sources are composed of any ventilation systems or components such as vents, laboratory hoods, room exhausts, and stacks that do not meet the criteria for a major source but are located in or vent from a radiological control area. Emissions from NNSA facility ventilation systems are estimated from radiation control data collected on airborne radioactivity concentrations in the work areas. Other emissions from unmonitored processes and laboratory exhausts are categorized as minor emission sources. Additionally, as explained in Section C.3, accidents can release radionuclides that can result in radiation exposure.

In addition, there are also areas of potential fugitive and diffuse sources at NNSA sites, such as contaminated soils and structures. Diffuse and fugitive sources include any source that is spatially distributed, diffuse in nature, or not emitted with forced air from a stack, vent, or other confined conduit. Radionuclides are transported entirely by diffusion or thermally driven air currents. Typical examples include emissions from building breathing; resuspension of contaminated soils, debris, or other materials; unventilated tanks; ponds, lakes, and streams; wastewater treatment systems; outdoor storage and processing areas; and leaks in piping, valves, or other process equipment.

Liquid discharges are another source of radiation release and exposure. Three types of liquid discharge sources at NNSA sites include treatment facilities, other point- and area-source discharges, and in-stream locations. A radiological monitoring plan is in place at NNSA sites required to address compliance with DOE orders and National Pollutant Discharge Elimination System (NPDES) Permits. Radiological monitoring of storm water is also usually required by the applicable NPDES permits.

C.1.2.2 *How Is Radiation Exposure Regulated?*

The release of radioactive materials and the potential level of radiation doses to workers and the public are regulated by the DOE for its contractor facilities. Under conditions of the *Atomic Energy Act* (as amended by the *Price-Anderson Amendments Act* of 1988), DOE is authorized to establish Federal rules controlling radiological activities at the DOE sites. The act also authorizes DOE to impose civil and criminal penalties for violations of these requirements. Some NNSA activities are also regulated through a DOE Directives System that is contractually enforced.

Occupational radiation protection is regulated by 10 CFR Part 835, Occupational Radiation Protection. DOE has set occupational dose limits for an individual worker at 5,000 millirem per year. NNSA sites have set administrative exposure guidelines at a fraction of this exposure limit

to help enforce the goal to manage and control worker exposure to radiation and radioactive material as low as reasonably achievable (ALARA).

Environmental radiation protection is currently regulated contractually with DOE Order 5400.5, Radiation Protection of the Public and the Environment. This Order is applicable to all DOE/NNSA contractor entities managing radioactive materials. This Order sets annual dose standards to members of the public, as a consequence of routine DOE operations, of 100 millirem through all exposure pathways. The Order requires that no member of the public receive an annual dose greater than 10 millirem from the airborne pathway and 4 millirem from ingestion of drinking water. In addition, the dose requirements in the Radionuclide National Emission Standards for Hazardous Air Pollutants (Rad-NESHAP) limit exposure of an individual member of the public to airborne releases of radionuclides to a maximum of 10 millirem per year.

Limits of exposure to members of the public and radiation workers are derived from International Commission on Radiological Protection (ICRP) recommendations. The U.S. Environmental Protection Agency (EPA) uses the National Council on Radiation Protection and Measurements and the International Commission on Radiological Protection recommendations and sets specific annual exposure limits (usually less than those specified by the Commission) in *Radiation Protection Guidance to Federal Agencies* documents.

Each regulatory organization then establishes its own set of radiation standards. The various exposure limits set by DOE and the EPA for radiation workers and members of the public are given in Table C.1-1.

Table C.1-1—Exposure Limits for Members of the Public and Radiation Workers

Guidance Criteria (organization)	Public Exposure Limit at the Site Boundary	Worker Exposure Limit
10 CFR Part 835 (DOE)	--	5,000 millirem per year ^a
10 CFR 835.1002 (DOE)	--	1,000 millirem per year ^b
DOE Order 5400.5 (DOE) ^c	10 millirem per year (all air pathways) 4 millirem per year (drinking water pathways) 100 millirem per year (all pathways)	--
40 CFR Part 61 (EPA)	10 millirem per year (all air pathways)	--
40 CFR Part 141 (EPA)	4 millirem per year (drinking water pathways)	--

^a Although this is a limit (or level) that is enforced by DOE, worker doses must be managed in accordance with as low as is reasonably achievable principles. Refer to footnote b.

^b This is a control level. It was established by DOE to assist in achieving its goal to maintain radiological doses as low as is reasonably achievable. DOE recommends that facilities adopt a more limiting 500 millirem per year Administrative Control.

^c Derived from 40 CFR Part 61, 40 CFR Part 141, and 10 CFR Part 20.

C.1.2.3 Data Sources Used To Evaluate Public Health Consequences From Routine Operations

Because NNSA operations have the potential to release measurable quantities of radionuclides to the environment that result in exposure to the worker and the public, NNSA conducts environmental surveillance and monitoring activities at its sites. These activities provide data that are used to evaluate radiation exposures that contribute doses to the public. Each year,

environmental data from the NNSA sites are collected and analyzed. The results of these environmental monitoring activities are summarized in an *Annual Site Environmental Report* (ASER). The environmental monitoring conducted at most NNSA sites consists of two major activities: effluent monitoring and environmental surveillance.

Effluent monitoring involves the collection and analysis of samples or measurements of liquid (waterborne) and gaseous (airborne) effluents prior to release into the environment. These analytical data provide the basis for the evaluation and official reporting of contaminants, assessment of radiation and chemical exposures to the public, and demonstration of compliance with applicable standards and permit requirements.

Environmental surveillance data provide a direct measurement of contaminants in air, water, groundwater, soil, food, biota, and other media subsequent to effluent release into the environment. These data verify the NNSA site's compliance status and, combined with data from effluent monitoring, allow the determination of chemical and radiation dose and exposure assessment of NNSA operations and effects, if any, on the local environment. The effluent and environmental surveillance data presented in the ASERs were used as the primary source of data for the analysis of radiation exposure to the public for the No Action Alternative.

C.1.3 Methodology for Estimating Radiological Impacts

The public health consequences of radionuclides released to the atmosphere from normal operations at NNSA sites are characterized and calculated in the applicable ASER. Radiation doses are calculated for the maximally exposed individual (MEI) and the entire population residing within 50 miles of the center of the site. In this SPEIS, dose calculations from normal operations were made using the CAP-88 package of computer codes, version 3 (EPA 2008), which was developed under EPA sponsorship to demonstrate compliance with 40 CFR Part 61, Subpart H, which governs the emissions of radionuclides other than radon from DOE facilities. This package implements a steady-state Gaussian plume atmospheric dispersion model to calculate concentrations of radionuclides in the air and on the ground and uses Regulatory Guide 1.109 (NRC 1977) food-chain models to calculate radionuclide concentrations in foodstuffs (vegetables, meat, and milk) and subsequent intakes by humans.

Meteorological data used in the calculations were in the form of joint frequency distributions of wind direction, wind speed class, and atmospheric stability category. For occupants of residences, the dose calculations assume that the occupant remained at home (actually, unprotected outside the house) during the entire year and obtained food according to the rural pattern defined in the NESHAP background documents (EPA 1989). This pattern specifies that 70 percent of the vegetables and produce, 44.2 percent of the meat, and 39.9 percent of the milk consumed are produced in the local area (e.g., a home garden). The remaining portion of each food is assumed to be produced within 50 miles of the site. The same assumptions are used for occupants of businesses, but the resulting doses are divided by two to compensate for the fact that businesses are occupied for less than one-half a year and that less than one-half of a worker's food intake occurs at work. For collective effective dose equivalent (EDE) estimates, production of beef, milk, and crops within 50 miles of the site was calculated using production rates provided with CAP-88.

C.1.4 Risk Characterization and Interpretation of Radiological Data

The Interagency Steering Committee on Radiation Standards (Lawrence 2002) recommended a risk estimator of 6×10^{-4} excess (above those naturally occurring) fatal cancers per person-rem of dose in order to assess health effects to the public and to workers. The probability of an individual worker or member of the public contracting a fatal cancer is 6×10^{-7} per millirem. Radiation exposure can also cause nonfatal cancers and genetic disorders. The probability of incidence of these is one third that of a cancer fatality (Lawrence 2002). In this SPEIS, only estimates of potential fatal cancers are presented.

The radiation exposure risk estimators are denoted as excess because they result in fatal cancers above the naturally occurring annual rate, which is 171.4 per 100,000 population nationally (Ries et al. 2002). Thus, approximately 1,714 fatal cancer deaths per year would be expected to naturally occur in the approximately one million people surrounding an NNSA site. The doses to which they are applied is the EDE, which weights the impacts on particular organs so that the dose from radionuclides that affect different organs can be compared on a similar (effect on whole body) risk basis. All doses in this document are effective dose equivalent unless otherwise noted.

The number of latent cancer fatalities (LCFs) in the general population or in the workforce is determined by multiplying 600 LCFs per million person-rem with the calculated collective population dose (person-rem), or calculated collective workforce dose (person-rem). For example, in a population of 100,000 people exposed only to natural background radiation of 0.3 rem per year, 18 cancer fatalities per year would be inferred to be caused by the radiation (100,000 persons \times 0.3 rem per year \times 0.0006 cancer fatalities per person-rem = 18 cancer fatalities per year).

Sometimes, calculations of the number of excess cancer fatalities associated with radiation exposure do not yield whole numbers and, especially in environmental applications, may yield numbers less than 1.0. For example, if a population of 100,000 were exposed as above, but to a total dose of only 0.001 rem, the collective dose would be 100 person-rem, and the corresponding estimated number of cancer fatalities would be 0.06 (100,000 persons \times 0.001 rem \times 0.0006 cancer fatalities/person-rem = 0.06 fatal cancers).

A nonintegral number of cancer fatalities such as 0.06 should be interpreted as a statistical estimate. That is, 0.06 is interpreted as the average number of deaths that would result if the same exposure situation were applied to many different groups of 100,000 people. In most groups, no person (0 people) would incur a cancer fatality from the 0.001 rem dose each member would have received. In a small fraction of the groups, one fatal cancer would result; in exceptionally few groups, two or more fatal cancers would occur. The average number of deaths over all the groups would be 0.06 fatal cancers (just as the average of 0, 0, 0, and 1 is 1/4, or 0.25). The most likely outcome is zero cancer fatalities.

These same concepts apply to estimating the effects of radiation exposure on a single individual. Consider the effects, for example, of exposure to background radiation over a lifetime. The

“number of cancer fatalities” corresponding to a single individual’s exposure over a (presumed) 70-year lifetime to 0.3 rem per year is the following:

$$1 \text{ person} \times 0.3 \text{ rem/year} \times 70 \text{ years} \times 0.0006 \text{ cancer fatalities/person-rem} = 0.013 \text{ cancer fatalities}$$

This could be interpreted that the estimated effect of background radiation exposure on the exposed individual would produce a 1.3 percent chance that the individual might incur a fatal cancer caused by the exposure.

Health effects resulting from exposure to both airborne and waterborne radionuclides may also be evaluated by comparing estimated concentrations to established radionuclide-specific, risk-based concentration values. For example, DOE Order 5400.5 establishes Derived Concentration Guidelines (DCGs) for the inhalation of air and the ingestion of water. The DCG is the concentration of a radionuclide in air or water that, under conditions of continuous exposure for one year by one exposure mode (i.e., ingestion of water, submersion in air, or inhalation) would result in an effective dose equivalent of 100 mrem per year. To ensure that exposure via the drinking water pathway does not exceed four millirem per year, as required by DOE Order 5400.5, four percent of the DCG values are used as comparison values.

Members of the public are assumed to ingest 730 liters per year (2 liters per day) of water or to inhale 8,400 cubic meters per year (23 cubic meters per day) of air. The DCG values are used as reference concentrations for conducting environmental protection programs at DOE sites, as screening values for considering best available technology for treatment of liquid effluents, and for making dose comparisons.

Because fatal cancer is the most probable serious effect of environmental and occupational radiation exposures, this SPEIS presents estimates of LCFs rather than cancer incidence. The numbers of LCFs can be used to compare the risks among the various alternatives. Nonfatal cancers can be estimated by comparing them with the LCF estimates (see Table C.1.4-1).

Table C.1.4-1—Nominal Health Risk Estimators Associated With Exposure to 1 Rem of Ionizing Radiation

Exposed Individual	Fatal Cancer	Nonfatal Cancer
Worker	0.0006	0.0008
Public	0.0006	0.0008

Source: DOE 2002d.

C.1.5 Risk Estimates and Health Effects for Potential Radiation Exposures to Workers

For the purpose of evaluating radiation exposure on an ongoing basis, NNSA workers may be designated as radiation workers, nonradiation workers, or visitors, based upon the potential level of exposure they are expected to encounter in performing their work assignments. For purposes of estimating radiation doses to workers resulting from potential accidents, NNSA looks at involved workers (those workers actually working with radioactive materials) and noninvolved workers (those workers performing other tasks near the involved workers).

Radiation workers have job assignments that place them in proximity to radiation-producing equipment and/or radioactive materials. These workers are trained for unescorted access to radiological areas, and may also be trained radiation workers from another DOE site. These workers are assigned to areas that could potentially contribute to an annual TEDE of more than 100 millirem per year. All trained radiation workers wear dosimeters.

Nonradiation workers are those not currently trained as radiation workers but whose job assignment may require their occasional presence within a radiologically controlled area with an escort. They may be exposed to transient radiation fields as they pass by or through a particular area, but their job assignments are such that annual dose equivalents in excess of 100 millirem are unlikely. Based upon the locations where such personnel work on a daily basis, they may be issued a Personal Nuclear Accident Dosimeter.

Visitors are individuals who are not trained radiation workers and are not expected to receive 100 millirem in a year. Their presence in radiological areas is limited, in terms of time and access. These individuals generally enter specified radiological areas on a limited basis for walk-through or tours with a trained escort. As appropriate, visitors participate in dosimetry monitoring when requested by the hosting division.

C.1.5.1 NNSA's Radiation Protection Program

A primary goal of the NNSA Radiation Protection Program is to keep worker exposures to radiation and radioactive material ALARA. Such a program must evaluate both external and internal exposures with the goal to minimize worker radiation dose. The worker radiation dose presented in this SWEIS is the total TEDE incurred by workers as a result of normal operations. This dose is the sum of the external whole body dose, including dose from both photons and neutrons, and internal dose, as required by 10 CFR Part 835. The internal dose is the 50-year CEDE. These values are determined through the NNSA External and Internal Dosimetry Programs.

The External Dosimetry Program at NNSA provides personnel monitoring information necessary to determine the dose equivalent received following external exposure of a person to ionizing radiation. The program is based on the concepts of effective dose equivalent, as described in publications of the ICRP and the International Commission on Radiation Quantities and Units.

Internal dose monitoring programs are conducted at NNSA sites to estimate the quantity and distribution of radionuclides to which a worker may have been exposed. The internal dose monitoring program consists of urinalysis, fecal analysis, lung counting, continuous air monitoring, and retrospective air sampling. Dose assessments are generally based on bioassay data. Bioassay monitoring methods and participation frequencies are required to be established for individuals who are likely to receive intakes that could result in a CEDE that is greater than 100 millirem.

C.2 HAZARDOUS CHEMICAL IMPACTS TO HUMAN HEALTH

C.2.1 Chemicals and Human Health

We use chemicals in our everyday tasks—as pesticides in our gardens, cleaning products in our homes, insulating materials in buildings, and as ingredients in medications. Potentially hazardous chemicals can be found in all of these products, but usually the quantities are not large enough to cause adverse health effects. In contrast to home use, chemicals used in industrial settings are often found in concentrations that may affect the health of individuals in the workplace and in the surrounding community.

For the programmatic alternatives considered in this SPEIS, the chemicals of with the highest hazards were determined to be nitric acid, hydrofluoric acid, formic acid, and chlorine. This determination was based on considerations of vapor pressure, acceptable concentration, and quantity available for release. The following sections describe both the carcinogenic and noncarcinogenic effects of chemicals on the body and how these effects are assessed.

C.2.1.1 *How Do Chemicals Affect the Body?*

Industrial pollutants may be released either intentionally or accidentally to the environment in quantities that could result in health effects to those who come in contact with them. Chemicals that are airborne, or released from stacks and vents, can migrate in the prevailing wind direction for many miles. The public may then be exposed by inhaling chemical vapors or particles of dust contaminated by the pollutants. Additionally, the pollutants may be deposited on the surface soil and biota (plants and animals) and subsequent human exposure could occur. Chemicals may also be released from industries as liquid or solid waste (effluent) and can migrate or be transported from the point of release to a location where exposure could occur.

Exposure is defined as the contact of a person with a chemical or physical agent. For exposure to occur, a chemical source or contaminated media such as soil, water, or air must exist. This source may serve as a point of exposure, or contaminants may be transported away from the source to a point where exposure could occur. In addition, an individual (receptor) must come into either direct or indirect contact with the contaminant. Contact with a chemical can occur through ingestion, inhalation, dermal contact, or external exposure. The exposure may occur over a short (acute or subchronic) or long (chronic) period of time. These methods of contact are typically referred to as exposure routes. The process of assessing all of the methods by which an individual might be exposed to a chemical is referred to as an exposure assessment.

Once an individual is exposed to a hazardous chemical, the body's metabolic processes typically alter the chemical structure of the compound in its efforts to expel the chemical from the system. For example, when compounds are inhaled into the lungs they may be absorbed depending on their size (for particulates) or solubility (for gases and vapors) through the lining of the lungs directly into the blood stream. After absorption, chemicals are distributed in the body and may be metabolized, usually by the liver, into metabolites that may be more toxic than the parent compound. The compound may reach its target tissue, organ, or portion of the body where it will exert an effect, before it is excreted via the kidneys, liver, or lungs. The relative toxicity of a compound is affected by the physical and chemical characteristics of the contaminant, the physical and chemical processes ongoing in the human body and the overall health of an individual. For example, infants, the elderly, and pregnant women are considered more susceptible to certain chemicals.

C.2.2 How Does DOE Regulate Chemical Exposures?

C.2.2.1 *Environmental Protection Standards*

DOE Order 450.1 requires implementation of sound stewardship practices that are protective of the air, water, land, and other natural and cultural resources impacted by the DOE operations and by which DOE cost-effectively meets or exceeds compliance with applicable environmental; public health; and resource protection laws, regulations, executive orders, and DOE requirements. The objective is accomplished by implementing Environmental Management Systems (EMSs) at DOE sites. An EMS is a continuing cycle of planning, implementing, evaluating, and improving processes and actions undertaken to achieve environmental goals. Applicable Federal and State environmental acts/agreements include:

- *Resource Conservation and Recovery Act (RCRA)*
- *Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA)* as amended by the *Superfund Amendments and Reauthorization Act (SARA)*
- Federal Facility Compliance Agreement
- *Endangered Species Act*
- *Safe Drinking Water Act*
- *Clean Water Act (CWA)*(which resulted in the establishment of the NPDES and pretreatment regulations for Publicly-Owned Treatment Works [POTW])
- *Clean Air Act (CAA)* (Title III, Hazardous Air pollutants Rad-NESHAP, Asbestos NESHAP)
- *Toxic Substances Control Act (TSCA)*
- *Federal Insecticide, Fungicide, and Rodenticide Act*

Many of these acts/agreements include environmental standards that must be met to ensure the protection of the public and the environment. Most of the acts/agreements require completed permit applications in order to treat, store, dispose of, or release contaminants to the environment. The applicable environmental standards and reporting requirements are set forth in the issued permits and must be met to ensure compliance.

The *Emergency Planning and Community Right-To-Know Act*, also referred to as SARA Title III, requires reporting of emergency planning information, hazardous chemical inventories, and environmental releases to Federal, State, and local authorities. The annual Toxics Release Inventory report addresses releases of toxic chemicals into the environment, waste management activities, and pollution prevention activities associated with those chemicals.

C.2.2.2 *Regulated Occupational Exposure Limits*

Occupational limits for hazardous chemicals are regulated by the Occupational Safety and Health Administration (OSHA). The permissible exposure limits (PELs) represent the legal concentration levels set by OSHA that are safe for 8-hour exposures without causing noncancer health effects. Other agencies, including the National Institute for Occupational Safety and Health (NIOSH) and the American Conference of Governmental Industrial Hygienists (ACGIH) provide guidelines. The NIOSH guidelines are Recommended Exposure Limits, and the ACGIH guides are threshold limit values (TLVs). Occupational limits are further defined as time-weighted averages (TWAs), or concentrations for a conventional 8-hour workday and a 40-hour workweek, to which it is believed nearly all workers may be exposed, day after day, without adverse effects. Often ceiling limits, or airborne concentrations that should not be exceeded during any part of the workday, are also specified. In addition to the TWA and ceiling limit, short-term exposure limits may be set. Short-term exposure limits are 15-minute TWA exposures that should not be exceeded at any time during a workday, even if the 8-hour TWA is within limits. OSHA also uses action levels to trigger certain provisions of a standard (e.g., appropriate workplace precautions, training, and medical surveillance) for workers whose exposures could approach the PEL.

C.2.2.3 *Department of Energy Regulation of Worker Safety*

DOE Order 440.1A, Worker Protection Management for DOE Federal and Contractor Employees, regulates the health and safety of workers at all DOE sites. This comprehensive standard directs the contractor facilities to establish the framework for an effective worker protection program that will reduce or prevent injuries, illnesses, and accidental losses by providing DOE Federal and contractor workers with a safe and healthful workplace. Baseline exposure assessments are outlined in this requirement, along with day-by-day health and safety responsibilities.

Industrial hygiene limits for occupational chemical exposures at Federal sites are regulated by 29 CFR Part 1910 and 29 CFR Part 1926, Occupational Safety and Health Standards, including the PELs set by OSHA. DOE requires that all sites comply with the PELs unless a lower limit (more protective) exists in the ACGIH TLVs.

C.3 **ACCIDENTS**

C.3.1 **Introduction**

An accident is a sequence of one or more unplanned events with potential unmitigated outcomes that endanger the health and safety of workers and the public. An accident can involve a

combined release of energy and hazardous materials (radiological or chemical) that might cause prompt or latent health effects. The sequence usually begins with an initiating event, such as a human error, equipment failure, or earthquake, followed by a succession of other events that could be dependent or independent of the initial event, which dictates the accident's progression and the extent of materials released. Initiating events fall into three categories:

- **Internal initiators** normally originate in and around the facility, but are always a result of facility operations. Examples include equipment or structural failures and human errors.
- **External initiators** are independent of facility operations and normally originate from outside the facility. Some external initiators affect the ability of the facility to maintain its confinement of hazardous materials because of potential structural damage. Examples include aircraft crashes, vehicle crashes, nearby explosions, and toxic chemical releases at nearby facilities that affect worker performance.
- **Natural phenomena initiators** are natural occurrences that are independent of facility operations and occurrences at nearby facilities or operations. Examples include earthquakes, high winds, floods, lightning, wild fires, and snow. Although natural phenomena initiators are independent of external facilities, their occurrence can involve those facilities and compound the progression of the accident.

If an accident were to occur involving the release of radioactive or chemical materials, workers, members of the public, and the environment would be at risk. Workers in the facility where the accident occurs would be particularly vulnerable to the effects of the accident because of their location. The offsite public would also be at risk of exposure to the extent that meteorological conditions exist for the atmospheric dispersion of released hazardous materials. Using approved computer models, the dispersion of released hazardous materials and their effects are predicted. However, prediction of latent potential health effects becomes increasingly difficult to quantify for facility workers as the distance between the accident location and the worker decreases. This is because the individual worker exposure cannot be precisely defined with respect to the presence of shielding and other protective features. The worker also may be injured or killed by physical effects of the accident itself.

The potential for facility accidents and the magnitudes of their consequences are important factors in evaluating the alternatives addressed in this SPEIS. The health risk issues are twofold:

- Whether accidents at any of the individual facilities (or reasonable combinations thereof) pose unacceptable health risks to workers or the general public; and
- Whether alternative locations for facilities (or reasonable combinations thereof) can provide lesser public or worker health risks. These lesser risks may arise either from a greater isolation of the site from the public or from a reduced frequency of such external accident initiators as seismic events.

Guidance for implementing Council on Environmental Quality (CEQ) regulation, 40 Code of Federal Regulations 1502.22, as amended (51 FR 15618), requires the evaluation of impacts which have low probability of occurrence but high consequences if they do occur; thus, facility accidents must be addressed to the extent feasible in this SPEIS. Further, public comments

received during the scoping process clearly indicated the public's concern with facility safety and consequent health risks and the need to address these concerns in the decision-making process.

For the No Action Alternative, potential accidents are defined in existing facility documentation, such as safety analysis reports, hazards assessment documents, NEPA documents, and probabilistic risk assessments. The accidents include radiological and chemical accidents that produce high consequences but have a low likelihood of occurrence, and a spectrum of other accidents that have a higher likelihood of occurrence and lesser consequences. The data in these documents include accident scenarios, probabilities, materials at risk, source terms (quantities of hazardous materials released to the environment), and consequences.

For new, modified, or upgraded NNSA facilities, the identification of accident scenarios and associated data would normally be a product of safety analysis reports performed on completed facility designs. However, facility designs have not been completed for the facility alternatives analyzed in the programmatic portion of this SPEIS. Accordingly, the accident information developed for this SPEIS was developed based upon existing information for similar facilities. The first step in the process was to review all of the potential types of facilities and processes that could be associated with the Consolidated Plutonium Center (CPC), Consolidated Uranium Center (CUC), and Assembly/Disassembly/High Explosives (A/D/HE) Center, with emphasis on building hazard classification and radionuclide inventories (including type, quantity, and physical form) and storage and use conditions. First, administrative buildings without radioactive materials were excluded. Then, buildings ranked as low hazard and those without radioactive materials were eliminated from consideration. The potential offsite consequences of facilities screened out would be well bounded by a nuclear facility's bounding accident scenarios.

The next step in the selection process was to identify the most current documentation describing/quantifying the hazards associated with each facility's operation. Current safety documentation, which is either classified or contains Unclassified Controlled Nuclear Information that is not releasable to the general public, was obtained for these facilities, and reviewed to determine a reasonable range of bounding accidents for the CPC, CUC, and A/D/HE Center. Documents such as those shown in Table C.3-1 were reviewed for applicable accident scenarios and data.

The process sought to identify a bounding accident in each of several classes of events (e.g., fire, explosion, spill, mechanical, criticality, natural phenomena initiators, and external initiators) applicable to the alternative. The process also sought to identify bounding accidents over the spectrum of high to low probability of occurrence in order to include high-consequence/low-probability and low-consequence/high-probability accidents. These accidents are generally referred to as beyond evaluation basis accidents and evaluation basis accidents, respectively.

Beyond evaluation basis accidents are generally in the probability of occurrence range of 1×10^{-7} to 10^{-6} per year, and evaluation basis accidents generally have a probability of occurrence greater than 1×10^{-6} per year. These two designations are used only if formal SARs have not been prepared. In cases where Safety Analyses Reports (SARs) have been prepared, they are the source documents for two equivalent designations "beyond design basis accidents" and "design basis accidents."

For each facility, applicable accidents were analyzed to estimate risk (i.e., mathematical product of an accident's probability of occurrence and the accident's consequences) and consequences (e.g., LCF) to a noninvolved worker, an MEI (a hypothetical member of the public located at the closest site boundary), and the surrounding population within 50 miles of the site. This analysis considers the potential differences in likelihood of accident initiators at specific sites (e.g., beyond design basis seismic events, and so forth). The likelihood and consequences of accidents (which are site dependent) are analyzed at each of the sites where a particular facility may be located. This calculation reflects the effects of such site parameters as population size and distribution, meteorology, and distance to the site boundary. Based on this process, the following reference report was prepared: *Topical Report—Supporting Documentation for the Accident Impacts Presented in the Complex Transformation Supplemental Programmatic Environmental Impact Statement* (Tetra Tech 2008).

The accidents described in Sections C.4 through C.6 were selected from a wide spectrum of potential accident scenarios. The selection process, screening criteria used, and conservative estimates of material at risk and source term ensure that the accidents chosen for evaluation in this SPEIS bound the impacts of all reasonably foreseeable accidents that could occur under an alternative. Thus, in the event that any other accident that was not evaluated in this SPEIS were to occur, its impacts on workers and the public would be expected to be within the range of the impacts evaluated. All accidents are assumed to result in ground-level, one-hour duration releases unless indicated otherwise. All releases are assumed neutrally buoyant except the uranium operations aircraft crash, for which the added heat was taken as 4.6 megawatts, the value used in the Lawrence Livermore Continued Operations SWEIS (DOE 2005a).

Of particular interest are the uncertainties in the estimates of cancer fatalities from exposure to radioactive materials. The numerical values of the health risk estimators used in this SPEIS were obtained by linear extrapolation from the nominal risk estimate for lifetime total cancer mortality resulting from exposures of 10 rad. There is uncertainty about cancer risk in the low-dose region and the possibility of no risk cannot be excluded. Because the health risk estimators are multiplied by conservatively calculated radiological doses to predict fatal cancer risks, the fatal cancer values presented in this EIS are expected to be overestimates.

For the purposes of this EIS, the impacts calculated from the linear model are treated as an upper-bound case, consistent with the widely used methodologies for quantifying radiogenic health impacts. This does not imply that health effects are expected. Moreover, in cases where the upper-bound estimators predict a number of LCFs greater than one, this does not imply that the LCF risk can be determined for a specific individual.

C.3.1.1 *Assessment of Vulnerability to Terrorist Threats*

The methodology for the assessment of vulnerability to terrorist threats is discussed in Appendix B, Section B.12.3.

C.3.2 Safety Design Process

Subsequent to this SPEIS, evaluation of the specific benefits achieved would be presented for each new facility in a Hazards Analysis Document. This document would identify and estimate the effects of all major hazards that have the potential to impact the environment, workers, and the public, and would be issued in conjunction with the Conceptual Design Package. Additional accident analyses for identified major hazards would be provided in a Preliminary SAR to be issued during the period of Definitive Design (Title II) Review. A Final SAR would be prepared during the construction period and issued before testing begins as final documented evidence that the new facility can be operated in a manner that does not present any undue risk to the health and safety of workers and the public.

One of the major design goals for any Complex Transformation facility is to achieve a reduced risk to workers and the public relative to that associated with similar facilities in the existing Nuclear Weapons Complex. Any new NNSA facilities would be designed to comply with current Federal, State, and local laws; DOE orders; and industrial codes and standards. As a result, a facility will be provided that is highly resistant to the effects of natural phenomena, including earthquake, flood, tornado, high wind, as well as credible events appropriate to the site, such as fire, explosions, and manmade threats. The facilities would be designed to maintain their continuing structural integrity in the event of any credible accident or event, including an aircraft crash, if credible at these sites.

The design process for new and modified facilities would comply with the requirements for safety analysis and evaluation in DOE Order 430.1B, Real Property Asset Management, assessment is required to be an integral part of the design process to ensure compliance with all DOE safety criteria by the time that the facilities are constructed and in operation.

For new facilities, the safety analysis process begins early in conceptual design by identifying hazards with the potential to produce unacceptable safety consequences to workers or the public. As the design develops, failure mode and effects analyses are performed to identify events that have the potential to release hazardous material. The kinds of events considered include equipment failure, spills, human error, fire and explosions, criticality, earthquake, electrical storms, tornado, flood, and aircraft crash. These postulated events become focal points for design changes or improvements to prevent unacceptable accidents. These analyses continue as the design progresses to assess the need for safety equipment and to assess the performance of this equipment in accident mitigation. Eventually, the safety analyses are formally documented in an SAR and/or in a probabilistic risk assessment. The probabilistic risk assessment documents the estimated frequency and consequence for an entire spectrum of accidents and helps to identify design improvements that could make meaningful safety improvements.

The first SAR is completed at the conclusion of conceptual design and includes identification of hazards and some limited assessment of a few enveloping design basis accidents. This analysis includes deterministic safety analysis and failure modes and effects analysis of major systems. A detailed, comprehensive Preliminary SAR is completed during preliminary design and provides a broad assessment of the range of design basis accident scenarios and the performance of

equipment provided in the facility specifically for accident consequence mitigation. A limited probability risk assessment may be included in that analysis.

The SAR continues to be developed during detailed design. The safety review of this report and any supporting probabilistic risk assessment is completed and safety issues resolved before the facility construction is initiated. The Final SAR documents safety-related design changes during construction and the impact of those changes on the safety assessment. It also includes the results of any safety-related research and development that has been performed to support the safety assessment of the facility.

C.3.3 Consequence Analysis Methodology

The MELCOR Accident Consequence Code System (MACCS) was used to estimate the radiological consequences of all stockpile stewardship and management facilities for all accidents. MACCS2 is a DOE/Nuclear Regulatory Commission (DOE/NRC)-sponsored computer code that has been widely used in support of probabilistic risk assessments for the nuclear power industry and in support of safety and NEPA documentation for facilities throughout the DOE Complex. A brief description of MAACS follows. A detailed description of the MACCS model is available in a three-volume report: *MELCOR Accident Consequence Code System* (MACCS) (NUREG 1990).

MACCS models the offsite consequences of an accident that releases a plume of radioactive materials to the atmosphere. Should such an accidental release occur, the radioactive gases and aerosols in the plume would be transported by the prevailing wind while dispersing in the atmosphere. The environment would be contaminated by radioactive materials deposited from the plume, and the population would be exposed to radiation. The objectives of a MACCS calculation are to estimate the range and probability of the health induced by the radiation exposures not avoided by protective actions.

The MACCS2 code uses three distinct modules for consequence calculations: The ATMOS module performs atmospheric transport calculations, including dispersion, deposition, and decay. The EARLY module performs exposure calculations corresponding to the period immediately following the release; this module also includes the capability to simulate evacuation from areas surrounding the release. The EARLY module exposure pathways include inhalation, cloudshine, and groundshine. The CHRONC module considers the time period following the early phase (i.e., after the plume has passed). CHRONC exposure pathways include groundshine, resuspension inhalation, and ingestion of contaminated food and water. Land use interdiction (e.g., decontamination) can be simulated in this module. Other supporting input files include a meteorological data file and a site data file containing distributions of the population and agriculture surrounding the release site.

In order to understand MACCS, one must understand its two essential elements: the time scale after an accident is divided into various "phases"; and the region surrounding the facility is divided into a polar-coordinate grid. The time scale after the accident is divided into three phases: emergency phase, intermediate phase, and long-term phase. The emergency phase begins immediately after the accident and could last up to seven days. In this period, the exposure of the

population to both radioactive clouds and contaminated ground is modeled. Various protective measures can be specified for this phase, including evacuation, sheltering, and dose-dependent relocation.

The intermediate phase can be used to represent a period in which evaluations are performed and decisions are made regarding the type of protective measure actions that need to be taken. In this period, the radioactive clouds are assumed to be gone, and the only exposure pathways are those from the contaminated ground. The only protective measure that can be taken during this period is temporary relocation.

The long-term phase represents all time subsequent to the intermediate phase. The only exposure pathways considered here are those resulting from the contaminated ground. A variety of protective measures can be taken in the long-term phase in order to reduce doses to acceptable levels: decontamination, interdiction, and condemnation of property.

As implemented, the MACCS2 model evaluates doses due to inhalation of airborne material, as well as external exposure to the passing plume. This represents the major portion of the dose that an individual would receive because of a facility accident. The longer-term effects of radioactive material deposited on the ground after a postulated accident, including the resuspension and subsequent inhalation of radioactive material and the ingestion of contaminated crops, were not modeled for this SPEIS because these pathways have been studied and found to contribute less significantly to the dosage than the inhalation of radioactive material in the passing plume; they are also controllable through interdiction. Instead, the deposition velocity of the radioactive material was set to zero, so that material that might otherwise be deposited on surfaces remained airborne and available for inhalation. Thus, the method used in this SPEIS is conservative compared with dose results that would be obtained if deposition and resuspension were taken into account.

The source terms were handled by the code by considering the materials at risk (MAR) as the inventory. The release fraction of each scenario was then the product of the various factors (damage ratio [DR], airborne release fraction [ARF], respirable fraction [RF], and leak path factor [LPF]) that describe the material available to actually impact a receptor. The meteorological data consisted of sequential hourly wind speed, wind direction, stability class, and precipitation for one year.

Each four-hour period of the annual meteorological site specific data set for each site was randomly sampled, assuring a good representation of the entire meteorological data set. The results from each of these samples were then ranked and combined (according to their frequency of occurrence) and a distribution of results is presented by the code. This distribution includes statistics such as 95th percentile, 50th percentile, and mean dose. The latter is presented in this SPEIS.

Because of assumptions used in this SPEIS analysis, not all of the code's capabilities were used. For example, it was conservatively assumed that no special actions would be taken to avoid or mitigate exposure to the general population following an accidental release of radionuclides.

Population and individual doses were statistically sampled by assuming an equally likely accident start time during any hour of the year. MEI and noninvolved worker doses were calculated using conservative assumptions, such as the wind blowing toward the MEI and locating the receptor along the plume centerline. The doses (50-year committed EDE) were converted into LCFs using the factor of 6×10^{-4} LCFs per person-rem for both members of the public and workers (DOE 2002d); calculated LCFs were doubled for individual doses greater than 20 rem (NCRP 1993). The MEI and noninvolved worker are assumed to be exposed for the duration of the release; they or DOE would take protective or mitigative actions thereafter if required by the size of the release. Exposure to the general population continues after the release as a result of resuspension and inhalation, external exposure and ingestion of deposited radionuclides.

C.3.3.1 *Analysis Conservatism and Uncertainty*

The analysis of accidents is based on calculations relevant to hypothetical sequences of events and models of their potential impacts. The models provide estimates of the frequencies, source terms, pathways for dispersion, exposures, and the effects on human health and the environment as realistic as possible within the scope of the analysis. In many cases, the scarcity of experience with the postulated accidents leads to uncertainty in the calculation of the consequences and frequencies. This fact has promoted the use of models or input values that yield conservative estimates of consequences and frequency. Additionally, since no credit is taken for safety systems that may function during an event, these events do not represent expected conditions within the facility at any point in its lifetime.

Due to the layers of conservatism built into the accident analysis for the spectrum of postulated accidents, the estimated consequences and risks to the public represent the upper limit for the individual classes of accidents. A conservative approach is appropriate and standard practice for analyses of this type, which involve high degrees of uncertainty associated with analytical factors such as accident frequency, MAR, and LPF.

C.3.3.2 *Mitigation Measures*

Mitigations to exposure and therefore mitigations to dose that would affect the postulated results of the accident scenarios are discussed below. In general, no mitigation was assumed for emergency response in the consequence analysis.

C.3.3.2.1 **Emergency Response and Protective Actions**

NNSA sites have detailed plans for responding to accidents of the type described in this SPEIS, and the response activities would be closely coordinated with those of local communities. NNSA personnel are trained and drilled in the protective actions to be taken if a release of radioactive or otherwise toxic material occurs. The underlying principle for the protective action guides (PAGs) is that under emergency conditions all reasonable measures should be taken to minimize the radiation exposure of the general public and emergency workers. In the absence of significant

constraints, protective actions could be implemented when projected doses are lower than the ranges given in the PAGs. No credit was taken for emergency response and protective actions in the consequence analysis.

C.3.3.2 High Efficiency Particulate Air Filtration

In all areas where unconfined plutonium or other radioactive materials can be handled and can exist in a dispersible form, high-efficiency particulate air (HEPA) filters provide a final barrier against the inadvertent release of radioactive aerosols into the outside environment. However, these filters would not trap volatile fission products such as the noble gases and iodine; such gases would be released into the outside environment.

HEPA filter efficiencies are 99.99 percent or greater with the minimum efficiency of 99.97 percent for 0.3-micron particles, the size most easily passed by the filter. To maximize containment of particles and provide redundancy, two HEPA filters in series would be used, as is the normal operational procedure at such NNSA facilities. Additional HEPA filtration would be used, as required, to ensure compliance with regulatory requirements. These HEPA filters are protected by building design features against the consequences of an earthquake or fire. Credit was taken for filtration in the consequence analysis when ventilation and building containment were shown by analysis to survive during the accident.

C.3.3.3 Chemical Releases

Consequences of accidental chemical releases were determined using the Aerial Location of Hazardous Atmospheres (ALOHA) computer code (EPA 1999b). ALOHA is an EPA/National Oceanic and Atmospheric Administration (NOAA)-sponsored computer code that has been widely used in support of chemical accident responses and also in support of safety and NEPA documentation for DOE facilities.

The ALOHA code is a deterministic representation of atmospheric releases of toxic and hazardous chemicals. The code can predict the rate at which chemical vapors escape (e.g., from puddles or leaking tanks) into the atmosphere; a specified direct release rate is also an option. Either of two dispersion algorithms is applied by the code, depending on whether the release is neutrally buoyant or heavier than air. The former is modeled similarly to radioactive releases in that the plume is assumed to advect with the wind velocity. The latter considers the initial slumping and spreading of the release because of its density. As a heavier-than-air release becomes more dilute, its behavior tends towards that of a neutrally buoyant release.

The ALOHA code uses a constant set of meteorological conditions (e.g., wind speed, stability class) to determine the downwind atmospheric concentrations. The sequential meteorological data sets used for the radiological accident analyses were re-ordered from high to low dispersion by applying a Gaussian dispersion model (such as that used by ALOHA) to the closest site boundary at each site. The median set of hourly conditions for each site (i.e., mean wind speed and mean stability) was used for the analysis; this is roughly equivalent to the conditions corresponding to the mean radiological dose estimates of MACCS2.

In addition to the source term and downwind concentration calculations, ALOHA allows for the specification of concentration limits for the purpose of consequence assessment (e.g., assessment of human health risks from contaminant plume exposure). ALOHA refers to these concentration limits as level-of-concern (LOC) concentrations. Safety analysis work uses the Emergency Response Planning Guidelines (ERPGs) and Temporary Emergency Exposure Limits (TEELs) for assessing human health effects for both facility workers and the general public. While ERPGs and TEELs are not explicitly a part of the ALOHA chemical database, ALOHA allows the user to input any value, including an ERPG or TEEL value, as the LOC concentration. The LOC value is superimposed on the ALOHA-generated plot of downwind concentration as a function of time to facilitate comparison. In addition, ALOHA will generate a footprint that shows the area (in terms of longitudinal and lateral boundaries) where the ground-level concentration reached or exceeded the LOC during puff or plume passage (the footprint is most useful for emergency response applications).

ERPG Definitions

ERPG-1 is the maximum airborne concentration below which nearly all individuals could be exposed for up to one hour without experiencing other than mild transient adverse health effects or perceiving a clearly defined objectionable odor.

ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to one hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action.

ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to one hour without experiencing or developing life-threatening health effects.

ALOHA contains physical and toxicological properties for the chemical spills included in the EIS and for approximately 1,000 additional chemicals. The physical properties were used to determine which of the dispersion models and accompanying parameters were applied. The toxicological properties were used to determine the levels of concern. Atmospheric concentrations at which health effects are of concern (e.g., ERPG-2) are used to define the footprint of concern because the meteorological conditions specified do not account for wind direction (i.e., it is not known a priori in which direction the wind would be blowing in the event of an accident) the areas of concern are defined by a circle of radius equivalent to the downwind distance at which the concentration decreases to levels less than the level of concern. The fraction of the area of concern actually exposed to the concentration of concern (footprint area/circle area) was noted. In addition, the concentration at 1,000 meters (3,281 feet) (potential exposure to a noninvolved worker) and at the nearest site boundary distance (exposure to maximum exposed offsite individual) are calculated and presented.

C.4 RADIOLOGICAL ACCIDENT SCENARIOS—CPC

CPC-related facility radiological and chemical accidents are described in Tables C.4-1 and C.4-2. These tables also identify the estimated maximum MAR and source term and accident frequency. Section C.5 provides additional data on release fractions such as damage ratio, leak

path factor, and estimated respirable release fraction (RRF) for each postulated accident. The RRF is the mathematical product of the ARF and the RF calculated by the equation $RRF = ARF \times RF$ (Tetra Tech 2008).

C.4.1 Postulated Accidents

The accident scenarios shown in Tables C.4-1 and C.4-2 cover the types of hazardous situations appropriate for the Complex Transformation SPEIS. The list includes fires, spills, criticality and explosions events, site-specific externally initiated events, and natural phenomena events. For radiological accidents, the material at risk is plutonium and the predominant form of exposure is through inhalation. For radiological accidents, the material at risk is plutonium and the predominant form of exposure is through inhalation. The list also includes the potential release of toxic chemicals used in CPC processes. The accidents listed in this section were selected from a wide spectrum of accidents described in the *Topical Report—Supporting Documentation for the Accident Impacts Presented in the Complex Transformation Supplemental Programmatic Environmental Impact Statement* (Tetra Tech 2008).

The results of the accident analysis indicate potential consequences that exceed the DOE exposure guidelines of 25 rem for a member of the public at the nearest site boundary. The analyses in these cases for NEPA purposes are based on unmitigated releases of radioactive material to select a site for the CPC. Following the Record of Decision (ROD) and selection of a site, additional NEPA action would be taken that would identify specific mitigating features that would be incorporated in the CPC design to ensure compliance with DOE exposure guidelines. These could include procedural and equipment safety features, additional HEPA filtration systems, and other design features that would protect radioactive materials from accident conditions and contain any material that might be released. DOE would prepare safety analysis documentation such as a safety analysis report to further ensure that DOE exposure guidelines would not be exceeded. The results of the safety analysis report are reflected in facility and equipment design and defines an operating envelope and procedures to ensure public and worker safety. Specific mitigation measures would be incorporated into a CPC design and operating procedures to ensure that consequences would not exceed the DOE exposure guidelines of 25 rem for a member of the public at the nearest site boundary for any of the site alternatives.

The accident source terms shown in Tables C.4-1 and C.4-2 indicate the quantity of radioactive and chemical material released to the environment with a potential for harm to the public and onsite workers. The radiological source terms are calculated by the equation:

Source Term = $MAR \times ARF \times RF \times DR \times LPF$, where:

MAR. The amount and form of radioactive material at risk of being released to the environment under accident conditions.

ARF. The airborne release fraction reflecting the fraction of damaged MAR that becomes airborne as a result of the accident.

RF. The respirable fraction reflecting the fraction of airborne radioactive material that is small enough to be inhaled by a human.

DR. The damage ratio reflecting the fraction of MAR that is damaged in the accident and available for release to the environment.

LPF. The leak path factor reflecting the fraction of respirable radioactive material that has a pathway out of the facility for dispersal in the environment.

The accident source terms for chemical accidents are shown in Table C.4-2. The impacts of chemical accidents are measured in terms of ERPG-2 and ERPG-3 concentration limits established by the American Industrial Hygiene Association. ERPG-2 is defined as the maximum airborne concentration below which it is believed nearly all individuals could be exposed for up to one hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their ability to take protective actions. ERPG-3 is defined as the maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to one hour without experiencing or developing life-threatening health effects.

Beyond evaluation basis earthquake with fire. The earthquake accident scenario postulates a seismic event and seismically induced failure of interior nonstructural walls. The collapsed walls cause a loss of confinement and a potential release of materials in multiple areas in the facility. Combustible materials in the area are ignited, and the resulting fire propagates to multiple areas of the facility, including storage vaults in three buildings containing the largest quantity of plutonium metal. The MAR for the 125 pits per year (ppy) production case includes 16,929 kilograms (37,322 pounds) metal, 36 kilograms (79 pounds) powder, and 24 kilograms (53 pounds) solution. The bounding seismic accident with fire conservatively assumes a damage ratio (DR) = 1.0 resulting in all of the MAR to be affected by the fire. The collapsed walls cause a loss of confinement resulting in an assumed leak path factor (LPF) = 1.0. The airborne respirable release fraction is estimated to be $ARF \times RF = 2.5 \times 10^{-4}$ (metal), 6×10^{-5} (oxide), and 2×10^{-3} (solution). No credit is taken for the mitigating effects of safety systems, fire suppression efforts and equipment, plutonium cladding, the shipping containers, or the final building state (building collapse and rubble bed). The resulting source term for the 125 ppy case is 4.23 kilograms (9.3 pounds) of plutonium metal, 0.0021 kilograms (0.0046 pounds) of plutonium oxide, and 0.048 kilograms (0.11 pounds) of plutonium solution. The accident frequency is estimated to be in the range of from 1×10^{-6} to 1×10^{-5} per year. For the purpose of risk calculations, a conservative frequency of 1×10^{-5} per year is assumed (Tetra Tech 2008).

Fire in a single building. A fire is postulated to start within a glovebox, processing room, or storage vault. Possible causes of the fire include an electrical short, equipment failure, welding equipment, or human error. The fire propagates to multiple areas of the facility involving the largest quantities of plutonium metal. The material at risk is a maximum 7,685 kilograms (16,943 pounds) of plutonium metal for the 125 ppy. The bounding fire accident conservatively assumes a DR = 1.0 resulting in all of the MAR to be affected by the fire. No credit is taken for safety systems, building confinement, or filtration resulting in an assumed LPF = 1.0. The airborne respirable release fraction is estimated to be $ARF \times RF = 2.5 \times 10^{-4}$. No credit is taken for the mitigating effects of fire suppression efforts and equipment, plutonium cladding, or the shipping containers. The resulting source term is a ground level, thermal release of 1.92 kilograms (4.23 pounds) of plutonium. The accident frequency is estimated to be in the range of from 1×10^{-6} to 1×10^{-4} per year. For the purpose of risk calculations, a conservative frequency of 1×10^{-4} per year is assumed (Tetra Tech 2008).

Table C.4-1—Postulated CPC-Related Facility Radiological Accidents

Accident	Accident Description	Material at Risk	Source Term	Event Frequency
Natural Phenomena Events				
1. Beyond Evaluation Basis Earthquake With Fire	A seismic event is postulated causing failure of interior nonstructural walls. The collapsed walls cause a loss of confinement and a potential release of materials in multiple areas of the facility. Combustible materials in the area are ignited and the fire propagates to multiple areas and storage vaults containing the largest quantity of plutonium metal.	16,988 kg plutonium-239 equivalent: 99.65% metal 0.21% powder 0.14% solution	4.23 kg metal 0.0021 kg oxide 0.048 kg solution	1.0×10^{-6} to 1.0×10^{-5} /yr
Externally Initiated Events				
Addressed in Classified Appendix	Addressed in Classified Appendix	Addressed in Classified Appendix	Addressed in Classified Appendix	Addressed in Classified Appendix
Internal Process Events				
1. Fire in a Single Building	A fire is postulated to start within a glovebox, processing room or storage vault. The fire propagates to multiple areas involving the largest quantities of plutonium metal.	7,685 kg plutonium metal	1.92 kg plutonium	1.0×10^{-6} to 1.0×10^{-4} /yr
2. Explosion in a Feed Casting Furnace	A steam explosion/over-pressurization is postulated to occur in a feed casting furnace in the foundry. The steam explosion occurs due to a cooling water leak or an over-pressurization event. The explosion/over-pressurization impacts molten plutonium metal in seven furnaces. Negligible impacts from the shock/blast are postulated for the solid plutonium metal in the glovebox.	4.5 kg molten plutonium metal	2.25 kg molten plutonium metal	1.0×10^{-4} to 1.0×10^{-2} /yr
3. Nuclear Criticality	An inadvertent criticality is postulated based on several potential events involving handling errors. Accumulation of fissile material in excess of criticality safety limits, addition of a moderator causing a critical configuration, or a seismic event causing collapse of storage vault racks are potential scenarios.	See Table 3-1 ^a	5×10^{17} fissions	1.0×10^{-2} /yr

Table C.4-2—Postulated CPC-Related Facility Chemical Accidents

Chemical Release Events				
1. Nitric Acid Release From Bulk Storage	Nitric acid is inadvertently released from bulk storage due to natural phenomena, equipment failure, mechanical impact, or human error during storage, handling, or process operations.	10,500 kg	10,500 kg	1.0×10^{-5} to $1.0 \times 10^{-4}/\text{yr}$
2. Hydrofluoric Acid Release From Bulk Storage	Hydrofluoric acid is inadvertently released from bulk storage due to natural phenomena, equipment failure, mechanical impact, or human error during storage, handling, or process operations.	550 kg	550 kg	1.0×10^{-5} to $1.0 \times 10^{-4}/\text{yr}$
3. Formic Acid Release From Bulk Storage	Formic acid is inadvertently released from bulk storage due to natural phenomena, equipment failure, mechanical impact, or human error during storage, handling, or process operations.	1,500 kg	1,500 kg	1.0×10^{-5} to $1.0 \times 10^{-4}/\text{yr}$

Source: Tetra Tech 2008.

Explosion in a feed casting furnace. A steam explosion/over-pressurization is postulated to occur in a feed casting furnace in the foundry. The steam explosion occurs due to a cooling water leak or an over-pressurization event. The explosion/over-pressurization impacts molten plutonium metal in seven furnaces. The furnace is assumed to contain 4.5 kilogram (9.9 pounds) of plutonium in the form of molten metal. The airborne respirable release fraction was estimated to be $ARF \times RF = 0.5$ for the 4.5 kilogram (9.9 pounds) of plutonium. Negligible impacts from the shock/blast are postulated for 9 kilogram (19.8 pound) of solid plutonium metal in the glovebox. The bounding scenario assumes a $DR = 1.0$ and an $LPF = 1.0$. The resulting source is 2.25 kilogram (5.0 pounds) of plutonium. The frequency of the accident is estimated to be in the range of from 1×10^{-4} to 1×10^{-2} per year. For the purpose of risk calculations, a conservative frequency of 1×10^{-2} was used (Tetra Tech 2008).

Nuclear criticality. An inadvertent criticality is postulated based on any one of several potential events involving handling errors. Accumulation of fissile material in excess of criticality safety limits, addition of a moderator causing a critical configuration, or a seismic event causing collapse of storage vault racks are potential scenarios. The estimated frequency of a criticality is 1×10^{-2} per year (Tetra Tech 2008).

Fire-induced release in the cargo restraint transporter storage room. A fire is postulated to start in cargo restraint transporter storage room. The fire is confined to the room. The MAR in the room is 600 kilogram (1,322.8 pounds) plutonium metal. The bounding scenario assumes a $DR = 1.0$ resulting in all of the MAR to be affected by the fire. No credit is taken for building confinement or filtration resulting in an assumed $LPF = 1.0$. The airborne respirable fraction is estimated to be $ARF \times RF = 2.5 \times 10^{-4}$. No credit is taken for the mitigating effects of fire suppression efforts and equipment, plutonium cladding, or shipping containers. The resulting source term is a ground-level thermal release of 0.15 kilogram (0.33 pound) of plutonium. The accident frequency is estimated to be in the range of from 1×10^{-4} to 1×10^{-2} per year. For the purpose of risk calculations, a conservative frequency of 1×10^{-2} per year is assumed (Tetra Tech 2008).

Radioactive material spill. A spill of radioactive material occurs in the metal reduction glovebox. A loss of confinement and spill of molten plutonium into the metal reduction glovebox is postulated. The spill occurs due to a failure or rupture of the feed casting furnace. The event does not impact any other material that may be in the glovebox. The spill is assumed to involve 4.5 kilogram (9.9 pounds) molten plutonium metal. An airborne release from disturbed metal surfaces is assumed the release mechanism. The airborne respirable release fraction is estimated to be $ARF \times RF = 1 \times 10^{-2}$. A $DR = 1.0$ was conservatively assumed. For a bounding scenario, no credit is taken for safety systems, building confinement, or ventilation/filtration corresponding to $LPF = 1.0$. The resulting source term is a ground level release of 0.045 kilogram (0.099 pounds) of plutonium. The accident frequency is estimated to be in the range of from 1×10^{-4} to 1×10^{-2} per year. For the purpose of risk calculations, a conservative frequency of 1×10^{-2} per year is assumed (Tetra Tech 2008).

Nitric acid release. An accidental release of nitric acid from bulk storage is postulated due to equipment failure, mechanical impact, or human error. The accident scenario postulates a major leak, such as a pipe rupture, and the released chemical forming a pool about one inch in depth in the area around the point of release. Nitric acid is corrosive and can cause severe burns to all

parts of the body. Its vapors may burn the respiratory tract and may cause pulmonary edema, which could prove fatal. The nitric acid is assumed to be stored in bulk quantity in an outdoor facility at a modern pit facility (MPF). The maximum amount of nitric acid that could be released is 10,500 kilogram (23,149 lb). The nitric acid is released by evaporation to the environment and is transported as an airborne plume with potential impacts in excess of ERPG-2 and ERPG-3 concentration limits to onsite workers and the offsite public. The ERPG-2 and ERPG-3 concentration limits for the chemical are 6 and 78 parts per million (ppm), respectively. The estimated frequency of this accident is in the range of from 1.0×10^{-5} to 1.0×10^{-4} per year. For the purpose of risk calculations, a conservative frequency of 1.0×10^{-4} is assumed (Tetra Tech 2008).

Hydrofluoric acid release. An accidental release of hydrofluoric acid from bulk storage is postulated due to equipment failure, mechanical impact, or human error. Hydrofluoric acid is extremely toxic and may be fatal if inhaled or ingested. It is readily absorbed through the skin, and skin contact may be fatal. It acts as a systemic poison, causes severe burns, and is a possible mutagen. The hydrofluoric acid is assumed to be stored in bulk quantity in an outdoor facility at MPF. The maximum amount of hydrofluoric acid that could be released is 550 kilogram (1,212.5 pounds). The hydrofluoric acid is released by evaporation to the environment and is transported as an airborne plume with potential impacts in excess of ERPG-2 and ERPG-3 concentration limits to onsite workers and the offsite public. The ERPG-2 and ERPG-3 concentration limits for the chemical are 20 and 50 ppm, respectively. The estimated frequency of this accident is in the range of from 1.0×10^{-5} to 1.0×10^{-4} per year. For the purpose of risk calculations, a conservative frequency of 1.0×10^{-4} per year is assumed (Tetra Tech 2008).

Formic acid release. An accidental release of formic acid from bulk storage is postulated due to equipment failure, mechanical impact, or human error. The accident scenario postulates a major leak, such as a pipe rupture, and the released chemical forming a pool about one inch in depth in the area around the point of release. Formic acid is corrosive and will cause severe burns. It is harmful by inhalation, ingestion, and readily absorbed through skin. It is very destructive to mucous membranes and the upper respiratory tract, eyes, and skin. Inhalation may be fatal. The formic acid is assumed to be stored in bulk quantity in an outdoor facility at MPF. The maximum amount of formic acid that could be released is 1,500 kilogram (3,307 pounds). The formic acid is released by evaporation to the environment and is transported as an airborne plume with potential impacts in excess of ERPG-2- and ERPG-3-concentration limits to onsite workers and the offsite public. The ERPG-2- and ERPG-3-concentration limits for the chemical are 10 and 30 ppm, respectively. The estimated frequency of this accident is in the range of from 1.0×10^{-5} to 1.0×10^{-4} per year. For the purpose of risk calculations, a conservative frequency of 1.0×10^{-4} per year is assumed (Tetra Tech 2008).

Results. Tables C.4-3 through C.4-12 show the consequences and risks of the postulated set of accidents for a noninvolved worker and the public (MEI and the general population living within 50 miles of the site), for the site alternatives for the CPC. Chemical accidents are shown in Tables C.4-13 through C.4-18.

C.4.2.2 50/80 Alternative

Under the 50/80 Alternatives at Los Alamos, the Plutonium Facility, Building 4 (PF-4) at TA-55 would be upgraded to provide a capability to produce up to 80 pits/year to the stockpile. The

changes to PF-4 to achieve this capability are assumed to be equivalent to the operations, processes, and technology and safety systems planned for a Greenfield CPC. As such, the potential hazards and accidents postulated for a Greenfield CPC would be applicable to the upgraded PF-4. However, for three of the accidents (Beyond Evaluation Basis Earthquake and Fire, Fire in a single building, and the Fire-induced release in the CRT Storage Room), the material-at-risk for the 50/80 Alternative would be approximately two-thirds as large as for the Greenfield CPC. The potential consequences and risks from accidents for the 50/80 Alternative are presented in Tables C.4-3a and C.4-4a.

C.4.7 Chemical Accident Frequency and Consequences—CPC

The chemicals selected for evaluation are based on the aqueous feed preparation process, as noted in each table, and are considered the most hazardous of all the chemicals used in this process. Determination of a chemical's hazardous ranking takes into account quantities available for release, protective concentration limits (ERPG-2), and evaporation rate. The most hazardous chemical used in an alternative method, the pyrochemical processing method is also analyzed as noted in the tables.

This section presents the impacts of potential chemical accidents at each of the five CPC site alternatives. The tables show the name of the chemical and the quantity released during a severe accident. The impacts of chemical releases are measured in terms of ERPG-2 protective concentration limits given in ppm. The distances at which the limit is reached are also provided for the ERPG-2 limit. The concentration of the chemical at 1,000 meters (3,281 feet) from the accident is shown for comparison with the concentration limit for ERPG-2. The distance to the site boundary and the concentration at the site boundary are also shown for comparison with the ERPG-2 concentration limits and for determining if the limits are exceeded offsite.

Table C.4-13—Chemical Accident Frequency and Consequences at Los Alamos

Chemical Released	Quantity Released (kg)	ERPG-2		Concentration ^a		Frequency
		Limit (ppm)	Distance to Limit (km)	At 1,000 m (ppm) ^b	At Site Boundary (ppm)	
Nitric acid	10,500	6	0.85	4.5	8.76	10 ⁻⁴
Hydrofluoric acid	550	20	0.5	5.05	10.4	10 ⁻⁴
Formic acid	1,500	10	0.215	0.54	1.06	10 ⁻⁴

^a At site boundary, approximately 0.7 miles from release.

Table C.4-14—Upgrade 80 Chemical Accident Frequency and Consequences

Chemical Released	Quantity Released (kg)	ERPG-2		Concentration ^a		Frequency
		Limit (ppm)	Distance to Limit (km)	At 1,000 m (ppm)	At Site Boundary (ppm)	
Nitric acid	3,420	6	0.5	1.46	2.85	10 ⁻⁴
Hydrofluoric acid	340	20	0.4	3.1	6.42	10 ⁻⁴
Hydrochloric acid	384	20	2.1	118	264	10 ⁻⁴

^a At site boundary, approximately 0.7 miles from release.

Table C.4-15—Chemical Accident Frequency and Consequences at NTS

Chemical Released	Quantity Released (kg)	ERPG-2		Concentration ^a		Frequency
		Limit (ppm)	Distance to Limit (km)	At 1,000 m (ppm)	At Site Boundary (ppm)	
Nitric acid	10,500	6	0.86	4.55	<0.1	10 ⁻⁴
Hydrofluoric acid	550	20	0.5	5.05	<0.1	10 ⁻⁴
Formic acid	1,500	10	0.215	0.54	<0.1	10 ⁻⁴

^a Site boundary is at a distance of 13.7.

Table C.4-16—Chemical Accident Frequency and Consequences at Pantex

Chemical Released	Quantity Released (kg)	ERPG-2		Concentration ^a		Frequency
		Limit (ppm)	Distance to Limit (km)	At 1,000 m (ppm)	At Site Boundary (ppm)	
Nitric acid	10,500	6	0.85	4.49	0.48	10 ⁻⁴
Hydrofluoric acid	550	20	0.5	5.1	0.55	10 ⁻⁴

^a Site boundary is at a distance of 2.2 miles.

Table C.4-17—Chemical Accident Frequency and Consequences at SRS

Chemical Released	Quantity Released (kg)	ERPG-2		Concentration ^a		Frequency
		Limit (ppm)	Distance to Limit (km)	At 1,000 m (ppm)	At Site Boundary (ppm)	
Nitric acid	10,500	6	0.17	0.189	<0.01	10 ⁻⁴
Hydrofluoric acid	550	20	0.12	0.21	<0.01	10 ⁻⁴
Formic acid	1,500	10	0.1	0.02	0	10 ⁻⁴

^a Site boundary is at a distance of 6.7 miles.

Table C.4-18—CPC Chemical Accident Frequency and Consequences at Y-12

Chemical Released	Quantity Released (kg)	ERPG-2		Concentration ^a		Frequency
		Limit (ppm)	Distance to Limit (km)	At 1,000 m (ppm)	At Site Boundary(ppm)	
Nitric acid	10,500	6	0.28	0.5	0.01	10 ⁻⁴
Hydrofluoric acid	550	20	0.35	2.0	0.016	10 ⁻⁴
Formic acid	1,500	10	0.08	0.07	0	10 ⁻⁴

^a At site boundary, approximately 1.3 miles from release.

C.5 RADIOLOGICAL ACCIDENT SCENARIOS—CUC

This section presents the estimated impacts of accidents that could occur at a CUC. The scenarios described here define the bounding envelope of accidents—that is, any other reasonably foreseeable accident at the CUC would be expected to have similar or smaller consequences. These accident analyses are conservative, with little or no credit taken for existing preventative and mitigating features in each building or operation analyzed or the safety procedures that are mandatory at NNSA sites.

C.5.1 Accident Scenarios

From the safety documents obtained through the process described in Section C.3.1, Table C.5-1 identifies the accident scenarios and source terms (release rates and frequencies) that were developed for the CUC (Tetra Tech 2008).

Table C.5-1—Potential CUC Accident Scenarios

Accident	Frequency	Source Term or Hazard	Notes/Assumptions
EU Metal Fabrication Complex			
Local fire	$10^{-2} - 10^{-4}$	N/A, No radiological consequences	
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Major fire	$10^{-4} - 10^{-6}$	EU = 17.9 kg (sum of metal and chips) DU = 452 kg (sum of metal and chips)	Release height = ground level Release duration = 1 hr
Aircraft Crash—Initiator for major fire	$1.5 \times 10^{-5} - 2.2 \times 10^{-5}$	See major fire	
Tanker Truck Accident—Initiator for major fire	$10^{-4} - 10^{-6}$	See major fire	
Earthquake	$10^{-2} - 10^{-4}$	Same as criticality	
High Winds	$10^{-2} - 10^{-4}$	Same as earthquake	
Rain/Snow	$10^{-2} - 10^{-4}$	Same as earthquake	
Assembly			
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Explosion	$10^{-4} - 10^{-6}$	2 kg EU (sum of metal and chips) 0.04 kg DU (sum of metal and chips)	Release height = 7.6 m Release duration = 1 hr
Fire	$10^{-4} - 10^{-6}$	Same as explosion	Release height = 7.6 m Release duration = 2 hr
Earthquake	$10^{-2} - 10^{-4}$	Bounded by fire	
Wind	$10^{-1} - 10^{-2}$	None	
Flood	$10^{-2} - 10^{-4}$	None	
Aircraft crash	$\sim 2 \times 10^{-5}$	Bounded by fire	
Manufacturing QE			
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Local fires	$10^{-2} - 10^{-4}$	No radiological releases	
Large Building Fire	$10^{-4} - 10^{-6}$	2.6 kg EU 54 kg DU 172 kg Th	Release height = <10 m Release duration = 1 hr
Aircraft Crash—Initiator for large building fire	$4.5 \times 10^{-5} - 5.0 \times 10^{-5}$	See large building fire	
Tanker Truck explosion—Initiator for large building fire	$10^{-4} - 10^{-6}$	See large building fire	
Earthquake	$10^{-2} - 10^{-4}$	Bounded by criticality	
Wind	$10^{-2} - 10^{-4}$	Bounded by criticality	
Rain/Snow	$10^{-2} - 10^{-4}$	Bounded by criticality	

Table C.5-1—Potential CUC Accident Scenarios (continued)

Accident	Frequency	Source Term or Hazard	Notes/Assumptions
EU Warehouse			
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Fire	$10^{-4} - 10^{-6}$	EU = 22.6 kg DU = 20.1 kg U-233 = 0.0066 kg Th = 0.13 kg (represents sum of metals, oxides, and combustibles) Pu = 1.0×10^{-6} kg Np-237 = 1.6×10^{-5} kg	Release height = 4 m Release duration = 1 hr
Aircraft crash—Initiator of fire	1.2×10^{-5}	Same as fire	
Earthquake-induced loss of confinement	$10^{-2} - 10^{-4}$	EU = 1.3 kg DU = 0.06 kg Th = 0.03 kg (the above all represent the sum of metals, oxides, and combustibles)	Release height = ground level Release duration = 15 min
Wind	$10^{-2} - 10^{-4}$	Bounded by criticality, fire	
Flood	$10^{-2} - 10^{-4}$	Bounded by criticality	
Lightning	$10^{-4} - 10^{-6}$	Bounded by fire	
HEUMF			
Design-basis fires ¹	$10^{-2} - 10^{-4}$	EU = 2.58 kg DU = 0.55 kg	Release height = 11.3 m Release duration = 1 hr
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Earthquake	$10^{-2} - 10^{-4}$	None	
Wind	$10^{-2} - 10^{-4}$	None	
Rain/Snow	$10^{-2} - 10^{-4}$	None	
Flood	$10^{-2} - 10^{-4}$	Bounded by criticality	
EU Operations			
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Uranium Solution Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	3.25×10^{18} fissions
Local fires	$10^{-2} - 10^{-4}$	8 kg EU (includes aqueous and organic solutions)	Release height = ground level Release duration = 15 min
Large fire	$10^{-4} - 10^{-6}$	14.8 kg EU (includes metals, oxides, aqueous and organic solutions)	Release height = “roof level” Release duration = 1 hr
Explosions	$10^{-2} - 10^{-4}$	None—localized effects	
Aircraft crash	$10^{-4} - 10^{-6}$	37.8 kg EU (includes metals, chips, oxides, and aqueous and organic solutions)	Release height = “roof level” Release duration = 15 min

¹ The source term for a design-basis fire at the HEUMF has been identified as the bounding (largest possible) source term, and reasonably bounds the source term that might result from any aircraft crash.

Table C.5-1—Potential CUC Accident Scenarios (continued)

Accident	Frequency	Source Term or Hazard	Notes/Assumptions
EU Operations (continued)			
Earthquake-induced fire	$10^{-2} - 10^{-4}$	Same as large fire	
Wind	$10^{-2} - 10^{-4}$	Bounded by earthquake	
Rain/Snow	$10^{-2} - 10^{-4}$	Bounded by earthquake	
Lightning	$10^{-2} - 10^{-4}$	Same as local fire	
Analytical Laboratory			
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Large fire	$10^{-2} - 10^{-4}$	0.06 kg EA (includes solutions, metals, oxides, etc.)	
Aircraft crash	1.4×10^{-5}	Same as large fire	
Machine Shop Special Materials			
Large fire	$10^{-4} - 10^{-6}$	96.6 kg DU (includes metals, fines, and oxides)	Release height = ground level Release duration = 1 hr
Inadvertent water leak into furnace	$10^{-2} - 10^{-4}$	32 kg DU	Release height = ground level Release duration = "short" (assume 15 min)
Machine Shop DU/Binary			
Large fire	$10^{-4} - 10^{-6}$	31.3 kg DU (includes bulk metal, chips, and fines)	Release height = "elevated" Release duration = 1 hr
Uranium Metal Criticality	$10^{-2} - 10^{-4}$	See Tables C.5-2 through C.5-4	1.0×10^{18} fissions
Earthquake	$10^{-2} - 10^{-4}$	Bounded by large fire	
High wind/tornado	$10^{-2} - 10^{-4}$	Bounded by large fire	
Rain/Snow	$10^{-2} - 10^{-4}$	Bounded by large fire

C.5.2 Estimated Health Effects

Table C.5-5 identifies the accidents that are analyzed in this SPEIS for the CUC. Tables C.5-6 through C.6-17 show the consequences and risks of the postulated set of accidents for a noninvolved worker and the public (MEI and the general population living within 50 miles of the site), for the site alternatives for the CUC.

Table C.5-5—Uranium Operations Accidents

Operation	Accident	Frequency	Source Term	Notes/Assumptions
EU Metal Fabrication	Major fire	$10^{-4} - 10^{-6}$	EU = 17.9 kg (sum of metal and chips) DU = 452 kg (sum of metal and chips)	Release height = ground level Release duration = 1 hour
Assembly	Explosion	$10^{-4} - 10^{-6}$	2 kg EU (sum of metal and chips) 0.04 kg DU (sum of metal and chips)	Release height = 7.6 m Release duration = 1 hour
EU Warehouse	Fire	$10^{-4} - 10^{-6}$	EU = 22.6 kg DU = 20.1 kg U-233 = 0.0066 kg Th = 0.13 kg (the above all represent the sum of metals, oxides, and combustibles) Pu = 1.0×10^{-6} kg Np-237 = 1.6×10^{-5} kg	Release height = 4 m Release duration = 1 hour
HEUMF	Design-basis fires	$10^{-2} - 10^{-4}$	EU = 2.58 kg DU = 0.55 kg	Release height = 11.3 m Release duration = 1 hour
EU Operations	Aircraft crash	$10^{-4} - 10^{-6}$	37.8 kg EU (includes metals, chips, oxides, and aqueous and organic solutions)	Release height = "roof level" Release duration = 15 min

C.5.3 Involved Worker Impacts

Workers in the facility where the accident occurs would be particularly vulnerable to the effects of the accident because of their location. For all of the accidents, there is a potential for injury or death to involved workers in the vicinity of the accident. However, prediction of latent potential health effects becomes increasingly difficult to quantify for facility workers as the distance between the accident location and the worker decreases. This is because the individual worker

exposure cannot be precisely defined with respect to the presence of shielding and other protective features. The worker also may be injured or killed by physical effects of the accident itself.

C.5.4 CUC Chemical Accident Frequency and Consequences

The chemicals selected for evaluation are based on the aqueous feed preparation process, as noted in each table, and are considered the most hazardous of all the chemicals used in this process. Determination of a chemical's hazardous ranking takes into account quantities available for release, protective concentration limits (ERPG-2) and evaporation rate. This section presents the impacts of potential chemical accidents at each of the five CUC site alternatives. The tables show the name of the chemical and the quantity released during a severe accident. The impacts of chemical releases are measured in terms of ERPG-2 protective concentration limits given in parts per million. The distances at which the limit is reached are also provided for the ERPG-2 limit. The concentration of the chemical at 1,000 meters (3,281 feet) from the accident is shown for comparison with the concentration limit for ERPG-2. The distance to the site boundary and the concentration at the site boundary are also shown for comparison with the ERPG-2 concentration limits and for determining if the limits are exceeded offsite. Conservative modeling of chemical release over the period of one hour was based on a spill and subsequent pool with evaporation resulting calculated down-wind concentrations (Tetra Tech 2008).

Table C.5-18—Chemical Accident Frequency and Consequences at Los Alamos

Chemical Released	Quantity Released (kg)	ERPG-2		Concentration ^a		Frequency
		Limit (ppm)	Distance to Limit (km)	At 1,000 m (ppm)	At Site Boundary (ppm) ^b	
Nitric acid	10,500	6	0.85	4.5	8.76	10 ⁻⁴

^a Site boundary is at a distance of approximately 1.3 miles.

C.6 ACCIDENT SCENARIOS—A/D/HE CENTER

This section presents the estimated impacts of accidents that could occur at an A/D/HE Center. The scenarios described here define the bounding envelope of accidents—that is, any other reasonably foreseeable accident at the A/D/HE Center would be expected to have similar or smaller consequences. These accident analyses are conservative, with little or no credit taken for existing preventative and mitigating features in each building or operation analyzed or the safety procedures that are mandatory at NNSA sites.

C.6.1 Radiological Accident Scenarios

Facilities and operations at Pantex were analyzed to identify all hazards and potential accidents associated with the facilities and process systems, components, equipment, or structures and to establish design and operational means to mitigate these hazards to prevent potential accidents. The results of these analyses are contained in SARs and other safety basis documentation (see Section C.3.1).

For each facility and operation at Pantex, DOE has developed a safety analysis report. In addition, other facility-specific safety analyses have been performed and documented (e.g., process hazards reviews, hazards analysis documents, and justifications for continued operations). These documents were also utilized for the identification of potential accidents at Pantex. The next step of the screening process involved the identification of representative accidents that contribute to the risk to public and worker health from A/D/HE Center operations that would be similar to the operations currently performed at Pantex. Ideally, a complete evaluation of A/D/HE Center risks would include all potential accident scenarios. However, this type of an approach is impractical. Therefore, the purpose of this step in the screening process was to identify a subset of accident scenarios that contribute a large fraction of the total risk from A/D/HE Center operations. This step of the screening process involved the grouping of potential accidents based on both the magnitude of the frequency of occurrence and the magnitude of the expected consequence. Once the accidents were grouped, the accidents corresponding to the highest risk in each group were chosen for further analysis. For the accidents described below,

which were identified as risk significant, consequence assessments were performed for the A/D/HE Center at the five site alternatives. Table C.6-1 presents the source terms for these accidents.

Scenario 1. Explosive-driven plutonium and tritium dispersal from an internal event.

Nuclear weapons may be made with either conventional or insensitive HE, depending upon weapon design. Scenario 1 represents the accidental detonation of conventional HE in the presence of plutonium due to an internally initiated event. HE is present with radioactive materials in facilities where nuclear explosives work occurs. Initiators for this scenario include accidental actuation of an electro-explosive device during disassembly and handling accidents. Insensitive HE is a negligible risk contributor because it is not susceptible to ignition under the conditions existing during assembly or disassembly (A/D) operations. Insensitive HE is, thus, not a credible explosive source for this scenario.

Scenario 1 is comprised of three individual cases in which an accidental HE detonation is postulated to be initiated by an internal event. These cases differ in where the accidental detonation occurs; i.e., in a nuclear weapons A/D cell, a bay, or a special purpose building. An HE detonation during A/D would lead to the dispersal of radioactive material. Weapons are designed so that, in the event of an accidental detonation, there will be no significant nuclear reactions. Positive measures are engineered into nuclear explosives to preclude a nuclear yield from an accidental HE detonation.

The frequency of Scenario 1 is estimated to be 1.1×10^{-5} per year. It is, thus, *extremely unlikely* (frequency of occurrence is less than 10^{-4} per year but greater or equal to 10^{-6} per year). The derivation of this frequency involves summing of probabilities of different initiating events in different facilities. Explosive-driven plutonium dispersal from an internal event can result from operations conducted in bays, cells, or special purpose facilities. The probability per operation that an operational error could cause an explosive-driven plutonium and tritium release was estimated for each facility using data from available safety analyses (Tetra Tech 2008).

Scenario 2. Tritium reservoir failure from an internal event. This scenario represents the release of tritium due to a reservoir failure during normal operations. Initiators for this scenario include an inadvertent squib valve actuation during weapon operations.

This type of event has occurred at Pantex, and the frequency of this event is strongly dependent on the number of weapon operations being performed. For the 2,000 weapons activity level, this scenario is *anticipated* (frequency greater than or equal to 10^{-2} per year). For the 500 weapons activity level, this event is *unlikely* (frequency of occurrence is less than 10^{-2} per year but greater than or equal to 10^{-4} per year). This scenario is dominated by handling accidents during weapon operations (Tetra Tech 2008).

Scenario 3. Pit breach from an internal event. This scenario represents a pit breach, with resultant plutonium release, during normal operations. Initiators that contribute to this scenario include a pit drop due to a handling accident and a pit breach due to a forklift accident (Pantex 1996a, DOE 1994w). This scenario is dominated by handling accidents in bays and

special purpose facilities. The overall likelihood of this scenario occurring is *unlikely* (frequency of occurrence is less than 10^{-2} per year but greater than or equal to 10^{-4} per year) (Tetra Tech 2008).

Scenario 4. Multiple tritium reservoir failure from an external event or natural phenomena. This scenario represents the release of tritium from reservoir failures caused by a fire in the tritium storage vault. The fire could be initiated by a seismic event or aircraft crash. The dominant event in this scenario is a seismic event initiated fire in the warehouse surrounding the tritium storage vault. For a release to occur, the protective vault fire door would have to be open and the fire protection system disabled by the seismic initiator. The overall likelihood of this scenario occurring is *not reasonably foreseeable* (frequency of occurrence is less than 10^{-6} per year) (Tetra Tech 2008).

Scenario 5. Fire-driven dispersal involving stored pits from an external event or natural phenomena. This scenario represents a pit breach, resulting in a plutonium release, initiated by a seismic event or aircraft accident. The overall likelihood of this scenario occurring is *extremely unlikely* (frequency of occurrence is less than 10^{-4} per year but greater or equal to 10^{-6} per year) (Tetra Tech 2008).

Scenario 6. Plutonium and tritium dispersal from an external event or natural phenomena. This scenario represents a tritium or plutonium release, without an explosion, caused by a seismic event or aircraft crash. Initiators include an aircraft impact-initiated fire in a nuclear explosive facility and a seismic collapse of a special purpose facility (Pantex 1993a). This scenario is dominated by seismic events resulting in structural failure of special purpose buildings containing nuclear explosives. Many stockpile support activities (e.g., testing and maintenance) are performed in older facilities without the structural strength of the storage magazines. Thus, these facilities are more vulnerable to external events and natural phenomena. The overall likelihood of this scenario occurring is *unlikely* (frequency of occurrence is less than 10^{-2} per year but greater than or equal to 10^{-4} per year) (Tetra Tech 2008).

C.6.2 Chemical Accident Scenarios

Chlorine has been identified as the hazardous chemical dominating the risk from nonradiological releases for an A/D/HE Center (DOE 1996c). Chlorine is the only chemical with the potential for significant adverse offsite consequences. Since chlorine is not carcinogenic, the consequences of exposure to chlorine (primarily acute effects) differ from the consequences of exposure to radionuclides (potential latent cancers). This difference precludes a direct comparison between the risk and consequences associated with hazardous chemical releases and radionuclide releases. A useful measure of potential human health effects resulting from exposure to non-carcinogenic chemicals is the hazard index. In its most general form, a hazard index is a ratio of the actual exposure of a human receptor to an established exposure limit. If this ratio is appreciably less than unity, no adverse human health effects are expected. If the hazard index is close to unity, some adverse human health effects may occur; and if the hazard index is substantially greater than unity, severe health effects can result.

Numerous exposure limits are available to form a hazard index. Since exposure to an accidental chlorine release is an unlikely, short-duration event, chronic exposure limits are inapplicable. Instead, ERPG values will serve to develop hazard indices for chlorine exposure.

Scenario 7. Chlorine release. The rooms in which chlorine gas would be used would be equipped with a chlorine sensor alarm system that consists of an alarm siren and flashing light located outside the building. The sensor system would be set to activate this alarm at a chlorine concentration of 1.0 part per million in the air. The rooms would also be ventilated with a floor-level exhaust fan and contain an elevated fresh air inlet.

A release of chlorine to the environment due to an earthquake is an unlikely event. Should an earthquake occur with sufficient magnitude to damage a facility that uses chlorine, could release the contents from a maximum of four chlorine cylinders in use. Other chlorine cylinders are not ordinarily expected to contribute to a release initiated by an earthquake. However, in the unlikely event that a chlorine cylinder is stored without its valve cap in place or is substandard structurally when delivered, it is conservatively postulated that Scenario 7 could involve a release from up to six chlorine cylinders. The magnitude of this chlorine release could be as high as 408 kilograms (900 pounds) (Tetra Tech 2008).

Workers in the vicinity of a chlorine release could be exposed to chlorine concentrations in

excess of EPRG-3 and threshold levels. No long-term adverse health effects are expected for workers who promptly evacuate the area. For any persons incapable of evacuating the area of the chlorine plume, no serious or irreversible health impacts are expected from EPRG-1 or EPRG-2 exposures since the exposure duration is less than 1 hour. Persons incapable of evacuating an area with EPRG-3 concentrations may experience adverse health impacts depending upon the actual chlorine concentrations encountered and the exposure duration. However, chronic lung disease, electrocardiographic changes, and death have occurred in humans exposed to high concentrations of chlorine as a consequence of industrial accidents (Calabrese 1991).

Tables C.6-12 through C.6-16 depict the potential impacts of conservative modeling of chemical release over the period of 1-hour was based on a spill and subsequent pool with evaporation resulting calculated down-wind concentrations.

C.7 TRANSPORTATION RADIOLOGICAL ACCIDENTS

The offsite transportation accident analysis considers the impacts of accidents during the transportation of radiological materials. Under accident conditions, impacts to human health and the environment may result from the release and dispersal of radioactive material. Accidents that could potentially breach the shipping container are represented by a spectrum of accident severities and radioactive release conditions. Historically, most transportation accidents involving radioactive materials have resulted in little or no release of radioactive material from the shipping container. Consequently, the analysis of accident risks takes into account a spectrum of accidents ranging from high-probability accidents of low severity to hypothetical high-severity accidents that have a correspondingly low probability of occurrence. This accident analysis calculates the probabilities and consequences from this spectrum of accidents.

To provide NNSA and the public with a reasonable assessment of radioactive waste transportation accident impacts, two types of analyses were performed. An accident risk assessment was performed that takes into account the probabilities and consequences of a spectrum of potential accident severities using a methodology developed by the NRC (NRC 1977). For the spectrum of accidents considered in the analysis, accident consequences in terms of collective dose to the population within 80 kilometers (50 miles) were multiplied by the accident probabilities to yield collective dose risk using the RADTRAN 5.6/RadCat 2.3 computer code (Weiner 2006).

The impacts for specific alternatives were calculated in units of dose (rem or person-rem). Impacts are further expressed as health risks in terms of estimated latent cancer fatalities in exposed populations. The health risk conversion factor of 0.0006 LCF/person-rem was derived from the Interagency Steering Committee on Radiation Standards report (ISCOR 2002), A Method for Estimating Radiation Risk from Total Effective Dose Equivalent (TEDE).

The risk analyses consider a spectrum of accidents of varying severity. Each first determines the conditional probability that the accident will be of a specified severity. Then, based on the accident environment associated with each severe accident, each models the behavior of the material being shipped and the response of the packaging. The models estimate the fraction of each species of radioactive material that might be released for each of the severe accidents being considered. Results of the RADTRAN runs are provided in Table C.7-1.

Table C.7-1—Results of RADTRAN Accident Runs for a Single Shipment

RADTRAN Run No.	Dose Risk (person-rem)	RADTRAN Run No.	Dose Risk (person-rem)
1	-	9b	4.8×10^{-6}
2a	3.5×10^{-8}	10	2.9×10^{-11}
2b	-	11a	-
3	9.3×10^{-12}	11b	1.5×10^{-4}

Appendix D
SUMMARY OF PUBLIC SCOPING DOCUMENTS

Appendix D

SUMMARY OF PUBLIC SCOPING COMMENTS

D.1 PUBLIC SCOPING PROCESS

As a preliminary step in the development of an environmental impact statement (EIS), regulations established by the Council on Environmental Quality (CEQ) (40 CFR 1501.7) and the U.S. Department of Energy (DOE) require “an early and open process for determining the scope of issues to be addressed and for identifying the significant issues related to a proposed action.” The purpose of this scoping process is: (1) to inform the public about a proposed action and the alternatives being considered, and (2) to identify and/or clarify issues that are relevant to the EIS by soliciting public comments.

On October 19, 2006, the National Nuclear Security Administration (NNSA), a semi-autonomous agency within DOE, published a Notice of Intent (NOI) in the *Federal Register* announcing its intent to prepare a *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement* (71 FR 61731). During the *National Environmental Policy Act* (NEPA) process, there are opportunities for public involvement (see Figure D.1-1). The NOI listed the issues initially identified by DOE for evaluation in the Complex Transformation¹ Supplemental Programmatic Environmental Impact Statement (SPEIS). Public citizens, civic leaders, and other interested parties were invited to comment on these issues and to suggest additional issues that should be considered in this SPEIS. NNSA accepted comments during the 90-day public scoping period via U.S. mail, e-mail, facsimile, and in person at public scoping meetings.

NNSA held public scoping meetings near each of the nine sites potentially affected by the alternatives and in Washington, DC. Meetings were held as shown on Figure D.1-2:

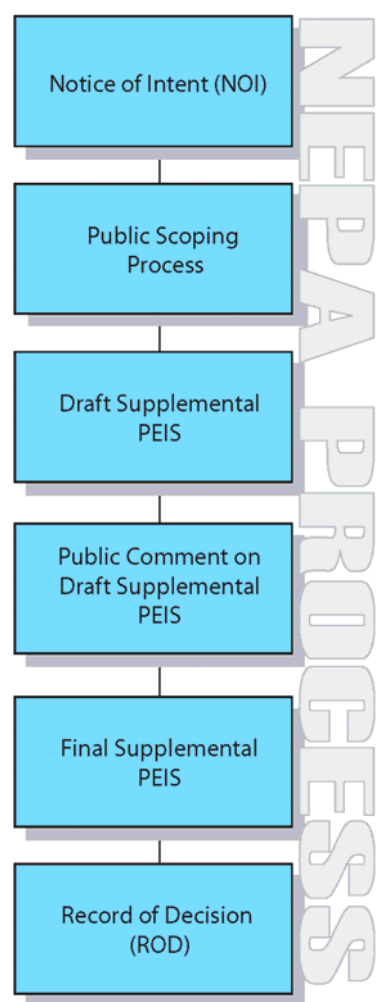

Figure D.1-1

¹ In the NOI, this supplement was referred to as the “Complex 2030” SPEIS.

Figure D.1-2—Public Scoping Meeting Locations and Dates

DOE chose an interactive format for the scoping meetings. Each meeting began with an open house session where the public could speak to DOE representatives followed by a presentation by a DOE representative who explained the background, purpose and need for agency action, the alternatives, and the NEPA process. Following the presentation, members of the public were given the opportunity to provide oral comments. These oral comments were recorded, and a transcript for each meeting was produced.

D.2 ISSUE IDENTIFICATION AND COMMENT DISPOSITION

Comments received during the scoping period were systematically reviewed by DOE. Where possible, comments on similar or related topics were grouped under comment issue categories as a means of summarizing the comments. Table D.2-1 lists topics (“bins”) used to categorize comments. More than 33,000 comment documents were received from individuals, interested groups, and Federal, state, and local officials during the public scoping period.

Table D.2-1—Comment Bin List

Topics and Subtopics	
1.	Policy
A.	Existing Treaties—general
B.	Presidential Directives, Public law, and current policies
C.	Nuclear Posture Review
D.	Comprehensive Test Ban Treaty
E.	Treaty on the Non-Proliferation of Nuclear Weapons
F.	Moscow Treaty
G.	International Policies
H.	Nuclear Waste Policy Act
2.	NEPA Process
A.	General NEPA process

Each comment document was read carefully. Scoping comments were identified and summarized. Each comment document was assigned a document number and was assigned to an appropriate issue category. Table D.2-2, provided at the end of this appendix, summarizes the comments received that fall within the scope of this SPEIS and also directs the reader to sections of this SPEIS that address these issues. In addition Table D.2-2 lists the comment documents which were assigned to that issue category.

Many comments were outside the scope of this SPEIS. These comments fell into the following general categories: 1) concerns about cost and schedule overruns; 2) moral/ethical issues; 3) the use of nuclear weapons; and 4) alternate uses of Federal funds. These comments are addressed, only to the extent they relate to the background discussion in Chapter 1: Introduction, and Chapter 2: Purpose and Need. Detailed design safety questions that are not covered in the Complex Transformation SPEIS would be covered in site-specific, tiered EISs.

D.3 SCOPING PROCESS RESULTS

More than 33,000 comment documents were received from individuals, interested groups, and Federal, state, and local officials during the public scoping period. In addition, approximately 350 individuals made oral comments during public meetings. Some commentators who spoke at the public meetings also prepared written statements. When the oral comments and written comments were identical, comments submitted by an individual commentator were counted once. Table D.3-1 provides a summary of the number of scoping comments received.

Table D.3-1—Scoping Documents Received

Document Type	Number Received

Campaign 14	21
Campaign 15	18,830
Campaign 16	3
Campaign 17	10
Campaign 18	6
Campaign 19	115
Campaign 20	15
Total Scoping Comment Documents Received	33,892

A comment is a distinct statement or question about a particular topic or a specific issue. Most of the oral and written public statements submitted during the EIS scoping period contained multiple comments on various issues.

A majority of the comment documents received were form letters or e-mail campaigns. A form letter is defined as a standard letter submitted by numerous individuals. An e-mail campaign has the same concept as a form letter, but is submitted via electronic mail. Twenty different form letters/e-mail campaigns were submitted during the scoping period. All contained comments similar to those summarized in Table D.2-2 except campaign letters 11 and 13, which addressed the regional socioeconomic benefits of the Y-12 National Security Complex in Tennessee and support for that site’s mission. A majority of the form letters/e-mail campaigns received were from Campaigns 1, 7, and 15. Table D.3-2 provides a summary of these documents.

Table D.3-2—Summary of Campaigns 1, 7, and 15

Document	Summary
Campaign 1 (Postcard)	Commentors stated the proposed action to build more nuclear weapons is dangerous and unnecessary. Commentors also stated that the U.S. cannot produce nuclear weapons while insisting other countries not pursue nuclear capabilities; the U.S. should meet its obligations under the Non-Proliferation Treaty to pursue disarmament; and resources should be spent on cleaning pollution from past production.
Campaign 7 (E-mail campaign)	Commentors wrote to express opposition to the proposed Complex Transformation plan. Commentors stated that the nuclear weapons complex is unnecessary and expensive and that new studies conclude that nuclear warheads will last at least 100 years. Commentors endorsed the proposal’s stated aim of downsizing the nuclear weapons infrastructure.
Campaign 15 (E-mail campaign)	Commentors stated that the EIS is too limited and should include an assessment of an alternative that would abandon plans to build nuclear weapons and make reductions in the nuclear stockpile. Commentors suggested that DOE prepare a nonproliferation impact assessment to determine how the proposals would affect the goal of stopping the spread of nuclear weapons.

In addition to the form letters/e-mail campaigns, NNSA received approximately 1,200 individual scoping documents. Scoping meeting transcripts from 17 meetings were also included in the comment analysis.

A summary of the major comments received during the scoping period and responses to these comments follows:

Comment: The majority of the comments expressed opposition to the nuclear weapons program and U.S. national security policies. Many of the comments stated that the U.S. is violating the Nuclear Non-proliferation Treaty (NPT). Many of the comments stated that NNSA should assess an additional alternative—disarmament in compliance with the NPT - and not design or build new nuclear weapons.

Response: The security policies of the U.S. require the maintenance of a safe, secure, and reliable nuclear weapons stockpile, and the maintenance of core competencies to design, manufacture, and maintain nuclear weapons. Article VI of the NPT obligates the parties “to pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an early date and to nuclear disarmament, and on a treaty on general and complete disarmament under strict and effective international

control.” Actions by the U.S., including its moratorium on nuclear testing accompanied by significant reductions in its strategic force structure, nuclear weapons stockpile, and production infrastructure, constitute significant progress toward these goals. However, unless and until there are significant changes in national security policy, NNSA is required to design, produce, and maintain the nuclear weapons stockpile pursuant to requirements established by the President and funded by Congress. In conjunction with the 2001 NPR, President Bush set an objective of “...achieving a credible nuclear deterrent with the lowest-possible number of nuclear warheads consistent with our national security needs...” In recognition of this objective and the reduction in the U.S. stockpile since the end of the Cold War, this SPEIS qualitatively evaluates changes in the alternatives that would be appropriate if the stockpile is reduced below the level called for by the Moscow Treaty. Accordingly, this SPEIS analyzes alternatives that satisfy requirements of the existing national security policy framework, as well as a capability-based alternative that, while not capable of meeting current requirements, could meet those requirements if the stockpile were reduced below the level called for by the Moscow Treaty.

Comment: Commentors stated that the reliable replacement warhead (RRW) was not needed and should not be pursued.

Response: RRW refers to possible future warhead designs that could replace existing “legacy” warheads. The RRW would not affect the proposed action of this SPEIS related to restructuring SNM facilities, or the proposed action to restructure R&D facilities. The proposed actions are independent of whether an RRW is developed. Because the environmental impacts analyzed are based on the maintenance of the legacy weapons that are currently in the stockpile, a conservative estimate of the environmental impacts is provided in this SPEIS. If RRW is approved as part of the national strategy for providing a nuclear deterrent, it would enable a shift to fewer hazardous operations. However, a production capacity for plutonium and highly-enriched uranium components, as well as for weapons assembly and disassembly, will be required for the foreseeable future with or without implementation of RRW. Chapter 2 provides a discussion of the RRW’s possible impact on the nuclear weapons stockpile and decisions about the Complex facilities.

Comment: Commentors stated that NNSA should develop a fair and objective statement for the purpose and need that takes into account the broader missions of NNSA that include preventing proliferation, ensuring the effectiveness of the NPT, and developing strategies to ensure the peaceful denuclearization of existing and threshold nuclear states, and the underlying legal obligations and treaty commitments.

Response: The fundamental principle underlying NNSA’s evaluation of alternatives is that the Stockpile Stewardship Program (SSP) must continue to support existing and reasonably foreseeable national security requirements. This is NNSA’s obligation and responsibility under the *Atomic Energy Act*² and the *National Nuclear Security*

² 42 U.S.C. 2011 *et seq.*

*Administration Act.*³ This SPEIS does not analyze alternatives to U.S. national security policy. Rather, it examines the environmental effects of proposed actions and reasonable alternatives for executing the SSP, which is based on requirements established by national security policy including the maintenance of a safe, secure, and reliable nuclear weapons stockpile, and the maintenance of core competencies to design, manufacture, and maintain nuclear weapons. NNSA continues work in other areas, including those identified in comments. Nuclear weapons knowledge has and will continue to enable nonproliferation; however, they are not dealt with in this SPEIS.

Comment: Commentors asked why NNSA was not assessing a consolidated nuclear production center (one site for plutonium, enriched uranium, and weapons assembly/disassembly) as a reasonable alternative for transforming the Complex.

Response: A consolidated nuclear production center (CNPC) alternative was added as a reasonable alternative and is discussed in Section 3.5 of this SPEIS. NNSA decided to analyze this alternative in order to assess the potential impacts of consolidating major nuclear weapons and SNM production missions at one site.

Comment: Commentors stated that pits will last up to 100 years and potentially longer; therefore, there is no need for new pit production capacity.

Response: This SPEIS addresses the environmental effects of both possessing and utilizing a pit production capacity in the event decisions are made to produce pits. While the current state of knowledge is that there may not be a need to produce pits in the near future because of the plutonium's longevity, NNSA cannot be certain that other issues associated with pits, other than the aging of plutonium materials, would never arise. Accordingly, prudent management requires that NNSA maintain a capacity to produce pits as long as this nation maintains its nuclear stockpile. A small pit fabrication capability is currently being maintained at LANL and is part of the No Action Alternative evaluated in this SPEIS.

Comment: Commentors asked why KCP was not being considered in this SPEIS, and stated that NNSA was not representing the full cost of Complex Transformation by excluding alternatives involving activities currently performed by KCP.

Response: Following the Non-nuclear Consolidation Environmental Assessment (DOE 1993), NNSA decided to consolidate most non-nuclear operations to improve efficiency. In the SSM PEIS (DOE 1996d), NNSA further considered alternatives with respect to non-nuclear operations, including relocating those capabilities to the NNSA national laboratories. The decision was made (61 FR 68014; December 26, 1996) to retain the existing facilities at the KCP. This was the environmentally preferable alternative, posed the least technical risk, and was the lowest cost alternative.

³ Title 32, *National Defense Authorization Act for Fiscal Year 2000*, Public Law 106-65

Because the non-nuclear operations at KCP are essential and do not duplicate the work at other sites, no proposal for combination or elimination of these missions was formulated. A recent analysis has concluded that transferring these KCP non-nuclear operations to a site other than one within the immediate Kansas City area would not be cost effective (SAIC 2008). Consequently, the non-nuclear operations would remain at either the current KCP or a new facility in the Kansas City area, and would neither affect nor be affected by the decisions regarding the alternatives in this SPEIS.

Comment: Commentors requested an analysis of the risks and impacts of terrorist attacks on NNSA facilities.

Response: With respect to intentional destructive acts, substantive details of attack scenarios and security countermeasures are not released to the public because disclosure of this information could be exploited by terrorists to plan attacks. Depending on the malevolent, terrorist, or intentional destructive acts, impacts may be similar to or would exceed accident impact analyses prepared for the SPEIS. A separate classified appendix to this Draft SPEIS has been prepared that evaluates the underlying facility threat assumptions with regard to malevolent, terrorist, or intentional destructive acts. The methodology for the analysis in this classified appendix is discussed in Appendix B. These data provide NNSA with information upon which to base, in part, decisions supported by this SPEIS.

Comment: Support for the continuation of the NNSA flight test mission at the Tonopah Test Range was received from the Tonopah community. Commentors demanded evidence of a compelling reason to move this mission from Tonopah.

Response: A detailed impact analysis was prepared for the NNSA flight testing alternatives and is presented in Section 5.15.4.2 of the SPEIS. The analysis discusses the potential socioeconomic impacts to the Tonopah community of NNSA flight testing alternatives.

Comment: Commentors expressed opposition to any new nuclear facilities. There was specific opposition to expanding pit production at LANL, as well as the proposed consolidated plutonium center (CPC). Commentors stated that the LANL Site-Wide EIS should follow the Complex Transformation SPEIS.

Response: NNSA added analysis of an alternative that would upgrade facilities at LANL for a smaller pit production capacity (up to 80 pits per year) than the baseline capacity (125 pits per year, single shift) of the proposed CPC (see Section 3.4.1.2). NNSA is evaluating increasing its current capacity to produce nominally 20 pits per year at LANL in a site-wide EIS (LANL 2006a). It is expected that a final LANL Site-wide EIS will be issued prior to completion of this SPEIS.

Comment: Commentors stated that a site near the Waste Isolation Pilot Plant (WIPP) near Carlsbad, New Mexico, should be considered as a reasonable location for a CPC.

Response: In order to determine the reasonable site alternatives for a CPC, all existing, major DOE sites were initially considered as a potential host location for a CPC. Sites that do not maintain Category I/II SNM were eliminated from consideration, as were sites that did not conduct major NNSA program activities. WIPP did not meet these siting criteria. Other DOE sites were not considered reasonable locations because they do not satisfy certain criteria such as population encroachment, mission compatibility, or synergy with the site's existing mission. Following this process, NNSA decided that Los Alamos, NTS, Pantex, SRS, and Y-12 constitute the range of reasonable site alternatives for a CPC.

As a result of the scoping process, NNSA made the following significant changes to the scope of the Complex Transformation SPEIS:

- A consolidated centers of excellence (CCE) alternative was added as a reasonable alternative (see Section 3.5). NNSA would consolidate plutonium, uranium, and weapon assembly/disassembly functions into a CNPC at one site or into Consolidated Nuclear Centers (CNCs) at two sites.
- A discussion was added of effects on the Complex of an even smaller nuclear weapons stockpile than the current level envisioned under the Moscow Treaty (see Section 5.11).
- A discussion was added of the RRW's possible impact on the nuclear weapons stockpile and decisions about Complex Transformation. An analysis was added to determine what, if any, changes to the Complex would be required if the RRW were to be developed (see Chapter 2).
- A more detailed analysis of the potential impacts of NNSA flight testing was added in order to inform the public and NNSA of the potential socioeconomic impacts to the Tonopah community from the alternatives (see Section 5.15.4.2).
- An analysis of a smaller pit production facility (50 to 80 pits per year) was added (see Section 3.4.1.2).
- A more detailed explanation of why the Kansas City Plant non-nuclear operations are not included in this SPEIS was added (see Section 3.2.10).

Table D.2-2—Summary of Scoping Comments

Topic 1. Policy

Subtopic	Comment Summary	Documents	SPEIS Reference
Existing Treaties—General	<p>Commentors believe that the current nuclear 'deterrence' policy has failed and has placed the world on the brink of nuclear winter.</p> <p>Enduring and legally binding U.S. Treaty Obligations must inform the domain of reasonable alternatives for analysis. As part of the supreme law of the land, U.S. treaty obligations are far more dispositive than the strategic ramblings of now discredited and departed senior Pentagon bureaucrats.</p> <p>As one of his first official acts, after taking office in January 1977, President Jimmy Carter asked the Secretary of Defense for an analysis of the implications of mutual U.S. and Soviet reductions in the number of strategic nuclear delivery vehicles to 200–250. If the President of the U.S. could find such a greatly reduced nuclear force to be sufficiently reasonable, at the height of the Cold War, to merit commissioning a Pentagon study of it, surely it is objectively reasonable for NNSA today—16 years after the dissolution of the Soviet empire that prompted deployment of U.S. nuclear weapons in such vast quantities—to analyze the implications of comparable and even smaller nuclear forces for the future configuration of the U.S. nuclear weapons complex.</p> <p>Commentors state that DOE should consider the 1996 World Court decision that nuclear weapons are illegal; the proposed action therefore violates this determination and is unlawful.</p>	2, 6, 104, 138, 196, 263, 348, 1209, 1220	Chapter 2
Presidential Directives, Public Law, and Current Policies	<p>Commentors state that DOE should take into consideration an adverse change in the American political climate as part of the global political climate due to expanding U.S. nuclear arsenal and wait until the next administration to continue with the project. DOE should adopt new policies that will favor disarmament and a 'no-first-use' policy.</p> <p>Commentors expressed concern that the U.S. has halted progress in the development of the Fissile Material Cutoff Treaty (FMCT) and that the artificial enrichment with plutonium or uranium will violate</p>	Campaign 18, 4, 67, 104, 111, 263, 281, 511, 320, 378, 516, 781, 1218, 947, 1152, 1190	Chapter 2, Chapter 3, Section 2.1.4, Chapter 5, Section 10.4

Table D.2-2—Summary of Scoping Comments (continued)

Topic 1. Policy

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>the current fissile material ban being negotiated by the Conference on Disarmament.</p> <p>Commentors also support a fissile materials treaty to prevent the creation and transportation of HEU and plutonium.</p>		
Nuclear Posture Review	<p>The December 2001 Nuclear Posture Review is not a sufficient basis for the purpose and need for agency action. It does not comprise an act of law or even a formal policy directive, and in no way establishes or constrains the domain of future stockpile requirements that may be considered reasonable. The theory advanced in the NPR that a weapons stockpile provides deterrent value is flawed and undermines nonproliferation work.</p>	2, 6, 1048, 1090, 1220	Sections 2.1, 2.1.2
Comprehensive Test Ban Treaty	<p>Commentors stated that the Complex Transformation plan goes against the NPT and would result in the end of the Comprehensive Test Ban Treaty. Complex Transformation is a step toward rejecting ratification of CTBT and is preventing ratification; ratification of the CTBT should be considered.</p>	104, 263, 333, 335, 1137, 1220, 263, 690, 1210, 4	Section 2.1.3
Treaty on the Non-Proliferation of Nuclear Weapons	<p>Commentors stated that the NOI is false in stating that the number of weapons to be produced would be consistent with international arms-control agreements. They are not consistent with the NPT. Commentors stated that accelerating nuclear weapons manufacture is a violation of the NPT as well as Article IV of the Constitution, and will further the global proliferation of nuclear weapons. Commentors believe the U.S. should be complying with NPT and denuclearizing our arsenal. Commentors suggested that the SPEIS should discuss existing treaty limitation concerning proliferation of nuclear material/weapons (including U.S. efforts to limit proliferation) and analyze how the proposed action will/will not jeopardize existing international agreements. Commentors stated that the U.S. should commit to the elimination of nuclear weapons no later than Transformation.</p>	<p>Campaign 4, Campaign 5, Campaign 6, Campaign 7, Campaign 10, Campaign 12, Campaign 14, Campaign 15, Campaign 17, Campaign 18,</p> <p>1, 2, 3, 4, 5, 6, 7, 9, 10, 18, 20, 22, 23, 24, 30, 31, 37, 57, 59, 60, 63, 65, 67, 71, 75, 80, 81, 83, 85, 87, 88, 91, 92, 94, 96, 102, 103, 104, 105, 107, 110, 111, 113, 126, 128, 132, 133, 134, 138, 141, 145, 152, 153, 164, 190, 196, 199, 204, 207, 208, 210, 234, 216, 217, 220, 260, 263, 281, 285, 286, 300, 303, 316, 318, 319, 320, 324, 326, 330, 333, 335, 338, 339, 343, 348, 355, 358, 360, 361, 363, 367, 371, 373, 378, 379, 380,391, 394, 396, 399, 401, 402, 403, 404, 405, 406, 408, 410, 411, 413, 414, 418, 423, 424, 425, 427, 428, 430, 437, 438, 434, 439, 444, 446, 454, 458, 464, 472, 476, 479, 488, 492, 497, 510, 524, 529, 530, 540, 536, 544,</p>	Chapter 2, Sections 2.1.3, 2.1.4, 2.1.5, 2.1.6

Table D.2-2—Summary of Scoping Comments (continued)

Topic 1. Policy

Subtopic	Comment Summary	Documents	SPEIS Reference
		550, 560, 585, 586, 587, 589, 571, 577, 596, 595, 597, 603, 607, 608, 615, 618, 619, 621, 626, 627, 634, 635, 636, 644, 649, 660, 674, 675, 686, 689, 695, 696, 697, 701, 716, 719, 721, 716, 723, 725, 732, 734, 737, 740, 741, 747, 749, 751, 753, 758, 760, 761, 762, 764, 765, 767, 769, 780, 843, 850, 860, 854, 872, 876, 878, 906, 898, 899, 902, 1087, 1099, 1188, 1123, 1126, 1128, 1143, 1208, 1209, 1210, 1217, 1218, 1219, 1222, 1223	
Moscow Treaty	Commentors stated that DOE must comply with Moscow Treaty. The Strategic Offensive Reductions Treaty commits us to the reduction of our strategic nuclear arsenal from the estimated 5,000 to at least 2,200 in the next six years. In this case it seems the Moscow Treaty is a flawed treaty that provides a minimal benefit that is insufficient to mitigate the negative implications of the proposed action.	Campaign 18, 145, 164, 263, 516, 898, 769, 943, 1004, 1181, 1190, 1211, 1212	Section 2.1.5
International Policies	Commentors criticized that the U.S. is legally obligated to adhere to the requirements of customary international law, such as START I and II, and is violating international law and treaties and should support a fissile materials treaty to prevent creation and transport of HEU and plutonium.	4, 426, 445, 138, 752, 524, 883, 904, 837, 823, 1101, 1009, 1059, 1043, 1046, 1047, 1050, 1178, 1190, 1194, 1153, 1208, 1211, 1212, 1219, 1210, 1215, 1222, 1223, 263, 313, 320, 383, 450, 482	Sections 2.1.2, 2.1.3, 2.1.4, 2.1.5; the proposed action would not violate any existing international law.
Nuclear Waste Policy Act	Transformation contradicts intent of NWPA and project operations must be in compliance to protect public health.		Section 10.3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 2. NEPA Process

Subtopic	Comment Summary	Documents	SPEIS Reference
General NEPA Process	<p>Commentor expressed opinion regarding the limitation of the NEPA process. Another commentor suggested that NNSA give a basic introduction of what is planned for people who are not technically proficient in the NEPA process.</p>	6, 1219	Section 1.5, 1.6
Whether To Prepare a New PEIS Versus a Supplemental PEIS	<p>Commentor stated that supplementing the aging and flawed SSM-PEIS of 1996 may not be the best strategy for NEPA review of “complex transformation.” The original SSM-PEIS was very far from comprehensive in its coverage: non-nuclear component manufacturing ,tritium production and recycling, and weapons-usable fissile material storage and disposition, all activities intrinsic to the operations of the U.S. nuclear weapons complex were segmented from the original proposal for a comprehensive post-cold war “Reconfiguration PEIS” and subsequently analyzed in separate NEPA documents supporting a series of staggered and haphazard restructuring decisions throughout the decade of the 1990’s.</p> <p>Commentor stated that the SSM PEIS focused by default on a narrow range of remaining “decisions” about the “reconfigured” complex, some of which had already in effect been made years earlier while others turned out to be far less consequential than originally advertised by NNSA’s predecessor DOE Defense Programs.</p> <p>The NOI is rife with evidence of rampant illegal segmentation of NEPA analysis in a manner that obstructs formulation of reasonable programmatic alternatives and analysis of cumulative and connected impacts.</p> <p>Commentors also stated that since the previous PEIS, Complex programs will have changed. A new PEIS is required, covering all aspects of the plan to develop 'replacement' nuclear weapons and facilities to provide opportunity of a review of the whole system.</p> <p>Commentors also suggested that tailoring the inclusion or exclusion of major and very costly proposed projects to suit the parochial interests of particular sites, or the immediate programmatic goals of NNSA as currently defined, defeats the purpose of a NEPA</p>	2, 4, 5, 9, 716, 1218	Chapter 1, Sections 1.5, 1.6, 2.0, 2.1, 2.5, Chapter 3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 2. NEPA Process

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>programmatic analysis, by creating “facts on the ground” that arbitrarily foreclose consideration of reasonable consolidation and location alternatives.</p>		
Stakeholder Involvement	<p>Commentors stated that DOE involve all stakeholders in the decision-making process including the Western Shoshone people in the central decision-making process, and request that International Atomic Agency (IAEA) and other international law experts formally submit comments to this proposed action.</p> <p>Commentors suggest polling long-time residents of Nevada concerning safe storage of radioactive waste in Nevada.</p> <p>One commentor stated that tables should be set up for the display of NGO literature and be in a prominent location where people can easily access provided information.</p> <p>Commentors also suggested that DOE speak with the communities, including Native American Tribes, surrounding the proposed sites and along transportation corridors regarding their current traditional and foreseeable future use of land and resources.</p>	215, 263, 763, 1208, 1223, 1179	<p>Section 1.6, Chapter 2</p> <p>Tables were provided to NGOs at scoping meetings.</p> <p>DOE conducts public meetings allowing the public to participate in the decision-making process.</p>
Scoping Process— Notification	<p>Commentors stated that the public comment period is only publicized and convenient to those who are educated. Public hearing notices should be published 45 days before the first hearing and should appear in the appropriate newspapers the Sunday before the hearings and also on the day before each hearing.</p>	9, 1179, 1209	Section 1.6
Length of Scoping Period— Number and Location of Scoping Meetings	<p>Commentors requested that the public comment period be extended from 60 days to 180 days and additional meetings be added. Commentors suggested that future hearings and meetings be properly and widely advertised and held in locations that are easily accessible to the public (i.e., via public transportation and all through the day and night to accommodate various work schedules). Commentor suggested discussing the logistics of meetings with community members in advance.</p> <p>Specific comments on locations of public meetings included changing the venue for the Los Alamos meetings, meetings should also be held in Espanola and Pojoaque, NM; additional public</p>	Campaign 19, 4, 5, 9, 47, 53, 191, 207, 215, 296, 315, 325, 500, 745, 763, 1048, 1044, 1048, 1050, 1083, 1216, 1218, 1125, 1134, 1179, 1209	Section 1.6

Table D.2-2—Summary of Scoping Comments (continued)

Topic 2. NEPA Process

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>hearings for SRS should be held at the state capital, additional meetings should also be held in Nevada, Utah, eastern California, Salt Lake City/St. George, near Livermore, and near Kansas City. Meetings should also be held at major population centers such as San Diego, CA; Phoenix, AZ; New York City, NY, Boise, ID; Las Vegas, NV, etc. In addition, meetings should also be conducted in areas downwind, down gradient, and along shipping routes</p> <p>One commentor had specific concerns about how the first public hearings were held in Clark County, as opposed to the actual proposed site of Tonopah.</p>		
<p>Scoping Meeting Format, Scoping Meeting Fact Sheets</p>	<p>Commentors suggested that a combination of an "open house" with roundtable discussions to allow for the possibility of real negotiations and questions/answers from both sides and a facilitated hearing is the best way to maximize the solicitation of scoping comments and inform the public of the proposed action with longer time for the public to speak. Some commentors stated that the poster session was insufficient. Commentors also suggested the use of a court reporter at hearings.</p> <p>Another commentor had a specific comment regarding an incomplete sentence on a fact sheet handed out during the scoping meetings and requested that the sentence be completed.</p> <p>Commentor questioned when the public would be able to sign up to speak.</p> <p>Commentor requested that detail on special security requirements be provided to the public and public leaders.</p> <p>Commentor requested that daycare be provided during scoping meetings.</p> <p>Commentor asked why RRWs are not on any other fact sheets other than the fact sheet entitled "Getting the Job Done."</p> <p>Commentor suggested being consistent with the use of "security" on</p>	<p>4, 5, 9, 167, 215, 303, 641, 763, 1048, 1050, 1146, 1212, 1213, 1217</p>	<p>Sections 1.6, 2.5</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 2. NEPA Process

Subtopic	Comment Summary	Documents	SPEIS Reference
	fact sheets.		
Scoping Comments	<p>Commentor suggested that DOE provide the opportunity to comment both in private and in public and that DOE report how many Complex Transformation scoping comments state that the proposed Transformation will result in proliferation, a decrease in proliferation, or will have no effect.</p> <p>Other commentors requested an explanation of the impacts the scoping comments from the public would have.</p>	4, 5, 146	Section 1.6
Availability of Information	<p>Commentors stated that insufficient information is provided to the public and that NNSA seems to be prejudicing the outcome of Complex Transformation by not providing handouts for all scenarios proposed.</p> <p>Commentors requested that DOE release secure documents and all previous tiered NEPA documents available on the project Web site and make all reference documents for the SPEIS available on the internet and on CD format.</p> <p>Commentors also stated that DOE should provide a complete listing and presentation of all documents upon which it intends to rely for the Complex Transformation along with all references, and related site-specific EAs and EISs.</p>	Campaign 19, 4, 5, 6, 9, 48, 263, 1209, 1218, 1225	<p>Chapter 2, 12</p> <p>The Administrative Record will be available to the public. NNSA has made every effort to provide the reader with sufficient information to satisfy NEPA requirements. Release of sensitive information is an issue of law and national security.</p>
NEPA Compliance	<p>Commentors believe that the project is not compliant with NEPA and its implementing regulations and it is speculated that DOE is intentionally circumventing meaningful NEPA compliance.</p> <p>Comments submitted regarding compliance with NEPA included concern about the chronological release of the LANL SWEIS and Complex Transformation process. The LANL SWEIS NEPA process should follow (not precede) the Complex Transformation NEPA process as the outcome of the LANL SWEIS may substantially determine NNSA's pit production strategy. In addition, the commentor objected to the declared intention to press ahead with an EIS and ROD covering modernization of Y-12 capabilities</p>	2, 4, 6, 18	Chapter 1, Sections 1.5.2, 1.5.4.2

Table D.2-2—Summary of Scoping Comments (continued)

Topic 2. NEPA Process

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>even as the Complex Transformation SPEIS gets underway. Under at least some reasonable scenarios for deep reduction in the nuclear stockpile, it would make economic, security, and logistical sense to consolidate a portion or all of these activities at LANL, or at some other site or sites closer to the geographic center of a future complex in the southwestern triangle formed by Pantex, SNL, and LANL.</p> <p>Commentors objected to the arbitrary and counter-productive exclusion of options for consolidating uranium, secondary, and case fabrication activities currently performed at Y-12 in Oak Ridge, TN.</p> <p>Commentors stated that the CMRR decision appears to prejudice both the current LANL SWEIS and Complex Transformation.</p>		
NEPA Conflict-of-Interest	<p>Commentors suggested that DOE has a conflict-of-interest with projects at LANL that would prejudice the present SPEIS decision-making process.</p>	6	Section 1.5.4.2

Table D.2-2—Summary of Scoping Comments (continued)

Topic 3. Programmatic Purpose and Need

Subtopic	Comment Summary	Documents	SPEIS Reference
Purpose and Need—General	<p>Commentors suggested that the SPEIS develop a fair and objective statement of the “Purpose and Need for the Proposed Action” that is based on more than the 2001 NPR. The purpose and need must also consider the NPT and International Court of Justice in the Hague opinion. The purpose and need should take into account the broader missions of the NNSA that include preventing proliferation, ensuring the effectiveness of NPT and developing strategies for ensuring the peaceful denuclearization of existing and threshold nuclear states and the legal obligations and treaty commitments that underpin them. The purpose and need must clearly state and include the full ramifications of the proposed project and how it will better secure the health and safety of the American people.</p> <p>Commentors also stated that the construction of the CPC is unjustified and questioned the purpose of the 125 certified pits. Commentor suggested that JASON’s review data should be considered and be included in the purpose and need.</p> <p>Commentors also suggested that the purpose and need should clarify the meaning of “modernization activities, changing character”, and developing a “responsive infrastructure.”</p>	2, 4, 9, 190, 215, 263, 323, 491, 690, 715, 769, 781, 1048, 1149, 1162, 1218, 1225	<p>Section 1.4 Chapter 2, Sections 2.1, 2.1.4, 2.1.5, 2.1.7, 2.2.2, 2.3.3, 2.3.4, 2.5.6, 3.1, 3.3.1, 3.4.1</p> <p>As NNSA dismantles more retired nuclear weapons, the number of pits in storage does increase.</p>
Relationship to Stockpile Stewardship and Management	<p>Commentors questioned why we are presently renewing our nuclear weapons under the Stockpile Stewardship Program, making our warheads last over 100 years. Has the 'no new plutonium sites' policy in the 1996 Final SSM PEIS changed?</p> <p>Commentors also questioned if any of the sites (Pantex, NTS, and Y-12) considered by the 1996 SSM PEIS were found NOT to be reasonable candidates for plutonium handling missions and had become plutonium sites since 1996?</p>	73, 92, 105, 111, 1220	<p>Chapter 2, Section 2.2.2</p> <p>NNSA is not proposing to create a new nuclear site in this SPEIS.</p> <p>This SPEIS has only proposed alternatives.</p>
Question the Need for Complex Transformation	<p>Commentors questioned the need for Complex Transformation when a nuclear weapons arsenal already exists and weapons that have been NNSA certified are available. Commentors stated that the SPEIS needs to explore the need for the proposed action and how it will better secure health and safety of the American people.</p>	Campaign 1, Campaign 2, Campaign 5, Campaign 7, Campaign 8, Campaign 9, Campaign 10, Campaign 14, Campaign 16, Campaign 17,	Chapter 2, Sections 2.1, 2.1.4, 2.1.5, 2.1.6, 2.1.7, 2.2.2, 2.3.1, 2.3.2, 2.3.3.2, 2.3.3, 2.4, 3.3.1

Table D.2-2—Summary of Scoping Comments (continued)

Topic 3. Programmatic Purpose and Need

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>Commentors stated that building up our nuclear capabilities makes no sense when our biggest threat is from non-state terrorist groups and the proliferation of weapons to other states. The U.S. cannot produce nuclear weapons while insisting other countries not pursue nuclear capabilities</p> <p>Numerous commentors stated that DOE must prove that the plutonium pit-aging phenomenon is occurring and problematic and explain why there is a need to expand pit production over existing capabilities when the number of pits is already oversized and unneeded.</p> <p>Commentors stated that consolidation and downsizing of the complex is not dependent on Complex Transformation and questioned how having a responsive infrastructure will help strengthen the global nonproliferation regime.</p> <p>Commentors stated that the U.S. should proceed with nuclear disarmament because there is no need to be armed with nuclear weapons.</p>	<p>Campaign 12, Campaign 18, 1, 2, 4, 5, 6, 10, 22, 31, 32, 48, 57, 66, 67, 68, 75, 76, 80, 96, 97, 99, 104, 107, 108, 110, 111, 128, 145, 146, 149, 153, 191, 193, 204, 207, 209, 211, 215, 263, 265, 266, 268, 272, 275, 277, 320, 323, 326, 327, 328, 330, 331, 333, 336, 340, 342, 343, 348, 354, 355, 359, 361, 368, 369, 380, 390, 391, 392, 402, 403, 406, 411, 413, 422, 423, 427, 428, 430, 431, 437, 440, 441, 443, 444, 445, 450, 491, 529, 535, 538, 540, 541, 548, 550, 552, 567, 571, 586, 587, 588, 589, 591, 593, 634, 652, 682, 684, 686, 687, 690, 693, 695, 697, 700, 723, 725, 743, 763, 765, 769, 770, 771, 781, 787, 798, 800, 801, 807, 810, 827, 820, 822, 828, 843, 845, 859, 861, 889, 907, 953, 962, 965, 972, 973, 974, 976, 1045, 1048, 1054, 1056, 1087, 1095, 1097, 1099, 1100, 1103, 1107, 1111, 1112, 1113, 1123, 1132, 1137, 1138, 1142, 1143, 1153, 1155, 1181, 1188, 1190, 1191, 1200, 1205, 1206, 1208, 1209, 1210, 1213, 1215, 1216, 1217, 1218, 1219, 1220, 1221, 1220, 1222, 1223, 1224</p>	

Table D.2-2—Summary of Scoping Comments (continued)

Topic 4. Programmatic No Action Alternative

Subtopic	Comment Summary	Documents	SPEIS Reference
No Action Alternative— General	Commentors suggested including an 'amended' no action alternative which aims to not expand the nuclear pit fabrication capacity of the U.S.	Campaign 5, Campaign 9, 52, 686, 693, 894, 1218, 1223	Section 3.3.1, 3.4.1.6
No Action Alternative Needs To Be a True No Action	Commentor stated that the “No Action” Alternative must be genuine. We object to the current NOI’s definition of “No Action” Alternative which actually incorporates a host of activities and proposed actions that a direct bearing on the future structure of the weapons complex under review. We strongly urge that analysis of major new projects covered by the ongoing Y-12 and LANL Site Wide EIS’s be placed on hold and made subordinate to the analysis and outcomes of the SPEIS process. To do otherwise would severely compromise the integrity and utility of the SPEIS, which would then be compelled to wrap itself around site-specific decisions and projects that will effectively predetermine and artificially constrain the consideration of programmatic alternatives for the complex as a whole.	2	Chapter 3
Viability of the No Action Alternative	This SPEIS must present a credible analysis of the No Action Alternative including the "viability" of the No Action Alternative for meeting existing pit production requirements necessary to satisfy requirements of stockpile stewardship inventories.	47, 904, 910, 937, 1057, 1213, 1216	Section 3.4.1.6
Justification of the No Action Alternative	Commentors requested a description of how the reduced operations and no action alternatives differ to require analyses in a complex-wide SPEIS as neither includes construction of a CPC, consolidation of SNM and elimination of duplicate facilities, flight testing, reduction of production capacities at Pantex, Y-12, and SRS, and dismantlement activities. In addition, DOE must provide legal justification for choosing or not choosing the No Action Alternative in the Draft SPEIS.	5, 1218	Section 3.1, 3.3, 3.6, Chapter 3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 5. Programmatic Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
<p>Programmatic Alternatives— General</p>	<p>The current proposal only has three options and is too limited; there should be more alternatives. The alternatives presented in the NOI are also unresponsive to key members of Congress and to the NPT.</p> <p>Commentors also stated that any alternative that contemplates developing weapons of mass destruction poses an unacceptable risk to the environment, country, species and the planet. Proposed alternatives threaten human health.</p> <p>Commentors also suggested that each alternative include an analysis of the potential for a new international arms race and the local, regional, and international impacts; how nuclear weapons increase global security; how proposed action will impact specifically Middle Eastern peace and security; who will benefit from a reciprocal reaction from other states; who will be impacted internationally, as well as locally, regionally, and nationally by proposed activity; who will benefit from the proposed alternatives; and the environmental and human health impacts both nationally and internationally from the arms race that would be instigated by a reciprocal action from other states.</p>	<p>Campaign 15, Campaign 17, 6, 555, 1216, 1135, 1153, 1154, 1210, 1217, 1218, 1223</p>	<p>Chapters 3, 5, Sections 2.1.4, 2.4 3.1, Sections 5.x.11 for all sites</p>
<p>Development of Programmatic Alternatives</p>	<p>Commentors questioned the development of the alternatives and stated that transformation is not a consolidation plan, it is a revitalization plan. It goes from 8 sites to 8 sites. Consider a real consolidation plan.</p> <p>Commentors expressed the concern that the nuclear weapons produced by Complex Transformation will be used in the future with negative consequences.</p> <p>One commentor stated that all major nuclear weapons sites are to be retained in NNSA's plan, an assumption which the House Appropriations Committee and the Secretary of Energy's SEAB have opposed. NNSA offers only two alternatives: (1) a somewhat reduced level of manufacturing expansion accompanied (by) some consolidation within sites and elimination of unspecified duplicate facilities; and (2) implementation of plans in place today, involving</p>	<p>6, 9, 104, 747, 1208, 1209, 1217, 1219, 1220, 1222, 1223</p>	<p>Chapter 3, Section 3.5, Appendix C</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 5. Programmatic Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>manufacturing expansion as well. The same commentor also stated that NNSA's plans to build thousands of new warheads in the RRW program over the next quarter century, which have not been endorsed by the DoD or approved by Congress, while at the same time maintaining and extending the working life of existing warheads until the new RRWs could take their place, appears to underlie the choice of alternatives in the Complex Transformation Plan. It should be unnecessary to remind NNSA that alternatives proposed by DOE's own SEAB is a reasonable alternative. The same commentor also stated that the NEPA history of radiographic hydrotesting is an object lesson in what must be avoided this time around. The Supplemental PEIS must include a comprehensive and detailed presentation of the full suite of presently planned and "reasonably foreseeable" hydrotesting capabilities, and "reasonable" alternatives thereto, over the full time period covered by the analysis.</p> <p>The set of "reasonable alternatives" for analysis for this and indeed all aspects of the SPEIS, is bounded not by what the proposing agency itself "desires" or "prefers" but by what an objective informed observer would regard as economically, technically, and environmentally reasonable in light of a reasonably foreseeable range of future nuclear weapons requirements. These alternatives in turn must be bounded by a "decent respect for the opinions of mankind."</p> <p>Even in the case of possibly legitimate fears of impending WMD attack, U.S. first use of nuclear weapons in a "preemptive strike" would likely result in a disproportionate, overwhelming, and indiscriminate use of military force in violation of international humanitarian law. We therefore find it entirely reasonable to insist that the range of reasonable alternatives for the 2030 nuclear weapons complex must embrace options that not only include very deep nuclear stockpile reductions, but also exclude NNSA complex support for weapons and capabilities required to implement illegal preemptive and preventive nuclear attacks.</p>		

Table D.2-2—Summary of Scoping Comments (continued)

Topic 5. Programmatic Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>Commentors also stated that national security is enhanced by this project through consolidation at one site.</p> <p>NNSA fails to name or consider any alternative which realistically treats environmental, economic, and geopolitical realities which the average citizen can recognize as being of great importance.</p> <p>All the alternatives fall short of a feasible long-term sustainable plan for facilitating the health and safety of U.S. citizens.</p>		
<p>Programmatic Proposed Action: Distributed Centers of Excellence</p>	<p>Commentors stated that this alternative directly contradicts the NPT obligation and needs to be proven that the CPC is necessary in light of our obligation to comply with the NPT to reduce the nuclear arsenal. Commentors suggested that this alternative be eliminated.</p> <p>Numerous commentors made suggestions regarding the analysis of this alternative. These include: discussion of the facilities and industrial processes that are involved with the CPC; define baseline capacity; question if the CPC is a design-build project and why; explain the rationale for the order of the baseline CPC schedule and why the need to approve the mission in 2008, will the decision be made before the ROD, questions whether this decision is prejudice, and will the decision to proceed with the CPC be made in the ROD?; what will the site decision be based on?; when analyzing CPC include analysis on environmental justice, environmental safety threats, and regional cumulative impacts; and requested that decisions on the replacement UPF be deferred pending evaluation of the consolidated complex.</p> <p>Commentors also expressed specific questions regarding the CPC:</p> <ul style="list-style-type: none"> • How will the CPC enhance deterrence when resumed industrial-scale nuclear weapons production could encourage other countries to follow the U.S.'s lead? • What is the ratio of pits produced to certified pits expected to be for the CPC? Is the ratio expected to be different for different 	<p>Campaign 5, 4, 5, 330, 792</p>	<p>Chapters 2, 5, 6, 13, Sections 1.5, 1.5.3, 3.1, 3.4, 3.16</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 5. Programmatic Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>pits? How is this ratio estimated? Does a baseline capacity mean 125 pits produced or certified pits?</p> <ul style="list-style-type: none"> • At which site will the CPC cause the most environmental impacts and need the most mitigation measures? 		
<p>Programmatic Alternative 2: Consolidated Nuclear Production Center</p>	<p>Commentor stated that in light of its lower security overhead and environmental advantages the CNPC proposal is objectively reasonable and must be analyzed for a range of stockpile sizes including very low levels of nuclear forces.</p>	<p>2</p>	<p>Section 3.5</p>
<p>Programmatic Alternative 3: Capability-Based</p>	<p>Commentors stated that a drawback of Alternative 3 is that the production capacity would not be sufficient to meet current national security objectives. Commentors requested the specific definition of “nominal level” as well as the justification for this determination.</p> <p>Another commentor suggested the elimination of plutonium production and surveillance and research and development for this alternative.</p> <p>Commentor is concerned that under this alternative the removal of Category I/II SNM from LANL would have instant ramifications on the site and result in the cancellation of more than a billion dollars in new construction projects listed and analyzed in the LANL SWEIS.</p>	<p>5, 6, 1210, 1215</p>	<p>Sections 2.3.3.2, 3.4.1.4, 3.5, 3.6</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 6. Project-Specific Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
High Explosives R&D	<p>Commentors were concerned about the effects this alternative would have on the environment and requested that environmental, socioeconomic, demolition and transportation impacts at all sites be evaluated and provide a baseline for each of these resources.</p> <p>Commentor expressed concern that DOE has predetermined that HE production, pressing, and machining will be located at Pantex.</p> <p>Commentors had specific questions regarding HE R&D:</p> <ul style="list-style-type: none"> • How many HE R&D experiments are conducted annually and will any alternatives reduce the number of HE R&D experiments? • Will downsizing of HE R&D require new buildings? 	4, 104, 1219	Sections 3.2.5, 3.8, 3.15, 5.10, 5.17, Chapter 5
Tritium R&D	<p>Commentors requested the necessity of this alternative especially if the production of nuclear weapons is abandoned. Commentors were also concerned about effects this alternative would have on the environment and requested that environmental, socioeconomic demolition and transportation impacts at all sites be evaluated and provide a baseline for each of these resources. Commentors also requested that environmental impacts at sites with increased activity due to consolidation of tritium R&D at some sites be analyzed and to consider the production of tritium and the commercial use of nuclear power reactors for tritium production.</p> <p>Commentors had specific questions regarding Tritium R&D:</p> <ul style="list-style-type: none"> • How many Tritium R&D experiments are conducted annually and will any alternatives reduce the number of Tritium R&D experiments? • Will downsizing of Tritium R&D require new buildings? • Will the downsizing of Tritium R&D have any effect on the location of a CPC? • Do the properties of tritium change? 	4, 1210, 1219	Chapter 3, Sections 2.1.4, 3.8, 3.9, 5.10, 5.17
NNSA Flight Test Operations	<p>Commentors were concerned about effects this alternative would have on the environment and requested that environmental,</p>	4, 47, 104, 1197, 1219	Sections 3.10, 3.10.1, 5.15, 5.15.5, 5.17

Table D.2-2—Summary of Scoping Comments (continued)

Topic 6. Project-Specific Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>socioeconomic, demolition, and transportation impacts at all sites be evaluated and provide a baseline for each of these resources.</p> <p>Commentors also had specific questions regarding flight test operations:</p> <ul style="list-style-type: none"> • How many flight tests are conducted annually and will any alternatives reduce the number tests? • Will the number of tests be reduced under this alternative? • Will the selection of a location for the flight tests have any effect on the location of a CPC? • What are the required geological conditions needed to successfully support all flight testing requirements? • Is it legal to perform these tests on Native American lands? <p>Commentors suggested evaluation of the relocation of the flight test operations without transformation of the whole complex. Commentors were also concerned that flight test operations may stir up radioactive dust from previous ground testing.</p>		<p>The CPC, which is a programmatic decision, has no bearing on the Flight Test Program, which is a project-specific decision.</p>
<p>Major Hydrodynamic Test Facilities</p>	<p>Commentors were concerned about the effects major hydrodynamic test facilities would have on the environment and the impacts of leaving waste from the tests on and in the ground. Commentors suggested that the SPEIS include a comprehensive and detailed presentation of presently planned and reasonably foreseeable hydrotesting capabilities and reasonable alternatives thereto over the full 30-year period covered by the analysis and also requested that environmental, socioeconomic, demolition, and transportation impacts at all sites be evaluated and provide a baseline for each of these resources. Commentors also suggested that the impacts from LANL, DARHT, and LLNL's Site 300 hydrotesting activities be analyzed, list all materials and amounts by isotope used in all types of hydrotesting including non-fissile radioactive isotopes.</p> <p>Commentors requested that DOE explain why LANL performed at least one hydrotest for a speculative RRW design while at the same time it is far behind on hydrotests designed to baseline the safety</p>	<p>2, 4, 104, 1219</p>	<p>Sections 3.11, 3.11.1, 3.11.1.2, 3.11.1.3, 3.11.2.1, 3.11.2.3, 5.16, 5.16.3, 5.17</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 6. Project-Specific Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>and reliability of existing nuclear weapons.</p> <p>Commentors suggested that the consolidation of hydrotesting be addressed without transformation of the whole complex and also consider ramping down hydrodynamic testing at all sites.</p> <p>Commentors stated that it seems that NNSA has predetermined the large-scale hydrotesting facility will be located at NTS.</p> <p>Commentors also had specific questions regarding major hydrodynamic test facilities:</p> <ul style="list-style-type: none"> • Is DARHT a large-scale hydrotest facility? • Is moving the location of these sub-critical experiments being considered? • Will any alternative reduce the number of hydrotest experiments? How many experiments are conducted annually? • Will consolidating hydrotesting require new buildings? If so, what are the projected costs? 		
<p>Major Environmental Test Facilities</p>	<p>Commentors were concerned about effects this alternative would have on the environment and requested that environmental, socioeconomic, demolition, and transportation impacts at all sites be evaluated and provide a baseline for each of these resources.</p> <p>Commentors requested that an explanation be provided regarding consolidating environmental test facilities which are contradictory with removing SNM.</p> <p>Commentors question the necessity in future event that production of nuclear weapons is abandoned.</p>	<p>4, 104, 1219</p>	<p>Sections 3.12.1, 5.17</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 7. Other Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
Other Alternatives—General	Commentors suggested that DOE identify other alternatives.	5, 774	Sections 3.1
Transportation of Nuclear Materials	Include an alternative which involves little to no transport of nuclear materials.	1210	Section 3.5.1
Disarmament, Dismantlement or Decommissioning Alternatives	<p>Commentors requested an option for disarmament or decommissioning of nuclear warheads and the elimination of the production of nuclear weapon components, the use of the volatile, toxic substances involved in weapons production.</p> <p>Commentors stated that NNSA needs to provide an alternative/plan that will put the warhead complex on a reasonable path toward dismantlement, while also maximizing security, minimizing costs and impacts, retaining a declining nuclear arsenal, and maximizing administrative freedom to pursue paths toward further nuclear disarmament by future administrations.</p>	<p>Campaign 5, Campaign 9, Campaign 12, Campaign 18, 4, 5, 6, 24, 26, 63, 65, 67, 68, 75, 79, 78, 111, 129, 138, 263, 286, 292, 300, 303, 316, 317, 318, 326, 333, 344, 348, 354, 355, 361, 368, 384, 387, 389, 391, 392, 397, 393, 400, 404, 406, 409, 413, 427, 428, 431, 440, 441, 443, 454, 457, 466, 469, 471, 472, 477, 519, 524, 540, 541, 549, 551, 552, 554, 559, 561, 564, 567, 571, 584, 585, 586, 588, 592, 599, 601, 602, 608, 613, 631, 636, 639, 644, 645, 652, 662, 664, 665, 672, 673, 674, 675, 688, 690, 704, 719, 725, 727, 732, 735, 737, 752, 754, 761, 762, 766, 769, 771, 772, 781, 811, 825, 829, 850, 855, 883, 887, 906, 938, 986, 1032, 1041, 1046, 1068, 1076, 1162, 1209, 1210, 1211, 1212, 1215, 1217, 1218, 1220, 1222, 1223, 1224</p>	<p>Sections 2.3.1, 2.3.2, 2.6, 3.15, Chapter 3</p>
Reduce Stockpile Alternatives	Commentors suggested including an option to reduce the current stockpile. Some commentors also suggested an alternative that requires the minimum amount of maintenance on our existing stockpile while simultaneously phasing out our nuclear weapons.	<p>Campaign 12, Campaign 15, Campaign 18, 2, 31, 111, 303, 332, 338, 339, 343, 354, 358, 360, 368, 396, 408, 418, 423, 425, 434, 438, 444, 445, 541, 544, Campaign 18, 571, 581, 569, 594, 872, 639, 643, 677, 678,</p>	<p>Sections 2.1.4, 2.1.5, 2.1.6, 2.1.7, 2.6, 2.6.3, 3.1</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 7. Other Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
		697, 710, 734, 735, 737, 738, 741, 749, 781, 825, 826, 830, 850, 938, 952, 1032, 1126, 1219, 1210, 1153, 1154, 1183, 1185, 1190, 1195, 1217, 1220, 1223	
Downsizing-in-Place Alternatives	<p>Commentor questioned whether downsizing of ETFs/ HE R&D/Tritium R&D/ hydrotesting will have an effect on the location selection of a CPC.</p> <p>Some comments received supported the proposal's stated aim for downsizing the nuclear weapons infrastructure.</p> <p>Commentors expressed that downsizing facilities in one place might cause increased activities at other sites. Commentors requested that the SPEIS include environmental impacts of increased activities as a result of downsizing facilities in one place.</p> <p>Commentors suggested that DOE provide an alternative with a consolidated network with refined capability with smaller size and maximum production.</p>	Campaign 7, 4, 673, 877, 1210	Chapters 3, 5, Sections 3.4.1, 5.17
Responsible Curatorship Alternatives	<p>Commentors requested that DOE include an alternative that evaluates a “Responsible Curatorship” case for the full range of reasonable stockpile sizes, that is built on the premise that no new or replacement nuclear components will be fabricated for the entire period covered by the SPEIS, and that pit and secondary refurbishment operations will be kept to the minimum level consistent with continued reliability and safety.</p>	Campaign 19, 2, 4, 6, 9, 32, 129, 529, 544, 747, 1083, 1218, 1219, 1220, 1222, 1223	Chapter 3, Section 3.15
Alternatives That Comply With the NPT	<p>Numerous commentors suggested alternatives that comply with the NPT. Commentors stated that an alternative should be added which would comply with [“comply with” or “satisfy” rather than “meet”?] the NPT by reducing current operations at active facilities to those necessary to perform critical storage, disassembly, dismantlement, and disposition missions. This alternative will put the warhead complex on a reasonable path toward dismantlement, while also maximizing security, minimizing costs and impacts, retaining a declining nuclear arsenal, and maximizing</p>	6, 367, 1056, 1095, 1134, 1135, 1212, 1220	Section 2.1.4, Chapter 3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 7. Other Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>administrative freedom to pursue paths toward further nuclear disarmament by future administrations</p> <p>Under an alternative that complies with the NPT, there would be no need to make pits; therefore, there is no need for a consolidated pit production facility, no need to operate LANL’s TA-55 facilities for pit production, and no need for a CMRR.</p>		
Comprehensive Test Ban Treaty Alternatives	Commentor suggested to be consistent with the CTBT define and evaluate an alternative that involves the complete cessation of NNSA weapons activities at NTS and the elimination of any underground nuclear experiments, wherever located.	2	Section 2.1.3
Security Alternatives	Commentors suggested including an option to secure current weapons inventory.	Campaign 12, 281, 320, 458, 464, 465, 111, 639, 781	Section 2.3.5
Safety Alternatives	Commentors suggested analyzing an option to store toxic materials like plutonium and HEU as safely as possible.	672	Sections 2.3.5, 3.5, 3.7
Alternatives Involving Policy	<p>Commentors suggested that DOE must analyze for an alternative where nuclear deterrence is not the cornerstone of U.S national security policy and for an alternative in which the U.S. complies with Article IV of the U.S. Constitution.</p> <p>Commentors also suggested another way to increase our nation’s security such as providing an alternative that aims to reduce the role of nuclear weapons in U.S. security strategies.</p>	Campaign 12, 5, 111, 570, 571	Section 2.3.5, Chapters 2, 3
Test readiness Alternative	Commentors stated the test readiness alternative should include an analysis which includes answers to issues relating to environmental impacts of maintaining test readiness; ability to certify the design of a nuclear weapon without testing; national and international environmental and public health impacts from past nuclear weapons testing; and the projected costs of compensation under the Radiation Exposure Compensation Act.	5	Chapter 3
Site Alternatives	<p>Numerous commentors suggested alternative uses for candidate sites:</p> <ul style="list-style-type: none"> • Consider lowering production at LANL and forget about the rest of the other potential locations. • Provide an alternative where LANL is used for better benefits 	2, 4, 9, 24, 30, 31, 32, 75, 264, 692, 747, 879, 1218, 1224, 1217, 1222	Sections 1.5.4.2, 2.3.3.2, 2.5, 3.1, 3.4.1.6, 3.6, 3.7.2, 3.15, Chapters 2, 3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 7. Other Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>than creating more nuclear weapon systems, consolidating plutonium, etc.</p> <ul style="list-style-type: none"> • The current production level of 20 pits per year at LANL is sufficient for maintaining deterrence. • Commentor urged that analysis of major new projects covered by the ongoing Y-12 and LANL SWEIS be placed on hold and made subordinate to the analysis and outcomes of this SPEIS. • Removal of nuclear materials/waste from LLNL • It would make economic, security, and logistical sense to consolidate a portion or all activities at LANL, Pantex and/or Sandia (southwestern triangle). • Suggest stopping the CMRR project since this building would become obsolete by the new consolidated plutonium facility. Instead co-locate future production capacity and radiological chemistry materials research workout. • DOE should consider the alternatives of joint operations of new LLNL facilities with other federal agencies such as DHS, FBI, NASA. • Convert nuclear weapons labs to facilities that promote technologies that meet human needs. • Analyze plutonium at existing Category I/II SNM sites, uranium at Y-12, A&D at Pantex, and tritium at SRS as an alternative without the so-called transformation and with existing facilities that could be downsized and consolidated. • Alternative missions for present day weapons sites must also be considered. • Develop alternative options for the research conducted at our national labs that would benefit our planet. • Define alternative consolidation plans for specific areas including hydrodynamic testing, strategic computing, environmental testing, flight testing, fissile material operations and storage, non-nuclear component fabrication, HE and detonator fabrication and testing and tritium operations and R&D. • Terminate all bomb development related tests and analyze the 		

Table D.2-2—Summary of Scoping Comments (continued)

Topic 7. Other Alternatives

Subtopic	Comment Summary	Documents	SPEIS Reference
	safest and secure locations to conduct maintenance tests.		
Nonproliferation Alternative	Commentors suggested that NNSA develop an alternative that focuses on nonproliferation. Include an alternative that excludes NNSA complex support for weapons and capabilities required to implement illegal preemptive and preventive nuclear attacks on other states that might in the future seek to arm themselves with weapons of mass destruction.	Campaign 5, Campaign 9, 2, 63, 213, 368, 387, 850, 734, 768, 1166, 1209, 1210, 1221, 1223, 68	Sections 1.2, 2.1.3, 2.1.4, 2.3.1, 2.3.2
Cleanup Alternatives	Commentors suggested that resources and expertise of national laboratories should be directed toward cleanup.	Campaign 4, Campaign 5, Campaign 6, Campaign 9, Campaign 12, Campaign 18, 1, 55, 164, 260, 287, 300, 303, 317, 318, 333, 368, 372, 380, 471, 499, 501, 525, 540, 541, 552, 555, 584, 585, 631, 681, 691, 747, 768, 781, 811, 861, 897, 962, 998, 1059, 1104, 1111, 1208, 1210, 1217, 1218, 1220, 1221, 1222, 1223, 1224	Chapter 2, Chapter 3, Section 3.15
New Triad	Commentors suggest providing alternatives that support the "New Triad" and the balance it brings concerning enemies and allies and discusses what the effects are of not having met the needs of this New Triad.	4	Section 2.3.1
Alternatives Promoting Peace	Commentors suggested that DOE should pursue more diplomatic alternatives, pursue the process of scientific conversion of military production to peaceful uses. Commentors also suggested an alternative where security is provided through conflict resolution and mediation.	Campaign 4, Campaign 6, 592, 1216	Section 3.15, Chapters 2, 3
Future of the Nuclear Weapons Complex	Commentors stated that the EIS should cover a range of alternatives that future presidents and Congress would face regarding our nuclear weapons Bombplex and abandon plans to build new nuclear weapons.	12, 57, 223, 326, 343, 358, 360, 396, 408, 418, 423, 425, 434, 444, 525, 710, 747, 749, 781, 938, 944, 1209, 1224, 1217, 1222, 1223	Section 3.1

Table D.2-2—Summary of Scoping Comments (continued)

Topic 8. Reliable Replacement Warhead

Subtopic	Comment Summary	Documents	SPEIS Reference
RRWs—General	A commentor expressed that the RRW program must be viewed as optional.	2	Sections 2.5, 2.5.1, 2.5.9
Opposition to RRWs	Commentors oppose the RRW because the RRW is not a legitimate element of the scope in this process and could imperil national security by substituting untested designs for already tested ones. Commentors also state that the RRW will promote nuclear proliferation.	4, 22, 32, 128, 168, 326, 1104, 1205, 1210	Section 2.5
RRWs and Pit Production	Commentors requested a discussion about the life cycle management of existing pits inventories and how new production will fit into existing management and disposition systems and questioned if different margins are expected for different pit sizes.	4, 26, 27, 587	Sections 2.5, 3.4.1
RRW—Analysis	Commentors submitted comments associated with the type of analysis that should be included regarding the RRW. These included: <ul style="list-style-type: none"> • Clarify the role of the RRW program as currently envisioned in Complex Transformation. • Analyze the environmental impacts for all RRW design concepts in the draft SPEIS. 	5, 1218	Section 2.5
Questions Regarding the RRW	Commentors submitted comments with questions on the RRW. These included: <ul style="list-style-type: none"> • How long will it take to produce an RRW to respond to geopolitical change? And why aren't current ones suited for this considering most types are understood to be variable yield? • Will our needs for a responsive infrastructure and war be the same in 2030 as they are now? • How would RRW, as new warheads be used towards emerging threats? Would they have a new military mission compared to existing U.S. nuclear weapons and if so this seems contrary to congressional intent? • Why are new weapons designs not mentioned in stockpile management activities on the fact sheets or under the proposed action? 	4, 503	Section 2.5

Table D.2-2—Summary of Scoping Comments (continued)

Topic 8. Reliable Replacement Warhead

Subtopic	Comment Summary	Documents	SPEIS Reference
	<ul style="list-style-type: none"> • What is the true need for new design nuclear weapons and for the production of 125 pits per year? • Will there be a time when there will be both RRW warheads and the warheads they are replacing in the stockpile? 		
Relationship Between the RRW and Complex Transformation	<p>Commentors questioned the relationship between the development of RRWs and alternatives for Complex Transformation.</p> <p>Commentors stated that if the complex must be reformed with or without new RRW designs, how can the RRW be the "enabler" for the project. Justification for the project seems to be a moving target therefore it is hard to discern if this SPEIS is for support of the existing stockpile, new design nuclear weapons, or some combination of the two.</p> <p>Commentors stated that expanded pit production is primarily about RRW pits for new nuclear weapons design and is the driver for the 125 pits per year desired level of production.</p>	4, 1219	Sections 2.5, 2.3.1
Question the Need for RRWs	Numerous commentors questioned the need for RRWs and the need to replace refurbished warheads with RRW warheads when a recent report indicates that the existing stockpile is not degrading.	4, 516, 603, 876, 942, 947, 1064, 1065, 1190, 1192, 1211, 1046, 1058, 1216	Section 2.5

Table D.2-2—Summary of Scoping Comments (continued)

Topic 9. Cost and Schedule

Subtopic	Comment Summary	Documents	SPEIS Reference
Cost-Effectiveness of Existing Nuclear Weapons Complex	Several comments were received regarding concern about the cost of the project and questioned anticipated costs, costs of accidents, and remediation efforts. Commentors also questioned the cost-effectiveness of Complex Transformation when DOE claims that the SSP is not failing after spending \$90 billion. Why then is the Program not adequate for maintaining the stockpile? How can increased costs for Complex Transformation be justified? Explain why the existing nuclear complex can't be made more cost effective. What needs to be changed to update it?	Campaign 2, Campaign 5, Campaign 4, Campaign 6, Campaign 7, Campaign 9, Campaign 10, Campaign 17, Campaign 18, 3, 4, 9, 10, 31, 75, 104, 107, 109, 110, 203, 208, 210, 303, 329, 335, 344, 351, 355, 367, 368, 391, 395, 402, 430, 432, 437, 445, 460, 525, 567, 584, 674, 689, 690, 693, 740, 727, 731, 732, 735, 738, 753, 752, 754, 765, 845, 860, 951, 955, 401, 1084, 790, 1089, 1100, 1126, 1218, 1142, 1143, 1149, 1161, 1162, 1200, 1209, 1210, 1220, 1223, 1217, 1218, 1219, 1222, 1223	Chapter 2, Section 3.1
Better Use of Resources	Numerous commentors provided suggestions for better use of resources. These include: <ul style="list-style-type: none"> • Funds should be spent on maintaining safety and security at existing sites • Funds should be spent on dismantlement • Funds should be spent on infrastructure 	Campaign 1, Campaign 19, 1, 5, 12, 19, 66, 67, 74, 77, 80, 96, 104, 109, 110, 126, 132, 133, 138, 153, 191, 368, 390, 541, 380, 320, 585, 684, 691, 692, 723, 740, 747, 758, 769, 783, 894, 1081, 1104, 1111, 1117, 1188, 1137, 1200, 1205, 1206, 1208, 1209, 1057, 1205, 1209, 1210, 1212, 1211, 1218, 1224, 1220, 1222	Chapter 2, Section 3.1
Factors That Could Increase Proposed Costs	Commentors expressed concern regarding factors that could increase proposed costs and requested additional discussion. Factors included: <ul style="list-style-type: none"> • Security • Increased mitigation and environmental restoration 	4, 1218, 1217, 1223	Chapter 2, Section 3.1
Cost of Cleanup	Commentors questioned the cost of the current cleanup that is needed.	1213	Chapter 2, Section 3.1

Table D.2-2—Summary of Scoping Comments (continued)

Topic 9. Cost and Schedule

Subtopic	Comment Summary	Documents	SPEIS Reference
Cost of Each of the Alternatives	<p>Commentors submitted comments on the cost of each of the alternatives and questioned if construction and operation costs would be the same at each candidate site. Commentors requested a discussion of the cost of siting the CPC at each of the candidate sites.</p> <p>A specific comment was submitted regarding TTR and remediation costs of associated with moving testing operation from TTR would be cost effective compared to keeping the testing at TTR. [Edit— words missing.]</p> <p>It was also suggested that transition to lower cost of operations for NNSA, without so-called transformation of the complex, be analyzed.</p>	4, 9, 685	Chapter 2, Section 3.1
Cost-Benefit Study	<p>Commentors requested the inclusion of a cost-benefit analysis of different alternatives (ETF/JFTP [joint flight testing program?]/HE R&D/Tritium R&D/Hydrodynamic Testing costs; an estimated breakout of all costs of downsizing-in-place and/or eliminating specific activities at sites performing Environmental Testings/JFTP/HE R&D/ Tritium R&D/Hydrodynamic Testing) including SNM consolidation without transformation and SNM consolidation as part of transformation.</p> <p>The cost-benefit analysis should also be based on a life cycle budget for the project including not only the cost of construction, but operation, decommissioning and waste disposal</p>	4, 5	Chapter 2, Section 3.1
Timeline	<p>Commentor submitted questions regarding the timeline of the proposal. These included:</p> <ul style="list-style-type: none"> • Is the schedule different for each site? • Explain rationale for the order of the baseline CPC schedule? Why approve the Mission Need (CD-0) in 2008? Will it be before the ROD? Isn't that prejudicial? Will the decision to proceed with the CPC be made in the ROD? 	4	Chapters 2 and 3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 10. Candidate Sites

Subtopic	Comment Summary	Documents	SPEIS Reference
Candidate sites—General	<p>Commentors submitted comments regarding candidate sites that were general in nature. While many commentors provided comments on specific sites, other comments stated:</p> <ul style="list-style-type: none"> • DOE must consider the psychological impact of living in a state with four sites devoted to nuclear weapons activities, as well as being the birthplace of the atomic bomb, and the site of its first detonation. • In order to comply with the 'no new plutonium sites' determination, plutonium activities should be placed at sites which currently have facilities with a history of safe plutonium operations. • Consider the synergistic impact of the location of two of the nation's nuclear weapons laboratories (LANL, SNL/NM) located within 60 miles of one another in New Mexico. • Discuss the reduction of NNSA sites. • The SEAB 2005 report contradicts the criteria for candidate site consideration (i.e., population encroachment) in the NOI stating that the majority of sites are bordered by residential and/or commercial communities. • Find financial means to make reparations to those communities whose soil, air and water have been contaminated. 	Campaign 12, 4, 5, 73, 111, 540, 792, 1218, 1208	Sections 2.3.4, 3.14, 4.1, 4.1.9, 4.6.9, 5.5.15, 5.9.15
LANL (New Mexico)	<p>Commentors submitted comments regarding the siting of “Complex Transformation” at LANL, these included:</p> <ul style="list-style-type: none"> • New studies need to be conducted to analyze the social, environmental, economic, and health impacts associated with an expansion at LANL. • Concern about safety from toxic wastes for residents residing upwind of Los Alamos. • Explain how NNSA came up with the 40% reduction of nuclear facility space at LANL. • Concern for safety and liability issues especially since security and environmental responsibility at LANL is lacking. • Provide justification for increasing the production at LANL from ~20 ppy to 200 ppy at a cost of ~\$4 billion. • LANL’s mission should be redirected to cleanup and securing 	Campaign 12, 2, 4, 5, 6, 73, 77, 111, 146, 209, 327, 333, 781, 792, 1128, 1215, 1217, 1218	Sections 1.1, 1.2, 1.5.3, 1.5.4.2, 2.3.3.2, 3.11.1.2, 3.4.1.5, 3.4.1.6, 3.7, 4.1, 4.1, 5.1, 5.1.4, 5.1.12, 10.6, Chapters 2, 4

Table D.2-2—Summary of Scoping Comments (continued)

Topic 10. Candidate Sites

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>the existing stockpile and waste.</p> <ul style="list-style-type: none"> • Explain why LANL was selected as a candidate site when its location is not favorable (on top of a windswept mountain, on an earthquake fault, in a wildfire zone, and at the source of a watershed that serves 10 million people). • Discuss containment methods for DARHT and explain if they conform to the DARHT EIS ROD. • Provide a discussion on facilities containing SNM and the management of these facilities by another group if by 2022 LANL is not expected to operate facilities containing Category I/II SNM. • Concern regarding LANL’s future direction. • The decision to locate a CPC at LANL is prejudicial and premature until a decision regarding the CMRR is made. • Concern regarding LANL’s chances of actually producing 10 certified W88 pits when it has yet to produce a certified pit. • LANL’s current weapons-related plutonium infrastructure should be more than sufficient to meet the needs of maintaining the U.S. nuclear stockpile. • Suggest performing another more updated EIS. • Concern about DOE's poor decision-making as shown in the decisions regarding the FXR facility the DARHT facility. <p>Some commentors also submitted comments in reference to the LANL SWEIS.</p>		
LLNL (California)	<p>Commentors submitted comments regarding the siting of “Complex Transformation” at LLNL, these included:</p> <ul style="list-style-type: none"> • Complex Transformation plan should terminate high explosives tests at Site 300 and concentrate on cleanup there and the main site. Address issues of encroachment to surrounding recreational and residential areas of pollutants from explosive testing. • LLNL would not be a suitable location because of its dense population, small facility and transportation and storage problems. LLNL is also a Superfund Site. • Direction from Congress to remove weapons usable material 	4, 9, 32, 1219, 1220, 1222	Sections 3.2.2, 3.3.1, 3.7.2, 3.8.1.1, 3.9.5.3, 3.13.2, 3.15, 4.2, Chapter 10

Table D.2-2—Summary of Scoping Comments (continued)

Topic 10. Candidate Sites

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>from LLNL.</p> <ul style="list-style-type: none"> • Complex Transformation would add to the already existing 2-mile plume that extends to the City of Tracy. • Discuss the closure of LLNL. • Discuss the role of the National Ignition Facility mega laser in Complex Transformation. • Concern regarding continued tritium operations. • Suggest phasing out operations at LLNL and move to LANL and make LLNL an alternative energy plant. • Concern regarding documentation by Tri-Valley CAREs showing the threat at least three-quarters of a million curies of tritium have come out of the twin stacks of Building 331. • Evaluate a proposal to place a National Bio and Agro Defenses Laboratory at LLNL. 		
NTS (Nevada)	<p>Commentors submitted comments regarding the siting of “Complex Transformation” at NTS, these included:</p> <ul style="list-style-type: none"> • NPR indicates concern over current 2-3 yr. nuclear test readiness at NTS which may not achieve the stated goal of a "responsive" complex. • Need to be very clear and explicit regarding assembly and disassembly of nuclear weapons at NTS as it is a new activity and not analyzed in the NTS SWEIS. • Discuss plan for an Advanced Hydrotest Facility. • Clarify how the mission of the NTS is to be realigned. • Evaluate to what extent the NTS would be a consolidation site. • Missions at NTS related to sub-critical tests are inconsistent with the proposed action. • NTS is an unsuitable location for siting the proposed CPC. • Discuss impacts, if sited at NTS, the proposed action would have on Yucca Mountain. • Consider impacts to Nellis Air Force Base, Area 5 and Area 3. • Concern in DOE’s poor decision-making as shown in the decisions regarding the AHF at NTS. 	2, 4, 215,587, 1048	Sections 2.1.2, 2.3.1, 3.2.3, 3.4.1, 3.12.3, 3.14.3, 6.2.3, Chapter 2, 3, 4
TTR (Nevada)	Commentor suggested that TTR be considered as a site for	793	Section 3.5.1, 3.10.1

Table D.2-2—Summary of Scoping Comments (continued)

Topic 10. Candidate Sites

Subtopic	Comment Summary	Documents	SPEIS Reference
	consolidation.		
Pantex (Texas)	<p>Commentors submitted comments regarding the siting of “Complex Transformation” at Pantex, these included:</p> <ul style="list-style-type: none"> • Examine integrating test flight operations with existing DoD test capabilities such as TTR. • Consider the dangers of airports in the area or consider moving location of flight paths so they are not over Pantex. • Pantex is not ready for W88 production because of shortage of existing resources. • Dismantlement should be given priority over weapons programs. • Stated that Pantex should not be considered a reasonable candidate site when Pantex has public access to fence lines that are only a short walk from the border of the site. 	4, 6, 73, 792, 1125, 1207, 1224	Sections 3.2.3, 3.10.4, 3.15, 4.5, 5.5.12
SNL (New Mexico)	<p>Commentor submitted comments requesting the following discussion for SNL/NM be included:</p> <ul style="list-style-type: none"> • Discuss the role SNL will play in certifying the plutonium pits. • Discuss the increased potential for tritium releases. • Discuss the increase in explosive components testing and the release of toxic contaminants. • Discuss if SNL will be operating its thermal treatment unit and what toxic pollutants will be released. • Discuss the potential for tritium accidents that can occur at SNL. • Suggest preparing a more updated EIS and specifically address water consumption rates. 	1217	Sections 3.2.6, 3.9.1.4, 3.12.1.3, 5.13, Chapters 2, 4
SRS (South Carolina)	<p>Commentors submitted comments regarding the siting of “Complex Transformation” at SRS, these included:</p> <ul style="list-style-type: none"> • Clarify if the SRS SNM is included in the consolidation. Is consolidation aimed at both weapons and non-weapons related SNM? • Consider that the attitude at SRS concerning support for Complex Transformation at SRS does not reflect the opinion of the entire state. 	4, 405	Section 3.7.1.3, Chapter 3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 10. Candidate Sites

Subtopic	Comment Summary	Documents	SPEIS Reference
Y-12 (Tennessee)	<p>Commentors submitted comments regarding the siting of “Complex Transformation” at Y-12, these included:</p> <ul style="list-style-type: none"> • Objection to the counter-productive exclusion of options for consolidating uranium, secondary, and case fabrication activities currently performed at Y-12 and the declared intention to press ahead with an EIS and ROD covering modernization of Y-12 capabilities even as the Complex Transformation SPEIS is underway. • Concern about soil, water, and air pollution caused by Y-12. • Concern about the construction of the HEU Facility in reference to the proposed construction of the CNPC at Y-12. • Suggested that environmental cleanup of the site be included as a key component. • Expressed support for Y-12 remaining the weapons’ complex center of excellence for uranium and other SNM. • Expressed concern about beryllium toxins in Oak Ridge. • Stated that Y-12 should not be considered a reasonable candidate site when Y-12 has public access to fence lines that are only a short walk from the border of the site. 	2, 73, 208, 322, 792, 795, 1129	Sections 1.5.4.2, 3.2.9, 3.5.1.1, 4.9, 5.9.12, Chapter 10

Table D.2-2—Summary of Scoping Comments (continued)

Topic 11. Additional Analysis

Subtopic	Comment Summary	Documents	SPEIS Reference
Additional Analysis— General	<p>Comments were received requesting that additional analysis be conducted. General comments included:</p> <ul style="list-style-type: none"> • Site-specific EIS evaluations and impact mitigation strategies for all potential CPC sites must be completed in the Draft SPEIS. • Separate impact studies should be conducted for downwind and down gradient communities. • SPEIS must list the number of augmentation weapons, reliability-reserve weapons and weapons to fulfill NATO commitments. 	4, 536	Sections 2.3, 4.x.4.11 for all sites, Chapter 5
Nuclear Weapons Activities	<p>Commentors submitted comments regarding additional analysis pertaining to nuclear weapons activities. These included:</p> <ul style="list-style-type: none"> • Analysis of historical, current, and international consequences due to U.S. nuclear weapons activities, including who have been impacted internationally, as well as locally, regionally, and nationally by the proposed future activities; who have benefited from the past nuclear weapons activities; how U.S. nuclear weapons have increased global security; and environmental and health impacts (nationally and internationally) from Cold War arms race. • Include analysis of possible use of one weapon currently in stockpile, an advanced concept, or RRW from smallest nuclear weapon to largest. • Include analysis showing the number of DOE-sponsored hydrodynamic shots at each site that are devoted to in whole or part of nuclear weapons development and for those that are strictly for maintenance. • SPEIS must list the number of augmentation weapons, reliability-reserve weapons and weapons to fulfill NATO commitments. • Clarify reliable or usable nuclear stockpile of weapons. • Study the phase-out of duplicative facilities. 	5, 9, 263, 1219, 1222	Sections 2.1, 2.2, 2.5, .5, 3.7, 3.8, 3.9, 3.11, 3.12, Chapter 5
Special Nuclear Material	Amount of SNM declared as surplus should increase as disarmament advances. Discuss how materials would be	9	Section 6.2.4, 6.3.4

Topic 11. Additional Analysis

Subtopic	Comment Summary	Documents	SPEIS Reference
	immobilized in forms that are difficult to assess and retrieve under the NPT Compliance/Disarmament Alternative.		
Environmental Analysis	Commentors submitted comments regarding the analysis of environmental impacts. These included: <ul style="list-style-type: none"> • DOE should provide a thorough analysis of the environmental effects of dismantling international anti-proliferation treaty and disarmament efforts with special attention to the U.S.'s effect on the international community as the world's superpower. • Include analysis focusing on global environmental effects from developing new nuclear weapons and furthering the nuclear arms race. • Due to increased rains a study of global warming and the increased flash floods needs to be done. Past studies will not be adequate if we are facing more storms and more runoff during the summer. 	Campaign 18, 31, 75, 339, 1128	Chapter 5

Table D.2-2—Summary of Scoping Comments (continued)

Topic 12. Kansas City Plant

Subtopic	Comment Summary	Documents	SPEIS Reference
KCP—General	The KCP should be relocated to Albuquerque to save travel between sites and facilities	574	Sections S.3.2.10, 1.5.2.1, and Chapters 1, 2
Objection to Exclusion of KCP	<p>Commentors object to the exclusion of KCP, as it blatantly seeks to prejudice and preempt the consideration of cost-effective complex consolidation options that would redistribute remaining KCP missions and capabilities to LANL and SNL where some 10% of KCP employees are already assigned. Commentors also state that the full cost of Complex Transformation is not being represented by the exclusion of KCP.</p> <p>Commentor also objects to the exclusion of an analysis of further non-nuclear consolidation and production modernization at the KCP as it seeks to prejudice the consideration of cost-effective complex consolidation options that would redistribute remaining KCP missions and capabilities to LANL and SNL.</p>	2, 4	Sections S.3.2.10, 1.5.2.1, and Chapters 1, 2
NEPA Analysis for KCP	Commentor questions where and what is the status of the separate NEPA analysis that the Complex Transformation NOI cites for KCP.	4	Sections S.3.2.10, 1.5.2.1, and Chapters 1, 2

Table D.2-2—Summary of Scoping Comments (continued)

Topic 13. Waste Isolation Pilot Plant

Subtopic	Comment Summary	Documents	SPEIS Reference
WIPP—General	Commentors submitted comments that were general in nature regarding WIPP. These included: <ul style="list-style-type: none"> • Commentors questioned what other WIPPs or extensions of WIPP are being considered for Complex Transformation. • Commentor suggested that WIPP or WIPP substitutes and TRU waste final disposition need to be considered and analyzed. • Not one site in the complex has been cleaned up because of WIPP. • Include an analysis on impacts of transportation of waste, not only to WIPP, but also to subsequent disposal facilities. 	4, 5, 1218	Sections 5.10, 5.11, 10.5.5
WIPP as a Candidate Site	Commentor requested an explanation as to why WIPP/Carlsbad was not considered as a site for Complex Transformation.	1218	Sections 3.1, 3.2, 3.3
Future of WIPP	Commentors questioned the plans for future waste disposal after WIPP is closed.	4, 5	Section 10.5.5
Support for WIPP as a Candidate Site	A commentor expressed support for Carlsbad because it has remote location to promote security, has the community support for nuclear weapons production, has two national labs, and has complete radiological monitoring capabilities.	1218	Sections 3.1, 3.2, 3.3, 10.5.5
Opposition to WIPP	Commentor expressed opposition to WIPP being redeveloped or maintained in NM or any other State. Another commentor expressed opposition to siting a Complex Transformation facility at WIPP/Carlsbad.	216, 1218	Sections 3.1, 3.2, 3.3, 10.5.5

Table D.2-2—Summary of Scoping Comments (continued)

Topic 14. Sabotage and Terrorism

Subtopic	Comment Summary	Documents	SPEIS Reference
Sabotage and Terrorism— General	<p>Commentor expressed concern about possible safety breaches at Y-12.</p> <p>Commentor stated that production of nuclear weapons and consolidation of storage of nuclear materials at one site would provide one target that is more susceptible to terrorist acts.</p>	<p>33, 71, 96, 104, 221, 286, 320, 374, 405, 450, 562, 525, 526, 723, 731, 845, 955, 1102, 1210, 1176, 1210, 1222, 1223</p>	<p>Section 1.1.2, Appendix H</p>
Evaluation of Sabotage and Terrorism	<p>Commentors generally expressed the opinion that Complex Transformation could be targets for sabotage and/or terrorism (intentional destructive acts).</p> <p>Commentors suggested that the SPEIS address safety issues and security risks if security is breached, calculate human error risks, and analyze the possibility of construction of an improvised nuclear device made from stolen or diverted plutonium or HEU.</p> <p>Several commentors expressed concern with risks associated with shipment of nuclear materials. Analyze terrorist attack associated with transportation of nuclear materials.</p> <p>Commentors requested that the SPEIS consider the additional security and emergency response capabilities that may be needed by the local governments immediately adjacent to facilities.</p>	<p>Campaign 7, Campaign 14, Campaign 19, 4, 5, 9, 31, 184, 191, 294, 329, 383, 405, 460, 516, 636, 725, 770, 861, 1083, 1188, 1187, 1209, 1213, 1217, 1218, 1219</p>	<p>Section 21.1.2, .3.5, Sections 5.x.12 for all sites, Appendix C, Appendix H</p>
Suggested Actions To Protect Against Sabotage and Terrorism	<p>Commentors expressed a concern over the possibility of sabotage and/or terrorism. Commentors provided suggested actions to protect against sabotage and/or terrorism. These included:</p> <ul style="list-style-type: none"> • Commentors expressed the need to consider possibility of accidental or intentional detonations of nuclear devices by accident or terrorist attack. • One commentor urged that tighter oversight and more token enforcement be applied at all levels of the mission. • Commentor requested an analysis of whether existing programs can be used to meet unanticipated events, instead of Complex Transformation. • Commentor suggested that a security assessment be done to provide input on the various ways the material will be made 	<p>4, 5, 9, 10, 322, 466, 568, 1044, 1213, 1216</p>	<p>Sections 1.1.2, 2.3.5, Chapter 2, Appendix C, Appendix H</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 14. Sabotage and Terrorism

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>vulnerable including storage, transportation, loading/unloading, packaging, processing, etc.</p> <ul style="list-style-type: none"> • Commentor suggested that an evaluation of the complex-wide safety and security problems be conducted and include plans to address these issues. • Commentor requested an explanation of the insecurity of current plutonium operations and the need for increased security. • Provide detailed analysis of expected increased safety that will occur. As a baseline, provide potential impacts of maintaining the current level of security and safety along with the impacts of upgrading current security. • Suggestion to perform an investigation into each police officer's background for terrorist activities or corruption; abuse of U.S. citizen, motorists and visitors; and the potential threat to U.S. security before storage of any nuclear material at one site. 		
LANL	<p>Some commentors had specific concerns on the risk at LANL. Some LANL facilities are relatively vulnerable to attack from the ground; most are vulnerable from the air. A commentor also stated that Complex Transformation threatens the LANL community with increased risk of warhead production.</p> <p>Another commentor stated that transportation of larger amounts of plutonium makes LANL a target for a terrorist attack.</p>	4, 6, 10, 320, 538	Sections 5.1.12, 5.2, Appendix H
Pantex	<p>Commentors had specific concerns on the risks at Pantex. Given the proximity of the airport to Pantex, constant air traffic, and addition of more dangerous operations, the consequences of a terrorist attack should be evaluated</p>	Campaign 20, 954, 1224	Appendix H
LLNL	<p>Commentors had specific concerns on the risks at LLNL. LLNL's plutonium should be moved only once and should not be used in new nukes. Moving plutonium twice is not safe or secure.</p>	4, 9	Section 3.7.2

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
Land Use			
Land use—General	<p>Commentor requested existing square footages and proposed square footages for all facilities (existing, proposed and proposed to be eliminated) and analyze environmental impacts at sites with increased activity due to consolidation of SNM at some sites.</p> <p>Another commentor suggested that cumulative impacts section include local renovation, expansion, and development information in the ROI. Commentor also suggested that all candidate sites complete a Land Use Management Plan EIS.</p>	4, 1225	Sections 3.4, 3.5, 3.6, 4.x.1 for all sites, 4.x.3 for all sites, 5.12
LANL	<p>Commentors provided specific comments on LANL land use. These included:</p> <ul style="list-style-type: none"> • Provide impacts of SNM on land use. • Provide impacts to pueblos and sites where facilities are to be developed. 	1217, 1219	Section 5.1.1
Pantex	<p>Commentors provided specific comments on Pantex land use. These included:</p> <ul style="list-style-type: none"> • Will the land area of Pantex need to be expanded? • Complete a full analysis of land use. 	330, 1212	Section 5.5.1
Visual Resources			
NTS	<p>Commentor requested that the SPEIS include an assessment of mitigation measures (use of existing facilities/infrastructure, "dark sky" measures, logical improvements and use of appropriate screening/structure colors) that can be included to abate cumulative visual impacts. Commentor also expressed concern on cumulative visual impacts to public land users' experiences.</p>	173	Section 5.3.1, 5.3.2
Site Infrastructure			
Site Infrastructure—General	<p>Commentor stated that specific information on supplier plans to meet expectations of increased demand on site infrastructure resources must be provided in detail.</p>	1225	Section 4.x.3 for all sites

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
LANL	Commentors provided specific comments on LANL site infrastructure. These included: <ul style="list-style-type: none"> • TA-55 remains without adequate continuous power supply. • Entire LANL site lacks a secure electrical power grid. • Concern that infrastructure and operation budget has been scaled back to account for future missions activities with subsequent inadequate reinvestment in HVAC and fire systems. • Concern that LANL still lacks ventilation and monitoring systems at PF-4 which will continue to function following serious accidents. LANL was still insisting on applying this same loose approach to its proposed new CMRR facility. • LANL does not have infrastructure to support Complex Transformation operations. 	6	Sections 4.1.3, 4.1.12
Pantex	Commentors provided specific comments on Pantex site infrastructure. These included: <ul style="list-style-type: none"> • Provide discussion of facilities that will be used and any modifications or new facilities that will be needed for the storage of SNM. • Provide water and utility needs be for the various combinations of current work. 	330	Sections 3.7.3, 5.5.3, 5.5.4, 5.12.3
SRS	Commentors stated that SRS has modern infrastructure with large-scale plutonium experience and national lab with core competency in plutonium R&D and is capable of handling operations dealing with Complex Transformation construction and operation.	922, 928, 929, 930, 931, 932, 933, 934, 935, 936, 912, 913, 915, 916, 918, 919, 920, 1212	Section 3.2.8
Y-12	Commentor stated that investment in the modernization of Y-12 must continue to ensure safe, secure working conditions.	1129	Section 3.3.1
Air Quality and Noise			
Air Quality and Noise— General	Commentors provided comments on air quality and noise that were general in nature. These included: <ul style="list-style-type: none"> • Incorporate plants and all other parts of the ecosystems that may be damaged by ozone. • NNSA must publish and make publicly available prior to the issuance of the Draft SPEIS a comprehensive list of "duplicative facilities." The Draft SPEIS must analyze the various alternatives for eliminating such duplicative facilities. 	525, 1225	Sections 3.8, 3.9, 3.11, 3.12 4.x.7 for all sites

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
LANL	<p>Commentors provided specific comments on LANL air quality and noise. These included:</p> <ul style="list-style-type: none"> • LANL must be required to reevaluate and broaden their air sampling programs. • Complex Transformation will increase dangerous air emissions. • Concern that no air quality studies, health studies or EJ studies have been performed downwind from LANL even though LANL has violated the CAA through its emissions. 	206, 536, 1128, 1218, 1221	Sections 4.1.4, 5.1.4,
Water Resources			
LANL	<p>Commentors provided specific comments on LANL water resources. These included:</p> <ul style="list-style-type: none"> • Expressed concern that chemicals and radionuclides have been found in plumes close to drinking water sources near Los Alamos and springs that feed the Rio Grande, which is a drinking water source and the largest source for irrigation water in NM. • Provide explanation on how NNSA proposes to remediate the aquifer under LANL. • Stated that data collected from groundwater wells at LANL is unreliable and that DOE is not in compliance with DOE Order 450.1 Environmental Protection Program, which requires LANL to have a groundwater surveillance monitoring program in place by December 31, 2005. • Expressed concern that proposed activities would increase water usage above the amount allotted to it from the regional aquifer. • Concern that groundwater contaminants from current operations have moved off-site and are contaminating the drinking water supply wells for Los Alamos County and the Buckman Wellfield, where over 40% of Santa Fe's drinking water supply is located. 	Campaign 12, 5, 48, 67, 96, 111, 206, 300, 320, 324, 536, 538, 507, 590, 684, 781, 1056, 1104, 1217, 1218, 1221, 1223	Sections 4.1.5, 5.1.5
LLNL	<p>Commentors provided specific comments on LLNL water resources. Commentor expressed concern about the serious problem of uranium in the water table. Another commentor questioned how many years before the water on the earthquake fault will be affected around LLNL.</p>	1219, 1220	Sections 4.2.4, 4.2.5, 4.2.6

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
NTS	Commentors provided specific comments on NTS water resources. These included: <ul style="list-style-type: none"> • Provide detail regarding the contamination of groundwater with physical data and show that the statement that "much of the radioactivity exclusive from tritium, remains captured in the original cavity, and thus not available to leach into the groundwater" is valid. • Concern that U-238 and tritium will be used in test shots because use of U-238 and tritium are not included in water permit. • Concern regarding DOE's ability to accurately characterize groundwater contamination and migration within the 300-square miles under NTS. 	215, 587, 1048, 1219	Section 4.3.5
TTR	Commentors provided specific comments on TTR water resources. These included: <ul style="list-style-type: none"> • Expressed that water is not an issue in the TTR area and that there is enough to support the complex. • There is commitment to protect the aquifer. 	534, 1212, 1213	Sections 4.4.4, 4.4.5
Pantex	Commentors provided specific comments on Pantex water resources. These included: <ul style="list-style-type: none"> • Concern about the project's impact on the water supply of the Ogallala Aquifer in reference to agriculture and potable water. • Concern about severe water shortage in Texas. • Concern about ecological effects to scarce water resources in the Great Basin. • Concern about impacts on water resources. • Stated that water impacts must be examined individually and cumulatively for each alternative. • Provide long-term ecological effects of leaving radioactive and chemical contaminants that may pollute water resources while other facilities are being built. 	153, 325, 388, 475, 700, 701, 757, 892, 893, 789, 1205, 1206, 1051, 1212, 1219, 1217, 1222, 1223, 1224	Sections 4.5.5, 4.5.7, 5.5.4, 5.5.7
SNL	Commentor questioned the anticipated impact on downstream cities when the aquifer is dried up.	1215	Section 4.6.5
WSMR	Commentor is concerned about the water supply contamination from WSMR activities.	1218	Section 4.7.5

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
SRS	<p>Commentors provided specific comments on SRS water resources. These included:</p> <ul style="list-style-type: none"> • Determine/ensure compliance of operations with current NPDES permit (i.e., Hg effluents). • Expressed concern on the Jasper-Beaufort Water District, which is measuring around 600pCi/L of tritium in the drinking water, which is a direct result of the current inventory and stockpiles of weapons-grade nuclear materials. • Concern about existing groundwater contamination as a result of tank residues. • Concern about cleanup/remediation of aquifer near SRS. • Concern about danger of further contamination of SC or GA water supply due to releases by SRS. 	405, 511, 572, 783, 1208, 1209	Sections 4.8.5, 10.5, 10.6.5
Water Resources			
Water Resources—General	Commentor stated that the groundwater around Rocky Flats is polluted, and needs to be cleaned up.	1217	Section 4.6.5
SRS	Commentor expressed concern about previous contamination of SRS and expressed a specific concern regarding the threat posed by tank residues to groundwater.	404	Section 5.8.5, 5.8.11
Geology and Soils			
Geology and Soils—General	Commentors expressed concern for the loss of fertile soils used for agriculture.	947	Sections 4.x.6 for all sites
LANL	<p>Commentors provided specific comments on LANL geology and soils. These included:</p> <ul style="list-style-type: none"> • Concern for the approximately 50,000 drums of TRU waste stored in tents at TA-54, one mile upwind from White Rock; an earthquake could cause drums to rupture and release approximately 1/4 of above-ground TA-54 radioactivity. • Seismic issues at LANL need to be adequately analyzed as most environmental assessments appear to be in significant error. 	6, 281, 947, 1177, 1217, 1218	Section 4.1.6, 4.1.6.3, 4.1.13, 5.1, 5.1.14, Chapter 7, Section 9.1
LLNL	Commentors expressed concern for the 7 million people that live in a 50-mile radius of LLNL where the main site is 200 feet from earthquake faults and Site 300 has a fault running through it.	9, 300, 320, 692	Sections 4.2, 5.2, 4.2.6.3

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
NTS	Commentors provided specific comments on NTS geology and soils. These included: <ul style="list-style-type: none"> • Need to determine the existing soil contamination data throughout NTS, surrounding areas, and areas downwind. • Soil analysis data should contain the inventory of radionuclides present at various depths to a depth of at the very least 20 cm. • Concern that the NTS area has experienced 620 earthquakes in the last 20 years with the largest a magnitude of 5.6. An earthquake with a magnitude of 7 is possible. Discuss how design of facilities can be built to prevent damage and radiological releases. NTS should not be considered for plutonium operations and SNM consolidation because of seismic activity. 	47, 215, 587, 1048, 1221	Sections 4.3, 4.3.6.2, 4.3.11, 5.3, 10.5, 10.6
SRS	Commentors expressed concern regarding location of SRS, which is located within proximity to a fault line responsible for the Charleston earthquake of 1868.	1208	Sections 4.8, 4.8.6
Y-12	Commentors stated that fractured limestone with caverns, fissures, sinkholes make recovery from project construction and operations impossible.		Sections 4.9, 5.9
Biological Resources			
Biological Resources—General	Commentors suggested that DOE consider the ecology and environment and characterize any changes to the Complex in order to take remedial action, if necessary. Commentors also expressed concern regarding explosive testing effects on T&E species.	459, 1225, 1189	Sections 4.x.7 for all sites, 5.x.7 for all sites
NTS	Commentor suggested that DOE explore whether various plants and animals within and near NTS have radionuclide concentrations.	1048, 215	Section 4.3.7
Cultural and Archaeological Resources			
Native American Resources	Commentors suggested that an assessment of the possible endangerment of the Native Americans and other indigenous people be considered. Numerous commentors were concerned about activities occurring on Native American lands or taking advantage of indigenous/aboriginal people and stated that Native Americans have been wiped out from nuclear material contamination.	104, 538, 1111, 1216, 1217	Sections 5.x.8 for all sites
Western Shoshone	Commentors stated that the SPEIS must include an explanation of how U.S. government and Shoshone Nation Agreement in the Treaty of Ruby Valley of 1872 can be ignored. The SPEIS must	9, 215, 763, 1048, 1223	Section 4.3.8

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
	also include how gradual encroachment (as the ICC alleged and was upheld by the Supreme Court) is a plausible reason for taking of Shoshone land when that is the ruling of only one Nation (the US). The IACHR and UNCERD decisions that the U.S. was unjust in the taking of land need to be considered.		
LANL	Commentors stated that the Jemez Mountain range is the ancestral homeland to the surrounding Sovereign Pueblo Nations and should be considered in the analysis of LANL.	538, 1056	Sections 4.x.8 for all sites, 5.x.8 for all sites
Socioeconomic Resources			
Socioeconomic Resources— General	<p>Commentors provided comments on socioeconomic resources that were general in nature. These included:</p> <ul style="list-style-type: none"> • Define the size of the workforce and the socioeconomic impacts to all proposed sites for the consolidated plutonium center, assembly/disassembly, hydrodynamic testing and sub-critical testing. • Create jobs and security through devising cleanup activities. • Consider the impacts to American exports abroad as a result of the use and development of nuclear weapons. • Consider whether the community is tied too closely to a dangerous and unstable industry and thus unable to attract other jobs, investments, and residents. • Concern that decision to support project are based on financial reasons (no other opportunity for local area employment) versus making decisions based on health. • Perform careful studies of the economies, populations, and tax structures of existing nuclear communities compared to similar but non-nuclear communities. • Concern that Complex Transformation would devastate real estate values and businesses. • Stated that New Mexico dependence on nuclear industry is not entirely true. • Provide an analysis of economic impacts to businesses from a nuclear incident. • Socioeconomic scope must be broader and include more factors relating to regional socioeconomic characteristics. • Perform assessment of socioeconomic impacts to local 	4, 327, 328, 376, 616, 747, 1125, 1208, 1209, 1210, 1217, 1218, 1224, 1125	Sections 4.2.9 for all sites, 5.x.9 for all sites

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>communities.</p> <ul style="list-style-type: none"> • Provide information on how many jobs will be lost from consolidation to one site. • Consider benefits from direct and indirect jobs, taxes and payments in lieu of taxes (PILT). • Consider whether too much of the land in the community would be taken up by the project and not be available for other economic uses and whether the jobs created would be relatively few and unstable jobs done for the most part by contractors. • Overall socioeconomic impact to local communities should be included as an evaluation criterion for deciding on a specific site. • Realistic estimates of increased/decreased workforce, identification of support industries and businesses that would be added/reduced, as well as indirect impacts to county infrastructure should be included. 		
LANL	<p>Commentors provided specific comments on LANL socioeconomic resources. These included:</p> <ul style="list-style-type: none"> • Stated that budgeted \$155 billion will benefit New Mexico with jobs and status and economic development. Benefit would be marginal. • Stated that for the past 20 years NM has received more net federal spending per capita, much military, yet social, environmental, and economic well-being have declined. Complex Transformation claims the budgeted 155 billion dollar project will benefit NM with jobs and status and economic development. How will it be different from past funding? • Concern about the Santa Fe tourism industry. 	10, 84, 146	Sections 5.1.9
NTS	<p>Commentors were concerned about how the employment profile would be affected since weapons assembly and disassembly would be a new activity at NTS and given the stated need to reduce the nuclear stockpile and update stockpile weapons. It should be assumed that the workforce for NTS would come from Nye County.</p>	1048, 1125, 215	Sections 4.3.9, 5.3.9

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
TTR	<p>Commentors provided specific comments on TTR socioeconomic resources. These included:</p> <ul style="list-style-type: none"> • Stated that the loss of 100-150 jobs will reduce resources and services in Tonopah and other Northern Nye and Esmeralda County communities. Commentor requests that the ROI take into account not only Tonopah but surrounding rural communities. • Expressed concern that closing TTR would significantly impact local community. Tonopah does not have the economic base to retain citizens within the community if jobs at TTR are lost. 50 percent of volunteers/organization members are County/State/TTR employees and 50 percent of the Tonopah Volunteer Fire Department is TTR employees. Mitigation measures should be presented for both adverse and beneficial impacts. • Consider that funds required to keep TTR operational are lower than facility upgrades at other sites. • Address impacts from continuation of operations at NTS and TTR using workforce primarily outside of Nye County; continuation and/or addition of operations using more workforce and resources from Nye County; and discontinuation or reduction of operations at NTS and TTR. 	724, 793, 858, 1125, 1197, 1196, 1213	Sections 4.4.9, 5.4.9, 5.15.4.2
SNL	<p>Commentor stated that for the past 20 years NM has received more net federal spending per capita, much military, yet social, environmental, and economic well-being have declined. Complex Transformation claims the budgeted 155 billion dollar project will benefit NM with jobs and status and economic development. How will it be different from past funding? Another commentor expressed concern about the tourism industry in Santa Fe.</p>	84, 146	Sections 5.6.9
Pantex	<p>Commentor stated that Pantex is a valuable economic asset for the region.</p>	1212	Sections 4.5.9, 5.5.9
SRS	<p>Commentors stated that SRS employees fill a variety of community service positions and that the CPC will employ over 2,500 people.</p>	923, 924, 1209	Sections 4.8.9, 5.8.9
Y-12	<p>Commentors supported the operations at Y-12 and stated that Y-12 has a tremendous economic impact on the region.</p>	463, 940, 941, 917, 918, 1198	Section 4.9.9, 5.9.9
Environmental Justice			

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
Environmental Justice— General	Commentors provided comments on environmental justice resources that were general in nature. These included: <ul style="list-style-type: none"> • Stated that the poorest communities bear most impacts. • Studies to ensure the poor/minority/disabled populations aren't suffering the brunt of emissions must be included. • Environmental justice analysis for transportation routes and disposal areas, private and public, needs to be included. • Provide an EJ analysis in case pueblos have to be abandoned for all options including LANL. • Include analysis of impacts to young children and women; health impacts related to exposure to radiation and other contaminants generated during the proposed activities (i.e., cancer fatalities, non-cancer effects, non-fatal instances of cancer, and psychological impacts); health impacts from the entire life cycle (including transportation); and health impacts from pathways used by indigenous people. 	Campaign 2, Campaign 8, 5, 76, 451, 536, 678, 715, 646, 653, 943, 1068, 1152, 1156, 1178, 1190, 1191, 1217	Sections 4.x.10 for all sites, 5.x.10 for all sites, 5.10
LANL	Commentors stated that operations at LANL are a major violation of environmental justice. New Mexico has the second highest minority population in the country and it is not possible that LANL activities would have no effect on these populations. Environmental justice issues in NM must be analyzed.	5, 260, 1056, 1221	Sections 4.1.10, 5.1.10
NTS	Commentors stated that the SPEIS should consider potential impacts on eastern Nevada, southern Nevada, western Utah, areas previously subject disproportionately to exposure to radiation from above and vented underground nuclear weapons tests.	302	Sections 4.3.9, 5.3.9
SNL	Commentors stated that DOE must analyze for the many environmental justice issues in NM.	5	Sections 4.6.9, 5.6.9
SRS	Commentor requested that an assessment of impacts from high levels of tritium in Savannah River to subsistence fishermen/women (i.e., especially those women who are pregnant and subsist on a diet primarily consisting of fish from the Savannah River) be included. Commentor also suggested that DOE consider adverse impacts to at-risk (minority or low-income) populations.	1209	Section 5.8.10
Health and Safety			

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
Health and Safety—General	<p>Several commentors provided comments on health and safety that were general in nature. These included:</p> <ul style="list-style-type: none"> • Concern about daily risks associated with operations. • Include the results of epidemiologic studies of radiation health of workers and communities, updating its Comprehensive Epidemiologic Resource program of the early 1990's. • Commentors expressed that the government should not consider the production of new nuclear weapons while we still are struggling to address past risks to the health of those living near or working in the weapons complex. • Suggested that cancer incidence published by the BEIR VII report for its cancer estimates since the report provides the most recent scientific assessment by the National Research Council. • Stated that nuclear weapons production poses a significant health hazard for workers and a human health risk assessment should be included in the SPEIS. • Requested that lethal dose of nuclear weapons in relation to human life be included. • Concern about increased incidence of cancer in surrounding communities due to increased exposure to radioactive materials from Complex Transformation. • Evaluate impacts to the worker, community, and environmental health from daily operations, emissions, and potential accidents associated with plutonium pit manufacturing. • Concern that the CPC would have similar or more detrimental effects on the environment and to surrounding communities than did Rocky Flats Plant. • Provide analysis of long-term environmental and public health effects of plutonium pit production. 	<p>Campaign 18, Campaign 20, 3, 4, 6, 31, 38, 39, 47, 96, 104, 111, 125, 129, 138, 145, 152, 153, 157, 190, 191, 203, 209, 210, 214, 268, 303, 324, 332, 337, 340, 344, 367, 386, 390, 395, 398, 405, 421, 422, 440, 460, 478, 504, 525, 541, 543, 557, 562, 564, 593, 571, 578, 594, 599, 611, 663, 668, 671, 673,</p> <p>674, 675, 678, 684, 698, 715, 719, 743, 747, 751, 767, 777, 781, 789, 811, 812, 872, 877, 954, 1083, 1101, 1102, 1104, 1126, 1128, 1135, 1152, 1156, 1183, 1202, 1208, 1209, 1210, 1212, 1217, 1218, 1219, 1215, 1222, 1223</p>	<p>Sections 5.x.11 for all sites, Chapter 6, Appendix C</p>
LANL	<p>Commentors provided specific comments on LANL health and safety. These included:</p> <ul style="list-style-type: none"> • Concern about health and safety issues at LANL. • Concern over elevated levels of americium in the northern foothills of Sangre de Cristo Mountains downwind from LANL. • Radioactive debris associated with uranium mining in NM 	<p>6, 209, 536, 538, 684, 777, 1216, 1218, 1221, 1223</p>	<p>Sections 4.1.7, 5.1, 5.1.11</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
	continues to be a significant source of sickness and premature death. <ul style="list-style-type: none"> • LANL has a poor history of providing adequate health and safety to workers and the community. • Concern about increased incidence of cancer in surrounding communities due to increased exposure to radioactive materials from increased operations at LANL. 		
LLNL	Commentor expressed concern about increased risk to public health as the population has grown significantly in the area surrounding the site. Commentor expressed concern about additional tritium activity.	27, 692	Sections 5.12, 5.13, 5.14
NTS	Commentors expressed concern for worker and the surrounding community's exposure to weapons assembly and disassembly activities and suggested that health implications for workers and the surrounding communities be addressed.	4, 215, 302, 587, 1048, 1213	Section 5.3.11
Pantex	Commentors requested that worker, community and environmental health impacts from daily CPC operations and emissions be evaluated and also to provide impacts to the Pantex region and nation if there were to be a nuclear detonation at Pantex. Commentors suggested that Pantex expansion needs to be conducted in a way that will not impair the health and safety of area residents or have adverse effects on the environment.	64, 184, 167, 330, 700, 884, 885, 1224	Section 5.5.11
SNL	Commentor requested that each facility be identified and a description of what levels will increase at each facility that will be involved in the new Complex Transformation and provide the risks to the public.	1217	Sections 5.13, 5.14, 5.16, 5.17
SRS	Commentor expressed concern that there is currently no monitoring of any radionuclide releases from SRS. Commentor suggested that a characterization study should be performed to account for the number of people who have been affected physically (health-wise) and who have died as a result of what is occurring at SRS.	1209	Sections 4.8.4, 4.8.5, 4.8.11
Transportation			
Transportation—General	Several commentors provided comments on transportation that were general in nature. These included: <ul style="list-style-type: none"> • Concern for the potential for release of materials during 	Campaign 14, 4, 104, 153, 329, 376, 383, 451, 546, 571, 606, 672, 674, 861, 725, 754, 1044,	Sections 1.5.4.1, 5.x.13 for all sites, 5.10

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
	<p>transportation accidents that would threaten the environment and human health/safety.</p> <ul style="list-style-type: none"> • Suggested that the transportation of plutonium should not occur until it is decided that it will not be moved again. • Consider transportation issues in/out of facilities and the need to bolster local security and emergency response capabilities. • Assess environmental and security risks associated with transportation of SNM as well as transport of nuclear bombs and bomb components. • Explain how ongoing transfers of SNM will not prejudice decisions yet to be made under the Complex Transformation SPEIS. 	1188, 1209, 1210, 1220	
LANL	<p>Commentors provided specific comments on LANL transportation. These included: Commentor suggested that quantities of hazardous materials shipped through the local airports be included.</p>	1225	Section 5.1.12
LLNL	<p>Impact analysis on traffic volumes and congestion of California highway system traffic analysis should be prepared.</p>	945	Section 5.212
NTS	<p>Commentors suggested considering the transportation of SNM and weapons into and out of NTS and its impacts to the surrounding region including Nevada highways and communities.</p> <p>Commentor suggested that the SPEIS assess cumulative impacts and risks to NV highways and communities from transportation of materials and wastes due to current NTS activities, the Yucca Mountain repository program, and Complex Transformation.</p> <p>Commentors suggested that rail transport of SNM at NTS offers security advantages over highway transport.</p>	4, 173, 215, 302, 546, 587, 1048, 1213	Sections 5.3.13, 5.10
TTR	<p>Commentor stated that transportation routes at TTR are well maintained due to the rural location, accidents are at a minimum.</p>	534	4.4.12
Pantex	<p>Given the proximity of the airport to Pantex, constant air traffic, and addition of more dangerous operations, the consequences of accidents should be evaluated.</p>	167, Campaign 20, 884, 954, 789, 1224	Section 5.10

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
SNL	Commentors provided specific comments on SNL transportation. These included: <ul style="list-style-type: none"> • Several questions regarding how materials will be transported, how much will be transported, who will be notified, and can safety be guaranteed. • Provide information on how the production of more nuclear weapons will affect the storage dump at KAFB. • Stated that use of Interstate 3 for transport of nuclear materials is not acceptable and questioned if DOE has been a party to the proposal to build Interstate 3. 	1210, 1217	Sections 5.8.12, 5.17
SRS	Commentor questioned whether there will be international traffic in nuclear materials through the Port of Savannah as part of Complex Transformation or other DOE programs.	1209	
Waste Management			

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
Waste Management— General	<p>Several commentors provided comments on waste management that were general in nature. These included:</p> <ul style="list-style-type: none"> • Concern about the storage location of the significant amount of waste generated from tritium production when the current storage sites remain radioactive and environmental threats. • SPEIS needs to include its current plans for disposing of radioactive waste and account for new research showing that synthetic zircons used to contain plutonium-rich materials are much less durable than previously thought. • Consider storing all waste on-site. • Clarify how plutonium storage, handling, production, destruction, or use is interchangeable in GNEP and Complex Transformation. • Include an analysis of the environmental and human health impacts and the costs of decommissioning, cleaning up, and waste disposal for all facilities which DOE proposes to construct, as well as existing facilities that will be demolished as a result of the proposal and how this is "economically sustainable." • Storage at Yucca Mountain needs to be addressed. • What are some of the specific factors related to disposal of hazardous wastes on- and off-site (volumes, types, how, where, impacts)? • A plan for long-term storage and mobilization should be developed. 	<p>Campaign 12, Campaign 20, 4, 5, 103, 104, 111, 153, 303, 376, 401, 428, 433, 450, 516, 525, 544, 552, 553, 578, 562, 570, 674, 684, 712, 735, 741, 789, 954, 1208, 1209, 1210, 1211, 1218, 1217, 1218, 1220, 1222, 1223, 1224,</p>	<p>Section 5.x.14 for all sites, 6.3.2</p>
LANL	<p>Commentors provided specific comments on LANL waste management. These included:</p> <ul style="list-style-type: none"> • Resuming pit production will significantly contribute to existing risks associated with waste management (generation, disposal, and storage). • Concern for use of 'transportainers' as temporary vaults of fissile material at TA-55. • Comment on impacts from improper waste storage at LANL, including what would happen in event of a large fire or weather event. 	<p>Campaign 12, 5, 6, 67, 111, 260, 300, 324, 769, 781, 947, 1218, 1221, 1223</p>	<p>Sections 5.1.14</p>

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
	<ul style="list-style-type: none"> • Explain the effects caused by rejected pits to the waste stream. • The SPEIS must analyze for the impacts of LANL becoming the second transuranic waste disposal facility in NM. • Address how NNSA proposes to deal with the huge nuclear waste dump on the Pajarito Plateau. • Explain how NNSA intends to deal with the 12,500 drums of nuclear waste at Area G buried before 1971 that are currently contaminating the aquifer under LANL. • LANL has inadequate waste storage practices with waste stored in temporary areas i.e., tents in fire-prone areas. 		
LLNL	<p>Commentors expressed concern that the LLNL site has been environmentally contaminated for years and cleanup is far from over.</p>	692, 1222	Section 5.2.14
NTS	<p>Commentors questioned if the radioactive material from weapons assembly and disassembly would be disposed of or stored at NTS.</p> <p>Commentors suggested that the nature of management of SNM be described (where and how, what volume, and the radioactive inventories that could be anticipated) be incorporated into the document, and for the document to also evaluate to what extent NTS would be a consolidation site.</p> <p>Commentors also suggested that disposal of material associated with sub-critical testing be addressed.</p>	4, 215, 302, 587, 1048	Section 5.3.14
Pantex	<p>Commentors requested a discussion of emissions and waste streams generated; facilities needed; disposal options; and waste processing or storage at Pantex.</p> <p>Commentors also expressed concern about safety with regards to waste management at Pantex.</p> <p>Commentors stated that the proposed expanded operations would generate 25,000 cubic meters of TRU and WIPP only has space for 17,130 cubic meters, the excess would have to be left on-site, either in Area G or in the canyons that flow into the Rio Grande.</p>	388, 330, 789, 1217, 1224	Sections 5.5.14, 10.5.5

Table D.2-2—Summary of Scoping Comments (continued)

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
SNL	<p>Commentor expressed concern on the ability of the current Hazardous Waste Management Facility at SNL to handle the increased quantities of RCRA hazardous waste (up from ~53K kilos) and infrastructure related wastes (~175K kilos/yr) and questioned how the facilities will be decontaminated.</p> <p>Another commentor expressed concern for mixed waste dumps found on land planned for housing projects.</p>	1216, 1217	Section 5.17
SRS	<p>Commentors requested that DOE assess incremental impact of managing TRU, LLW, and HLW due to the siting of the project at SRS.</p> <p>Another commentor requested that the need for plutonium storage facilities apart from the current KAMS facility must be examined from an environmental, security, and cost perspective</p>	572, 1188, 1209	Section 5.8.14
Y-12	<p>Commentor suggested considering the disposition of the radioactive materials and how they will be staged, stored, or used in manufacturing at Y-12.</p>	463, 1147, 1210	Section 5.9.14
Facility Accidents			
	<p>Commentors provided comments regarding the analysis of facility accidents that were general in nature. Commentors were generally concerned about the danger of facility accidents. Other commentors suggested:</p> <ul style="list-style-type: none"> • Including the basis for its estimates of the probabilities of accidents so that the public can comment upon the reasonableness of the estimates. • Including information on the ability of the nuclear weapons complex to respond to a problem with a deployed warhead. • For severe accident consequences (i.e., large fires involving plutonium or facility-wide plutonium spill) a part of the risk analysis between alternatives should be a comparison of the consequences, given that the event occurs. • Providing a reasonable scenario of an unanticipated event. • The SPEIS should include an estimate of the consequences to the present national nuclear posture in the case that a severe event (i.e., facility wide plutonium spill) would occur, and an 	3, 4, 138, 562, 770, 1218, 1209	Sections 5.x.12 for all sites, Appendix C, Appendix H

Topic 15. Resources

Subtopic	Comment Summary	Documents	SPEIS Reference
	evaluation of whether the entire site would have to be abandoned or closed, or whether parts of operation could be continued in some locations, etc.		
LANL	Commentors provided specific comments on facility accidents at LANL and their concern regarding the occurrence of facility accidents at LANL. Some commentors suggested: <ul style="list-style-type: none"> • Provide a description of consequences of major spills at LANL or major fires in terms of cancer deaths. • Extending accident analysis radius to include impacts on Albuquerque for all alternatives including LANL. • Providing a detailed analysis of the consequences of severe plutonium releases on the Rio Grande, on the economy and society of nearby communities, of NM, and of states near NM for all alternatives including LANL. • Including an estimate of consequences to economy and society of NM in case of severe event for all alternatives including LANL. 	3, 781, 1223	Sections 5.1.5, 5.1.9, 5.1.10, 5.1.11, 5.1.12, Appendix C

Table D.2-2—Summary of Scoping Comments (continued)

Topic 16. General

Subtopic	Comment Summary	Documents	Response/SPEIS Reference
General Support for Complex Transformation	Commentors provided statements in support of the Complex Transformation proposal.	6, 73, 576, 580, 1209, 1218, 166, 171, 331, 305, 310, 311, 366, 416, 539, 545, 568, 576, 580, 759, 794, 775, 784, 960, 1208, 1209, 1218, 1222	Comment noted.
Support for the No Action Alternative	Commentor supports the No Action Alternative	1220	Comment noted.
Support for CNPC	Commentors provided statements in support of a CNPC as it would offer advantages in environmental impact, security, cost, shipping, waste management, and technical support.	73, 535, 539, 941	Comment noted.
Support for the Capability-Based and Reduced Operations Alternative	Commentors provided statements in support of the Capability-based and Reduced Operations alternative as it has significant advantages over DCE and CNPC alternatives, including no new facility construction, no increase in Pu production, reduction in # of sites with Category I/II SNM, reductions in production capacity at certain sites, and continued D&D.	460, 322	Comment noted.
Support for Siting at LANL	Commentors provided statement in support of siting at LANL because pit production would provide legitimacy for LANL.	6, 49	Comment noted.
Support for Siting at LLNL	Commentors provided statement in support of siting at LLNL because LLNL has the best combination of scientific capabilities and scientific staff in the United States and it has a long, thoroughly demonstrated track record of accomplishments that are second to none.	201, 1221, 1222	Comment noted.
Support for Siting at NTS	Commentor provided statements in support of consolidating SNM to fewer locations, nuclear storage, HE R&D, and hydrotesting at NTS.	44, 534, 576, 1213	Comment noted.
Support for Siting at Pantex	Commentor provided statements in support of keeping site plutonium functions where storage and handling capability already exists.	64, 202, 282, 493, 506, 884, 885, 1067, 1201, 1202, 1203, 1204, 1212, 1218	Comment noted.
Support for Siting at SRS	Commentor provided statements in support of siting at SRS. Nearly 90 percent of the land at SRS is open and free of the encroachment issues compared to other DOE sites and SRS has the established	36, 73, 199, 288, 290, 299, 304, 331, 364, 365, 366, 419, 420, 459, 523, 522, 523, 632, 657, 730, 755, 792, 912, 913, 914, 915, 916, 917, 918,	Comment noted.

Table D.2-2—Summary of Scoping Comments (continued)

Topic 16. General

Subtopic	Comment Summary	Documents	Response/SPEIS Reference
	infrastructure to support operations of Complex Transformation.	919, 920, 921, 922, 923, 924, 926, 927, 928, 929, 930, 931, 932, 933, 934, 936, 948, 958, 959, 960, 961, 1055, 1208, 1209	
Support for Siting at Y-12	Commentors provided statements in support of siting Complex Transformation at Y-12 because Y-12 is acknowledged as America’s center of uranium excellence.	Campaign 11, Campaign 13, 46, 90, 98, 199, 205, 206, 222, 223, 226, 261, 298, 416, 417, 518, 520, 521, 532, 547, 580, 628, 630, 640, 661, 706, 707, 709, 711, 713, 714, 733, 736, 739, 742, 759, 773, 775, 784, 788, 795, 856, 871, 873, 874, 875, 880, 881, 956, 786, 788, 969, 956, 1088, 1122, 1147, 1170, 1198, 1211	Comment noted.
Opposition to Complex Transformation	Commentors provided general statements in opposition to the Complex Transformation proposal.		Comment noted.
Campaign 3, Campaign 4, Campaign 6, Campaign 7 Campaign 8, Campaign 10, Campaign 15, Campaign 16, 1, 10, 11, 12, 13, 17, 21, 22, 23, 25, 50, 51, 52, 54, 55, 56, 57, 58, 59, 60, 61, 62, 67, 80, 94, 95, 157, 158, 159,160,161,162, 165, 168, 170, 172, 174,175,176, 177, 178,180, 179, 181, 182, 183, 185, 186, 187, 189, 190, 192, 193, 194, 195, 196, 197, 199, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 262, 278, 279, 280, 281 330, 536, 1048, 104, 63, 65, 66, 68, 74, 72, 69, 71, 75, 76, 216, 219, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 283, 284, 285, 286, 287, 291, 292, 332, 334, 335, 336, 337, 338, 340, 341, 346, 347, 349, 351, 352, 353, 354, 355, 356, 357, 359, 361, 368, 387, 390, 391, 392, 394, 395, 397, 400, 401, 402, 403, 406, 407, 409, 410, 411, 412, 413, 414, 421, 422, 427, 428, 430, 429, 431, 432, 433, 436, 437 , 440, 441, 442, 443, 445, 541, 542, 543, 544, 549, 550, 551, 553, 554, 555, 546, 140, 141, 142, 143, 144, 145, 293, 297, 300, 301, 306, 307, 308, 309, 312, 313, 315, 316, 317, 318, 319, 321, 323, 370, 371, 372, 373, 374, 375, 378, 379, 380, 381, 382, 383, 384, 446, 447, 448, 449, 450, 452, 453, 454, 455, 456, 457, 461, 462, , 1082467, 468, 469, 470, 471, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 492, 495, 496, 497, 498, 499, 500, 501, 502, 504, 585, 588, 589, 591, 592, 593, 572, 575, 577, 578, 579, 581, 582, 583, 584, 556, 557, 559, 560, 561, 562, 564, 565, 567, 569, 570, 594, 111, 113, 114 115, 116, 117, 118, 120, 596, 597, 598, 595, 598, 599. 600, 662, 664, 665, 666, 667, 668, 669, 670, 672, 673, 674, 675, 676, 846, 847, 848, 849, 850, 851, 852, 853, 855, 857, 860, 854, 677, 678, 679, 680, 681, 682, 683, 686, 687, 688, 689, 690, 691, 726, 725, 727, 729, 732, 734, 148, 149, 151, 152, 154, 153, 125, 129, 130, 137, 138, 139, 146, 147, 723, 738, 740, 743, 744, 746, 747, 748, 751, 752, 753, 754, 756, 758, 524, 525, 526, 527, 528, 529, 533, 535, 540, 508, 509, 510, 514, 515, 601, 602, 603, 604, 605, 606, 608, 609, 610, 611, 612, 613, 614, 615, 617, 618, 619, 620, 621, 622, 623, 625, 626, 629, 631, 633, 635, 636, 637, 638, 639, 642, 644, 645, 646, 647, 649, 651, 653, 656, 658, 659, 660, 876, 878, 888, 889, 891, 892, 893, 894, 906, 907, 897, 898, 899, 900, 901, 902, 903, 904, 905, 760, 762, 764, 765, 766, 767, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 966, 970, 971, 972, 975, 976, 977, 978, 979, 980, 951, 953, 955, 957, 963, 964, 1077, 1078, 1079, 1080, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 1081, 1085, 1086, 1090, 1091, 1093, 1096, 1097, 1098, 785, 787, 790, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 1105, 1106, 1107, 1109, 1110, 1112, 1113, 1114, 1115, 1116, 1117, 1119, 1120, 770, 771, 772, 777, 781, 782, 783, 1123, 1126, 1130, 1131, 1133, 1134, 1136, 1137, 1138, 1139, 1140, 1141, 1145, 1148, 1149, 1150, 1151, 1153, 1154, 1151, 1157, 1158, 1159, 1160, 1161, 1163, 1164, 1165, 1166, 1205, 1210, 1219, 937, 943, 944, 945, 947, 949, 950, 906,908, 909, 910, 911, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000, 1001, 1002, 1003, 1004, 1005, 1006, 1007, 1008, 1009, 1010, 1011, 1012, 1013, 1014, 1015, 1016, 1017, 1018, 1019, 1020, 1021, 1022, 1023, 1024, 1025, 1026, 1027, 1028, 1029, 1030, 1031, 1032, 1033, 1034, 1035, 1036, 1037, 1041, 1041, 1043, 1045, 1046, 1047, 1049, 1050, 1052, 1053, 1054, 1056, 1057, 1059, 1060, 1061, 1064, 1065, 1068, 1069, 1070, 1071, 1167, 1168, 1169, 1171, 1172, 1173, 1175, 1176, 117, 1178, 1180, 1181, 1182, 1184, 1186, 1189, 1191, 1192, 1194, 1199 1212, 1211, 1213, 1224, 1217, 1220, 1219, 1215, 1221, 1216, 1222, 1223

ADDITIONAL PROJECT DETAILS

This appendix includes additional project details specific to project sites discussed in Chapter 4 of the Complex Transformation Supplemental Programmatic Environmental Impact Statement (SPEIS).

WATER CONTAMINATION ISSUES IN THE RIO GRANDE, FROM THE COLORADO BORDER TO THE MIDDLE-RIO GRANDE

SUMMARY

Public meetings held by the U.S. Department of Energy (DOE), National Nuclear Security Administration in 2006 identified public concerns regarding contamination of the Rio Grande. The Rio Grande has been a source for drinking water supply since the earliest settlements. Land practices in the upper and middle Rio Grande basins have contributed to contamination of soils, surface water and groundwater resources. Contaminant pathways into the Rio Grande and onto public lands are poorly understood and continue to be a focus of ongoing research. While contamination from DOE activities in the upper and middle Rio Grande basins has occurred, it has not caused exceedances of regulatory standards off DOE property.

Since the 1920s, the Federal government has intervened in the management of flows to assist in delivery of water to communities for drinking water supply, irrigation, industrial and agricultural uses. Communities in New Mexico traditionally utilize groundwater resources as community potable water sources. However, drought conditions and over-mining groundwater resources has prompted many to seek surface water resources to replace or augment their community drinking water source. The Rio Grande is the fifth largest river in North America. Its flows are sustained by surface water runoff and San Juan-Chama Project water. The San Juan-Chama Project, initiated in 1962 and managed by the U.S. Bureau of Reclamation, transfers water from the San Juan River basin in southern central Colorado to the Rio Grande basin in northern central New Mexico through a system of diversion structures and tunnels. Recent changes to San Juan-Chama Project agreements has enabled communities the opportunity to directly access San Juan-Chama water from the Rio Grande. Although several communities have expressed an interest in developing direct access to the San Juan-Chama water, three diversion projects are in various stages of development.

E.1 INTRODUCTION

In 2006, the U.S. Department of Energy (DOE), National Nuclear Security Administration (NNSA) undertook an effort to analyze the environmental impacts of the continued transformation of the United States' nuclear weapons complex by implementing the NNSA's vision of the complex as it would exist in the future, otherwise known as Complex 2030 (71 FR 61731). Scoping meetings held for the Complex Transformation project in 2006 identified several areas of concern in New Mexico, one of them being concern over water issues. In this paper, water issues in northern New Mexico are examined based upon existing research conducted by various agencies and groups. No new studies were completed for this analysis.

This paper focuses upon the Rio Grande and its major tributaries in northern New Mexico, from the Colorado border to Albuquerque, in central New Mexico (Figure E.1-1). The Rio Grande is the fifth largest river in North America. It flows 1,885 miles from southern Colorado to extreme southern Texas, where the river empties into the Gulf of Mexico (USDA 1998). The discharge area of the Rio Grande in New Mexico is estimated at 27,760 square miles, with direct tributary drainage area of 24,760 square miles (USDA 1998). Rio Grande headwater elevations range from 8,000 to 12,000 feet and flatten to between 5,225 to 4,450 feet in the middle Rio Grande Valley, near Albuquerque (USDA 1998). For the purposes of this discussion, the tributaries in the upper and middle Rio Grande basins are Red River, Rio Hondo, Rio Pueblo de Taos, Rio Chama, Santa Fe River, Jemez River, and the Santa Fe River. Predominant communities along these tributaries are the Town of Taos, Cities of Española, Los Alamos, Santa Fe and Albuquerque, Pueblo of Taos, Ohkay Owingeh Pueblo (formerly San Juan Pueblo), Pojoaque Pueblo, Tesuque Pueblo, San Ildefonso Pueblo, Picuris Pueblo, Cochiti Pueblo, Santa Ana Pueblo, and Sandia Pueblo.

E.2 HISTORY OF ACTIVITIES

The Rio Grande has been a source of water for generations. At the time of first European contact, there were more than 50,000 Pueblos living in over 100 villages in the middle and upper basins of the Rio Grande (USDA 1998). Irrigation ditch agriculture was limited at this time, but intensified as larger populations settled the areas. Acequia systems took root as conveyors for drinking water, bathing, washing clothes, irrigation, and watering livestock (USDA 1998). As irrigation intensified, river flow in the Rio Grande was severely reduced or even halted. Reduced flows in the Rio Grande have been recorded since 1925.

In 1923, Federal legislation established conservancy districts to address surface water issues. These conservancies were tasked with regulating stream flow, developing or reclaiming sources of water, and generating electrical energy. In 1928, a plan to develop various water control measures was announced, which called for the construction of dams and diversions along the Rio Grande. From 1930 to 1934, six diversion dams, the El Vado dam and storage reservoir on the Chama River, 250 miles of main irrigation canals, 350 miles of drainage canals, and 190 miles of levees was completed (USDA 1998). Between 1935 and 1975, the Middle Rio Grande Conservancy District, the U.S. Army Corps of Engineers (ACOE) and the U.S. Bureau of Reclamation (BOR) constructed and presently manages six major dams on the upper and middle Rio Grande drainages to control floods, store water, and catch sediment (Table E.2-1).

Table E.2-1—Upper and Middle Rio Grande Dams and Reservoirs

Name	Stream	Year Completed
Flood Control- Water Storage		
El Vado	Chama	1936
Jemez Canyon	Jemez	1953
Abiquiu	Chama	1963
Heron	Willow	1963
Galisteo	Galisteo	1970

The San Juan-Chama project was initiated in 1962 (BOR 2006). The San Juan-Chama Project diverts water from the upper tributaries of the San Juan River, through the Continental Divide, and into the Rio Grande Basin. It consists of a two storage dams, two reservoirs, three diversion dams, six carriage facilities, five tunnels and the Azotea Creek and Willow Creek Conveyance Channels for transmountain movement of water, originating in Archuleta County in southern central Colorado and Rio Arriba County in northern central New Mexico (BOR 2006). The San Juan-Chama Project provides an average annual diversion of about 110,000 acre-feet of water (BOR 2006). The primary purposes of the San Juan-Chama Project are to furnish a water supply to the upper and middle Rio Grande valley for municipal, domestic, and industrial uses. The San Juan-Chama Project is also authorized to provide supplemental irrigation water and incidental recreation and fish and wildlife benefits. The BOR is the agency responsible for the San Juan-Chama Project.

E.3 LOS ALAMOS NATIONAL LABORATORY

Los Alamos National Laboratory (LANL) was established in 1943 with the mission to research and develop the world’s first atomic bomb. The mission of LANL has continued to evolve as our Nation’s needs change. Improvements in laboratory practices and establishment of environmental regulations fostered stewardship of the environment. LANL sits atop Pajarito Plateau in north central New Mexico, approximately 40 miles northwest of Santa Fe. The Pajarito Plateau consists of a series of east-west oriented mesas separated by deep canyons with perennial and intermittent streams. LANL is bounded on the west by the Jemez Mountains and on the east by the Rio Grande.

From 1943 to the present, operations at LANL have generated, treated, stored and disposed of solid wastes, hazardous wastes, and hazardous wastes mixed with radioactive wastes. Solid, hazardous, and radioactive waters were disposed of in numerous septic systems, surface impoundments, pits, trenches, shafts, landfills, waste piles, and other sites located throughout LANL. The types of hazardous and solid wastes that have been handled and disposed of include chlorinated and non-chlorinated solvents, high explosives, metals, polychlorinated biphenyls (PCBs), nitrates, and radionuclides (NMED 2005a). Over the last 50+ years, the wastes from LANL began to migrate down the complicated mesa-and-canyon geography, toward the Rio

Grande (Buske 2003). Past LANL activities have resulted in contamination of sediments both onsite and downstream, primarily transported by effluent discharges from LANL outfalls and stormwater runoff (LANL 2008). Figure E.3-1 shows the major liquid release sources at LANL. Current LANL operations are stringently controlled to minimize the amount of contamination introduced into the local canyons. LANL has 21 outfalls currently permitted which discharge into six local canyons. Five canyon that previously received LANL discharges are no longer receiving nay industrial effluent L Pueblo, Cañada del Buey, Guaje, Chaquehui, and Ancho Canyons. Total effluent discharges from LANL decreased by about 50 percent over the past five years (LANL 2008).

Source: LANL 2008.

Figure E.3-1—Major Liquid Release Sources at LANL

The Cerro Grande Wildfire in 2000 revealed how dramatically changing conditions can suddenly flush contaminants from LANL towards the Rio Grande. Springs on the flanks of the Sierra de los Valles supply base flow into upper reaches of some of the canyons (Guaje, Los Alamos, Pajarito, Cañon del Valle, and Water Canyons), but the amount is insufficient to maintain surface flow across the plateau before it is depleted by evaporation, transpiration, and infiltration. Runoff from heavy thunderstorms or heavy snowmelt reaches the Rio Grande several times a year in some drainages (Purtymun 1995). Spring discharge in lower Pajarito and Ancho Canyons is of sufficient volume to support perennial flow into White Rock Canyon and the Rio Grande (Purtymun 1995). Table E.3-1 shows the surface water and sediment contamination

attributable to LANL operations (LANL 2008). Other possible sources of surface water impacts are isolated spills, former photographic processing facilities, highway runoff, and residual Cerro Grande Fire ash (LANL 2008).

Table E.3-1—Surface Water and Sediment Contamination Attributed to LANL Operations

Contaminant	Onsite	Offsite	Significance	Trends
Radionuclides in sediments	Higher than background in sediments because of LANL contributions in Pueblo, DP, Los Alamos, Pajarito and Mortandad Canyons	Yes, in Los Alamos, Acid, and Pueblo Canyons; and slightly elevated in the Rio Grande and Cochiti Reservoir.	Sediments below health concern, except onsite along a short distance of Mortandad Canyon; exposure potential is limited.	Increased transport of contaminated sediments in Pueblo Canyon in response to post-fire flooding and increased urbanization.
Radionuclides in surface water	Higher than background in runoff in Pueblo, DP, Los Alamos, and Mortandad Canyons.	Yes, in Los Alamos and Pueblo Canyons.	Minimal exposure potential because storm events are sporadic. Mortandad Canyon surface water is 60 percent of Derived Concentration Guide.	Flows in Pueblo Canyon occurring more often after the Cerro Grande Fire. Flows in other LANL canyons recovered to near pre-fire levels.
Polychlorinated biphenyls in sediments	Detected in sediment in nearly every canyon.	Yes, particularly in Los Alamos and Pueblo Canyons.	Wildlife exposure potential in Sandia Canyon. Elsewhere, findings included LANL and non-LANL sources.	None
Polychlorinated biphenyls in surface water	Detected in Sandia Canyon runoff and base flow above New Mexico Water Quality Standards.	No.	Wildlife exposure potential in Sandia Canyon. Elsewhere, findings included LANL and non-LANL sources.	None
Dissolve copper in surface water	Detected in many canyons above New Mexico acute aquatics life standards.	Yes, in Los Alamos Canyon.	Origins uncertain; probably multiple sources.	None
High explosive residues and Barium in surface water	Detections near or above screening values in Cañon de Valle base flow and runoff.	No.	Minimal potential for exposure,	None
Benzo(a)pyrene	Detections near or above industrial screening levels in Los Alamos Canyon.	Yes, in Los Alamos and Acid Canyons.	Origins uncertain; probably multiple sources.	None

Source: LANL 2008.

Three zones of groundwater occur on the Pajarito Plateau: (1) perched alluvial groundwater in canyon bottoms, (2) zones of intermediate depth perched groundwater whose location is controlled by availability of recharge and by subsurface changes in permeability; and (3) the regional aquifer beneath Pajarito Plateau (LANL 2008). Alluvial water is groundwater that occurs in canyon-floor sediments. Perched intermediate groundwater is water that has moved downward from the surface and becomes trapped above tight geologic formations, such as basalts and clay-rich rocks. The regional groundwater is the deep reliable source of drinking water for residents of Los Alamos, Española, Santa Fe and neighboring Pueblos. The regional

aquifer discharges to springs along the Rio Grande. The knowledge base of recharge, discharge, and how waterborne contaminants interact with and move through geology into perched water zone and the regional aquifer below LANL is growing. Models are being improved based upon updated data for groundwater and surface water from LANL and NMED (LANL 2008).

Perched water bodies are important elements of the hydrogeology of LANL for several reasons. There is a probability that the zones can intercept contaminants that are being transported downward through the vadose zone. The perched water can be a permanent or long-term residence for contaminants because the chemical makeup of the geology may result in adsorption. Perched water can also serve as a place where dilution occurs lowering the concentration of contaminants. There is a possibility that perched zones may be intersected by streams in the lower parts of the canyons, resulting in lateral flow under the influence of gravity out of the canyon walls into the aquifer, and subsequently the Rio Grande (LANL 2008). Little contamination reaches the deep regional aquifer because it is separated from the perched groundwater by hundreds of feet of dry rock (LANL 2008). Results of groundwater monitoring show the presence of LANL-produced contamination, above water quality standards, in the alluvial groundwater and in some perched intermediate groundwater in Mortandad, Los Alamos, Cañon del Valle DP and possibly Pueblo Canyons (LANL 2006). Groundwater in Mortandad Canyon area is contaminated with tritium, perchlorate, chloride, and nitrate at levels below drinking water standards (NMED 2005b).

A separate study, conducted by George Rice for Concerned Citizens for Nuclear Safety (CCNS), found that contamination from LANL is likely to reach the Rio Grande (Rice 2004). Citing data from NMED and LANL, Rice models groundwater transport from LANL to the Rio Grande. He concluded that although the travel time of contaminants varies, it is possible for contaminants from LANL to reach the Rio Grande in 61 years or less (Rice 2004).

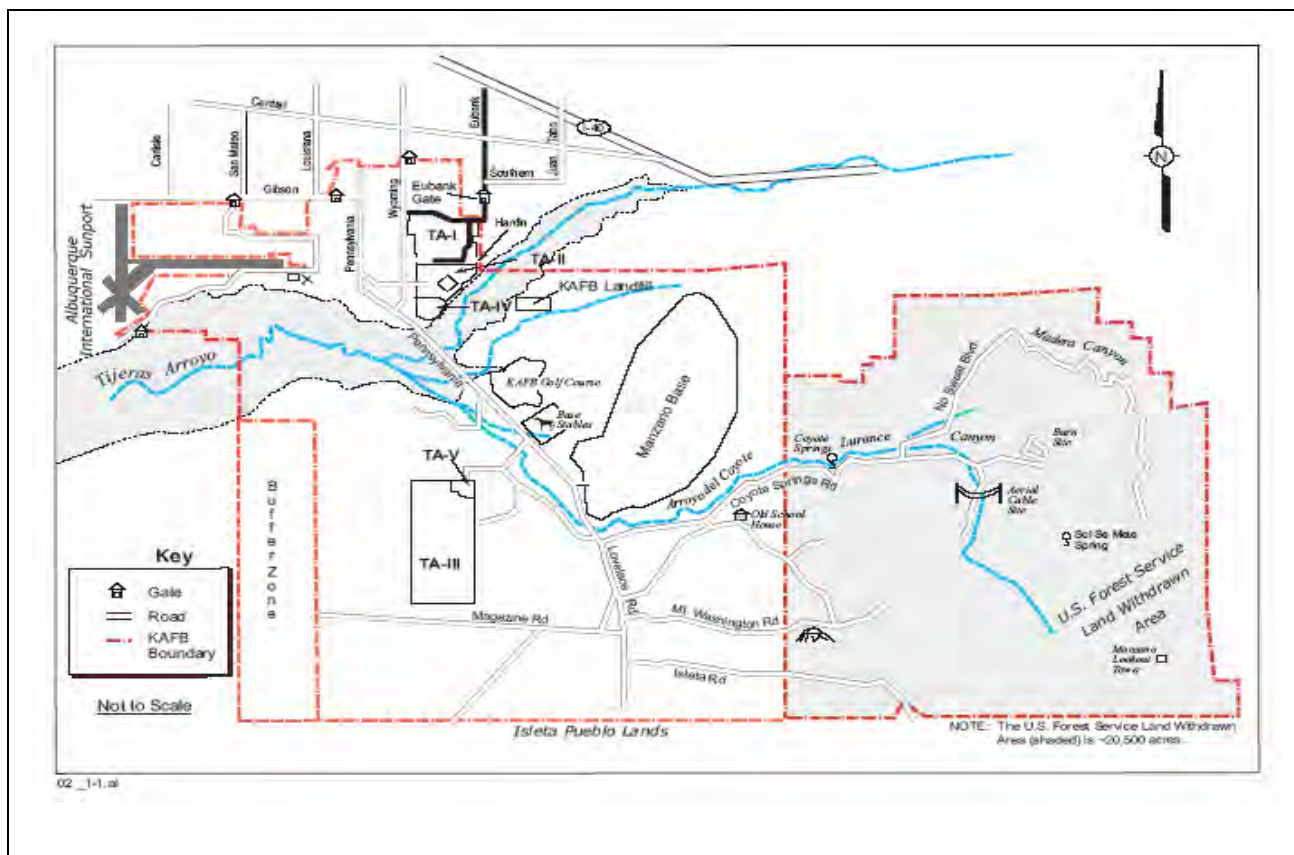

Further groundwater studies conducted jointly by The RadioActivitst Campaign (TRAC) and the CCNS indicated that radioactive waste has migrated from LANL via groundwater pathways to springs seeping into the Rio Grande, albeit at levels far too low to be considered a public health concern (Buske 2003). Low levels of radioactive cesium-137 (Cs-137) from LANL have been detected in groundwater seeping into Pajarito Stream, which flows into the Rio Grande (Buske 2003). This is the first report of radioactivity entering the Rio Grande directly connected with LANL activities. Additional analysis is necessary to adequately characterize and identify the pathway and extent of contamination.

E.4 SANDIA NATIONAL LABORATORY

Sandia National Laboratory (SNL) is located on Kirtland Air Force Base (KAFB) in Albuquerque, New Mexico, along the eastern portion of the Sandia Mountains in the southeast quadrant of the city. SNL began in 1945 as a part of the Manhattan Project, which produced the world's first nuclear weapon (SNL/NM 2006). SNL's enduring mission is to provide science and engineering support for the nuclear weapons stockpile (SNL/NM 2006).

SNL is situated at the base of the Sandia Mountains. The Sandia Mountains form a 13-mile long escarpment distinguished by steep cliffs, pinnacles, and narrow canyons. Tijeras Canyon divides

the Sandia Mountains to the north from the Manzanita Mountains to the south. Sediments transported from the canyons and draws of these mountains have formed coalescing alluvial fans, called bajadas. These bajadas slope west across KAFB and are dissected by the Tijeras Arroyo, smaller arroyos and washes. Tijeras Arroyo traverses across SNL in a southwestern direction, and discharges to the Rio Grande approximately 8 miles west of the KAFB boundary (Figure E.4-1). The major surface drainages at SNL are Tijeras Arroyo and Arroyo del Coyote. With the exception of two short sections of channel with intermittent flow (spring fed), these drainages flow only during storm events. Tijeras Arroyo is the only substantial outlet for surface water exiting KAFB. Arroyo del Coyote joins Tijeras Arroyo approximately 2 miles up stream where Tijeras Arroyo leaves KAFB, northwest of the KAFB Golf Course.

Source: SNL/NM 2006.

Figure E.4-1—Map of SNL

E.4.1 Surface Water Monitoring

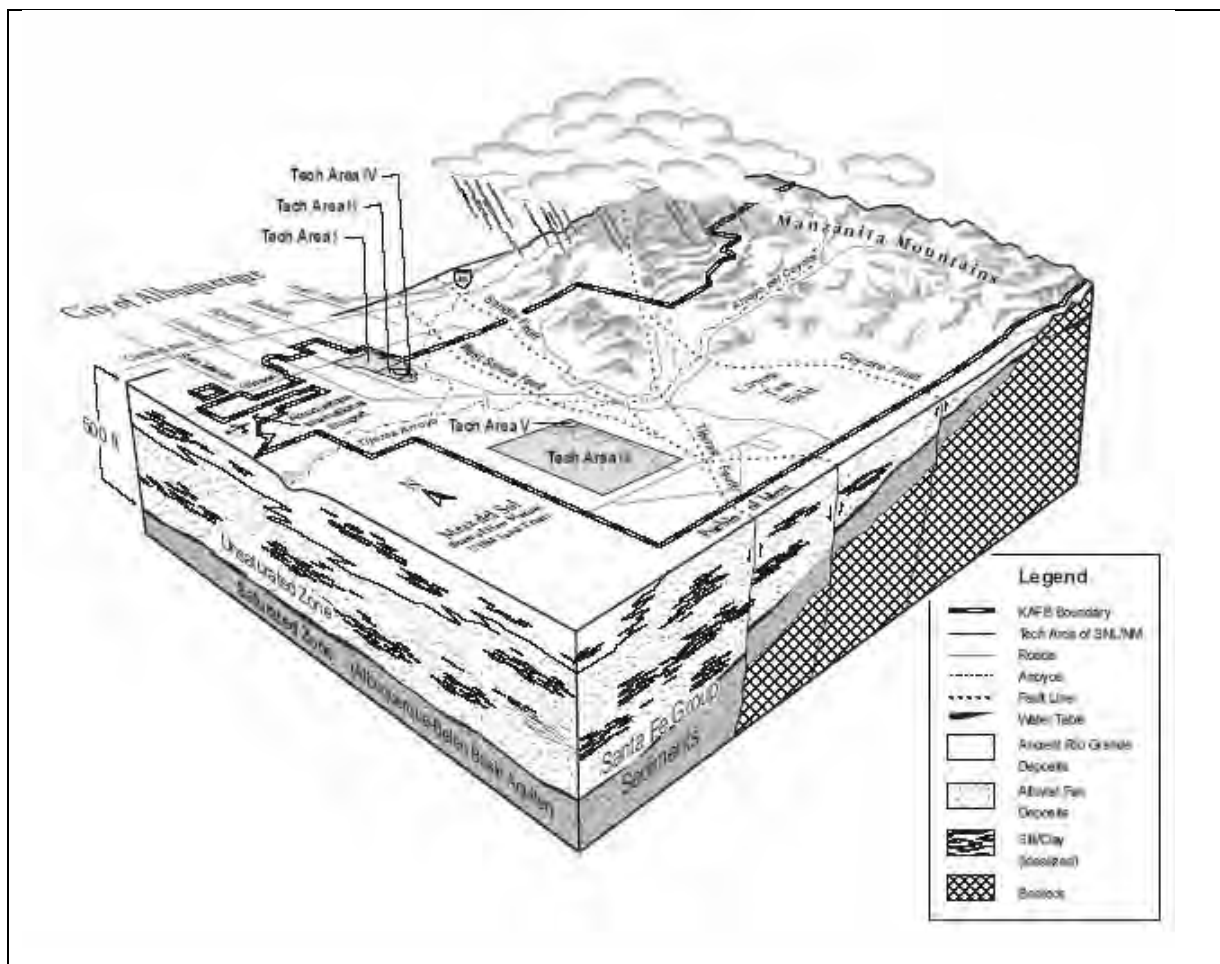

The surface water system on KAFB is a reflection of the dry high-desert climate of the area. Surface water flows through several major and many minor unnamed arroyos, primarily during summer monsoon events. With the exception of flow from two springs, there are no perennial streams or other surface water bodies at KAFB. Several unnamed arroyos and drainages to the south of Arroyo del Coyote dissipate as the topographic relief decreases to the west. Storm water in this area either evaporates or infiltrates into the soil. Therefore, there is no hydrologic surface connection from these areas to Tijeras Arroyo or the Rio Grande.

Surface discharges are releases of water and water based compounds made to roads, open areas or impoundments. Surface discharges are only made with the approval of the Internal Surface Discharge Program. Proposed discharges are evaluated for potential contaminants and concentration levels to determine if the discharge complies with strict water quality guidelines for surface releases. Uncontaminated water discharges must also be approved since large volumes of water discharged in areas of prior contamination could increase infiltration rates and move contaminants deeper into the soil column.

E.4.2 Groundwater Monitoring

Water resources at SNL are characterized through an extensive network of wells and monitoring stations. The network supports an active environmental monitoring program covering groundwater, surface water and air. The Groundwater Protection Program (GWPP) and the Environmental Restoration (ER) Project collect groundwater data at SNL. Both programs coordinate to monitor wells throughout SNL. The GWPP establishes baseline water quality and groundwater flow information, determines if any impact from SNL operations is affecting groundwater quality, and maintains compliance with local, state, and federal regulations. The ER Project conducts groundwater monitoring in six project areas: Chemical Waste Landfill (CWL), the Mixed Waste Landfill (MWL), Technical Area V (TA-V), Tijeras Arroyo Groundwater (TAG, formerly Sandia North) Investigation, Canyons Area, and Drain and Septic Systems (DSS).

The groundwater beneath the western portion of KAFB is part of an interconnected series of water-bearing geologic units within the Albuquerque Basin that form the Albuquerque-Belen aquifer (Figure E.4-2.). Groundwater beneath the eastern portion of KAFB occurs in limited quantities in fractured bedrock. Over 170 wells are used to monitor and supply water to KAFB and the surrounding areas of the City of Albuquerque. The ER project has detected chromium concentrations exceeding EPA maximum containment level values. However, these exceedances correlate with nickel results and may be attributed to corrosion of Type 304 stainless steel well screens (SNL/NM 2007). The stainless steel corrosion product is in a particulate form, and as such, is unlikely to migrate into groundwater. Although water levels may fluctuate over the course of the year in response to seasonal recharge and groundwater withdrawal, the overall level of the regional aquifer within the basin continues to decline at about one foot per year (SNL/NM 2006).

Source: DOE 1999.

Figure E.4-2—Conceptual Diagram of Groundwater Systems Underlying KAFB

In 2006, the GWPP reported the detection of trace amounts of VOCs, elevated nonmetal inorganic compounds, and levels of beryllium and uranium above the MCL¹, and elevated gross alpha (SNL/NM 2007). None of the VOCs exceeded MCL standards. VOCs are attributed to laboratory cross-contamination or residual disinfection products. Elevated concentrations of non-metal inorganic compounds (e.g., chloride, sulfate, fluoride, etc.) are attributable to natural sources in the local area (SNL/NM 2007). At all locations except one perchlorate was detected at concentrations above the detection limit. However, perchlorate was detected at 1.26 milligrams per liter and 1.08 milligrams per liter (SNL/NM 2007). No MCL or MAC are established for perchlorate. In 2006, metals were detected below the MCLs and MACs at all locations except Coyote Springs and EOD Hill. Beryllium detected at Coyote Springs appears to be of natural origin and consistent with previous analysis (SNL/NM 2007). Uranium was detected above the MCL at EOD Hill. Mercury was not detected in any of the groundwater

¹ The U.S. EPA regulates drinking water constituents by setting a maximum contaminant levels (MCLs). The New Mexico Water Quality Control Commission (NMWQCC) regulates drinking water constituents by establishing maximum allowable concentrations (MACs).

samples. Additionally, analysis for radionuclide activity, when uncorrected, shows values above the MCL. However, removing the natural sources from the analysis, results in radioactivity levels below the MCLs. Exceedances for uranium and corrected gross alpha were detected above the recently established MCL at EOD Hill (SNL/NM 2007). Corrected gross alpha accounts for natural uranium levels in the surrounding environment. Wells with elevated uranium are located east of the Tijeras fault complex, where groundwater contacts bedrock material that contains minerals naturally high in uranium (SNL/NM 2007). Radium-226 was detected above the MCL for combined radium-226 and -228 (SNL/NM 2007).

The groundwater beneath the SNL and adjacent areas is the source of drinking water for SNL, KAFB, adjacent portions of the City of Albuquerque, and the Pueblo of Isleta. Groundwater quality can be influenced by the presence of contaminants in the soil column above the groundwater, as well as the groundwater itself. These influences are of major concern to the ER Project, which is investigating the nature and extent of groundwater contamination from past activities. All known groundwater contamination is the result of past activities that occurred before the enactment of environmental regulatory laws. The ER Project monitors sites of known or potential groundwater contamination. Measurements indicate that some contaminants exceed regulatory limits (Table E.4-1). Investigations or remediation of these sites is on-going. The following discussion on groundwater contaminants is based on 2005 monitoring and assessment data (SNL/NM 2006).

Past surface water sampling results from 1998 and 1999 analysis have shown a presence of metals such as zinc, magnesium, and iron elevated above the benchmark values. No unusual characteristics were observed in 2001, 2002, and 2003. No monitoring was required in 2000. Monitoring results in 2004 identified elevated levels of total suspended solids (TSS) and magnesium. Albuquerque's semiarid climate with sparse vegetative cover and high erosion rates naturally produce high TSS levels. SNL has reduced TSS levels in developed areas through best management practices, such as retention and detention ponds, landscaping conducive to infiltration and lining of storm drain channels for erosion reduction. All monitoring points show elevated levels of magnesium even though they are separated by several miles and collect runoff from several different drainages. The presence of zinc, magnesium and iron may be due to natural conditions associated with rocks and soils derived from the igneous/metamorphic complex of the Manzanita Mountains.

Table E.4-1—ER Project Groundwater Monitoring Results from Calendar Year 2006

Sample	Concentration	Period
Beryllium MCL = 0.004 mg/L	0.00805 mg/L	February/March 2006

MAC = maximum allowable concentration

MCL = maximum contaminant level

mg/L = milligrams per liter

pCi/L = picocuries per liter

µg/L = micrograms per liter

Studies by the New Mexico Bureau of Mines and Mineral Resources and the USGS have concluded that the volume of water-producing zone within the Albuquerque Aquifer is much less than earlier studies had estimated (NMMMR 1992; USGS 1993, 1995). USGS estimated the aquifer is being depleted at a rate that is twice that of the recharge to the aquifer from the Rio Grande and other sources (USGS 1995). As a result, the reliance on the regional Albuquerque Aquifer as the sole drinking water source for the City, including SNL and KAFB facilities, is unsustainable.

E.5 COMMUNITIES ALONG THE RIO GRANDE

Most communities use groundwater for drinking water sources. Predominant communities along the upper and middle Rio Grande basins are the Town of Taos, Cities of Española, Los Alamos, Santa Fe and Albuquerque, Pueblo of Taos, Ohkay Owingeh Pueblo (formerly San Juan Pueblo), Pojoaque Pueblo, Tesuque Pueblo, San Ildefonso Pueblo, Picuris Pueblo, Cochiti Pueblo, Santa Ana Pueblo, and Sandia Pueblo. Surface water contamination issues are of particular importance to area Pueblos, as many use local surface water sources for sacred and traditional ceremonies, including immersion in and ingestion of untreated surface waters.

Recent challenges to drinking water resources, such as drought conditions, ground subsidence, and contamination issues, are forcing communities to seek alternative sources to replace or augment their present drinking water sources. In 2006, the BOR converted the original water service contracts for the San Juan-Chama Project, enabling individual communities to access directly their allotments of San Juan-Chama water (OSE 2006). Seven communities in the upper and middle Rio Grande basins have expressed an interest in direct access to San Juan-Chama water delivered by the Rio Grande: the City of Santa Fe, City of Española, Town of Taos, Santa Fe County, Los Alamos County, Village of Los Lunas, and the Village of Taos Ski Valley. At this time, none of the Pueblos have expressed an interest in pursuing similar projects. The City

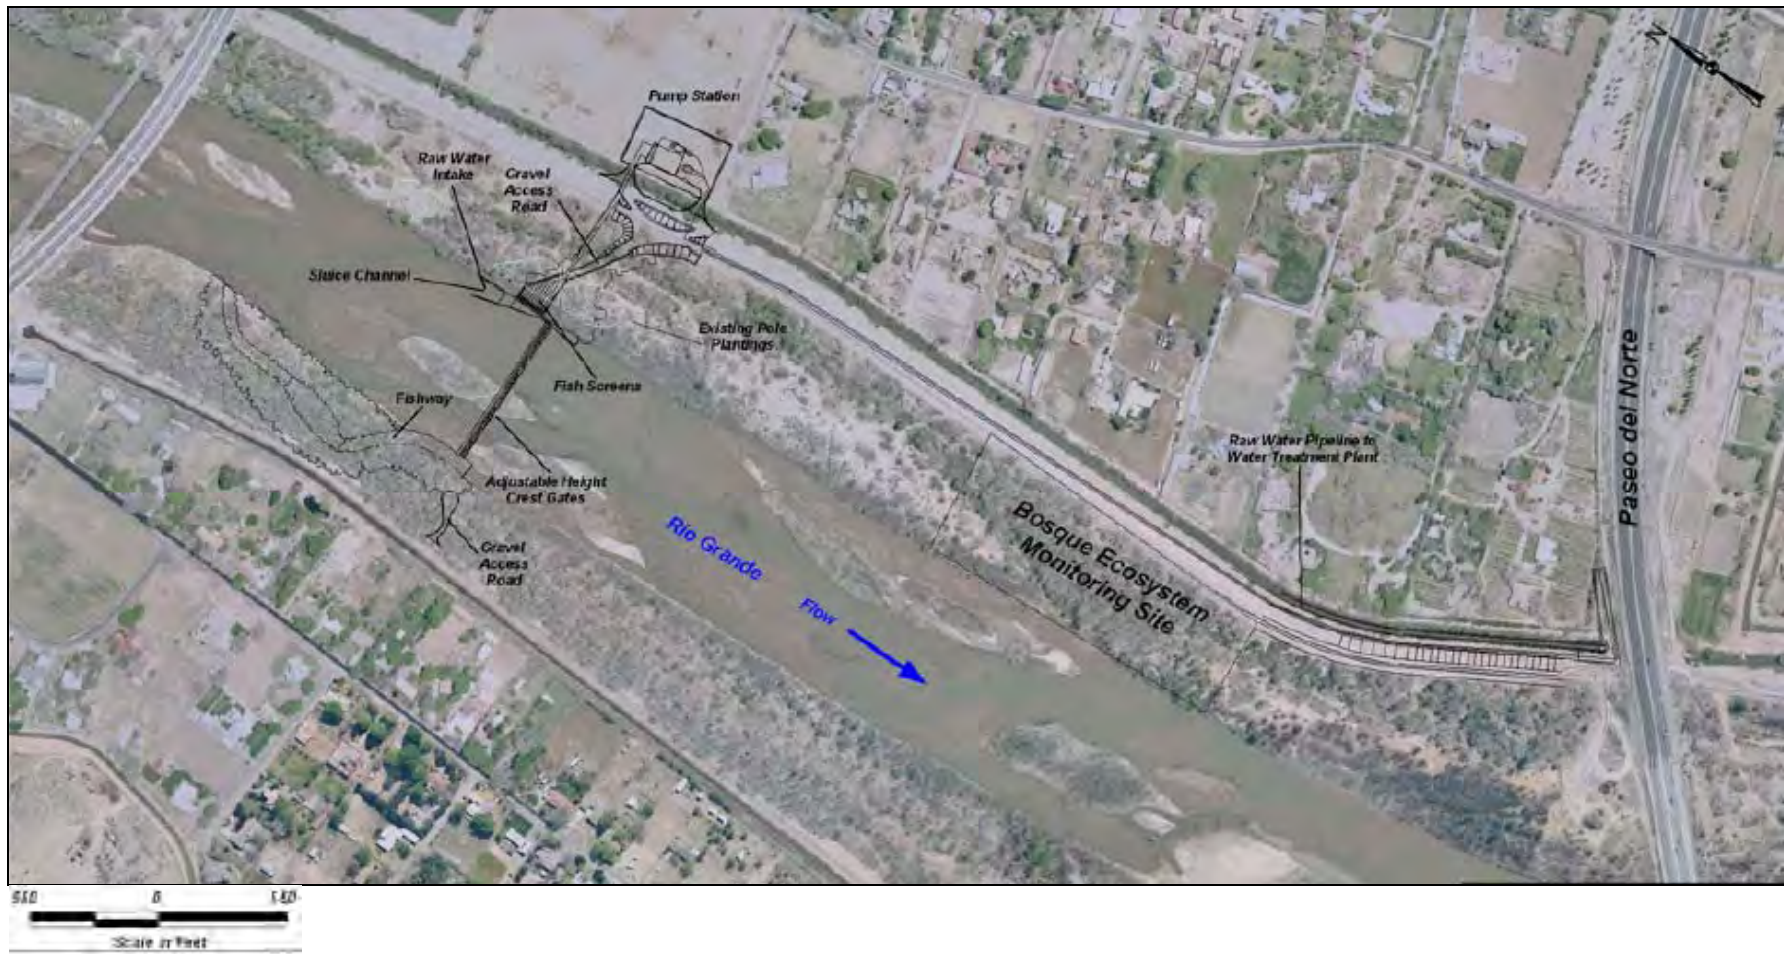

of Albuquerque and the USFS, on behalf of the City of Santa Fe, Santa Fe County, and Las Campanas Limited Liability Corporation (Las Campanas), are pursuing diversions on the Rio Grande to access San Juan-Chama surface water for community drinking water. Each project is described below.

E.5.1 City of Albuquerque Drinking Water Supply Project (CABQ and USBR 2004)

With the implementation of the San Juan-Chama Drinking Water Project, the City of Albuquerque projects the need for pumping groundwater would be substantially reduced to approximately 730,000 acre-feet per year by 2060 (CABQ and USBR 2004). For the 2006-2040 period, the USGS projects the overall annual aquifer recovery to range between 187,000 acre-feet per year to 242,000 acre-feet per year with the implementation of water conservation programs and the San Juan-Chama Drinking Water Project (USGS 2004). The San Juan-Chama, Drinking Water Project is projected to supply approximately 70-percent of the City of Albuquerque's future water use (CABQ 2008).

Several projects are necessary to complete the infrastructure requirement for the Drinking Water Supply Project. These projects, collectively referred to as the San Juan-Chama Drinking Water Project, are proposed to reduce the dependency on groundwater resources (CABQ 2005). The San Juan-Chama Drinking Water Project consists of four elements: diverting surface water from the Rio Grande; transporting the raw water to a new water treatment plant; treating the raw water to drinking water standards; and distributing the treated, potable water to the community. The construction of a diversion to utilize about 97,000 acre-feet per year of San Juan-Chama and Rio Grande surface water is in progress- scheduled for completion in 2007. Figure E.5-1 shows the diversion structure. The North I-25 Industrial Recycling and Northside Non-Potable Surface Water Reclamation Projects have been completed. The Southside Water Reclamation Plant is designed to provide safe use of surface water directly for municipal water supply and is scheduled to be completed in 2008.

With the implementation of the San Juan-Chama Drinking Water Project, the City of Albuquerque projects the need for pumping groundwater would be substantially reduced to approximately 730,000 acre-feet per year by 2060 (CABQ and USBR 2004), which would reduce aquifer drawdown from 3-5 feet per yr to 1-3 feet per year (Stomp 2006). For the period 1994 to 2020, the USGS projects the overall annual aquifer withdrawal for the City to range between 98,700 acre-feet per year to 177,000 acre-feet per year (32,178.37 – 57,705.89 million gallons per year) (USGS 1995). Implementation of the San Juan-Chama Drinking Water Project is projected to supply approximately 70-percent of the City of Albuquerque's future water use (CABQ 1997).

Source: CABQ and USBR 2004.

Figure E.5-1—Map of Paseo del Norte Diversion Structure for the CABQ Drinking Water Supply Project

E.5.2 U.S. Forest Service Buckman Water Diversion Project (USFS 2004)

As demonstrated by drought conditions in 1996, 2000, and 2002, continuing water shortages in the City of Santa Fe and Santa Fe County resulted in a critical and immediate need for water. Presently, the City and County utilize groundwater resources from the Buckman Well Field for community drinking water sources. However, the well field cannot provide a reliable and sustainable source of water. Well yields have been reduced; hydraulic heads in the confined ground water aquifer near the well field have undergone substantial declines; and depletions of nearby streams could cause limitations to pumping. At current well production levels, undesirable consequences to ground water levels and continued depletion of nearby streams are expected to occur unless an alternate reliable water supply is found. In addition to ground water concerns, storage levels in the City's two surface water reservoirs located on the Santa Fe River, a tributary of the Rio Grande, fluctuate widely depending on seasonal and annual runoff conditions and potable water demand. These reservoirs receive surface water runoff from the Santa Fe Canyon watershed above the City. Overall Santa Fe River reservoir capacities cannot provide the necessary dependability to provide the water quantities needed to sustain the Santa Fe region during drought conditions.

The proposed Buckman Water Diversion Project (Buckman Project) is designed to address the immediate need for a sustainable means of accessing water supplies for the applicants, the City of Santa Fe, New Mexico (City), Santa Fe County (County), and Las Campanas Limited Partnership (Las Campanas). Most of the water to be diverted would be derived from the San Juan-Chama Project, which is a U.S. Bureau of Reclamation (Reclamation) inter-basin water transfer project that supplies water from the greater Colorado River basin to the Rio Grande basin through a tunnel system. The remainder would be native water rights owned by the parties and diverted from the Rio Grande. The proposed point of diversion is located on the east bank of the Rio Grande in northern New Mexico, about 15 miles northwest of the City of Santa Fe. It is located about 3 miles downstream from where Route 4 crosses the Rio Grande at the Otowi Bridge, which is where streamflow data have been recorded by the U.S. Geological Survey (USGS) for more than a century. In addition to the diversion, the project would involve treatment and conveyance of water through pipelines that would generally follow roads and existing utility corridors.

The facilities necessary to implement the Buckman Project include a diversion structure on the eastern bank of the Rio Grande, sediment separation facilities, booster stations, storage and treatment facilities, water conveyance pipelines, Buckman Road improvements, and power upgrades. The locations of facilities associated with the Proposed Action and other alternatives are illustrated on Figure 7. Two new water treatment plants would be required, where the raw water would be processed to safe drinking water standards. The Las Campanas treatment plant would be located on Las Campanas land and operated by Las Campanas. The City and County treatment plant would be located on U.S. Bureau of Land Management land leased to the City, just west of Caja del Rio Road. New treated water pipelines would be installed from the treatment plants to convey water into the existing Las Campanas and City and County water distribution systems.

Source: USFS 2004.

Figure E.5-2—Map of Proposed Buckman Water Diversion Project

Estimated water diversion quantities are based on annual demand projections that extend to the year 2010 for the City and County, while the demand for Las Campanas is projected through community build out (1,717 homes). These projections translate to approximately 8,730 acre-feet

per year, currently estimated to be 5,230 acre-feet per year for the City; 1,700 acre-feet per year for the County; and 1,800 ac-ft per yr for Las Campanas. The proposed diversion facility is sized for a combined net peak diversion of approximately 28.2 cubic feet per second, which meets the combined peak needs of the City, County, and Las Campanas.

The USFS is coordinating with Federal and state agencies to address environmental concerns. The final environmental impact statement will be released in 2007. Upon release, the public will be given an opportunity to provide comments on the document.

E.5.3 City of Española Drinking Water Project (BOR and CE 2002)

The City of Española is facing tremendous challenges in its ability to provide potable water with good groundwater resources in sufficient quantities to meet even basic demand requirements of the local communities. Since 1986, the City has been forced to abandon seven of the thirteen groundwater production wells, due to either contamination or well failure. The contaminants include solvents, fluoride, and nitrates wither naturally occurring or from on-site wastewater disposal systems (e.g., septic systems) located throughout the Española Valley. The City of Española is exploring alternative water resources, including surface water diversion of San Juan-Chama water from the Rio Grande. The City of Española is working with the BOR to develop a project description. Engineering planning documents are being developed to facilitate the discussion of a diversion as a viable solution to the drinking water source challenges facing the City of Española.

E.6 CONCLUSION

Contaminant pathways into the Rio Grande and onto public lands are still being studied and are poorly understood due to the complex geohydrology of northern New Mexico. Area studies and LANL have confirmed that radioactive and toxic wastes of LANL origin have reached the Rio Grande. While contamination from DOE activities has occurred, it has not caused exceedances of regulatory standards off-site. Both LANL and SNL have contamination from legacy wastes created during the Cold War era, prior to modern environmental laws and regulations. Contamination of surface water and groundwater has been documented at LANL and SNL. The results from ongoing environmental monitoring programs at LANL and SNL were consistent with historical measurements and did not exceed Federal or state standards.

Communities and Pueblos in the upper and middle Rio Grande basins traditionally use groundwater sources for community drinking water. Many Pueblos use surface waters for traditional and ceremonial uses. The three largest communities in the upper and middle Rio Grande basins are seeking alternative drinking water supply resources. Presently, they all utilize groundwater aquifers and the primary drinking water source. Challenges from drought conditions, contaminants (naturally occurring and human-caused), and land subsidence, has heightened the need for communities to provide a sustainable water supply. The City of Albuquerque has initiated construction on diversion structure and the necessary infrastructure to facilitate the use of surface water from the Rio Grande. The City of Albuquerque will use 48,200 acre-feet per year of San Juan-Chama water and approximately 47,000 acre-feet per year of native Rio Grande surface water. After the San Juan-Cham water is fully consumed, the

native Rio Grande water, approximately 47,000 acre-feet per year, would be returned to the Rio Grande. The USFS is completing the environmental impact statement for the proposed Buckman Project, which would supply 3,500 acre-feet per year of surface water from the Rio Grande to the City of Santa Fe, Santa Fe County and Las Campanas subdivision in Santa Fe County. The USFS is expected to issue the final environmental impact statement in 2007. The City of Española has expressed an interest in developing a surface water diversion on the Rio Grande and is presently developing preliminary planning documents to further explore this option.

Appendix F
PROJECT NOTICES

Appendix F PROJECT NOTICES

This appendix includes project notices in relation to, or used as reference materials, in the preparation of the *Complex Transformation¹ Supplemental Programmatic Environmental Impact Statement*. These notices are not intended to be an all-inclusive list. Chapter 12 of this SPEIS provides an all-inclusive list of the references used to prepare this EIS.

The following are included as part of this appendix:

- *Notice of Intent to Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement - Complex 2030*
- *Notice of Intent to Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement - Complex 2030 (Correction)*
- *Change in Scoping Meeting Schedule for the Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement - Complex 2030*
- *Notice of Availability and Public Hearings for the Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement*
- *Extension of Comment Period for the Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement*

¹ In the Notice of Intent (71 FR 61731, October 19, 2006), this vision was referred to as “Complex 2030” and the supplement was called the “Complex 2030 SPEIS”. NNSA thinks that the term “Complex Transformation” more accurately reflects the vision and has renamed the supplement as the “Complex Transformation SPEIS”.

DEPARTMENT OF ENERGY

Notice of Intent To Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030

AGENCY: National Nuclear Security Administration, Department of Energy.

ACTION: Notice of intent.

SUMMARY: The National Nuclear Security Administration (NNSA), an agency within the U.S. Department of Energy (DOE or Department), announces its intent to prepare a *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030* (Complex 2030 SEIS or SEIS, DOE/EIS-0236-S4), pursuant to the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 *et seq.*), the Council on Environmental Quality's (CEQ's) and DOE's regulations implementing NEPA (40 CFR parts 1500–1508 and 10 CFR part 1021, respectively). The SEIS will analyze the environmental impacts from the continued transformation of the United States' nuclear weapons complex by implementing NNSA's vision of the complex as it would exist in 2030, which the Department refers to as Complex 2030, as well as alternatives. Since the end of the Cold War, there continue to be significant changes in the requirements for the nation's nuclear arsenal, including reductions in the number of nuclear weapons. To fulfill its responsibilities for certifying the safety and reliability of nuclear weapons without underground testing, DOE proposed and implemented the Stockpile Stewardship and Management (SSM) Program in the 1990s. Stockpile Stewardship includes activities required to maintain a high level of confidence in the safety and reliability of nuclear weapons in the absence of underground testing, and in the capability of the United States to resume nuclear testing if directed by the President. Stockpile Management activities include dismantlement, maintenance, evaluation, repair, and replacement of weapons and their components in the existing stockpile.

NNSA's proposed action is to continue currently planned modernization activities and select a site for a consolidated plutonium center for long-term research and development, surveillance, and pit¹ manufacturing; consolidate special nuclear materials throughout the complex; consolidate,

relocate, or eliminate duplicative facilities and programs and improve operating efficiencies; identify one or more sites for conducting NNSA flight test operations; and accelerate nuclear weapons dismantlement activities. This Notice of Intent (NOI), the initial step in the NEPA process, informs the public of NNSA's intention to prepare the Complex 2030 SEIS, announces the schedule for public scoping meetings, and solicits public input. Following the scoping period, NNSA will prepare and issue a draft of the Complex 2030 SEIS that will describe the Complex 2030 proposal, the alternatives analyzed, and potential impacts of the proposal and the alternatives.

This NOI also announces that NNSA has cancelled the previously planned *Supplemental Programmatic Environmental Impact Statement on Stockpile Stewardship and Management for a Modern Pit Facility* (DOE/EIS-0236-S2).

DATES: NNSA invites comments on the scope of the Complex 2030 SEIS. The public scoping period starts with the publication of this NOI in the **Federal Register** and will continue through January 17, 2006. Scoping comments received after this date will be considered to the extent practicable. NNSA will hold public scoping meetings to discuss issues and receive oral and written comments on the scope of the Complex 2030 SEIS. The locations, dates, and times for these public scoping meetings are listed below and will be announced by additional appropriate means. NNSA requests federal agencies that desire to be designated as cooperating agencies on the SEIS to contact NNSA's Office of Transformation at the address listed under **ADDRESSES** by the end of the scoping period.

North Augusta, South Carolina, North Augusta Community Center, 495 Brookside Avenue. November 9, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.

Oak Ridge, Tennessee, Oak Ridge City Center Club Room, 333 Main Street. November 13, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.

Amarillo, Texas, Amarillo Globe-News Center, Education Room, 401 S. Buchanan. November 15, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.

Las Vegas, Nevada, Cashman Center, 850 Las Vegas Boulevard North (at Washington). November 28, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.

Tonopah, Nevada, Tonopah Convention Center, 301 Brougner Avenue. November 29, 2006, 6 p.m.—10 p.m.

Socorro, New Mexico, Macey Center (at New Mexico Tech), 801 Leroy Place. December 4, 2006, 6 p.m.—10 p.m.

Albuquerque, New Mexico, Albuquerque Convention Center, 401 2nd St. NW. December 5, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.

Los Alamos, New Mexico, Mesa Public Library, 2400 Central Avenue. December 6, 2006, 10:30 a.m.—2:30 p.m.

Santa Fe, New Mexico, Genoveva Chavez Community Center, 3221 Rodeo Road. December 6, 2006, 6 p.m.—10 p.m.

Livermore, California, Robert Livermore Community Center, 4444 East Avenue. December 12, 2006, 11 a.m.—3 p.m.

Tracy, California, Tracy Community Center, 950 East Street. December 12, 2006, 6 p.m.—10 p.m.

U.S. Department of Energy, 1000 Independence Avenue, SW., Room 1E-245, Washington, DC. December 14, 2006, 1 p.m.—5 p.m.

NNSA officials will be available to informally discuss the Complex 2030 proposal during the first hour. Following this, NNSA intends to hold a plenary session at each scoping meeting in which officials will explain the Complex 2030 proposal and the SEIS, including preliminary alternatives. The meetings will provide the public with an opportunity to provide oral and written comments to NNSA on the scope of the SEIS. Input from the scoping meetings will assist NNSA in preparing the draft SEIS.

ADDRESSES: General questions concerning the NOI can be asked by calling toll-free 1-800-832-0885 (ext. 63519), e-mailing to Complex2030@nnsa.doe.gov, or writing to Theodore A. Wyka, Complex 2030 SEIS Document Manager, Office of Transformation, U.S. Department of Energy, NA-10.1, 1000 Independence Avenue, SW., Washington, DC 20585. Written comments on the scope of the SEIS or requests to be placed on the document distribution list can be sent to the Complex 2030 SEIS Document Manager. Additional information regarding Complex 2030 is available on Complex2030PEIS.com.

For general information on the DOE NEPA process, please contact Carol M. Borgstrom, Director, Office of NEPA Policy and Compliance, U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585, (202) 586-4600 or 1-800-472-2756. Additional information regarding DOE NEPA activities and access to many DOE NEPA documents are available on the Internet through the DOE NEPA Web site at <http://www.eh.doe.gov/nepa>.

SUPPLEMENTARY INFORMATION:

¹ A pit is the central core of a nuclear weapon typically containing plutonium-239 that undergoes fission when compressed by high explosives.

Background: The early days of the nuclear weapons complex after World War II saw a rapid build-up of capability and capacity to support the growth of the stockpile to fight the Cold War. By the 1960s, the United States had built a large stockpile of nuclear weapons, and the nation began to focus on improving, rather than expanding, the stockpile. NNSA's predecessor agencies began to consolidate operations and close some production facilities. In the 1980s, facilities were shut down across the nuclear weapons complex, including certain facilities at the Savannah River Site in South Carolina; the Oak Ridge Reservation in Tennessee; the Rocky Flats Plant in Colorado; the Fernald Site in Ohio; the Hanford Reservation in Washington; and elsewhere.

Prior DOE NEPA Reviews: DOE completed a Nuclear Weapons Complex Reconfiguration ("Complex-21") Study in January 1991, which identified significant cost savings that could be achieved by further downsizing of the nuclear weapons complex.

DOE then initiated a programmatic EIS (Reconfiguration PEIS) examining alternatives for reconfiguring the nuclear weapons complex. However, in December 1991, the Department decided to separate proposals for transforming non-nuclear production from the Reconfiguration PEIS because (1) proposals to consolidate non-nuclear facilities might not require preparation of an EIS, and (2) proposals and decisions regarding transformation of non-nuclear production would neither significantly affect nor be affected by proposals and decisions regarding transformation of nuclear production. On January 27, 1992, the Department issued an NOI (57 FR 3046) to prepare an environmental assessment (DOE/EA-0792) for the consolidation of non-nuclear production activities within the nuclear weapons complex. Following the collapse of the Soviet Union, the United States reduced the budget for the nuclear weapons program. President George H. W. Bush imposed a moratorium in 1992 on underground nuclear testing.

On September 14, 1993, DOE published a Finding of No Significant Impact (FONSI) regarding its proposal to consolidate non-nuclear component production (58 FR 48043). This proposal included termination of non-nuclear production missions at the Mound Plant in Ohio, the Pinellas Plant in Florida, and the Rocky Flats Plant in Colorado. The electrical and mechanical manufacturing functions were consolidated at the Kansas City Plant. Detonators and beryllium capabilities for technology and pit support were

consolidated at Los Alamos National Laboratory (LANL) in New Mexico, and neutron generator production was relocated to Sandia National Laboratories in New Mexico.

In October 1993, President William J. Clinton issued Presidential Decision Directive 15 (PDD-15), which directed DOE to establish the Stockpile Stewardship Program. PDD-15 significantly redirected the nuclear weapons program. Throughout the Cold War, the Department of Defense (DOD) and DOE's nuclear weapons laboratories had based a portion of their confidence in the reliability of nuclear weapons on performance data from atmospheric and underground tests. To ensure weapons reliability during the moratorium on testing, DOE proposed to invest in new scientific tools to assess the complex phenomena involved in the detonation of nuclear weapons. DOE also began to develop sophisticated tools and computer-based simulation techniques to assess various aging phenomena as nuclear weapons continued to serve well beyond their originally anticipated lifetimes. These actions enhanced research and development (R&D) and deferred spending on the production complex.

DOE concluded in October 1994 that the alternatives described in the Reconfiguration PEIS no longer contained realistic proposals for reconfiguration of the nuclear weapons complex. That conclusion was based on several factors, including: comments offered at the September-October 1993 Reconfiguration PEIS scoping meetings; the anticipation that no production of new nuclear weapons types would be required for the foreseeable future; budget constraints; and the Department's decision to prepare a separate PEIS on Storage and Disposition of Weapons-Usable Fissile Materials (DOE/EIS-0229; NOI published June 21, 1994, 59 FR 17344).

Consequently, the Department separated the Reconfiguration PEIS into two new PEISs: (1) A Tritium Supply and Recycling PEIS (DOE/EIS-0161); and (2) the SSM PEIS (DOE/EIS-0236). The Final PEIS for Tritium Supply and Recycling was issued on October 27, 1995 (60 FR 55021). In its Record of Decision (ROD) on May 14, 1999 (64 FR 26369²), DOE decided it would produce the tritium needed to maintain the nuclear arsenal at commercial light water reactors owned and operated by the Tennessee Valley Authority and

² This ROD also contains decisions for the EIS for Construction and Operation of a Tritium Extraction Facility at the Savannah River Site (DOE/EIS-0271) and EIS for the Production of Tritium in a Commercial Light Water Reactor (DOE/EIS-0288).

extract tritium at a new DOE-owned Tritium Extraction Facility at the Savannah River Site. With regard to the SSM PEIS, DOE issued an NOI on June 6, 1995 (60 FR 31291), a final SSM PEIS on November 19, 1996 (61 FR 58871), and a ROD on December 26, 1996 (61 FR 68014) announcing its decision to transform the weapons production complex by (1) reducing the weapon assembly capacity located at the Pantex Plant in Texas; (2) reducing the high-explosives fabrication capacity at Pantex; (3) reducing the uranium, secondary, and case fabrication capacity in the Y-12 National Security Complex in Tennessee; (4) reducing nonnuclear component fabrication capacity at the Kansas City Plant; and (5) reestablishing a modest interim pit fabrication capability at Los Alamos National Laboratory in New Mexico while evaluating the need for greater pit manufacturing capacity in the future.

In accordance with the decisions in the SSM PEIS, the *Non-nuclear Consolidation Environmental Assessment* (EA), and the Tritium Supply and Recycling PEIS, DOE began transforming the nuclear weapons complex to its present configuration. DOE has also prepared other EISs that facilitated the transformation of the complex. The relevant RODs for these site-wide and project-specific EISs are listed below:

- 1996 ROD for the *EIS for the Nevada Test Site and Off-Site Locations in the State of Nevada* (61 FR 65551, December 13, 1996).
- 1997 ROD for the *EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (62 FR 3880, January 27, 1997).
- 1999 ROD for the Site-wide EIS for Continued Operation of the Los Alamos National Laboratory (64 FR 50797, September 20, 1999).
- 1999 ROD for the *EIS for Site-wide Operation of Sandia National Laboratories* (64 FR 69996, December 15, 1999).
- 2000 *Amended ROD for the Nevada Test Site EIS* (65 FR 10061, February 25, 2000).
- 2002 ROD for the *Site-wide EIS for the Oak Ridge Y-12 National Security Complex* (67 FR 11296, March 13, 2002).
- 2002 ROD for the *EIS for the Relocation of Technical Area 18 Capabilities and Materials at the Los Alamos National Laboratory* (67 FR 79906, December 31, 2002).
- 2004 ROD for the *EIS for the Chemistry and Metallurgy Research Building Replacement Project, Los*

Alamos National Laboratory (69 FR 6967, February 12, 2004).

- 2005 ROD for the *Site-wide EIS for Continued Operation of Lawrence Livermore National Laboratory and Supplemental Stockpile Stewardship and Management Programmatic EIS* (70 FR 71491, November 29, 2005).

Nuclear Weapons Complex: The current nuclear weapons complex consists of eight major facilities located in seven states. NNSA maintains a limited capability to design and manufacture nuclear weapons; provides surveillance of and maintains nuclear weapons currently in the stockpile; and dismantles retired nuclear weapons. Major facilities and their primary responsibilities within the nuclear weapons complex are listed below:

Savannah River Site (SRS) (Aiken, South Carolina)—Extracts tritium (when the Tritium Extraction Facility becomes operational in 2007); provides loading, unloading and surveillance of tritium reservoirs. SRS does not maintain Category I/II³ quantities of special nuclear material (SNM)⁴ associated with weapons activities, but does maintain Category I/II quantities of SNM associated with other Department activities (e.g., environmental management).

Pantex Plant (PX) (Amarillo, Texas)—Dismantles retired weapons; fabricates high-explosives components; assembles high explosive, nuclear, and non-nuclear components into nuclear weapons; repairs and modifies weapons; and evaluates and performs non-nuclear testing of weapons. Maintains Category I/II quantities of SNM for the weapons program and material no longer needed by the weapons program.

Y-12 National Security Complex (Y-12) (Oak Ridge, Tennessee)—Manufactures nuclear weapons secondaries, cases, and other weapons components; evaluates and performs testing of weapon components; maintains Category I/II quantities of SNM; conducts dismantlement, storage, and disposition of nuclear weapons materials; and supplies SNM for use in naval reactors.

Kansas City Plant (KCP) (Kansas City, Missouri)—Manufactures and acquires

non-nuclear weapons components; and evaluates and performs testing of weapon components. No Category I/II quantities of SNM are maintained at the KCP.

Lawrence Livermore National Laboratory (LLNL) (Livermore, California)—Conducts research and development of nuclear weapons; designs and tests advanced technology concepts; designs weapons; maintains a limited capability to fabricate plutonium components; and provides safety and reliability assessments of the stockpile. Maintains Category I/II quantities of SNM associated with the weapons program and material no longer needed by the weapons program.

Los Alamos National Laboratory (LANL) (Los Alamos, New Mexico)—Conducts research and development of nuclear weapons; designs and tests advanced technology concepts; designs weapons; provides safety and reliability assessments of the stockpile; maintains interim production capabilities for limited quantities of plutonium components (e.g., pits); and manufactures nuclear weapon detonators for the stockpile. Maintains Category I/II quantities of SNM associated with the nuclear weapons program and material no longer needed by the weapons program.

Sandia National Laboratories (SNL) (Albuquerque, New Mexico; Livermore, California)—Conducts system engineering of nuclear weapons; designs and develops non-nuclear components; conducts field and laboratory non-nuclear testing; conducts research and development in support of the nuclear weapon non-nuclear design; manufactures non-nuclear weapon components; provides safety and reliability assessments of the stockpile; and manufactures neutron generators for the stockpile. Maintains Category I/II quantities of SNM associated with the nuclear weapons program.

Nevada Test Site (NTS) (Las Vegas, Nevada)—Maintains capability to conduct underground nuclear testing; conducts experiments involving nuclear material and high explosives; provides capability to disposition a damaged nuclear weapon or improvised nuclear device; conducts non-nuclear experiments; and conducts research and training on nuclear safeguards, criticality safety and emergency response. Maintains Category I/II quantities of SNM associated with the nuclear weapons program.

Purpose and Need for the Stockpile Stewardship and Management Program: Under the Atomic Energy Act of 1954 (42 U.S.C. 2011 et seq.), DOE is responsible for providing nuclear

weapons to support the United States' national security strategy. The National Nuclear Security Administration Act (Pub. L. 106-65, Title XXXII) assigned this responsibility to NNSA within DOE. One of the primary missions of NNSA is to provide the nation with safe and reliable nuclear weapons, components and capabilities, and to accomplish this in a way that protects the environment and the health and safety of workers and the public.

Changes in national security needs and budgets have necessitated changes in the way NNSA meets its responsibilities regarding the nation's nuclear stockpile. As a result of a changed security environment, unilateral decisions by the United States and international arms control agreements, the nation's stockpile is significantly smaller today and by 2012, it will be the smallest since the Eisenhower administration (1953-1961). The Treaty of Moscow will eventually lead to a level of 1,700-2,200 operationally-deployed strategic nuclear weapons.

However, nuclear deterrence will continue to be a cornerstone of United States national security policy, and NNSA must continue to meet its responsibilities for ensuring the safety and reliability of the nation's nuclear weapons stockpile. The current policy is contained in the Nuclear Posture Review, submitted to Congress in early 2002, which states that the United States will:

- Change the size, composition and character of the nuclear weapons stockpile in a way that reflects that the Cold War is over;
- Achieve a credible deterrent with the lowest possible number of nuclear warheads consistent with national security needs, including obligations to allies; and
- Transform the NNSA nuclear weapons complex into a responsive infrastructure that supports the specific stockpile requirements established by the President and maintains the essential United States nuclear capabilities needed for an uncertain global future.

Complex 2030 SEIS: NNSA has been evaluating how to establish a more responsive nuclear weapons complex infrastructure since the Nuclear Posture Review was transmitted to Congress in early 2002. The Stockpile Stewardship Conference in 2003, the Department of Defense Strategic Capabilities Assessment in 2004, the recommendations of the Secretary of Energy Advisory Board (SEAB) Task Force on the Nuclear Weapons Complex Infrastructure in 2005, and the Defense

³ Category I/II quantities of special nuclear material are determined by grouping materials by type, attractiveness level, and quantity. These grouping parameters are defined in DOE Manual 470.4-6, Nuclear Material Control and Accountability [see <https://www.directives.doe.gov>].

⁴ As defined in section 11 of the Atomic Energy Act of 1954, special nuclear material are: (1) Plutonium, uranium enriched in the isotope 233 or in the isotope 235, and any other material which the U.S. Nuclear Regulatory Commission determines to be special nuclear material; or (2) any material artificially enriched by plutonium or uranium 233 or 235.

Science Board Task Force on Nuclear Capabilities in 2006 have provided information for NNSA's evaluations.

In early 2006, NNSA developed a planning scenario for what the nuclear weapons complex would look like in 2030. See <http://www.nnsa.doe.gov> for

more information regarding Complex 2030 planning. The Complex 2030 planning scenario incorporates many of the decisions NNSA has already made based on the evaluations in the SSM PEIS, Tritium Supply and Recycling PEIS, and other NEPA documents. See

discussion in background above. The following table identifies which components of Complex 2030 are based on the existing SSM PEIS and Tritium PEIS RODs, including RODs for subsequent tiered EISs:

Components of Complex 2030 that reflect earlier decisions	SSM PEIS ROD	Tritium PEIS ROD
Maintain but reduce the existing weapon assembly capacity located at Pantex	X
Maintain but reduce the high-explosives fabrication capacity at Pantex	X
Maintain but reduce the existing uranium, secondary, and case fabrication capacity at the Y-12 Plant at Oak Ridge	X
Reduce the non-nuclear component fabrication capacity at the Kansas City Plant	X
Reestablish limited pit fabrication capability at Los Alamos National Laboratory while evaluating the need for a larger capability	X
Irradiate tritium producing rods in commercial light water reactors; construct and operate a new Tritium Extraction Facility at DOE's Savannah River Site	X

Types of Decisions that Would Be Based on the Complex 2030 SEIS: The decisions set forth in the Complex 2030 ROD would:

- Identify the future missions of the SSM Program and the nuclear weapons complex; and
- Determine the configuration of the future weapons complex needed to accomplish the SSM Program.

For specific programs or facilities, NNSA may need to prepare additional NEPA documents to implement the decisions announced in the ROD. The baseline that will be used for the analyses of program and facility needs in the SEIS is 1,700–2,200 operationally-deployed strategic nuclear weapons, in addition to augmentation weapons, reliability-reserve weapons and weapons required to meet NATO commitments. The numbers are consistent with international arms-control agreements. Consistent with national security policy directives, replacement warhead design concepts may be pursued under the alternatives as a means of, for example, enhancing safety and security, improving manufacturing practices, reducing surveillance needs, and reducing need for underground tests.

The SEIS will evaluate reasonable alternatives for future transformation of the nuclear weapons complex. The Proposed Action and alternatives to the Proposed Action will assume continued implementation of the following prior siting decisions that DOE made in the SSM PEIS and Tritium PEIS RODs, including RODs for subsequent tiered EISs:

- Location of the weapon assembly/disassembly operations at the Pantex Plant in Texas.
- Location of uranium, secondary, and case fabrication at the Y-12

National Security Complex in Tennessee.

- Location of tritium extraction, loading and unloading, and support operations at the Savannah River Site in South Carolina.

NNSA does not believe it is necessary to identify additional alternatives beyond those present in the SSM PEIS. Regarding the uranium, secondary, and case fabrication at Y-12, NNSA is currently preparing a Y-12 Site-wide EIS to evaluate reasonable alternatives for the continued modernization of the Y-12 capabilities. The Complex 2030 SEIS will incorporate any decisions made pursuant to the Y-12 Site-wide EIS.

While the Complex 2030 planning scenario proposes to consolidate further non-nuclear production activities performed at the Kansas City Plant, this proposal will be evaluated in a separate NEPA analysis, as was done in the 1990s. NNSA believes that it is appropriate to separate the analyses of the transformation of non-nuclear production from the SEIS because decisions regarding those activities would neither significantly affect nor be affected by decisions regarding the transformation of nuclear production activities.

The SSM PEIS ROD announced NNSA's decision to establish a small interim pit production capacity at LANL. In the 1999 LANL Site-wide EIS ROD, NNSA announced it would achieve a pit production capacity at LANL of up to 20 pits per year. The 2006 draft LANL Site-wide EIS evaluates a proposal for a production capacity of 50 certified pits annually. This proposed capacity is based on an annual production rate of 80 pits per year in order to provide NNSA with sufficient flexibility to obtain 50

certified pits. Any decisions made pursuant to the LANL Site-wide EIS will be included in the Complex 2030 SEIS.

Based upon the studies⁵ and analyses that led to NNSA's development of the Complex 2030 scenario, NNSA has developed alternatives that are intended to facilitate public comment on the scope of the SEIS. NNSA's decisions regarding implementation of Complex 2030 will be based on the following alternatives, or a combination of those alternatives.

The Proposed Action—Transform to a More Modern, Cost-Effective Nuclear Weapons Complex (Complex 2030). This alternative would undertake the following actions to continue the transformation of NNSA's nuclear weapons complex:

- Select a site to construct and operate a consolidated plutonium center for long-term R&D, surveillance, and manufacturing operations for a baseline capacity of 125 qualified pits per year at a site with existing Category I/II SNM.
- Reduce the number of sites with Category I/II SNM and consolidate SNM to fewer locations within each given site.
- Consolidate, relocate or eliminate duplicative facilities and programs and improve operating efficiencies, including at facilities for nuclear materials storage, tritium R&D, high explosives R&D, environmental testing, and hydrotesting facilities.
- Identify one or more sites for conducting NNSA flight test operations.

⁵ The Stockpile Stewardship Conference in 2003, the Department of Defense Strategic Capabilities Assessment in 2004, the recommendations of the Secretary of Energy Advisory Board (SEAB) Task Force on the Nuclear Weapons Complex Infrastructure in 2005, and the recommendations of the Defense Science Board Task Force on Nuclear Capabilities in 2006.

Existing DOD and DOE test ranges (e.g., White Sands Missile Range in New Mexico and Nevada Test Site in Nevada) would be considered as alternatives to the continued operation of the Tonopah Test Range in Nevada.

- Accelerate dismantlement activities.

The DOE sites that will be considered as potential locations for the consolidated plutonium center and consolidation of Category I/II SNM include: Los Alamos, Nevada Test Site, Pantex Plant, Y-12 National Security Complex, and the Savannah River Site. Other DOE sites are not considered

reasonable alternative locations because they do not satisfy certain criteria such as population encroachment, or mission compatibility or synergy with the site's existing mission.

Alternatives to the Proposed Action

No Action Alternative. The No Action Alternative represents the status quo as it exists today and is presently planned. It includes the continued implementation of decisions made pursuant to the SSM PEIS and the Tritium Supply and Recycling PEIS (as summarized above) and related site-specific EISs and EAs. These decisions

are contained in RODs and Findings of No Significant Impact (FONSI)s, including those discussed above, and copies can be located on the DOE NEPA Document Web page at <http://www.eh.doe.gov/nepa/documents.html>.

The No Action Alternative would also include any decisions made as a result of the new Y-12 Site-wide EIS and the LANL Site-wide EIS once these EISs are finished. NNSA expects to issue RODs on these EISs prior to publication of the draft Complex 2030 SEIS.

The No Action Alternative is illustrated in the following matrix:

Capability	Sites (no action alternative)							
	KCP	LANL	LLNL	NTS	Y-12	PX	SNL	SRS
Weapons assembly/Disassembly				X		X		
Nonnuclear components	X	X					X	
Nuclear components:								
—Pits		X						
—Secondaries and cases					X			
High explosives components						X		
Tritium Extraction, Loading and Unloading								X
High explosives R&D		X	X			X	X	
Tritium R&D		X	X					X
Large Scale Hydrotesting		X	X	X				
Category I/II SNM Storage		X	X	X	X	X	X	X

The No Action Alternative also includes continuation of environmental testing at current locations and flight-testing activities at the Tonopah Test Range in Nevada.

Reduced Operations and Capability-Based Complex Alternative

In this alternative, NNSA would maintain a basic capability for manufacturing technologies for all stockpile weapons, as well as laboratory and experimental capabilities to support stockpile decisions, but would reduce production facilities to a "capability-based" ⁶ capacity. This alternative would not have a production capacity sufficient to meet current national security objectives. This alternative would be defined as follows:

- Do not construct and operate a consolidated plutonium center for long-term R&D, surveillance, and manufacturing operations; and do not expand pit production at LANL beyond 50 certified pits per year.
- Reduce the number of sites with Category I/II SNM and consolidate SNM to fewer locations within a given site.
- Consolidate, relocate or eliminate duplicative facilities and programs and improve operating efficiencies, including at facilities for nuclear

materials storage, tritium R&D, high explosives R&D, environmental testing facilities, and hydrotesting facilities.

- Identify one or more sites for conducting NNSA flight test operations. Existing DOD and DOE test ranges (e.g. White Sands Missile Range in New Mexico and Nevada Test Site in Nevada) would be considered as potential alternatives to the continued operation of the Tonopah Test Range in Nevada.

- Production capacities at Pantex, Y-12, and the Savannah River Site would be considered for further reductions limited by the capability-based capacity.

- NNSA would continue dismantlement activities.

Proposal Not Being Considered for Further Analysis. The SEAB Task Force on the Nuclear Weapons Complex Infrastructure recommended that NNSA pursue a consolidated nuclear production center (CNPC) as a single facility for all research, development, and production activities relating to nuclear weapons that involve significant amounts (i.e. Category I/II quantities) of SNM. The CNPC, as envisioned by the SEAB Task Force, would contain all the nuclear weapons manufacturing, production, assembly, and disassembly facilities and associated weapon surveillance and maintenance activities for the stockpile weapons. The CNPC would include the plutonium activities

of the consolidated plutonium center proposed by NNSA in its Complex 2030 vision, as well as the consolidated activities of the uranium, tritium, and high explosive operations. DOE believes that creation of a CNPC is not a reasonable alternative and does not intend to analyze it as an alternative in the SEIS because of the technical and schedule issues involved in constructing a CNPC, as well as associated costs. NNSA invites and will consider comments on this matter during the scoping process.

The SEAB Task Force developed three business cases for transforming the nuclear weapons complex, two of which were characterized as high risk. Its preferred least-risk option was to establish a CNPC "quickly" by accelerating site selection, NEPA analyses, regulatory approvals, and construction. The Task Force assumed that NNSA could, under these circumstances, begin operating a CNPC in 2015, start consolidation of SNM shortly thereafter, accelerate dismantlements, and begin other major transformational activities. Until the CNPC was completed, NNSA would have to maintain, and in some cases improve, existing production and research facilities. According to the Task Force's estimates, this option would require an additional 1 billion dollars per year for weapons programs

⁶ The capability to manufacture and assemble nuclear weapons at a nominal level.

activities for the next 10 years, and lead to a net savings through 2030 of 15 billion dollars.

Accelerated construction of a CNPC would not allow NNSA to avoid immediate expenditures to restore and modernize interim production capabilities to meet essential Life Extension Program (LEP) schedules and support the existing stockpile during the next decade. LEP is the refurbishment of nuclear weapons parts and components to extend the weapon deployment life. NNSA has concluded that the SEAB Task Force underestimated the nonfinancial challenges of constructing a CNPC. A CNPC would require moving a unique and highly skilled workforce to a new location. It would require NNSA to obtain significant regulatory approvals rapidly, and to construct a unique and complex facility on a tight schedule. It would put many of the significant aspects of the weapons complex transformation into "one basket"—until the CNPC began operations, all the other facilities and activities would be delayed. NNSA's Proposed Action would achieve many of the benefits of the CNPC approach—consolidation of SNM and facilities, integrated R&D and production involving SNM, and aggressive dismantlements—in a way that addresses immediate national security needs in a technically feasible and affordable manner.

Nuclear Materials Consolidation: DOE is pursuing SNM consolidation from all DOE sites including those that comprise the nuclear weapons complex. The SEIS will look at alternatives for the storage and consolidation of nuclear materials within the nuclear weapons complex including materials needed to maintain the United States' nuclear weapons arsenal. There is a potential overlap between the SEIS and the activities of the Department's other nuclear materials consolidation activities, and DOE will ensure that there is appropriate coordination between the two activities.

Supplemental Programmatic Environmental Impact Statement on Stockpile Stewardship and Management for a Modern Pit Facility: NNSA issued a *Draft Supplemental Programmatic Environmental Impact Statement on Stockpile Stewardship and Management for a Modern Pit Facility* (MPF) on June 4, 2003 (68 FR 33487; also 68 FR 33934, June 6, 2003) that analyzed alternatives for producing the plutonium pits that are an essential component of nuclear weapons. On January 28, 2004, NNSA announced that it was indefinitely postponing any decision on how it would obtain a large capacity pit

manufacturing facility. Because the Complex 2030 SEIS will analyze alternatives for plutonium-related activities that include pit production, DOE, effective upon publication of this NOI, cancels the MPF PEIS.

Public Scoping Process: The scoping process is an opportunity for the public to assist the NNSA in determining the issues for analysis. NNSA will hold public scoping meetings at locations identified in this NOI. The purpose of these meetings is to provide the public with an opportunity to present oral and written comments, ask questions, and discuss concerns regarding the transformation of the nuclear weapons complex and the SEIS with NNSA officials. Comments and recommendations can also be communicated to NNSA as discussed earlier in this notice.

Complex 2030 PEIS Supplement Preparation Process: The SEIS preparation process begins with the publication of this NOI in the **Federal Register**. NNSA will consider all public comments that it receives during the public comment period in preparing the draft SEIS. NNSA expects to issue the draft SEIS for public review during the summer of 2007. Public comments on the draft SEIS will be received during a comment period of at least 45 days following the U.S. Environmental Protection Agency's publication of the Notice of Availability in the **Federal Register**. Notices placed in local newspapers will specify dates and locations for public hearings on the draft SEIS and will establish a schedule for submitting comments on the draft SEIS, including a final date for submission of comments. Issuance of the final SEIS is scheduled for 2008.

Classified Material: NNSA will review classified material while preparing the SEIS. Within the limits of classification, NNSA will provide the public as much information as possible to assist its understanding and ability to comment. Any classified material needed to explain the purpose and need for the action, or the analyses in the SEIS, will be segregated into a classified appendix or supplement, which will not be available for public review. However, all unclassified information or results of calculations using classified data will be reported in the unclassified section of the SEIS, to the extent possible in accordance with federal classification requirements.

Issued in Washington, DC on October 11, 2006.

Linton F. Brooks,

Administrator, National Nuclear Security Administration.

DEPARTMENT OF ENERGY

Federal Energy Regulatory Commission

[Docket No. IC07-538-000; FERC-538]

Commission Information Collection Activities, Proposed Collection; Comment Request; Extension

October 13, 2006.

AGENCY: Federal Energy Regulatory Commission, DOE.

ACTION: Notice.

SUMMARY: In compliance with the requirements of Section 3506(c) (2) (a) of the Paperwork Reduction Act of 1995 (Pub. L. 104-13), the Federal Energy Regulatory Commission (Commission) is soliciting public comment on the specific aspects of the information collection described below.

DATES: Comments on the collection of information are due by December 21, 2006.

ADDRESSES: Copies of the proposed collection of information can be obtained from and written comments may be submitted to the Federal Energy Regulatory Commission, Attn: Michael Miller, Office of the Executive Director, ED-34, 888 First Street NE., Washington, DC 20426. Comments may be filed either in paper format or electronically. Those parties filing electronically do not need to make a paper filing. For paper filings, the original and 14 copies of such comments should be submitted to the Office of the Secretary, Federal Energy Regulatory Commission, 888 First Street, NE., Washington, DC 20426 and refer to Docket No. IC07-538-000.

Documents filed electronically via the Internet must be prepared in WordPerfect, MS Word, Portable Document Format, or ASCII format. To file the document, access the Commission's Web site at <http://www.ferc.gov> and click on "Make an E-filing," and then follow the instructions for each screen. First time users will have to establish a user name and password. The Commission will send an automatic acknowledgement to the sender's e-mail address upon receipt of comments.

All comments may be viewed, printed or downloaded remotely via the Internet

Corrections

Federal Register

Vol. 71, No. 205

Tuesday, October, 24, 2006

This section of the FEDERAL REGISTER contains editorial corrections of previously published Presidential, Rule, Proposed Rule, and Notice documents. These corrections are prepared by the Office of the Federal Register. Agency prepared corrections are issued as signed documents and appear in the appropriate document categories elsewhere in the issue.

DEPARTMENT OF ENERGY

Notice of Intent To Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030

Correction

In notice document E6-17508 beginning on page 61731 in the issue of

Thursday, October 19, 2006, make the following correction:

On page 61731, in the second column, under the heading “**DATES**”, in the sixth line, “January 17, 2006” should read “January 17, 2007”.

[FR Doc. Z6-17508 Filed 10-23-06; 8:45 am]

BILLING CODE 4000-01-P

ELECTION ASSISTANCE COMMISSION

Sunshine Act Notice

AGENCY: United States Election Assistance Commission.

ACTION: Notice of public meeting for the Technical Guidelines Development Committee.

DATE AND TIME: Monday, December 4, 2006, 9 a.m. to 5:30 p.m. EST. Tuesday, December 5, 2006, 8:30 a.m. to 2 p.m. EST.

PLACE: National Institute of Standards and Technology, 100 Bureau Drive, Building 101, Green Auditorium, Gaithersburg, Maryland 20899-8900.

STATUS: This meeting will be open to the public. There is no fee to attend, but, due to security requirements, advance registration is required. Registration information will be available at <http://www.vote.nist.gov> by November 4, 2006.

SUMMARY: The Technical Guidelines Development Committee (the "Development Committee") has scheduled a plenary meeting for December 4th & 5th, 2006. The Committee was established to act in the public interest to assist the Executive Director of the U.S. Election Assistance Commission (EAC) in the development of voluntary voting system guidelines. The Development Committee held previous meetings on July 9, 2004; January 18 and 19, 2005; March 9, 2005; April 20 and 21, 2005; September 29, 2005 and March 29, 2006. The purpose of the seventh meeting of the Development Committee will be to review and approve draft documents that will form the bases for recommendations for future voluntary voting system guidelines to the EAC. The draft documents respond to tasks

defined in resolutions passed at previous Technical Guideline Development Committee meetings.

SUPPLEMENTARY INFORMATION: The Technical Guidelines Department Committee (the "Development Committee") has scheduled a plenary meeting for December 4th & 5th, 2006. The Committee was established pursuant to 42 U.S.C. 15361, to act in the public interest to assist the Executive Director of the Election Assistance Commission in the development of the voluntary voting system guidelines. The Technical Guidelines Development Committee held their first plenary meeting on July 9, 2004. At this meeting, the Development Committee agreed to a resolution forming three working groups: (1) Human Factors & Privacy; (2) Security & Transparency; and (3) Core Requirements & Testing to gather information and public input on relevant issues. The information gathered by the working groups was analyzed at the second meeting of the Development Committee January 18 & 19, 2005. Resolutions were debated and adopted by the TGDC at the January plenary session. The resolutions defined technical work tasks for NIST that will assist the TGDC in developing recommendations for voluntary voting system guidelines. At the March 9, 2005 meeting, NIST scientists presented preliminary reports on technical work tasks defined in resolutions adopted at the January plenary meeting and adopted one additional resolution. The Development Committee approved initial recommendations for voluntary voting system guidelines at the April 20th & 21st, 2005 meeting. The Development Committee began consideration of future recommendations for voluntary voting system guidelines at the September 29, 2005 meeting. At the March 29th, 2006 meeting, the Development Committee approved draft technical guidance documents that will form the bases for recommendations for future voluntary voting system guidelines and passed an additional resolution. The Committee will review additional technical guidance documents for recommendations for future voluntary voting system guidelines at the December 4th & 5th, 2006 meeting.

CONTACT INFORMATION: Allan Eustis 301-975-5099. If a member of the public would like to submit written comments concerning the Committee's affairs at any time before or after the meeting, written comments should be addressed

to the contact person indicated above, or to Voting@nist.gov.

Thomas R. Wilkey,

Executive Director, U.S. Election Assistance Commission.

BILLING CODE 6820-KF-M

ELECTION ASSISTANCE COMMISSION

Sunshine Act Notice

AGENCY: United States Election Assistance Commission.

ACTION: Notice of public meeting.

DATE AND TIME: Thursday, December 7, 2006, 10 a.m.-3p.m.

PLACE: U.S. Election Assistance Commission, 1225 New York Ave, NW., Suite 150, Washington, DC 20005. (Metro Stop: Metro Center).

AGENDA: The Commission will receive presentations on public comments received for the DRAFT Procedural Manual for Voting System Testing and Certification Program and the proposed final document will be considered for approval. The Commission will receive presentations from election officials, community interest groups, academicians and technology experts regarding the 2006 election. The Commission will elect officers for 2007 and consider other administrative matters.

This meeting will be open to the public.

FOR FURTHER INFORMATION CONTACT: Bryan Whitener, Telephone: (202) 566-3100.

Thomas R. Wilkey,

Executive Director, U.S. Election Assistance Commission.

DEPARTMENT OF ENERGY

Change in Scoping Meeting Schedule for the Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030

AGENCY: National Nuclear Security Administration, Department of Energy.

ACTION: Notice of Change in Scoping Meeting Schedule.

SUMMARY: On October 19, 2006, NNSA published a Notice of Intent (NOI) to Prepare a *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030* (Complex

2030 Supplemental PEIS; DOE/EIS-0236-S4; 71 FR 61731). NNSA has changed the location of the public scoping meeting scheduled for Los Alamos, New Mexico, and has extended the time for the public scoping meeting scheduled for Livermore, California.

DATES: The NOI identified the Mesa Public Library as the location of the public scoping meeting in Los Alamos, New Mexico. NNSA will instead hold the meeting at the Hilltop House Best Western, 400 Trinity Drive, Los Alamos, New Mexico. The meeting date and time, which are unchanged, are December 6, 2006, 10:30 a.m.–2:30 p.m.

The NOI listed the time of the meeting on December 12, 2006, in Livermore, California, as 11 a.m.–3 p.m. NNSA has extended the public comment portion of the meeting until 10 p.m. The meeting starting time of 11 a.m. is unchanged, and the meeting location is unchanged: Robert Livermore Community Center, 4444 East Avenue, Livermore, California.

NNSA is not changing the location or schedule for any other public scoping meeting announced in the NOI. This includes the meeting in Tracy, California, which still will be held on December 12, 2006, from 6 p.m.–10 p.m. at the Tracy Community Center, 950 East Street.

FOR FURTHER INFORMATION CONTACT: Please direct questions regarding these changes to Mr. Theodore A. Wyka, Complex 2030 Supplemental PEIS Document Manager, Office of Transformation, National Nuclear Security Administration (NA-10.1), U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585. Questions also may be telephoned, toll free, to 1-800-832-0885 (ext. 63519) or e-mailed to Complex2030@nnsa.doe.gov. Written comments on the scope of the Complex 2030 Supplemental PEIS or requests to be placed on the document distribution list can be sent to the Document Manager. Additional information regarding Complex 2030 is available at <http://Complex2030PEIS.com>.

Issued in Washington, DC, on November 14, 2006.

Thomas P. D'Agostino,

Deputy Administrator for Defense Programs, National Nuclear Security Administration.

BILLING CODE 6450-01-P

ENVIRONMENTAL PROTECTION AGENCY

[EPA-HQ-OPPT-2006-0929; FRL-8103-1]

Forum on State and Tribal Toxics Action; Notice of Public Meeting

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice.

SUMMARY: EPA is announcing the meeting of the Forum on State and Tribal Toxics Action (FOSTTA) to enable state and tribal leaders to collaborate with EPA on environmental protection and pollution prevention issues. Representatives and invited guests of the Chemical Information and Management Project (CIMP), the Pollution Prevention (P2) Project, and the Tribal Affairs Project (TAP), components of FOSTTA, will be meeting December 11, 2006. The meeting is being held to provide participants an opportunity to have in-depth discussions on issues concerning the environment and human health. This notice announces the location and times for the meeting and sets forth some tentative agenda topics. EPA invites all interested parties to attend the public meeting.

DATES: The meeting will be held on December 11, 2006, from 8 a.m. to 5 p.m.

Requests to participate in the meeting, identified by docket identification (ID) number EPA-HQ-OPPT-2006-0929 must be received on or before December 7, 2006.

To request accommodation of a disability, please contact the technical contact person listed under **FOR FURTHER INFORMATION CONTACT**, preferably at least 10 days prior to the meeting, to give EPA as much time as possible to process your request.

ADDRESSES: The meeting will be held at the Radisson Hotel & Suites Austin, 111 E. Cesar Chavez St., Austin, TX 78701, telephone number: (800) 333-3333, fax number: (512) 473-8399.

Requests to participate in the meeting, identified by docket ID number HQ-OPPT-2006-0929, may be submitted to the technical person listed under **FOR FURTHER INFORMATION CONTACT**.

FOR FURTHER INFORMATION CONTACT: For general information contact: Colby Lintner, Regulatory Coordinator, Environmental Assistance Division (7408M), Office of Pollution Prevention and Toxics, Environmental Protection Agency, 1200 Pennsylvania Ave., NW., Washington, DC 20460-0001; telephone number: (202) 554-1404; e-mail address: TSCA-Hotline@epa.gov.

For technical information contact: Pam Buster, Environmental Assistance Division (7408M), Office of Pollution Prevention and Toxics, Environmental Protection Agency, 1200 Pennsylvania Ave., NW., Washington, DC 20460-0001; telephone number: (202) 564-8817; fax number: (202) 564-8813; e-mail address: Buster.Pamela@epa.gov.

SUPPLEMENTARY INFORMATION:

I. General Information

A. Does this Action Apply to Me?

This action is directed to the public in general. This action may, however, be of interest to all parties interested in FOSTTA and in hearing more about the perspectives of the States on EPA programs and the information exchange regarding important issues related to human health and environmental exposure to toxics. Since other entities may also be interested, the Agency has not attempted to describe all the specific entities that may be affected by this action. However, in the interest of time and efficiency, the meetings are structured to provide maximum opportunity for State and EPA participants to discuss items on the predetermined agenda. At the discretion of the chair, an effort will be made to accommodate participation by observers attending the proceedings. If you have any questions regarding the applicability of this action to a particular entity, consult the people listed under **FOR FURTHER INFORMATION CONTACT**.

B. How Can I Get Copies of this Document and Other Related Information?

1. *Docket.* EPA has established a docket for this action under docket ID number EPA-HQ-OPPT-2006-0929. Publicly available docket materials are available electronically at <http://www.regulations.gov> or, if only available in hard copy, at the OPPT Docket in the EPA Docket Center (EPA/DC). The EPA/DC suffered structural damage due to flooding in June 2006. Although the EPA/DC is continuing operations, there will be temporary changes to the EPA/DC during the clean-up. The EPA/DC Public Reading Room, which was temporarily closed due to flooding, has been relocated in the EPA Headquarters Library, Infoterra Room (Room Number 3334) in the EPA West Building, located at 1301 Constitution Ave., NW., Washington, DC. The EPA/DC Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the EPA/DC Public Reading Room is (202)

Commission's Rules of Practice and Procedure.

(G) The Secretary is directed to publish a copy of this order in the **Federal Register**.

(H) The refund effective date in Docket No. EL08-8-000 established pursuant to section 206(b) of the Federal Power Act is 5 months from the date of the filing of the complaint.

By the Commission.

Kimberly D. Bose,
Secretary.

BILLING CODE 6717-01-P

DEPARTMENT OF ENERGY

National Nuclear Security Administration

Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement

AGENCY: National Nuclear Security Administration, U.S. Department of Energy.

ACTION: Notice of Availability and Public Hearings.

SUMMARY: The National Nuclear Security Administration (NNSA), a semi-autonomous agency within the U.S. Department of Energy (DOE), announces the availability of the Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement (Draft Complex Transformation SPEIS, DOE/EIS-0236-S4). The Draft Complex Transformation SPEIS analyzes the potential environmental impacts of reasonable alternatives to continue the transformation of the U.S. nuclear weapons complex to one that is smaller, more efficient, more secure, and better able to respond to changes in national security requirements. While NNSA has revised the document title from that indicated in the Notice of Intent, it remains a supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement. NNSA has prepared this document in accordance with the National Environmental Policy Act (NEPA), the Council on Environmental Quality (CEQ) regulations that implement the procedural provisions of NEPA (40 CFR Parts 1500-1508), and DOE procedures implementing NEPA (10 CFR Part 1021).

DATES: NNSA invites comments on the Draft Complex Transformation SPEIS during the 90-day public comment period, which ends on April 10, 2008. NNSA will consider comments received

after this date to the extent practicable as it prepares the Final Complex Transformation SPEIS. NNSA will hold 19 public hearings on the Draft Complex Transformation SPEIS. The locations, dates, and times are listed in the **SUPPLEMENTARY INFORMATION** section.

ADDRESSES: Requests for additional information on the Draft Complex Transformation SPEIS, including requests for copies of the document, should be directed to: Mr. Theodore A. Wyka, Complex Transformation SPEIS Document Manager, Office of Transformation, NA-10.1, Department of Energy/NNSA, 1000 Independence Avenue, SW., Washington, DC 20585, toll free 1-800-832-0885 ext. 63519. Written comments on the Draft Complex Transformation SPEIS should be submitted to the above address, by facsimile to 1-703-931-9222, or by e-mail to complextransformation@nnsa.doe.gov. Please mark correspondence "Draft Complex Transformation SPEIS Comments."

For general information regarding the DOE NEPA process contact: Ms. Carol M. Borgstrom, Director, Office of NEPA Policy and Compliance, GC-20, U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585, telephone 202-586-4600, or leave a message at 1-800-472-2756. Additional information regarding DOE NEPA activities and access to many of DOE's NEPA documents are available on the Internet through the DOE NEPA Web site at <http://www.eh.doe.gov/nepa>.

SUPPLEMENTARY INFORMATION: Public Hearings and Invitation to Comment. NNSA will hold 19 public hearings on the Draft Complex Transformation SPEIS. The hearings will be held at the following locations, dates, and times:

- North Augusta, South Carolina, North Augusta Community Center, 495 Brookside Avenue, North Augusta, SC, Thursday, February 21, 2008 (11 a.m.-3 p.m. and 6 p.m.-10 p.m.)
- Oak Ridge, Tennessee, New Hope Center, 602 Scarborough Road (Corner of New Hope and Scarborough Roads), Oak Ridge, TN, Tuesday, February 26, 2008 (11 a.m.-3 p.m. and 6 p.m.-10 p.m.)
- Amarillo, Texas, Amarillo Globe-News Center, Education Room, 401 S. Buchanan, Amarillo, TX, Thursday, February 28, 2008 (11 a.m.-3 p.m. and 6 p.m.-10 p.m.)
- Tonopah, Nevada, Tonopah Convention Center, 301 Brougner Avenue, Tonopah, NV, Tuesday, March 4, 2008 (6 p.m.-10 p.m.)
- Las Vegas, Nevada, Atomic Testing Museum, 755 E. Flamingo Road, Las

- Vegas, NV, Thursday, March 6, 2008 (11 a.m.-3 p.m. and 6 p.m.-10 p.m.)
- Socorro, New Mexico, Macey Center (at New Mexico Tech), 801 Leroy Place, Socorro, NM, Monday, March 10, 2008 (6 p.m.-10 p.m.)
- Albuquerque, New Mexico, Albuquerque Convention Center, 401 2nd Street NW, Albuquerque, NM, Tuesday, March 11, 2008 (11 a.m.-3 p.m. and 6 p.m.-10 p.m.)
- Los Alamos, New Mexico, Hilltop House, 400 Trinity Drive at Central, Los Alamos, NM, Wednesday, March 12, 2008 (6 p.m.-10 p.m.)
- Los Alamos, New Mexico, Hilltop House, 400 Trinity Drive at Central, Los Alamos, NM, Thursday, March 13, 2008 (11 a.m.-3 p.m.)
- Santa Fe, New Mexico, Genoveva Chavez Community Center, 3221 Rodeo Road, Santa Fe, NM, Thursday, March 13, 2008 (6 p.m.-10 p.m.)
- Tracy, California, Holiday Inn Express, 3751 N. Tracy Blvd., Tracy, CA, Tuesday, March 18, 2008 (6 p.m.-10 p.m.)
- Livermore, California, Robert Livermore Community Center, 4444 East Avenue, Livermore, CA, Wednesday, March 19, 2008 (11 a.m.-3 p.m. and 6 p.m.-10 p.m.)
- Washington, DC, Forrestal Building, 1000 Independence Ave, SW., Washington, DC, Tuesday, March 25, 2008 (11 a.m.-3 p.m.)

Individuals who would like to present comments orally at these hearings must register upon arrival at the hearing. NNSA will allot three to five minutes, depending upon the number of speakers, to each individual wishing to speak so as to ensure that as many people as possible have the opportunity to speak. More time may be allotted by the hearing moderator as circumstances allow. NNSA officials will be available to discuss the Draft Complex Transformation SPEIS and answer questions during the first hour. NNSA will then hold a plenary session at each public hearing in which officials will explain the Draft Complex Transformation SPEIS and the analyses in it. Following the plenary session, the public will have an opportunity to provide oral and written comments. Oral comments from the hearings and written comments submitted during the comment period will be considered by NNSA in preparing the Final Complex Transformation SPEIS.

The Draft Complex Transformation SPEIS and additional information regarding complex transformation are available on the Internet at <http://www.ComplexTransformationSPEIS.com> and <http://www.nnsa.doe.gov>. The Draft

Complex Transformation SPEIS and referenced documents are available to the public at the DOE Reading Rooms and public libraries listed below:

California

Lawrence Livermore National Laboratory, NNSA/LSO Public Reading Room, LLNL Discovery Center (Visitors Center), Building 651, East Gate Entrance, Greenville Road, Livermore, CA 94550, Phone: (925) 422-4599.

Livermore Public Library, 1188 S. Livermore Avenue, Livermore, CA 94550, Phone: (925) 373-5500.

Tracy Public Library, 20 East Eaton Avenue, Tracy, CA 95376, Phone: (209) 937-8221.

Georgia

Southeastern Power Administration, Technical Library, 1166 Athens Tech Road, Elberton, GA 30635, Phone: (706) 213-3815.

Missouri

Kansas City Public Library, 14 West 10th Street, Kansas City, MO 64105, Phone: (816) 701-3400.

North-East Branch of the Kansas City Library, 6000 Wilson Road, Kansas City, MO 64123, Phone: (816) 701-3485.

Nevada

NNSA Nevada Site Office, Public Reading Room, 755 E. Flamingo Road, Las Vegas, NV 89119, Phone (702) 295-3521.

Tonopah Public Library, 167 S. Central Street, Tonopah, NV 89049, Phone: (775) 482-3374.

Washington, DC

U.S. Department of Energy, Public Reading Room, 1000 Independence Avenue, SW., Washington, DC 20585, Phone: (202) 586-3142.

Background. The national security of the United States requires NNSA to maintain a safe, secure, and reliable nuclear weapons stockpile and core competencies in nuclear weapons. The Nation's national security requirements are established by the President and funded by the Congress, which have assigned to NNSA the responsibility of maintaining a nuclear arsenal and a complex of nuclear facilities capable of supporting this highly technical mission. The Draft Complex Transformation SPEIS is a Supplement to the 1996 Stockpile Stewardship and Management Programmatic Environmental Impact Statement, which analyzed programmatic alternatives for the weapons complex in the absence of nuclear testing. NNSA maintains the safety, security, and reliability of nuclear weapons through the Stockpile Stewardship Program. This program currently involves integrated activities at three NNSA national laboratories, four industrial plants, and a nuclear weapons test site. The effects of old facilities, aging weapons, and evolving national security requirements have led NNSA to propose further changes to the Complex in order to create a smaller and more responsive, efficient, and secure infrastructure, especially with regards to special nuclear materials (SNM).¹

Today's Complex consists of eight major sites located in seven states, and the Tonopah Test Range (TTR). It enables NNSA to design, develop, manufacture, and maintain nuclear weapons; certify their safety, security, and reliability; conduct surveillance on

them; store Category I/II² quantities of SNM; and dismantle and disposition retired weapons. The major sites within the Complex are the Y-12 National Security Complex (Y-12), Oak Ridge, Tennessee; Savannah River Site (SRS), Aiken, South Carolina; Pantex Plant (Pantex), Amarillo, Texas; Los Alamos National Laboratory (LANL), Los Alamos, New Mexico; Lawrence Livermore National Laboratory (LLNL), Livermore, California; Sandia National Laboratories (SNL), Albuquerque, New Mexico, and other locations; Nevada Test Site (NTS), 65 miles northwest of Las Vegas, Nevada; and the Kansas City Plant (KCP), Kansas City, Missouri.

NNSA conducted a public scoping process that began with the publication of a Notice of Intent (NOI) in the **Federal Register** on October 19, 2006 (71 FR 61731), in which NNSA announced it intended to prepare a SPEIS and invited public comment on the scope of the environmental review. In the NOI, NNSA's proposed action was referred to as Complex 2030. NNSA now believes that the term Complex Transformation better reflects the proposed action and alternatives evaluated because NNSA anticipates that it would be able to accomplish much of the proposed transformation in the next decade (i.e., well before 2030). The NOI also announced the schedule for public scoping meetings that were held in November and December 2006, near sites that might be affected by continued transformation of the Complex and in Washington, DC. In addition to the meetings, the public was encouraged to provide comments via mail, e-mail, and fax. More than 33,000 comment documents were received from individuals, interested groups, Federal, state, and local officials, and Tribes during the scoping period. All comments received during the 90-day public scoping period were considered by NNSA in preparing the Draft Complex Transformation SPEIS. All late comments received were also reviewed and, in general, determined to be similar to comments submitted within the 90-day period. NNSA's development and analysis of alternatives for the SPEIS reflect consideration of these comments.

The Draft Complex Transformation SPEIS analyzes two proposed actions. The first proposed action would restructure SNM facilities (facilities that use plutonium and highly enriched uranium to produce components for the nuclear weapons stockpile). The second

¹ As defined in Section 11 of the *Atomic Energy Act of 1954*, SNM is: (1) Plutonium, uranium enriched in the isotope 233 or in the isotope 235; or (2) any material artificially enriched by any of the foregoing and any other material which the U.S. Nuclear Regulatory Commission determines to be special nuclear material.

² Special nuclear materials are grouped into Security Categories I, II, III, and IV based on the type, attractiveness level, and quantity of the materials. Categories I and II require the highest level of security.

proposed action would restructure research and development (R&D) and testing facilities. These two proposed actions differ in their magnitude and timing. The alternatives for restructuring SNM facilities, which would take 10 years or more, are necessarily broad and address issues such as where to locate these facilities and whether to construct new facilities or renovate existing ones for these functions. As such, the Draft Complex Transformation SPEIS analysis is "programmatic" for the proposed action of restructuring SNM facilities. Tiered, project-specific NEPA documents would likely be needed to inform decisions unless existing site-wide EIS's or other NEPA documents were sufficient.

In comparison, NNSA proposes to pursue restructuring of R&D and testing facilities in the near-term, independent of decisions it may make as to restructuring of SNM facilities. The proposed action to restructure R&D and testing facilities would likely not require further NEPA documentation to implement decisions after NNSA issues the Final Complex Transformation SPEIS and Record of Decision.

The alternatives for restructuring SNM facilities are: (1) No Action; (2) Distributed Centers of Excellence; (3) Consolidated Centers of Excellence; and (4) Capability-Based. Common to each of these are alternatives to consolidate storage of certain SNM. The No Action Alternative represents continuation of the status quo including implementation of decisions already made on the basis of prior NEPA analyses. Under the No Action Alternative, NNSA would not make major changes to the missions assigned to NNSA sites.

The Distributed Centers of Excellence Alternative retains the three major SNM functions (plutonium, uranium, and weapon assembly/disassembly) involving Category I/II quantities of SNM at up to three sites. This alternative would create a consolidated plutonium center for R&D, storage, processing, and manufacture of plutonium parts for nuclear weapons. The following sites are evaluated for the consolidated plutonium center: Los Alamos, NTS, Pantex, SRS, and Y-12. Uranium storage and operations (including the storage and use of highly enriched uranium) would remain at Y-12. Weapons assembly, disassembly, and high explosive fabrication would remain at Pantex.

The Consolidated Centers of Excellence Alternative consolidates the three major SNM functions (plutonium, uranium, and weapon assembly/disassembly) involving Category I/II

quantities of SNM at one or two sites. The single site option is referred to as the Consolidated Nuclear Production Center option and the two site option is referred to as the Consolidated Nuclear Center option. Three major facilities are involved in this alternative: a Consolidated Plutonium Center, a Consolidated Uranium Center, and an assembly/disassembly/high explosives facility, which would assemble and disassemble nuclear weapons, and fabricate high explosives. The following sites are evaluated for these facilities: Los Alamos, NTS, Pantex, SRS, and Y-12.

Under the Capability-Based Alternative, NNSA would maintain basic capabilities for manufacturing components for all stockpile weapons, as well as laboratory and experimental capabilities to support stockpile decisions, but would reduce production capabilities at existing or planned facilities. Under this alternative, pit production at LANL would not be expanded beyond a capability to provide 50 pits³ per year. Production capacities at Pantex, Y-12, and SRS (tritium production) would be reduced to capability-based levels.

To consolidate Category I/II quantities of SNM, NNSA proposes to remove Category I/II SNM from LLNL by approximately 2012, and phase-out operations at LLNL involving Category I/II quantities of SNM.⁴ NNSA is also proposing to transfer more than 10,000 pits currently stored at Pantex in Zone 4 to Zone 12, enabling all Category I/II quantities of SNM at Pantex to be consolidated into a central location, close to assembly, modification, and disassembly operations.

For the proposed action to restructure R&D and testing facilities, the alternatives focus on immediate options to consolidate, relocate, or eliminate duplicative facilities and programs and to improve operating efficiencies. The following five functional capabilities are evaluated for this proposed action: tritium R&D; high explosives R&D; hydrodynamic testing; major environmental testing; and flight test operations. The sites potentially affected by decisions regarding these alternatives are: LANL, LLNL, SNL, NTS, Pantex,

³ A pit is the central core of a nuclear weapon, typically containing plutonium-239, that undergoes fission when compressed by high explosives.

⁴ The LLNL Site-wide EIS (DOE/EIS-0348 and DOE/EIS-0236-S3, March 2005) assesses the environmental impacts of transporting SNM to and from LLNL and other sites as part of the proposed action, which NNSA decided to implement (70 FR 71491, November 29, 2005). That analysis includes consideration of transportation actions involving greater quantities of SNM and more shipments than are identified in this draft SPEIS.

TTR, SRS, Y-12, and the White Sands Missile Range (WSMR). The WSMR, located in south-central New Mexico, is the largest installation in the Department of Defense. WSMR is being considered as a location for NNSA's flight test operations that are now conducted at TTR. Alternatives to relocate the current non-nuclear component design and engineering work at SNL/California also are being evaluated in this proposed action.

While NNSA has proposed to modernize its facilities that produce non-nuclear components in Kansas City, Missouri, this proposal is evaluated in a separate NEPA analysis. The General Services Administration (GSA), as the lead agency, and NNSA, as a cooperating agency, announced the availability of a draft Environmental Assessment on December 10, 2007 (72 FR 69690) that evaluates the potential environmental impacts of a proposal for GSA to procure the construction of a new facility to house NNSA's procurement and manufacturing operations for non-nuclear components. A recent analysis demonstrates that transferring non-nuclear operations outside of the Kansas City area is not cost effective. Whether non-nuclear operations remain at the current Kansas City Plant or move to a new facility in the vicinity of Kansas City would not affect nor be affected by decisions NNSA makes regarding alternatives evaluated in the Draft Complex Transformation SPEIS.

Other Federal Agency Involvement. The Department of the Air Force and U.S. Army Garrison White Sands are cooperating agencies in the preparation of the Draft Complex Transformation SPEIS.

Issued in Washington, DC, on January 7, 2008.

Thomas P. D'Agostino,
Administrator, National Nuclear Security Administration.

BILLING CODE 6450-01-P

ENVIRONMENTAL PROTECTION AGENCY

[ER-FRL-6694-9]

Environmental Impact Statements and Regulations; Availability of EPA Comments

Availability of EPA comments prepared pursuant to the Environmental Review Process (ERP), under section 309 of the Clean Air Act and section 102(2)(c) of the National Environmental Policy Act as amended. Requests for

long-range spectrum planning and policy reforms for expediting the American public's access to broadband services, public safety, and digital television. The Committee functions solely as an advisory body in compliance with the FACA.

Matters to Be Considered: The Committee will receive recommendations and reports from working groups of its Technical Sharing Efficiencies subcommittee and Operational Sharing Efficiencies subcommittees. It will consider matters to be taken up at its next meeting. It will also provide an opportunity for public comment on these matters.

Time and Date: The meeting will be held on April 30, 2008, from 1:30 p.m. to 3:30 p.m. Eastern Daylight Time. These times and the agenda topics are subject to change. Please refer to NTIA's web site, <http://www.ntia.doc.gov>, for the most up-to-date meeting agenda.

Place: U.S. Department of Commerce Herbert C. Hoover Building, 1401 Constitution Avenue N.W., Room 1412, Washington, DC 20230. The meeting will be open to the public and press on a first-come, first-served basis. Space is limited. When arriving for the meeting, attendees must present photo or passport identification and/or a U.S. Government building pass, if applicable, and should arrive at least one-half hour prior to the start time of the meeting. The public meeting is physically accessible to people with disabilities. Individuals requiring special services, such as sign language interpretation or other ancillary aids, are asked to notify Mr. Gattuso, at (202) 482-0977 or jgattuso@ntia.doc.gov, at least five (5) business days before the meeting.

Status: Interested parties are invited to attend and to submit written comments. Interested parties may file written comments with the Committee at any time before or after a meeting. If interested parties wish to submit written comments for consideration by the Committee in advance of this meeting, comments should be sent to the above-listed address and must be received by close of business on April 23, 2008, to provide sufficient time for review. Comments received after April 23, 2008, will be distributed to the Committee but may not be reviewed prior to the meeting. It would be helpful if paper submissions also include a three and one-half inch computer diskette in HTML, ASCII, Word or WordPerfect format (please specify version). Diskettes should be labeled with the name and organizational affiliation of the filer, and the name of the word processing program used to create the document. Alternatively, comments

may be submitted electronically to spectrumadvisory@ntia.doc.gov. Comments provided via electronic mail may also be submitted in one or more of the formats specified above.

Records: NTIA is keeping records of all Committee proceedings. Committee records are available for public inspection at NTIA's office at the address above. Documents including the Committee's charter, membership list, agendas, minutes, and any reports are or will be available on NTIA's Committee web site at <http://www.ntia.doc.gov/advisory/spectrum>.

Dated: April 8, 2008.

Kathy D. Smith,

Chief Counsel, National Telecommunications and Information Administration.

DEPARTMENT OF ENERGY

Extension of Comment Period for the Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement

AGENCY: National Nuclear Security Administration, Department of Energy.

ACTION: Extension of Comment Period for the Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement.

SUMMARY: On January 11, 2008, NNSA published a Notice of Availability and Public Hearings for the Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement (Draft Complex Transformation SPEIS, DOE/EIS-0236-S4; 73 FR 2023). That notice invited public comment on the Draft Complex Transformation SPEIS through April 10, 2008. NNSA has extended the public comment period through April 30, 2008.

DATES: NNSA invites comments on the Draft Complex Transformation SPEIS through April 30, 2008. NNSA will consider comments received after this date to the extent practicable as it prepares the Final Complex Transformation SPEIS.

ADDRESSES: Written comments on the Draft Complex Transformation SPEIS, as well as requests for additional information and requests for copies of the Draft Complex Transformation SPEIS, should be directed to Mr. Theodore A. Wyka, Complex Transformation Supplemental PEIS Document Manager, Office of Transformation (NA-10.1), National Nuclear Security Administration, U.S. Department of Energy, 1000

Independence Avenue, SW., Washington, DC 20585. Comments also may be submitted by facsimile to 1-703-931-9222, or by e-mail to complextransformation@nnsa.doe.gov. Please mark correspondence "Draft Complex Transformation SPEIS Comments."

SUPPLEMENTARY INFORMATION: On January 11, 2008, NNSA published a Notice of Availability and Public Hearings for the Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement (Draft Complex Transformation SPEIS, DOE/EIS-0236-S4; 73 FR 2023). That notice invited public comment on the Draft Complex Transformation SPEIS through April 10, 2008. In response to public requests, NNSA has extended the public comment period through April 30, 2008. NNSA will consider comments received after this date to the extent practicable as it prepares the Final Complex Transformation SPEIS.

The Draft Complex Transformation SPEIS and additional information regarding complex transformation are available on the Internet at <http://www.ComplexTransformationSPEIS.com> and <http://www.nnsa.doe.gov>.

Issued in Washington, DC, on April 9, 2008.

NEPA DISCLOSURE STATEMENT FOR PREPARATION OF THE *COMPLEX TRANSFORMATION SUPPLEMENTAL PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT*

CEQ Regulations at 40 CFR 1506.5(c), which have been adopted by the DOE (10 CFR 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term “financial interest or other interest in the outcome of the project” for purposes of this disclosure is defined in the March 23, 1981 guidance “Forty Most Asked Questions Concerning CEQ’s National Environmental Policy Act Regulations,” 46 FR 8026-18038 at Question 17a and b.

“Financial or other interest in the outcome of the project” includes “any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm’s other clients).” 46 FR 18026-18038 at 18031.

In accordance with these requirements, the offeror and any proposed subcontractors hereby certify as follows: (check either (a) or (b) to assure consideration of your proposal).

- (a) X Offeror and any proposed subcontractor have no financial or other interest in the outcome of the project.
- (b) Offeror and any proposed subcontractor have the following financial or other interest in the outcome of the project and hereby agree to divest themselves of such interest prior to award of this contract.

ABSTRACT: The National Nuclear Security Administration (NNSA), an agency within the Department of Energy, has the responsibility to maintain the safety, security, and reliability of the United States' nuclear weapons stockpile. This Complex Transformation Supplemental Programmatic Environmental Impact Statement (SPEIS) analyzes the potential environmental impacts of reasonable alternatives to continue transformation of the nuclear weapons complex to be smaller, and more responsive, efficient, and secure in order to meet national security requirements. The current Complex consists of sites located in seven states (California, Missouri, Nevada, New Mexico, South Carolina, Tennessee, and Texas). This SPEIS evaluates alternatives that would restructure special nuclear materials manufacturing and research and development facilities; consolidate special nuclear materials throughout the Complex; consolidate, relocate, or eliminate duplicative facilities and programs and improve operating efficiencies; and identify one or more sites for conducting NNSA flight test operations.

COOPERATING AGENCIES: The Department of the Air Force and the U.S. Army Garrison White Sands are cooperating agencies in the preparation of this Complex Transformation SPEIS.

PUBLIC COMMENTS: The Draft Complex Transformation SPEIS was issued for public review and comment on January 11, 2008. Comments on the Draft SPEIS were requested during a period of 90 days following publication of the U.S. Environmental Protection Agency's (EPA's) Notice of Availability in the *Federal Register*. Twenty public hearings to solicit comments on the Draft SPEIS were held during the public comment period. Prior to the end of this comment period, NNSA extended the public comment period by 20 additional days, until April 30, 2008. All comments received during the comment period were considered during preparation of the Final SPEIS. Late comments were also considered, to the extent practicable.

The Final SPEIS contains revisions and new information based in part on comments received on the Draft SPEIS. Vertical change bars in the margins indicate the locations of these revisions and new information. Volume 3 contains the comments received during the public comment period on the Draft SPEIS and NNSA's responses to the comments. NNSA will use the analysis presented in this Final SPEIS, as well as other information, in preparing the Record(s) of Decision (RODs) regarding Complex Transformation. NNSA will issue one or more RODs no sooner than 30 days after the EPA publishes a Notice of Availability of this Final SPEIS in the *Federal Register*. This document and related information are available on the Internet at www.ComplexTransformationSPEIS.com.

Final Complex Transformation Supplemental Programmatic Environmental Impact Statement

Summary

October 2008

Prepared by:

National Nuclear Security Administration
U.S. Department of Energy

Summary

S.1 INTRODUCTION

This *Complex Transformation Supplemental Programmatic Environmental Impact Statement*¹ (SPEIS) evaluates alternatives for transforming the nuclear weapons complex (Complex) into a smaller, more efficient enterprise that can respond to changing national security challenges. A more responsive enterprise would help ensure the long-term safety, security, and reliability of the nuclear weapons stockpile while reducing the possibility that the United States (U.S.) would need to resume nuclear testing. These changes would build upon decisions made in the 1990s following the end of the Cold War and the cessation of U.S. nuclear weapons testing.

National security policies require the U.S. Department of Energy (DOE), through the National Nuclear Security Administration (NNSA), to maintain the U.S. nuclear weapons stockpile,² as well as core competencies in nuclear weapons.³ Since completion in 1996 of the *Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (SSM PEIS, DOE 1996d) and associated Record of Decision (ROD), DOE has implemented these policies through the Stockpile Stewardship Program (SSP).⁴ The SSP emphasizes development and application of greatly improved scientific and technical capabilities to assess the safety, security, and reliability of existing nuclear warheads without the use of nuclear testing. Throughout the 1990s, DOE also took steps to consolidate the Complex from 12 sites to its current configuration of three national laboratories (plus an associated flight test range), four industrial plants, and a nuclear test site, as shown in Figure S.1-1.

National Nuclear Security Administration

Established by Congress in 2000, the National Nuclear Security Administration (NNSA) is a separately organized agency within the U.S. Department of Energy (DOE).

NNSA's primary mission is to provide the U.S. with safe, secure, and reliable nuclear weapons and to maintain core competencies in nuclear weapons. The NNSA needs a nuclear weapons enterprise with facilities capable of supporting this highly technical mission.

NNSA also has complementary missions in nuclear nonproliferation programs, excess fissile materials disposition, and provision of naval nuclear propulsion systems.

NNSA now proposes to continue the transformation of the Complex by further consolidating operations, which could result in the relocation of activities among sites. These changes, particularly alternatives that involve the construction or modification of major nuclear facilities, could have environmental impacts. These changes could also produce significant benefits, including improved safety, security, and environmental systems, reduced operating costs, and greater responsiveness to future changes in national

¹ In the Notice of Intent to prepare this SPEIS (71 FR 61731), NNSA's proposed action was referred to as "Complex 2030." NNSA now believes that the term Complex Transformation better reflects the proposed changes and alternatives evaluated, and has renamed this document the Complex Transformation SPEIS.

² The nuclear weapons stockpile consists of nuclear weapons that are both deployed to the military services ("operationally-deployed") and "reserve weapons" that could be used to augment the operationally-deployed weapons or to provide replacements for warheads that experience safety or reliability problems.

³ Core competencies in nuclear weapons include research, design, development, and testing (including the ability to conduct nuclear testing); reliability assessment; certification; manufacturing; and surveillance capabilities.

⁴ In 1996, the program was named the Stockpile Stewardship and Management Program. It is now called the Stockpile Stewardship Program. There has been no change in the content or purpose of the program.

security policy. NNSA's preferred alternatives (described in Section S.3.17) would achieve these benefits.

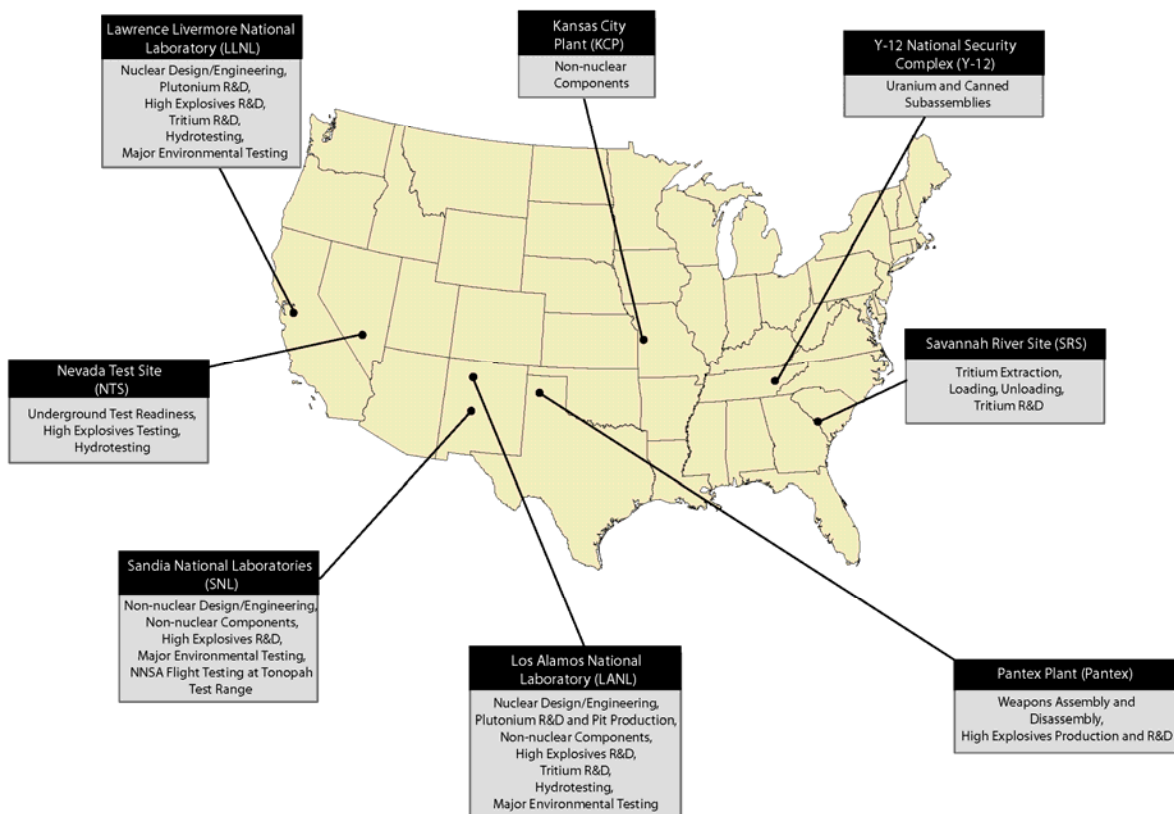

Figure S.1-1—Nuclear Weapons Complex Sites and Current Major Responsibilities

The alternatives analyzed in this SPEIS are divided into two categories: programmatic and project-specific. Programmatic alternatives involve the restructuring of facilities that use or store significant (i.e., Category I/II⁵) quantities of special nuclear material (SNM).⁶ These facilities produce plutonium components (commonly called pits), produce highly-enriched uranium (HEU) components and canned subassemblies (CSAs), and assemble and disassemble nuclear weapons (including related high explosive component fabrication).

This SPEIS analyzes the potential environmental impacts of locating these facilities at up to three of five NNSA sites: Los Alamos National Laboratory (LANL) in Los Alamos, New Mexico; Nevada Test Site (NTS) north of Las Vegas, Nevada; Pantex Plant (Pantex) in Amarillo, Texas;

⁵ Special nuclear material is categorized into Security Categories I, II, III, and IV based on the type, attractiveness level, and quantity of material. Categories I and II require the highest level of security.

⁶ As defined in section 11 of the *Atomic Energy Act of 1954*, SNM is: (1) plutonium, uranium enriched in the isotope 233 or in the isotope 235; or (2) any material artificially enriched by any of the foregoing and any other material which the U.S. Nuclear Regulatory Commission determines to be special nuclear material.

Savannah River Site (SRS) in Aiken, South Carolina; and Y-12 National Security Complex (Y-12) in Oak Ridge, Tennessee. The programmatic alternatives include different configurations of facilities (consolidated or distributed) and different capacities (ranging from 200 units per year with multiple shifts to about 10 units per year). A minimum set of fundamental capabilities is required under all alternatives to meet national security requirements. In each of these programmatic action alternatives, NNSA also proposes to consolidate the storage of SNM currently at Pantex.

Based on this SPEIS and other information, NNSA expects to decide where facilities for plutonium, HEU, and assembly/disassembly activities would be located, whether to construct new or renovate existing facilities for these functions, and whether to further consolidate SNM storage. The programmatic alternatives are described in more detail in sections S.3.3 through S.3.7. Any programmatic decisions resulting from this SPEIS may require further project-specific *National Environmental Policy Act* (NEPA) review before implementation.

This SPEIS also analyzes project-specific alternatives to restructure research and development (R&D) and testing facilities. NNSA intends this SPEIS to provide sufficient analysis of potential environmental impacts to enable implementation of decisions related to these project-specific alternatives without further NEPA review. The decisions NNSA expects to make include:

- whether to eliminate or consolidate duplicative facilities for tritium and high explosives R&D, hydrodynamic testing, major environmental test facilities, and certain weapons support functions; where these facilities and operations would be located; and where construction activities might be required for future operations; and
- where to conduct NNSA flight test operations for gravity weapons.

The project-specific alternatives are described in sections S.3.8 through S.3.13.

The potential environmental impacts of each alternative are summarized in Section S.3.16 and discussed in detail in Chapter 5. NNSA has identified its preferred programmatic and project-specific alternatives in this Final SPEIS. These are described in Section S.3.17.

S.1.1 Relevant History

In 1996, DOE prepared the SSM PEIS, which evaluated alternatives for maintaining the safety and reliability of the U.S. nuclear weapons stockpile and preserving competencies in nuclear weapons in the post-Cold War era. The SSM PEIS ROD (61 FR 68014) documented important decisions related to fulfilling these requirements without underground nuclear testing. Since issuing that ROD, NNSA has been implementing those decisions.

In the 1996 SSM PEIS, no new production facilities were proposed. The enduring types of weapons in the stockpile were at the mid-point of their anticipated design life of 20-25 years, and the life extension program plans for the enduring weapons were not yet fully developed. The weapons in the stockpile are now more than a decade older than when the SSM PEIS was prepared. Because the U.S. will maintain a nuclear deterrent in the form of a safe, secure, and

reliable stockpile with the smallest number of weapons possible, NNSA needs to preserve its core competencies in nuclear weapons, and invest in some replacement nuclear facilities for research and production. Because these major nuclear facilities are more than 50 years old, the ability to keep them safe, secure, and performing within realistic economic constraints is declining.

The 2001 Nuclear Posture Review⁷ concluded that a nuclear deterrent relying on a balance of capabilities and a smaller deployed weapons stockpile would provide a credible deterrent in a future of uncertain and evolving threats. The Nuclear Posture Review was the foundation for the *Moscow Treaty*,⁸ which was ratified by the U.S. and Russia in 2003. Implementation of the *Moscow Treaty* is cutting the U.S. nuclear weapons stockpile to about one-half the size in the *Strategic Arms Reduction Treaty II*, which was ratified by the U.S. in 1996 and Russia in 2000. To achieve the new balance between a responsive infrastructure and deployed stockpile size, one of the main purposes of the proposed actions in this SPEIS is to make the Complex more responsive. As discussed in Section S.2.1, responsiveness means the ability to successfully execute requirements of the national security mission on schedule and to efficiently react to new developments. A transformed Complex with demonstrated capabilities would ensure that the nation's nuclear deterrent would remain credible, and could support additional reductions in the stockpile, if directed by the President. A transformed Complex is also expected to be safer, more secure, and less costly to maintain.

S.1.2 Proposed Approach to Transformation of the Complex

In 2006, NNSA developed a planning scenario for the future of the Complex (NNSA 2006). This was a continuation of NNSA's effort to establish a Complex that is more responsive to changing national security requirements, as determined by the President and Congress, and that is operated as efficiently as possible. Accordingly, NNSA developed the planning scenario after evaluating how significant economic and security benefits could be realized if the Complex were reduced in size, capacity, number of sites with Category I/II SNM (and locations of Category I/II SNM within sites), and redundant activities at facilities eliminated—in other words, whether and how the Complex could be made more secure and efficient.

NNSA's proposed approach to continuing transformation of the Complex builds on existing programs and management structures, so that transformation can be accomplished within currently projected funding levels as much as practicable. The cost and potential environmental impacts of the alternative actions in this SPEIS are primarily associated with the potential construction of replacement nuclear facilities. Thus, a wide range of alternative configurations for these nuclear facilities is being evaluated from an economic perspective. NNSA has completed economic studies of the alternatives (TechSource 2007a, 2007b, 2007c, 2007d, 2008a, 2008b, 2008c, 2008d, 2008e, 2008f, 2008g).

⁷ The Nuclear Posture Review is a classified report prepared by the Department of Defense that establishes the broad outline for future U.S. nuclear strategy, force levels, and infrastructure.

⁸ Treaty Between the United States of America and the Russian Federation on Strategic Offensive Reductions

S.1.3 The Nuclear Weapons Complex Today

As shown on Figure S.1-1, the current Complex consists of eight sites located in seven states. The Complex enables NNSA to design, develop, manufacture, maintain, and work on nuclear weapons; certify their safety, security, and reliability; conduct surveillance on weapons in the stockpile; store Category I/II SNM; and dismantle and disposition retired weapons. Major sites within the Complex and their current primary responsibilities are described below.

Y-12 National Security Complex (Y-12) (Oak Ridge, Tennessee) – Y-12 manufactures uranium components for nuclear weapons, cases, and other nuclear weapons components comprising CSAs; evaluates and tests these components; maintains Category I/II quantities of highly-enriched uranium; conducts component dismantlement, storage, and disposition of their nuclear materials; and supplies highly-enriched uranium for use in naval reactors.

Savannah River Site (SRS) (Aiken, South Carolina) – SRS extracts tritium and performs loading, unloading, surveillance of tritium reservoirs, and conducts tritium R&D.⁹ SRS does not maintain Category I/II quantities of SNM associated with NNSA weapons activities, but does maintain Category I/II quantities of SNM associated with other DOE activities.

Pantex Plant (Pantex) (Amarillo, Texas) – Pantex dismantles retired weapons; fabricates high-explosive (HE) components and performs HE R&D; assembles HE, nuclear, and non-nuclear components into nuclear weapons; work on and modifies weapons; performs non-intrusive pit modification;¹⁰ and evaluates and performs surveillance of weapons. Pantex maintains Category I/II quantities of SNM for the weapons program and stores SNM in the form of surplus plutonium pits pending transfer to SRS for disposition.

Kansas City Plant¹¹ (KCP) (Kansas City, Missouri) – KCP manufactures and procures non-nuclear weapons components, and evaluates and tests these weapons components. KCP has no SNM.

Los Alamos National Laboratory (LANL) (Los Alamos, New Mexico) – LANL conducts research, design, and development of nuclear weapons; designs and tests advanced technology concepts; provides safety, security, and reliability assessments and certification of stockpile weapons; maintains production capabilities for limited quantities of plutonium components (i.e., pits) for delivery to the stockpile; manufactures nuclear weapon detonators for the stockpile; conducts plutonium and tritium R&D, hydrotesting, HE R&D, and environmental testing; and maintains Category I/II quantities of SNM.

⁹ Tritium is an isotope of hydrogen produced in nuclear reactors and used in nuclear weapons. Because of its short half-life, tritium must be replenished routinely. The Watts Bar Nuclear Power Plant (Spring City, Tennessee) is a commercial nuclear power plant owned and operated by the Tennessee Valley Authority (TVA) which produces tritium that is extracted from target rods at SRS. As a commercial power station, the Watts Bar Plant is not considered part of the nuclear weapons complex.

¹⁰ A pit is the central core of a nuclear weapon, usually made of plutonium or enriched uranium. Non-intrusive pit modification is modification to the external surfaces and features of a pit.

¹¹The General Services Administration (GSA), as the lead agency, and NNSA, as a cooperating agency, prepared an Environmental Assessment and Finding of No Significant Impact regarding the potential environmental impacts of moving the facilities and infrastructure for the non-nuclear production activities conducted at the KCP to a number of locations (GSA 2008). This SPEIS does not assess alternatives for the activities conducted at the KCP (see Section S.3.2.10 and Section 1.5.2.1).

Lawrence Livermore National Laboratory (LLNL) (Livermore, California) – LLNL conducts research, design, and development of nuclear weapons; designs and tests advanced technology concepts; provides safety, security, and reliability assessments and certification of stockpile weapons; conducts plutonium and tritium R&D, hydrotesting, HE R&D, and environmental testing; and maintains Category I/II quantities of SNM.

Sandia National Laboratories (SNL) (Albuquerque, New Mexico; Livermore, California; and other locations) – SNL conducts systems engineering of nuclear weapons; conducts research, design, and development of non-nuclear components; manufactures non-nuclear weapons components including neutron generators for the stockpile; provides safety, security, and reliability assessments of stockpile weapons; and conducts HE R&D and environmental testing. In 2008, SNL/NM completed removal of its Category I/II SNM. It no longer stores or uses Category I/II SNM on a permanent basis, although it may use Category I/II SNM for limited activities in the future. The principal laboratory is located in Albuquerque, New Mexico (SNL/NM); a division of the laboratory (SNL/CA) is located in Livermore, California. SNL also operates the Tonopah Test Range (TTR) near Tonopah, Nevada, for flight testing of gravity weapons. No Category I/II quantities of SNM are permanently maintained at the TTR, although some test operations have involved SNM.

Nevada Test Site (NTS) (65 miles northwest of Las Vegas, Nevada) – NTS maintains the capability to conduct underground nuclear testing; conducts high hazard experiments involving nuclear material and high explosives; provides the capability to disposition a damaged nuclear weapon or improvised nuclear device; conducts non-nuclear experiments; conducts hydrotesting and HE testing; conducts research and training on nuclear safeguards, criticality safety, and emergency response; and maintains Category I/II quantities of SNM.

S.1.4 Public Participation

The process of preparing an environmental impact statement provides opportunities for public involvement. These opportunities occur during the scoping process and the public comment period. The scoping process is required by 40 CFR 1501.7 and 10 CFR Part 311, while the public comment period is required by 40 CFR 1503.1 and 10 CFR Part 313. Section S.1.4.1 summarizes the scoping process, major comments received from the public during scoping, and changes made by NNSA in response to those comments. Section S.1.4.2 summarizes the public comment period process, the major comments raised by the public at that time, and NNSA's responses to these comments. Volume III, Parts 1 and 2 of the SPEIS (Comment Response Document) considers all of the comments that were submitted on the Draft SPEIS and NNSA's responses.

S.1.4.1 Scoping Process

The Council on Environmental Quality (CEQ) NEPA regulations require “an early and open process for determining the scope of issues to be addressed in an EIS and for identifying the significant issues related to a proposed action” (40 CFR 1501.7). This is known as the public scoping process. The purpose of this scoping process is to: (1) inform the public about the

proposed action and the alternatives being considered, and (2) identify and clarify issues by soliciting public comments.

NNSA published a Notice of Intent (NOI) in the *Federal Register* on October 19, 2006 (71 FR 61731) and held public scoping meetings in November and December 2006 near all sites that might be affected and in Washington, D.C. In addition to the meetings, the public was encouraged to provide comments via mail, e-mail, and fax. All comments received during the 90-day scoping period, as well as late comments, were reviewed by NNSA in preparing the Draft Complex Transformation SPEIS.

More than 33,000 comment documents were received from individuals, interested groups, tribes, and Federal, State, and local officials during the public scoping period. A majority of the documents received were copies of 20 different form letters or e-mail campaigns. A summary of the major scoping comments is provided below and in more detail in Appendix D.

S.1.4.1.1 Summary of Major Scoping Comments

The majority of the comments received during scoping were related to nuclear weapon policies. Many commentors expressed opposition to the nuclear weapons program, stating that the United States is violating the *Nuclear Non-Proliferation Treaty* (NPT). Many of the comments stated that NNSA should assess an additional alternative—disarmament in compliance with the NPT—and not design or build new nuclear weapons. Commentors expressed opposition to any new nuclear facilities. There was specific opposition to expansion of pit production at LANL, as well as the proposed consolidated plutonium center (CPC). Commentors stated that the *Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory* (LANL SWEIS) should be issued after the Complex Transformation SPEIS. Many commentors stated that a reliable replacement warhead (RRW) was not needed and should not be pursued. Some commentors stated that NNSA should develop a fair and objective statement for the purpose and need that takes into account the broader missions of NNSA, including prevention of proliferation, implementation of the NPT, and development of strategies to ensure the peaceful denuclearization of the world. Some commentors asked why NNSA was not assessing a consolidated nuclear production center (CNPC) (one site for plutonium, enriched uranium, and weapons assembly/disassembly) as a reasonable alternative for transforming the Complex. Commentors also stated that pits will last up to 100 years and potentially longer; therefore, there is no need for new pit production capacity. Some commentors asked why KCP's activities were not being considered in this SPEIS and stated that NNSA was not representing the full cost of Complex Transformation by excluding alternatives involving activities currently performed there. Commentors requested an analysis of the risks and impacts of terrorist attacks on NNSA facilities. Support for the continuation of the NNSA flight test mission at TTR was received from the Tonopah community.

As a result of the scoping process, NNSA made the following significant changes to the scope of the SPEIS as originally described in the 2006 NOI:

- A Consolidated Centers of Excellence (CCE) Alternative was added as a reasonable alternative (Section 3.5). Under this alternative, NNSA would consolidate plutonium,

uranium, and weapon assembly/disassembly functions into a CNPC at one site or into Consolidated Nuclear Centers (CNCs) at two sites.

- A discussion was added of effects on the Complex of an even smaller nuclear weapons stockpile than the current level envisioned under the *Moscow Treaty* (Section 3.6.3).
- A discussion was added of an RRW's possible impact on the nuclear weapons stockpile and decisions about Complex Transformation. An analysis was added to determine what, if any, changes to the Complex would be required if an RRW were to be developed (Chapter 2).
- A more detailed analysis of the potential impacts of NNSA flight testing was added in order to inform the public and NNSA of the potential socioeconomic impacts on the Tonopah community from the alternatives (Section 5.15.4.2).
- An analysis of a smaller pit production capacity (50–80 pits per year) was added (Section 3.4.1.2).
- A more detailed explanation of why the KCP's operations are not included in this SPEIS was added (Section 1.5.2.1).

Each of these changes was included in the Draft SPEIS issued for public review

S.1.4.2 *Public Comments on the Draft SPEIS*

Once a draft environmental impact statement is prepared, regulations require that it be issued to obtain public comments (40 CFR 1503.1). On January 11, 2008, NNSA announced a 90-day public comment period— twice the legal requirement —for the Draft Complex Transformation SPEIS beginning on January 11, 2008, and scheduled to end on April 10, 2008 (73 FR 2023). In response to public requests, on April 11, 2008, NNSA announced in the *Federal Register* that it was extending the comment period until April 30, 2008 (73 FR 19829). All comments received were considered.

During the comment period, NNSA held 20 public hearings in the following locations: North Augusta, SC (two hearings), Oak Ridge, TN (two hearings), Amarillo, TX (two hearings), Tonopah, NV (one hearing), Las Vegas, NV (two hearings), Socorro, NM (one hearing), Albuquerque, NM (two hearings), Los Alamos, NM (two hearings), Santa Fe, NM (one hearing), Tracy, CA (one hearing), Livermore, CA (two hearings), Washington, D.C. (one hearing), and Española, NM (one hearing). Figure S.1.4.2-1 shows the locations and dates of the hearings. In addition, NNSA encouraged the public to provide comments via mail, facsimile, or electronically via e-mail or the project Web site (www.ComplexTransformationSPEIS.com).

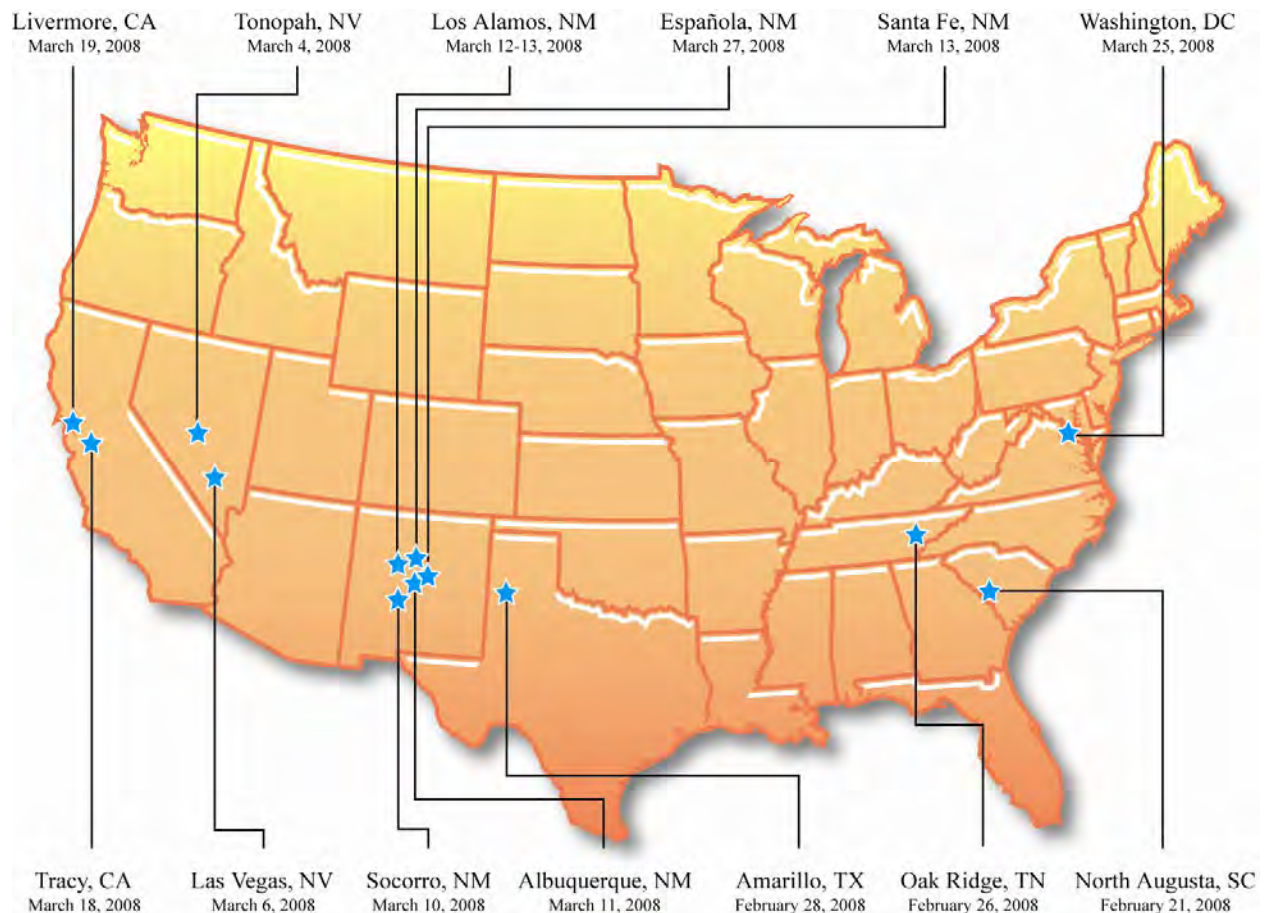

Figure S.1.4.2-1—Public Hearing Locations and Dates

S.1.4.2.1 Summary of Major Comments Received During the Public Comment Period on the Draft Complex Transformation SPEIS

NNSA received approximately 100,000 comment documents (including approximately 98,000 comment documents as part of 38 e-mail, letter, and postcard campaigns) from individuals, interested groups, tribal governments, and Federal, State, and local agencies during the comment period. Approximately 1,000 comment documents were received via e-mail, and approximately 625 commenters spoke at the public hearings. The majority of the comments focused on policy issues related to the appropriateness or the need for nuclear weapons:

- Many commenters oppose nuclear weapons and transformation of the nuclear weapons Complex. They state that:
 - The United States is not in compliance with Article VI of the NPT;
 - Nuclear weapons lead to nuclear weapons proliferation;
 - Nuclear weapons are immoral;
 - Nuclear weapon activities put NNSA sites and surrounding communities at risk of accidents and terrorist activities;

- Nuclear weapons take money away from the clean-up of sites already contaminated;
 - More nuclear weapon activities will produce contamination at NNSA sites; and
 - Nuclear weapon activities result in adverse health and safety impacts in communities surrounding NNSA sites.
-
- Many commentors stated that the 2001 Nuclear Posture Review does not reflect the changed threat environment since September 11, 2001, and should not be used by NNSA in establishing or defining programmatic requirements. Commentors stated that Complex Transformation should not proceed before a new Nuclear Posture Review is completed in 2009 by the incoming Administration, as required by the Congress. NNSA's "transformation" proposal should be withdrawn until then.
 - Many commentors believe that there are better ways in which taxpayer money could be spent, such as: feeding the poor, providing better housing, improving energy efficiency, and cleaning up contaminated sites.
 - Many commentors stated that there was no need to build any nuclear weapons and NNSA failed to consider an alternative that would provide a nuclear weapons complex that would not manufacture them. Many commentors stated that NNSA should operate only those facilities needed for the safe, secure, and efficient dismantlement of nuclear weapons and the disposition of their parts. Many commentors stated that NNSA should include a No Production Alternative under which NNSA would pursue dismantlement and refrain from further weapons design and production.
 - Many commentors questioned the need for new pit production.
 - Many commentors oppose an RRW Program. Many commentors believe an RRW Program was just an excuse to develop new design nuclear weapons.
 - Many commentors stated that the activities at the Kansas City Plant (KCP) should be included in the SPEIS. Commentors stated that KCP is an integral part of the nuclear weapons complex and therefore alternatives for its modernization should be considered in the SPEIS rather than in a separate environmental assessment. By excluding alternatives for activities currently performed at KCP, commentors stated that NNSA was not accurately representing the impacts of the entire nuclear weapons complex.
 - Several Native American groups (the Santa Clara Pueblo, Pueblo de San Ildefonso, and the Western Shoshone National Council) submitted comments on the Draft SPEIS. Some of the major comments from these groups focused on the need for government-to-government consultations prior to the issuance of a ROD, and a more detailed analysis of environmental impacts on tribal lands that cannot be avoided. In addition, the Santa Clara Pueblo commented that the new Administration will be required to perform a new Nuclear Posture Review. The Santa Clara Pueblo also stated that the version of the CAP-88 computer model used to estimate human health impacts was dated, that the newest version should be used, and that even this model does not assess exposure pathways

unique to tribal members (see Section S.1.4.2.2). Other tribal comments stated that the Draft SPEIS ignored past contamination issues, that there is no waste disposal path for transuranic waste, and that impacts to specific tribal lands were not analyzed, especially with respect to rivers and other water resources. The Western Shoshone commented that their treaty claims had not been considered.

S.1.4.2.2 Major Changes from the Draft Complex Transformation SPEIS

In order to: (1) respond to comments received on the Draft Complex Transformation SPEIS; (2) include data not available when the Draft SPEIS was prepared; and (3) correct errors and omissions, NNSA made changes to the Draft SPEIS. The Summary and Volumes I and II of this Final Complex Transformation SPEIS contain changes, which are indicated by a vertical sidebar in the margin. A summary of the more significant changes is provided below.

- In response to numerous comments requesting a No Production Alternative, NNSA added a No Net Production/Capability-Based Alternative to Section 3.6 of the Final SPEIS. Chapter 5 of the SPEIS includes an analysis of the potential impacts of this alternative. Under this alternative, NNSA would maintain capabilities to continue surveillance of the weapons stockpile, produce limited life components, and continue dismantlement, but would not add new types or increased numbers of weapons to the total stockpile.
- Several commentors stated that the cumulative impacts of nuclear-related weapons activities at three sites within a few hundred miles of each other in New Mexico need to be considered, especially since the 50-mile radius analysis of impacts of LANL and SNL/NM overlap. In response to these comments, NNSA added a new section (Section 6.4) to provide more information on the potential cumulative impacts of nuclear activities in New Mexico. This analysis considers nuclear activities at LANL, SNL/NM, the WIPP near Carlsbad, and the National Enrichment Facility in Lea County.
- One commentor noted that NNSA used an outdated version of CAP-88, an atmospheric transport model designed by the U.S. Environmental Protection Agency (EPA), to estimate dose and risk from radionuclide air emissions as part of compliance with the *Clean Air Act*. The Draft SPEIS used EPA's 1992 version of the CAP-88 model (Version 1.0). According to EPA, users "may use any of the three versions of CAP-88 for enforcement purposes. To allow for updates and refinement of the software, Subpart H of 40 CFR Part 61 does not specify any version. However, because Version 3 incorporates the latest science and is more versatile than the older versions, it is recommended" (EPA 2008). In response to this comment, NNSA revised the dose calculations using the CAP-88, Version 3, software. As shown in Chapter 5, all doses from normal operations are expected to remain below regulatory standards.
- NNSA received many comments on the project-specific flight test alternatives. Many commentors stated that an earlier NNSA study indicated that a high-tech mobile option at Tonopah was at least \$20 million less expensive than a high-tech mobile option at the White Sands Missile Range (WSMR). Other commentors stated that NNSA's own business case report states that TTR is the most favorable alternative. Numerous

commentors stated that closure of TTR would result in economic disaster for the community of Tonopah as well as surrounding communities, which rely on the social and health amenities of Tonopah. In response to these comments, NNSA added additional socioeconomic information to Section 5.15.4.2.2, and updated the “Campaign Mode Operation of TTR” alternative. For this alternative, NNSA added several options that would maintain the flight test operations at TTR, but with reduced full-time employment that would be supplemented with staff from SNL/NM and upgraded equipment. Details about this alternative may be found in Section 3.10.3 of the Final SPEIS.

- NNSA received many comments stating that the water usage and quality data for LANL and SRS were outdated and unrepresentative. In response, NNSA revised the water usage and water quality sections at LANL and SRS (sections 4.1.5 and 4.8.5, respectively).
- Several commentors indicated that the presentation of the preferred alternative was confusing and did not provide sufficient specific discussion of the environmental impacts of the alternative compared to others. In response to these comments, NNSA also added Section 5.20, which provides more information on the impacts of the preferred alternative.
- Some commentors stated that tritium production activities should be included in the SPEIS in order to represent the impacts of the entire nuclear weapons complex. Commentors also stated that the Watts Bar reactors are part of the nuclear weapons complex. In response to these comments, NNSA added a summary of the environmental impacts of producing tritium in TVA reactors (Section 5.19).
- Some commentors stated that radiation exposure can also cause nonfatal cancers and genetic disorders, yet the Draft SPEIS only estimates potential fatal cancers. This SPEIS presents estimates of latent cancer fatalities (LCFs) because they are the principal metric for comparing the potential human health effects from low-dose radiation exposure. In response to these comments, NNSA added a discussion in Appendix C regarding nonfatal cancers and genetic effects.
- Several commentors stated that the cumulative impacts of activities at LLNL Site 300 must be analyzed in the Complex Transformation SPEIS. NNSA had filed (now since withdrawn) an application for an air permit with the San Joaquin Valley Air Pollution Control District for increased activities over current levels. Commentors stated that the environmental impacts of these activities, whether conducted by the U.S. Department of Defense (DoD) or the Department of Homeland Security, should be analyzed in the Complex Transformation SPEIS. Even though NNSA recently withdrew this permit application, NNSA added additional discussion of these potential cumulative impacts at LLNL Site 300 (Section 6.5).
- NNSA added an option of constructing a smaller underground storage facility in Zone 12 at Pantex (Section 3.7.3). NNSA would rely on continued storage of surplus pits in existing facilities in Zone 4 at Pantex until they are transferred to SRS for disposition.

- In the Draft SPEIS, a 9,000 square foot addition to the Chemistry and Metallurgy Research Replacement (CMRR) Facility was evaluated as a means to support consolidation of plutonium operations to LANL from LLNL, provide increased analytical chemistry support for increased pit production capacity, and ensure sufficient nuclear space as a contingency. Subsequent to that assessment, NNSA decided that the 9,000 additional square feet would be unnecessary for the consolidation of plutonium activities. Therefore, an addition of 9,000 square feet to the CMRR is no longer being pursued.
- The preferred alternatives are the same as the preferred alternatives identified in the Draft SPEIS, with the following exceptions:
 - For plutonium manufacturing and R&D, the Draft SPEIS identified a production capacity of up to 80 pits per year. In the Final SPEIS, NNSA has stated that until completion of a new Nuclear Posture Review in 2009 or later, the net production at Los Alamos would be limited to a maximum of 20 pits per year.
 - For plutonium manufacturing and R&D, the Draft SPEIS identified a production capacity of up to 80 pits per year. In the Final SPEIS, NNSA has stated that until completion of a new Nuclear Posture Review in 2009 or later, the net production at Los Alamos would be limited to a maximum of 20 pits per year.
 - For consolidation of Category I/II SNM, the Draft SPEIS stated that NNSA would phase-out Category I/II operations at LLNL Superblock by the end of 2012. Because that action is included in the No Action Alternative and would be carried out regardless of any decisions in the SPEIS, the Final SPEIS clarifies that NNSA's preferred alternative is to continue with the No Action Alternative.
 - For NNSA flight test operations, the Draft SPEIS stated that NNSA would cease operation of TTR in 2009 and conduct flight testing at a DoD facility. The Final SPEIS identifies the preferred alternative as Campaign Mode Operation of TTR (Option 3—Campaign under Reduced Footprint Permit).
 - For HE R&D, the Draft SPEIS stated that LLNL would be the HE R&D center for formulation, processing, and testing (less than 10 kg) HE at the High Explosives Application Facility (HEAF). In the Final SPEIS, NNSA has stated that formulation and processing of HE would be conducted either at a new HEAF Annex to be built adjacent to HEAF, or at existing Site 300 facilities.
 - For hydrodynamic testing, the preferred alternative identified in the Draft SPEIS was to close the Contained Firing Facility (CFF) at LLNL in approximately 2015, which would enable transfer or closure of Site 300. In the Final SPEIS, NNSA has stated that hydrotesting at CFF would be consolidated to a smaller footprint by 2015. The Final SPEIS no longer states that this would enable transfer or closure of Site 300.

- For the SNL/CA weapons support functions, the Draft SPEIS did not identify a preferred alternative. For these functions, NNSA has identified the No Action Alternative as preferred.

S.2 PURPOSE AND NEED FOR AGENCY ACTION

NNSA maintains the safety, security, and reliability of the U.S. nuclear weapons stockpile through the Stockpile Stewardship Program (SSP). The SSP involves the integrated activities of three NNSA national laboratories, four industrial plants, and a nuclear test site. The SSP helps identify the changes in the Complex that may be required for NNSA to continue to meet its national security requirements as established by the President and funded by Congress. The purpose and need underlying the alternatives analyzed in this Complex Transformation SPEIS derive from changes in national security policy since the 1996 SSM PEIS ROD, as well as considerations of aging facilities at nuclear sites, aging weapons, and evolving safeguards and security requirements for Category I/II SNM. The underlying purpose and need addressed in this SPEIS is to:

- Maintain core competencies in nuclear weapons;
- Maintain a safe and reliable nuclear weapons stockpile; and
- Create a responsive nuclear weapons infrastructure that is cost-effective, and has adequate capacity to meet reasonably foreseeable national security requirements; and consolidate Category I/II SNM at fewer sites and locations within sites to reduce the risk and safeguards costs.

The fundamental principle underlying NNSA's evaluation of alternatives is that the SSP must continue to support existing and reasonably foreseeable national security policy. This is NNSA's obligation and responsibility under the *Atomic Energy Act* (42 USC. 2011 et seq.) and the *National Nuclear Security Administration Act* (Public Law 106-65, Title XXXII). This SPEIS does not analyze alternative U.S. national security policies. Rather, it examines the environmental effects of proposed actions and reasonable alternatives for execution of the program based on the existing policy and foreseeable changes in this policy.

This SPEIS discusses producing RRWs as compared to maintaining legacy warheads¹² with Life Extension Programs.¹³ Transformation of the Complex infrastructure is required whether or not development of RRW proceeds. Section S.3.15 provides additional information relative to RRW.

S.2.1 Responsiveness of the Nuclear Weapons Complex Infrastructure

The current nuclear weapons production infrastructure is not sufficiently responsive or cost-effective. Responsiveness is the ability to quickly react to new developments and threats and

¹² A legacy warhead is a weapon in the current stockpile.

¹³ NNSA has taken an aggressive approach to warhead refurbishment. Through enhanced surveillance and assessment efforts, NNSA has developed an improved understanding of the effects of aging on warhead safety, security, and reliability. Using this knowledge, NNSA is able to plan refurbishments to replace or fix components systematically, before aging-related changes jeopardize warhead safety or reliability. This is known as the Life Extension Program.

successfully execute SSP requirements. Lack of responsiveness is evidenced by difficulties in executing weapon production schedules in support of maintenance, retrofit and Life Extension Programs, and by the lack of a sufficient pit production capability.

A reliable and responsive infrastructure is a cornerstone of the new triad discussed in the 2001 Nuclear Posture Review (Figure S.2-1) and in Section 3111 of the *National Defense Authorization Act* for fiscal year (FY) 2006 (Public Law 109-163). The purpose of a reliable and responsive infrastructure is to deter adversaries from trying to seek advantage, i.e., an attempt to seek advantage would be detected and negated by a quick response. A more responsive infrastructure is expected to permit further reductions in the nuclear weapons stockpile. In the context of the SSP, this responsiveness could permit deeper reductions in the number of reserve weapons that support the deployed stockpile.

Figure S.2-1—Transition to the New Triad

S.2.2 Laboratory Technical and Industrial Base Capabilities

The underlying purpose and need for the laboratory technical and industrial base capabilities of the SSP remain unchanged from that described in the 1996 SSM PEIS. National security policies still require the core competencies and capabilities of NNSA and its national laboratories, production plants, and the test site. They are basic needs that must be maintained for the foreseeable future in order for NNSA to meet its national security obligations.

S.2.3 Adequate Production Capacity for a Smaller Stockpile

A precise prediction of the future production capacity needed to work on or replace aging legacy weapons cannot be made. Further, a capacity to produce components does not mean that those quantities of components would actually be produced. National security requirements will determine actual production. The Complex must be able to produce what is likely to be required.

For the nuclear production alternatives, this SPEIS assesses manufacturing capacity operated in a single shift, five days per week, to produce, depending upon the alternative, 10-125 weapons per year. The bounding case of producing up to 200 weapons per year assumes operations in multiple shifts and extended work weeks.

S.2.4 A Smaller Infrastructure Footprint for More Cost-Effective Operations

In 2005, a Secretary of Energy Advisory Board (SEAB) task force recommended that NNSA consider a smaller, modernized infrastructure footprint to improve responsiveness, cost effectiveness, and security for high-risk SNM (SEAB 2005).

S.2.5 Enhanced Security for Special Nuclear Materials

The attacks of September 11, 2001, altered security requirements in the NNSA Complex. As a result, security measures and their costs have increased significantly. Most of the effects on NNSA infrastructure are a result of changes to the Design Basis Threat (DBT). The DBT is a profile of the type, composition, and capabilities of a potential adversary. The DBT is used to design safeguards systems to protect against acts of sabotage and to prevent theft of high-risk (Category I/II) SNM. The details of the DBT, which DOE uses to establish its safeguards systems, are classified. However, the net effect of changes in the DBT has stimulated proposed actions and an examination of alternatives for consolidating Category I/II SNM at fewer sites and locations within sites to improve security and reduce costs.

S.3 ALTERNATIVES

S.3.1 Development of Reasonable Alternatives

NNSA has been evaluating how to establish a more responsive nuclear weapons infrastructure since the Nuclear Posture Review was transmitted to Congress in early 2002. The Stockpile Stewardship Conference in 2003 (DoD 2003), the Department of Defense Strategic Capabilities Assessment in 2004 (DoD 2004), the recommendations of the SEAB Task Force on the Nuclear Weapons Complex Infrastructure in 2005 (SEAB 2005), and the Defense Science Board Task Force on Nuclear Capabilities in 2006 (DoD 2006) have provided information for NNSA's evaluation. In 2006, NNSA developed a planning scenario for the future of the Complex (NNSA 2006). As a result of these studies, NNSA developed alternatives that would reduce the size, capacity, number of sites with Category I/II SNM (and locations of Category I/II SNM within sites), and excess and redundant facilities.

S.3.1.1 *Proposed Actions*

NNSA's proposed action is to restructure the nuclear weapons complex to make it smaller and more responsive, efficient and secure, while meeting national security requirements. Two basic types of proposed actions result from the needs identified for a more responsive NNSA Complex infrastructure:

- Restructure SNM Facilities (Programmatic Alternatives)

- Restructure R&D and Testing Facilities (Project-Specific Alternatives)

S.3.1.1.1 Restructure SNM Facilities

The following functional capabilities are evaluated in this SPEIS:

- Plutonium operations, including pit manufacturing, Category I/II SNM storage, and related R&D;
- Enriched uranium operations, including canned subassembly¹⁴ manufacturing, assembly, and disassembly; Category I/II SNM storage; and related R&D; and
- Weapons assembly and disassembly (A/D) and high explosives (HE) production.

To consolidate SNM facilities, which would be a long-term process carried out over a decade or more, the SPEIS alternatives address broad issues such as where to locate those facilities and whether to construct new or renovate existing facilities for these functions. As such, this SPEIS analysis is “programmatic” for the proposed action to restructure SNM facilities, meaning that tiered, project-specific NEPA documents could be needed to inform decisions on these facilities if existing site-wide EISs or other NEPA documents were insufficient.

As shown on Figure S.3.1-1, these “programmatic alternatives” are:

- **No Action Alternative.** As described in Section S.3.3, the No Action Alternative represents continuation of the status quo including implementation of past decisions. Under the No Action Alternative, NNSA would not make major changes to the SNM missions now assigned to NNSA sites. With respect to SNM consolidation, the actions to transfer Category I/II SNM from LLNL are included within the No Action Alternative.
- **Programmatic Alternative 1: Distributed Centers of Excellence (DCE).** As described in Section S.3.4, the DCE alternative would locate the three major SNM functional capabilities (plutonium operations, uranium operations, and weapon assembly/disassembly) involving Category I/II quantities of SNM at two or three separate Complex sites. This alternative would create a CPC for R&D, storage, processing, and manufacture of plutonium parts (pits) for the nuclear weapons stockpile. Production rates of up to 125 pits per year for single shift operations and 200 pits per year for multiple shifts and extended work weeks are assessed for a CPC.¹⁵ A CPC could consist of new facilities, or modifications to existing facilities at one of the following sites: Los Alamos,¹⁶ NTS, Pantex, SRS, or Y-12. This SPEIS also evaluates an alternative that would upgrade facilities at Los Alamos to produce up to 80 pits per year. Highly-enriched uranium and uranium storage, and uranium operations, would continue at Y-12. As part of this alternative, a new Uranium Processing Facility (UPF) and an upgrade to

¹⁴ Canned subassembly – The component of a nuclear weapon which contains the secondary, including uranium and lithium components.

¹⁵ See Section S.3.14 for a discussion of a new CPC with a smaller capacity.

¹⁶ In general, when referring to the Los Alamos National Laboratory, this SPEIS refers to this site as “LANL.” The term “Los Alamos” is used to describe this site as an alternative location for a CPC or Consolidated Nuclear Production Center (CNPC).

existing facilities at Y-12 are both analyzed. The weapons Assembly/Disassembly/High Explosives (A/D/HE) mission would remain at Pantex.

- **Programmatic Alternative 2: Consolidated Centers of Excellence (CCE).** As described in Section S.3.5, NNSA would consolidate the three major SNM functions (plutonium, uranium, and weapon assembly/disassembly) involving Category I/II quantities of SNM at one or two sites under this alternative. Two options are assessed: (1) the single site option (referred to as the consolidated nuclear production center [CNPC] option); and (2) the two-site option (referred to as the CNC option). The CCE Alternative assesses three major facilities: (1) a CPC; (2) a consolidated uranium center (CUC), which would be similar to the UPF but would also include HEU storage and non-nuclear support functions; and (3) an A/D/HE Center, which would assemble/disassemble nuclear weapons, and fabricate high explosives. Under the CNPC option, a new CNPC could be established at Los Alamos, NTS, Pantex, SRS, or Y-12. This SPEIS analyzes the impacts of each of these facilities separately and in combination. If Pantex or Y-12 were not selected for this option, weapons operations at Pantex, Y-12, or both would cease. Under the CNC option, the plutonium and uranium nuclear component manufacturing missions could be separate from the A/D/HE mission. The A/D/HE functions could remain at Pantex or be transferred to the NTS, while the plutonium and/or uranium missions could be located at sites different than the A/D/HE function. The CCE Alternative assumes production rates of up to 125 weapons per year for single shift operations and 200 weapons per year for multiple shifts and extended work weeks.¹⁷
- **Programmatic Alternative 3: Capability-Based Alternative.** As described in Section S.3.6, under this alternative, NNSA would maintain a basic capability for manufacturing components for all stockpile weapons, as well as laboratory and experimental capabilities to support stockpile decisions, but would reduce production capabilities to the extent that would allow NNSA to produce a nominal level of replacement components (approximately 50 components per year). Under this alternative, pit production capacity at LANL would not be expanded beyond the capability to produce 50 pits per year. Production capacities at Pantex, Y-12, and the SRS would be reduced to similar levels.¹⁸ Within this alternative, NNSA also added a No Net Production/Capability-Based Alternative, in which NNSA would maintain capabilities to continue surveillance of the weapons stockpile, produce limited life components, and continue dismantlement. This alternative involves a minimum production (production of 10 sets of components or assembly of 10 weapons per year).

¹⁷ See Section S.3.14 for a discussion of a new CNPC with a smaller capacity.

¹⁸ A capability-based capacity is defined as the capacity inherent in facilities and equipment required to manufacture up to 50 pits per year. In the Notice of Intent for this SPEIS, this capacity was referred to as a “nominal capacity.”

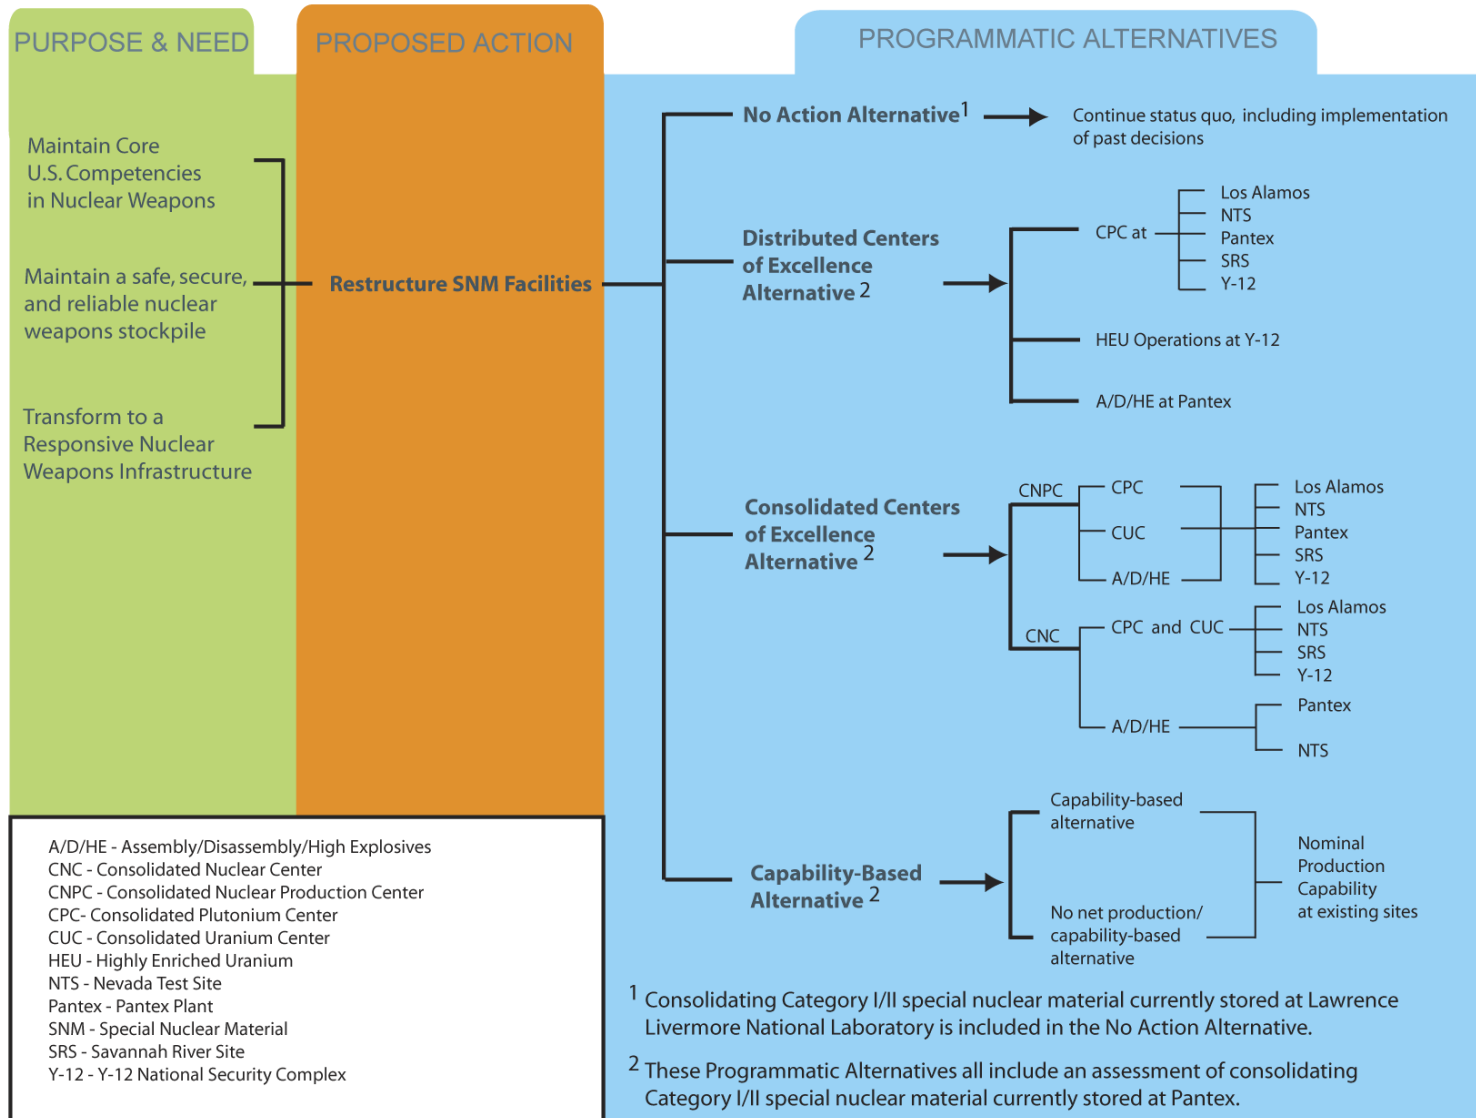

Figure S.3.1-1—Programmatic Alternatives

The DCE Alternative, CCE Alternative, and the Capability-Based Alternative all include proposals to consolidate Category I/II SNM involving LLNL¹⁹ and Pantex. Those proposals are described in Section S.3.7.

S.3.1.1.2 Restructure R&D and Testing Facilities

In pursuit of a more responsive and cost-effective infrastructure, NNSA is considering a restructuring of the R&D and testing facilities within the Complex. For this proposed action, the alternatives focus on near-term issues to consolidate, relocate, or eliminate facilities and programs and improve operating efficiencies. The following capabilities are being evaluated in this SPEIS:

- High Explosives R&D
- Tritium R&D
- Flight Test Operations
- Hydrodynamic Testing
- Major Environmental Testing

The analysis of alternatives for these capabilities is “project specific,” meaning that further NEPA review might not be needed to implement decisions consistent with the alternatives analyzed in this SPEIS. Restructuring of these facilities is expected to be pursued regardless of which programmatic alternative is selected for SNM facilities. NNSA developed the project-specific alternatives, shown on Figure S.3.1-2, to achieve significant benefits in making the Complex more secure and efficient. In addition to these project-specific alternatives for restructuring R&D and testing, this SPEIS also addresses alternatives related to non-nuclear component design and engineering work at SNL/California.

Project-Specific Analysis

A project-specific analysis is a detailed analysis of the environmental impacts of a proposed action and the reasonable alternatives. The project-specific analysis is intended to be sufficiently detailed to allow implementation of the selected alternative after NNSA makes a decision, without any additional NEPA analysis.

¹⁹ The LLNL SWEIS (DOE 2005) assesses the environmental impacts of transporting SNM to and from LLNL and other NNSA sites, SRS, and WIPP. That analysis includes consideration of transportation activities involving greater quantities of SNM and more shipments than are proposed in this SPEIS. As such, the transportation activities associated with consolidating SNM from LLNL are included in the existing No Action Alternative and can proceed without additional NEPA analysis. For completeness, however, this SPEIS includes the environmental impacts associated with such actions.

Figure S.3.1-2—Alternatives to Restructure R&D and Testing Facilities

S.3.2 Overview of NNSA Sites and Missions

S.3.2.1 *Los Alamos National Laboratory*

LANL was established as a nuclear weapons design laboratory in 1943. Its facilities are located on approximately 28,000 acres about 25 miles northwest of Santa Fe, New Mexico. LANL is a multidisciplinary research facility engaged in a variety of programs for NNSA, DOE, other Government agencies, and the private sector. Its primary mission is the implementation of the Stockpile Stewardship Program. Other missions involve emergency response, arms control, nonproliferation, and environmental activities. LANL conducts R&D activities in the basic sciences, mathematics, and computing, with application to these mission areas and to a broad range of programs including: non-nuclear defense; nuclear and non-nuclear energy; material science; atmospheric, space, and geosciences; bioscience and biotechnology; and the environment.

With regard to nuclear weapons, LANL is responsible for the design of the nuclear explosive package in certain U.S. weapons (LLNL has this responsibility for the other weapons).²⁰ LANL performs research, design, development, testing, surveillance, and assessment activities, and maintains certification capabilities in support of the SSP. In addition, LANL produces a small number of plutonium pits pursuant to a programmatic decision based on the SSM PEIS (61 FR 68014) and a site-specific decision based on the 1999 LANL SWEIS (64 FR 50797) to establish an interim production capability of up to 20 pits per year. LANL also conducts surveillance of pits and manufactures some non-nuclear components (e.g., detonators). NNSA completed a revised LANL SWEIS in 2008, but will not make any decisions related to pit production at LANL prior to the completion of this SPEIS.

NNSA issued a ROD for the continued operation of LANL on September 26, 2008. NNSA announced in the ROD its decision to continue the no action alternative with the addition of some elements of the expanded operations alternative that NNSA concluded needed to be implemented to support the safe and successful execution of the laboratory's mission. None of these decisions affect the alternatives considered in this SPEIS.²¹

S.3.2.2 *Lawrence Livermore National Laboratory*

LLNL was established as a nuclear weapons design laboratory in 1952. LLNL's main site is located on approximately 821 acres in Livermore, California. LLNL also operates a 7,000-acre "Experimental Test Site" known as Site 300, which is located approximately 12 miles east of the

²⁰ The general responsibilities assigned to LLNL and LANL for nuclear explosive packages are complementary. LANL and LLNL compete for assignment of the responsibility for design and development of the nuclear explosive package for a nuclear weapons system. In the early design definition phase, both laboratories perform systems studies, preliminary development work, and initial design definition. NNSA, in consultation with the DoD and the cognizant military service, then selects either LANL or LLNL to work with SNL to design and develop the new weapon system. LANL or LLNL designs and develops the nuclear physics package and associated support hardware; SNL designs and develops the arming, fuzing, and firing system, other warhead electronics, external cases and mounts, and performs systems integration to develop the complete weapon system. There are nuclear explosive packages in the current legacy stockpile that have been designed and developed by both LANL and LLNL.

²¹ See ROD for the continued operation of the LANL for decisions from the expanded operations alternative (see 73 FR 55833).

main laboratory. Site 300 is used primarily for high explosives testing, hydrodynamic testing, and other experimentation, such as particle beam research.

LLNL is a multidisciplinary research facility engaged in a variety of programs for NNSA, DOE, other government agencies, and the private sector. Its primary mission is implementation of the SSP. Other missions involve related emergency response, arms control, and nonproliferation activities. LLNL conducts research and development activities in the basic sciences, mathematics, and computing, with application to these mission areas, and to a broad range of programs including: non-nuclear defense; nuclear and non-nuclear energy; high-energy density physics; atmospheric, space, and geosciences; bioscience and biotechnology; and the environment. With respect to nuclear weapons, LLNL is responsible for the design of the nuclear explosive package in certain weapons (LANL has this responsibility for the other weapons). LLNL maintains research, design, development, testing, surveillance, assessment, and certification capabilities in support of Stockpile Stewardship.

S.3.2.3 *Nevada Test Site*

NTS occupies approximately 880,000 acres in the southeastern part of Nye County in southern Nevada. It is located about 65 miles northwest of Las Vegas. It is a remote, secure facility with restricted airspace that maintains the capability for conducting underground testing of nuclear weapons and evaluating the effects of nuclear weapons on military communications systems, electronics, satellites, sensors, and other materials. The first nuclear test at NTS was conducted in 1951. Since the signing of the *Threshold Test Ban Treaty* in 1974, it has been the only U.S. site used for nuclear weapons testing. The last nuclear test was conducted in 1992. Approximately one-third of the land (located in the eastern and northwestern portions of the site) has been used for nuclear weapons testing; one-third (located in the western portion of the site) is reserved for future missions, and one-third is reserved for R&D, nuclear device assembly, diagnostic canister assembly, and radioactive waste management. In addition, DOE has submitted an application to the Nuclear Regulatory Commission for authorization to construct and operate a repository for spent nuclear fuel and high-level radioactive waste at Yucca Mountain, an area on the southwestern boundary of the site.

A primary NNSA mission at NTS is the implementation of SSP, and includes maintaining the readiness and capability to conduct underground nuclear weapons tests and conducting such tests within 24-36 months if so directed by the President. Other aspects of stockpile stewardship at NTS include conventional HE tests, dynamic experiments, and hydrodynamic testing. The Search Augmentation Team maintains the readiness to respond to any type of nuclear emergency, including search and recovery for lost or stolen weapons, and conducts training exercises related to nuclear weapons and radiation dispersal threats. The Device Assembly Facility houses criticality machines and stores SNM in support of a range of NNSA missions.

S.3.2.4 *Tonopah Test Range*

The Tonopah Test Range (TTR), managed and operated by SNL, is a 179,200-acre site located at the very northern end of the Nevada Test and Training Range, about 32 miles southeast of Tonopah, Nevada. TTR is used for NNSA flight testing of gravity-delivered nuclear weapons

(bombs). The actual flight tests are conducted with one or more denuclearized warheads, called joint test assemblies, which are dropped from DoD aircraft or simply flown over the test range. The primary purpose of evaluation activities is the timely detection and correction of problems in the hardware interfaces for gravity weapons, and to ensure that components conform to design and reliability requirements throughout their life. DoD also currently uses TTR for exercises and as an emergency divert base for aircraft.

S.3.2.5 *Pantex Plant*

Pantex is located approximately 17 miles northeast of Amarillo, Texas, on 15,997 acres. Its missions are research and development of chemical high explosives for nuclear weapons; fabrication of high-explosives components essential to nuclear weapon function; assembly, disassembly, maintenance, and surveillance of nuclear weapons in the stockpile; dismantlement of nuclear weapons being retired from the stockpile; and interim storage of plutonium components from dismantled weapons. Weapons activities involve the handling (but not processing) of uranium, plutonium, and tritium components, as well as a variety of non-radioactive hazardous or toxic chemicals.

Pantex's mission is to assemble, disassemble, and modify weapons as set forth in the ROD for the *Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapons Components* that was issued on January 27, 1997 (62 FR 3880). Although the specifics of nuclear weapons operations at Pantex are classified, approximately one-half of the current and future Pantex workload involves dismantling nuclear weapons. Under all alternatives, dismantlement operations would continue and there are no proposals in this SPEIS to increase activity levels beyond those previously evaluated.²²

S.3.2.6 *Sandia National Laboratories*

SNL was established as a non-nuclear design and engineering laboratory separate from LANL in 1949. The principal laboratory is located in Albuquerque, New Mexico (SNL/NM); a division of the laboratory (SNL/CA) is located in Livermore, California, near LLNL. Sandia Corporation (the contractor that operates SNL under contract with NNSA) also operates the TTR in Nevada.

SNL conducts multidisciplinary research and engineering activities in a variety of programs for NNSA, DOE, other Government agencies, and the private sector. Its primary missions for NNSA are implementation of the SSP and related systems engineering and non-nuclear component design and engineering, and system qualification testing for Stockpile-to-Target Sequence environments. Other missions involve arms control and nonproliferation activities. In addition, SNL conducts R&D activities in advanced manufacturing, electronics, information, pulsed power, energy, environment, transportation, and biomedical technologies.

²² In the Notice of Intent for this SPEIS, NNSA stated that the proposed action would accelerate nuclear weapons dismantlement activities; these activities are already occurring. For example, during fiscal year 2007, NNSA increased its rate of dismantling nuclear weapons by 146 percent over the previous year's rate (NNSA 2007a). This rate was well below the maximum number of weapon dismantlements analyzed in the Pantex SWEIS (DOE 1996c).

SNL is responsible for cradle-to-grave oversight and qualification testing of the non-nuclear components in nuclear weapons and is the system integrator for assuring the safety and reliability of the entire weapons system using computational methodologies combined with data from its test facilities. SNL maintains research, design, development, testing, surveillance, assessment, and certification capabilities in support of the SSP. In addition, SNL performs some non-nuclear manufacturing functions, including the fabrication of neutron generators and production of limited quantities of microelectronic parts.

S.3.2.7 *White Sands Missile Range*²³

WSMR, located in south central New Mexico, is the largest installation in the DoD. WSMR is a Major Range and Test Facility Base under the Department of the Army Test and Evaluation Command, Developmental Test Command, providing test and evaluation services to the Army, Air Force, Navy, other government agencies, and industry. The range covers more than 3,000 square miles of land and 10,026 square miles of contiguous restricted airspace fully managed, scheduled, and controlled by WSMR. Holloman Air Force Base is located adjacent to the range's east boundary and has capabilities for aircraft support and staging. WSMR has a full suite of flight test instrumentation including radar, telemetry, and optical equipment that would allow for complete coverage of a NNSA gravity weapons flight test. WSMR has extensive experience conducting flight tests with requirements and flight test scenarios similar to the NNSA flight test program.

S.3.2.8 *Savannah River Site*

SRS is located in south-central South Carolina and occupies approximately 198,420 acres in Aiken, Barnwell, and Allendale Counties. The site was established in 1950 and is approximately 15 miles southeast of Augusta, Georgia, and 12 miles south of Aiken, South Carolina. The major nuclear facilities at SRS have included fuel and target fabrication facilities, nuclear material production reactors, chemical separation plants used for recovery of plutonium and uranium isotopes, a uranium fuel processing area, and the Savannah River National Laboratory, which provides technical support. The initial mission at SRS was production of heavy water and strategic radioactive isotopes (plutonium-239 and tritium) in support of national defense. Today, the main weapons mission at SRS is tritium supply management and R&D.

Tritium, an important component of nuclear weapons, decays and must be replaced periodically to meet weapons specifications. Tritium recycling facilities empty tritium from weapons reservoirs, purify it to eliminate the helium decay product, and fill replacement reservoirs with specification tritium for nuclear stockpile weapons. Filled reservoirs are delivered to Pantex for weapons assembly and to the DoD as replacements for weapons reservoirs. The Tritium Extraction Facility takes rods, which have been irradiated in a commercial light water reactor (Watts Bar reactor operated by the Tennessee Valley Authority), and extracts tritium for use in the nation's nuclear weapons. As an NNSA-managed activity separate from weapons activities,

²³ WSMR is not currently part of the NNSA nuclear weapons complex. However, NNSA is considering WSMR as a location for NNSA Flight Testing.

a mixed oxide fuel fabrication facility is under construction and NNSA plans to build a pit disassembly and conversion facility at SRS to disposition surplus plutonium.

S.3.2.9 *Y-12 Site*

Y-12 is one of three primary installations on the DOE Oak Ridge Reservation (ORR), which covers a total of approximately 35,000 acres in Oak Ridge, Tennessee. The other installations are the Oak Ridge National Laboratory (ORNL) and the East Tennessee Technology Park (formerly the Oak Ridge K-25 Site). Construction of Y-12 started in 1943 as part of the World War II Manhattan Project. Y-12 consists of approximately 800 acres. The early missions of the site included the separation of uranium-235 from natural uranium by electromagnetic separation and the manufacture of weapons components from uranium and lithium. Y-12 is the primary site for enriched uranium processing and storage, and one of the primary manufacturing facilities for maintaining the U.S. nuclear weapons stockpile. Y-12 is the source of secondaries, cases, and certain other weapons components that comprise CSAs. Y-12 also dismantles weapons components, stores and manages SNM, supplies SNM to naval and research reactors, and disposes surplus materials.

S.3.2.10 *Kansas City Plant and Non-Nuclear Fabrication*

The bulk of the manufacturing of non-nuclear components for the stockpile is done at the KCP. This manufacturing consists of electrical, electronic, electromechanical, and mechanical components (plastics, metals, and composites), and assembly of arming, fuzing, and firing systems of a nuclear warhead. Some limited manufacturing of non-nuclear components also occurs at Y-12 (fabrication of large metal components), SNL (neutron generators and microelectronic parts), and LANL (detonators). Other than limited production of non-nuclear components at LANL, Y-12, and SNL, the remaining non-nuclear components are either acquired by or manufactured at the KCP. The KCP also performs surveillance inspection and testing of non-nuclear weapons components. For the reasons set forth below, this SPEIS does not evaluate alternatives for continuing the transformation of non-nuclear manufacturing activities.

In the 1990s, DOE prepared the Non-nuclear Consolidation Environmental Assessment (DOE 1993) for the purpose of better managing non-nuclear manufacturing activities within the Complex and decreasing the long-term operating costs of these activities. This Environmental Assessment proposed consolidating most non-nuclear manufacturing functions in existing facilities at the KCP; it also analyzed three alternatives in which the manufacture of electrical and mechanical components would be consolidated at sites other than the KCP. Based on the evaluations in this Environmental Assessment, DOE issued a Finding of No Significant Impact (FONSI) (58 FR 48043) on its proposal to consolidate non-nuclear component manufacturing and related activities, and decided to consolidate most non-nuclear operations at the KCP to improve efficiency. DOE explained its determination that the non-nuclear consolidation proposal could be separated from the Reconfiguration Programmatic Environmental Impact Statement (PEIS) (59 FR 17344) because decisions regarding the configuration and consolidation of facilities for the manufacture of non-nuclear components would not affect or

predetermine the outcome of alternatives or decisions regarding the configuration of the nuclear activities of the weapons complex.

In the SSM PEIS (1996), DOE considered additional alternatives with respect to non-nuclear operations, including relocating those capabilities to one or more of the national security laboratories. DOE decided (61 FR 68014) to retain the existing facilities at the KCP because this was the environmentally preferable alternative, posed the least technical risk, and was the lowest cost alternative. Because the non-nuclear operations at the KCP are essential and do not duplicate work at other sites, no proposal for combination or elimination of these missions was deemed reasonable for evaluation in this supplement to the SSM PEIS.

The KCP occupies a large and aging industrial complex in Kansas City located on a site with other facilities operated by the U.S. General Services Administration (GSA). The current KCP complex is much larger than is required by NNSA and, because of its age and size, is expensive to operate. GSA, as the lead agency, and NNSA, as a cooperating agency, issued a Final Environmental Assessment (GSA 2008) and FONSI on April 21, 2008 (73 FR 23244) on their proposal to procure the construction of a new facility to house NNSA's operations concerning non-nuclear components.

The selected alternative is for GSA to lease a new facility from a private developer on NNSA's behalf, and for NNSA to relocate its operations from the existing KCP at the Bannister Federal Complex in Kansas City to the new facility. The relocation would involve moving approximately two-thirds of the existing capital and process equipment to the new facility. The proposed facility would be at least 50 percent smaller than the existing facility and would be designed to allow for rapid reconfiguration to meet changing requirements. The new facility would reduce annual operating costs and improve responsiveness, facility utilization, and reliability in supplying non-nuclear components. In addition to these operating improvements, the new facility would reduce the environmental footprint of KCP operations, including improved energy efficiency, lower emissions, and less waste generation.

The selected alternative would continue the consolidation and reduction of the manufacture and maintenance of non-nuclear components that DOE began after completion of the Non-nuclear Consolidation EA in 1993 and continued after the SSM PEIS in 1996.

Because the non-nuclear operations at KCP are essential and do not duplicate work at other sites, no proposal to combine or eliminate these operations was formulated. Thus, NNSA is not proposing to relocate these activities to another geographic area. Nonetheless, NNSA did evaluate three alternatives that involved moving these operations to another geographic area. One alternative evaluated moving KCP's operations to SNL/NM, one alternative evaluated moving those operations to LLNL, and a third alternative evaluated moving those operations to LANL. In addition to the analysis in the EA, a recent analysis of transferring KCP operations to a site other than one within the immediate Kansas City area concluded that "no prospects for economic benefits are apparent" (SAIC 2008). This is primarily because of the longer move, the restart period that would be required, and the costly transfer or reconstitution of the skilled workforce in a new region, which would forfeit a potential savings of approximately \$100 million per year. In addition, relocation outside of the Kansas City area would require extending operation of the current facility in order to build the inventory that would be needed for a long

transition; this could result in additional loss of key personnel, require additional training, and result in other unnecessary management challenges. Moreover, because of the nature of KCP operations, constructing and operating a new facility in a different location from Kansas City is unlikely to offer any significant benefits. Because no significant environmental impacts were identified in the KCP EA, NNSA and GSA issued a FONSI and are moving forward with this project in order to achieve significant benefits, including cost savings, continuity of operations, and preservation of technical competence independent of other proposals for transformation of the Complex. Consequently, these non-nuclear operations would remain in the Kansas City area. This decision will neither affect nor be affected by the decisions regarding the alternatives evaluated in this SPEIS.

S.3.3 No Action Alternative

Under the programmatic No Action Alternative, NNSA would continue operations to support national security requirements using the existing Complex. As shown on Figure S.1-1, the current Complex consists of multiple sites located in seven states. The Complex enables NNSA to design and manufacture nuclear weapons; conduct surveillance on nuclear weapons in the stockpile; and dismantle retired nuclear weapons. Under the No Action Alternative, NNSA sites would continue to perform the weapons functions identified in Section S.3.2. A summary of the functions, and the sites where these functions are performed, follows.

Weapon Design and Certification. Nuclear weapons are designed at three NNSA national laboratories; these laboratories also certify the weapons safety and reliability for inclusion in the stockpile. LLNL and LANL design and engineer the nuclear physics package for nuclear weapons. SNL/NM designs and engineers non-nuclear components and is responsible for systems engineering of nuclear weapons. SNL/CA conducts non-nuclear component design and engineering work. The laboratories provide the science and technology foundation for the SSP and rely on facilities across the Complex to support essential plutonium, uranium, non-nuclear materials, tritium, and high explosives research and development, as well as hydrodynamic, environmental, and flight testing.

Plutonium Operations and Pit Manufacture. Pits refer to the central nuclear core of the primary of a nuclear weapon, and typically contain Pu-239 and/or HEU. Subsequent to the 1996 SSM PEIS ROD, an interim pit manufacturing capability was established at LANL. In the 1999 LANL SWEIS ROD, DOE decided that LANL would produce up to 20 pits per year. In May 2008, NNSA issued the Final LANL SWEIS that evaluates an alternative to produce up to 80 pits per year in order to obtain 50 certified pits per year. LANL manufactures pits in the Plutonium Facility Complex, which consists of six primary buildings located in Technical Area-55 (TA-55). This activity is supported by numerous laboratory, storage facilities, administrative offices and waste management facilities, located throughout LANL. Both LANL and LLNL currently perform R&D on Category I/II quantities of plutonium.

Uranium Operations and Secondary and Case Fabrication. The energy released by the primary explosion of a weapon activates the secondary assembly. Secondary assemblies may contain HEU, lithium deuteride, and other materials. Implosion of the secondary assembly creates the thermonuclear explosion. Heavy metal cases surround the secondary assemblies. Uranium operations and secondary and case fabrication are generally performed at Y-12, where

they are combined into CSAs. Most highly-enriched uranium materials reserved for weapons are retained at Y-12. NNSA is currently constructing a Highly-Enriched Uranium Materials Facility (HEUMF) at Y-12 to consolidate highly-enriched uranium storage. LANL, LLNL, and NTS currently retain smaller Category I/II quantities of highly-enriched uranium for R&D. This activity requires high security facilities as well as support, laboratory, waste management, and administrative facilities.

Weapons Assembly/Disassembly and High Explosives Production. Weapons assembly and disassembly refers to the assembly, dismantlement, and reassembly of complete nuclear weapons. This activity is primarily conducted at Pantex, which is the principal facility in the Complex that handles complete nuclear weapons. Facilities include heavily fortified work areas, storage facilities, administrative buildings and support laboratories. Waste management facilities are also required. Pantex also produces and machines the high explosives that surround the nuclear components of nuclear weapons. Pantex is authorized to assemble, disassemble, and modify weapons in accordance with the ROD for the *Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapons Components* (62 FR 3880). Although the specifics of nuclear weapons operations at Pantex are classified, approximately one-half of its current and future workload is associated with dismantling nuclear weapons.

Category I/II SNM Storage. Quantities of SNM are categorized into security Categories I, II, III, and IV based on the type, attractiveness level, and quantity of material. Category I/II SNM are the most attractive materials and require the most extensive and expensive security provisions. These facilities consist of heavily fortified storage or processing buildings surrounded by security fences with highly trained, heavily armed security personnel. Category I/II SNM storage facilities are currently located at LANL, LLNL, Pantex, SRS (not associated with NNSA weapons activities), Y-12, and NTS. In 2008, SNL/NM removed its Category I/II SNM, and no longer stores or uses Category I/II SNM quantities on a permanent basis. The potential transfer of LLNL's Category I/II SNM has previously been assessed in the LLNL SWEIS (DOE 2005) and is included in the No Action Alternative.

Tritium Production and R&D. Tritium is a short-lived radioactive isotope of hydrogen used to increase yield in nuclear weapons. The production of tritium is carried out in a Tennessee Valley Authority reactor. Tritium extraction, purification, and reservoir loading (which are collectively referred to as the "tritium supply management" missions) are carried out at SRS in the Tritium Extraction Facility, which became operational in late 2006, and the H-Area New Manufacturing Facility, which became operational in 1994. Tritium R&D is primarily performed at SRS and LANL (in the Weapons Engineering Tritium Facility). Very limited tritium operations are performed at LLNL in the Tritium Facility within Superblock²⁴ to support preparation of tritium targets for the National Ignition Facility, and at SNL/NM in the Neutron Generator Production Facility to support neutron generator production. Tritium operations require supporting laboratory, waste management, and administrative facilities.

High Explosives R&D. High explosives are used in the primary assembly of nuclear weapons. The development of safer, more stable and more energetic forms of this material is referred to as

²⁴ "Superblock," LLNL's defense plutonium research and development facilities.

high explosives R&D. The R&D work includes confined and unconfined detonation of experimental quantities of high explosives. High explosives R&D is conducted at LANL, LLNL, SNL/NM, Pantex, and NTS. This activity entails development laboratories, administrative buildings and test fire facilities. Waste management facilities are also required.

Flight Test Operations. Flight test operations assess how weapon systems function in realistic delivery conditions. Denuclearized test weapons²⁵ are assembled at Pantex. These denuclearized weapons are then subjected to realistic aircraft flight and release conditions. This program is conducted at the TTR for gravity weapons (bombs). Facilities include a drop zone, target facilities, observation and test equipment, and administrative buildings. Flight testing for ballistic and cruise missiles is conducted at existing DoD test ranges.

Hydrodynamic Test Facilities. Hydrodynamic testing refers to high-explosive experiments to study weapons physics and to assess the performance and safety of nuclear weapons. These activities are principally conducted at LLNL and LANL, with some supporting activities at NTS, SNL/NM and Pantex. High energy radiographic facilities support the hydrodynamic testing capabilities with dynamic radiography. This activity also entails laboratory and administrative office space.

Major Environmental Test Facilities. Environmental test facilities are used to assess the safety, reliability and performance of the nation's nuclear weapons systems through subjecting weapons to differing environmental conditions (shock, vibration, high temperatures, etc.). These facilities test complete (denuclearized) weapons or major weapons subsystems. Major environmental test facilities are located at SNL/NM, LLNL, LANL, and NTS. These facilities are supported by storage, support laboratory, and administrative office building space. Small environmental test laboratories and capabilities also exist at Pantex and SRS. These smaller test laboratories support component R&D and production, and are an integral part of the production/certification process.

S.3.3.1 *Limitations of the Existing Complex*

The existing Complex is aging, too big, and maintains redundant capabilities that were required to sustain the Cold War stockpile. Many of the facilities are being operated beyond their useful life. In fact, parts of the Complex were built during the Manhattan Project of the 1940s and several production facilities still in use today date from that period. There are high costs to maintain this infrastructure. Reliance on aging facilities increases operating costs and in some instances subjects workers to unnecessary risk.

The liability and cost of aging infrastructure is an escalating problem throughout the NNSA Complex. In the past, preventive facility maintenance has been deferred for higher priorities. The current DOE budgeting process allocates 5 to 8 percent less for infrastructure and repair than the industrial average (LANL 2008). Over time, this practice has resulted in a backlog of repairs that

²⁵ Denuclearized test weapons are designed to simulate the nuclear weapon in its operational configuration as much as possible, but do not contain the physics package with special nuclear materials. During flight tests, these test weapons are expected to operate as if they were an actual nuclear weapon, except for the lack of a nuclear detonation.

threatens to overtake NNSA's ability to effectively address these problems. Because the cost of operations and maintenance for aging facilities (many over 40 – 50 years old) is significant and growing, leaving this problem unaddressed would impact NNSA's ability to carry out its stockpile stewardship mission. Additionally, there are operational safety issues at some facilities that use Category I/II SNM that call into question their viability for use beyond the next five to ten years. One is the Chemistry and Metallurgy Research (CMR) facility at LANL, and another is the CSA production facility, Building 9212, at Y-12. The NNSA Administrator told the House Armed Services Subcommittee on July 17, 2008, "We cannot continue to do 21st Century national security business with a 50-year-old Cold War infrastructure. Take the 50-year-old Chemistry and Metallurgy Research (CMR) Facility at Los Alamos, for example. The [Defense Nuclear Facilities Safety Board] DNFSB has clearly stated that the CMR has significant safety issues which cannot be addressed in the existing structure. Similar issues exist at Y-12 with regards to Building 9212 which currently houses many of our legacy uranium processing operations" (D'Agostino 2008). The need to address these issues is an important factor in the development of NNSA's proposed actions regarding plutonium and uranium.

There are several thousand buildings in the Complex today, covering more than 35 million square feet of floor space, that support weapons activities. Maintaining this much space requires the expenditure of extensive resources for maintenance, safety, and security. In 2006, approximately 27,000 management and operating contractor personnel were employed at major NNSA sites to support weapons activities. NNSA is continuing to consolidate operations and reduce floor space, on a site-by-site basis, and these efforts would continue under the No Action Alternative.

S.3.4 Programmatic Alternative 1: Distributed Centers of Excellence

Under this alternative, NNSA would transform the Complex by consolidating the major functions required to support the nuclear weapons stockpile to distributed centers of excellence (DCE). The major decisions regarding implementation of the DCE programmatic alternative would be setting the baseline plutonium production capacity and locating a facility for long-term plutonium component (pit) manufacturing and R&D. The facility for long-term plutonium operations is referred to as the consolidated plutonium center, or CPC. The CPC could either be a completely new configuration of buildings at Los Alamos, NTS, Pantex, SRS, or Y-12, or an upgrade of existing and planned facilities at Los Alamos (two alternatives, referred to as the "50/80" and "Upgrade") or planned facilities at SRS. For uranium operations, this alternative includes a new UPF or an upgrade to existing facilities at Y-12. No changes are envisioned for the A/D/HE mission at Pantex.

S.3.4.1 Consolidated Plutonium Center (CPC)

CPC Requirements and Assumptions

- A CPC would provide the facilities and equipment to perform pit manufacturing, pit surveillance, SNM storage to support production, and plutonium R&D.
- Stockpile requirements are based on national security requirements directed by the President based on joint recommendations from DOE and DoD. CPC capacity and

production output would be designed to meet the national security requirements, which could include production of new pits for maintenance of the legacy stockpile or replacement weapons (e.g., Reliable Replacement Warheads).

- A CPC would provide a manufacturing capacity of 125 pits per year (single shift) with a contingency of 200 pits per year through multiple shifts and extended work weeks.²⁶ A CPC would be capable of supporting the surveillance program at a rate of one pit being destructively evaluated per pit type in the stockpile per year. For Los Alamos, this SPEIS also assesses an alternative (referred to as the “50/80 Alternative”) that would result in a smaller pit production capacity (up to 80 pits per year), based on the use of the existing and planned plutonium infrastructure at that site.
- A new CPC would be constructed over a six-year period, and would be fully operational by approximately 2022. A CPC would be designed for a service life of at least 50 years.
- The NNSA sites being considered as potential locations for a CPC and consolidation of Category I/II SNM are Los Alamos, NTS, Pantex, SRS, and Y-12.
- A newly constructed CPC would consist of a central core area, surrounded by a Perimeter Intrusion Detection and Assessment System (PIDAS), which encloses all operations involving Category I/II quantities of SNM (Figure S.3.4.1-1). The area enclosed by the PIDAS would be approximately 40 acres. A buffer area would provide unobstructed view of the area surrounding the PIDAS. All administrative and non-SNM support buildings would be located outside of the buffer area. Approximate 110 acres would be required for all CPC facilities. Land requirements for the CPC Alternatives are shown in Table S.3.4-1.

Table S.3.4-1—Land Requirements for CPC Alternatives

Greenfield Alternative ²⁷ (Los Alamos, NTS, Pantex, SRS, Y-12)	Construction (acres)	Operation (acres)	
	140	110*	
PIDAS		Non-PIDAS	
	40	70	
Upgrade Alternative (Los Alamos)	13	6.5 (All within PIDAS)	
50/80 Alternative (Los Alamos)	6.5	2.5 (All within PIDAS)	

* Includes a buffer area that would provide unobstructed view of the area surrounding the PIDAS.

S.3.4.1.1 Site Alternatives

Figures S.3.4.1-2 through S.3.4.1-6 identifies the reference locations for a CPC at the five alternative sites. NNSA would not make a decision as to a specific location at any site for a new

²⁶ If NNSA were to construct a new CPC to produce 80 pits per year, the reduction in square footage would be small compared to the square footage of a new facility designed for 125 pits per year. From a facility design perspective, a 125 pits per year plant is an optimal minimum, and no major cost savings can be achieved from designing a new facility with a capacity less than 125 pits per year. Section S.3.4.1.2 discusses smaller capacity pit production related to upgrades to facilities at LANL.

²⁷ The term “greenfield” is not meant to imply that the land upon which a CPC could be constructed has never been previously utilized by DOE/NNSA. Rather, in the context of this SPEIS, greenfield refers to a completely new facility that would not use existing facilities and therefore requires significantly more acreage.

CPC based on this SPEIS; specific locations would be evaluated in a future NEPA review for the site selected if required.²⁸ The reference locations were identified at each site to provide a basis to evaluate the potential environmental impacts of a CPC. The characterization of the affected environment in Chapter 4 of this SPEIS addresses the entire site and the affected region surrounding the site, which generally extends to a 50-mile radius.

Two of the sites under consideration for the pit production function (Los Alamos and SRS) have existing or planned facilities that could be used to support pit production activities, and which could influence the location of any new facilities. This SPEIS analyzes options that would use these facilities. Section S.3.4.1.2 discusses the Los Alamos options. At SRS, the reference location was selected to provide proximity to the planned Pit Disassembly and Conversion Facility (PDCF). This location would support either a new independent CPC or use the infrastructure associated with the PDCF to support a CPC.

²⁸ Such a specific location at Los Alamos is evaluated in the LANL SWEIS recently completed.

S.3.4.1.2 Los Alamos CPC Alternatives

For purposes of assessing a CPC at Los Alamos, this SPEIS evaluates three approaches: (1) a Greenfield CPC alternative (previously discussed in Section S.3.4.1), in which new nuclear facilities would be constructed to achieve consolidation of plutonium capabilities; (2) an alternative in which existing and planned facilities at Los Alamos are upgraded and augmented with new facilities to achieve a baseline of 125 pits per year (Upgrade Alternative); and (3) an upgrade to existing and planned facilities at Los Alamos to provide up to approximately 80 pits per year (50/80 Alternative²⁹). These latter two approaches are addressed in this section.

S.3.4.1.2.1 Los Alamos Upgrade Alternative

Los Alamos could support pit production requirements using existing and/or new facilities at TA-55, which is the current site for the Plutonium Facility (PF-4). The planned CMRR Facility would be located in TA-55. In addition, LANL has several existing and planned facilities, all of which are included in the No Action Alternative, capable of supporting plutonium operations, including: the Radioactive Liquid Waste Treatment Facility, the solid waste characterization and disposal site (in TA-54), the Sigma Building (in TA-03), the Radiochemistry Facility (in TA-48), a new radiography facility (in TA-55), and a new solid-waste staging facility.

Estimated Modifications to Support the Los Alamos Upgrade Alternative

Using the existing and planned facilities in TA-55, pit production capacity could be increased to approximately 125 pits per year (single shift) by the following:

1. Expanding the scope and the size of the planned CMRR Facility; and/or
2. Constructing a new facility (known as the “Manufacturing Annex”) to augment existing pit-manufacturing capacity, the planned CMRR Facility, and related infrastructure capacity.

Both approaches would result in the addition of up to 400,000 square feet of additional space at TA-55, either as one or more stand-alone facilities (e.g., the Manufacturing Annex, which would be comprised of a Manufacturing Annex Nuclear Facility and a light laboratory/utility/office building) or as an addition to the CMRR. This SPEIS analyzes the environmental impacts of the addition of a Manufacturing Annex to provide the additional pit manufacturing, supply/recovery, and/or analytical chemistry support.

Based on prior planning information (NNSA 2007), the new Manufacturing Annex would be approximately the same size as the buildings in the current CMRR project (which would consist of the Chemistry and Metallurgy Research Replacement Nuclear Facility and a radiological laboratory/utility/office building). This annex would be located near the existing PF-4 structure to minimize the logistics of material and personnel movements between the facilities, which would take place through hardened tunnels. An overhead conceptual view of this configuration is shown in Figure S.3.4.1-7.

²⁹ The name “50/80 Alternative” reflects the fact that this alternative would expand pit production capacity up to 80 pits per year.

RLUOB = Radiological Laboratory/Utility/Office Building
 CMRR NF = Chemistry and Metallurgy Research Replacement Nuclear Facility
 LLUOB = Light Laboratory/Utility/Office Building

Figure S.3.4.1-7—TA-55 Site Plan Showing the Proposed CMRR and Manufacturing Annex Facilities

S.3.4.1.2.2 Los Alamos Upgrade Alternative to Provide Up To 80 Pits per Year (“50/80 Alternative”)

The 50/80 Alternative is evaluated to allow NNSA to consider an alternative with a pit production capacity of less than 125 pits per year. Minor internal modifications to Building PF-4 and completion of the CMRR Facility would be needed to support production of up to 80 pits per year.³⁰ PF-4 at TA-55 is the only existing plutonium facility capable of being upgraded to support national security requirements at this level (50/80 pits per year) without major construction. Implementation of this 50/80 Alternative (if selected) would be planned to minimize disruption of LANL’s interim pit production activities.

The 50/80 Alternative differs from a Greenfield CPC in several important aspects. First, NNSA assumes this facility would produce up to approximately 80 pits per year; a CPC would produce

³⁰ In the Draft SPEIS, a 9,000 square foot addition to the CMRR was assessed as a means to support consolidation of plutonium operations from LLNL, provide increased analytical chemistry support for increased pit production capacity, and ensure sufficient nuclear space as a contingency. Subsequent to that assessment, NNSA concluded that the 9,000 additional square feet is unnecessary to support the consolidation of plutonium activities. Therefore, NNSA is no longer considering an addition of 9,000 square feet to the CMRR.

125 pits per year (single shift) and is assessed at the higher rate of 200 pits per year (multiple shifts and extended work weeks). Second, the upgraded facility may not have a design life of 50 years (the design life for a CPC) without additional upgrades because some parts of the existing facility have already operated about 40 years. Modifications would include major upgrades to the residue recovery/metal feed facilities in the 400 Area of PF-4. Many of the gloveboxes in this part of the facility would have to be replaced. Replacement of these older gloveboxes would be required to ensure that the recovery/feed process operations are adequate to supply plutonium metal to the manufacturing operations. There would also be significant glovebox decontamination/decommissioning/disposal operations as new process development and certification operations are moved into other areas of PF-4. In addition, various manufacturing equipment would be added to or replaced in the fabrication areas of PF-4 to increase capacity and reliability. Minor internal modifications to Building PF-4 could be required to accommodate additional workers employed in pit manufacturing. The construction of the CMRR Facility would disturb 6.5 acres during construction and add approximately 2.5 acres to the permanent TA-55 footprint.

S.3.4.2 *Uranium Processing Facility at Y-12*

Y-12 manufactures nuclear weapons secondaries, cases, and other weapons components; evaluates and performs testing of these weapon components; maintains Category I/II quantities of HEU; conducts dismantlement, storage, and disposition of nuclear weapons materials; and supplies HEU for use in naval reactors. A proposed UPF would consolidate many of Y-12's operations into an integrated manufacturing facility sized to satisfy all identified programmatic needs. A UPF would be sited adjacent to the HEUMF (which recently completed construction) to allow the two facilities to function as one integrated operation. Transition of Y-12 operations to this configuration would enable the high security area to be reduced by 90 percent. This would significantly improve physical protection; optimize material accountability; enhance worker, public, and environmental, safety, and health protection; and consolidate operations to greatly reduce operational costs.

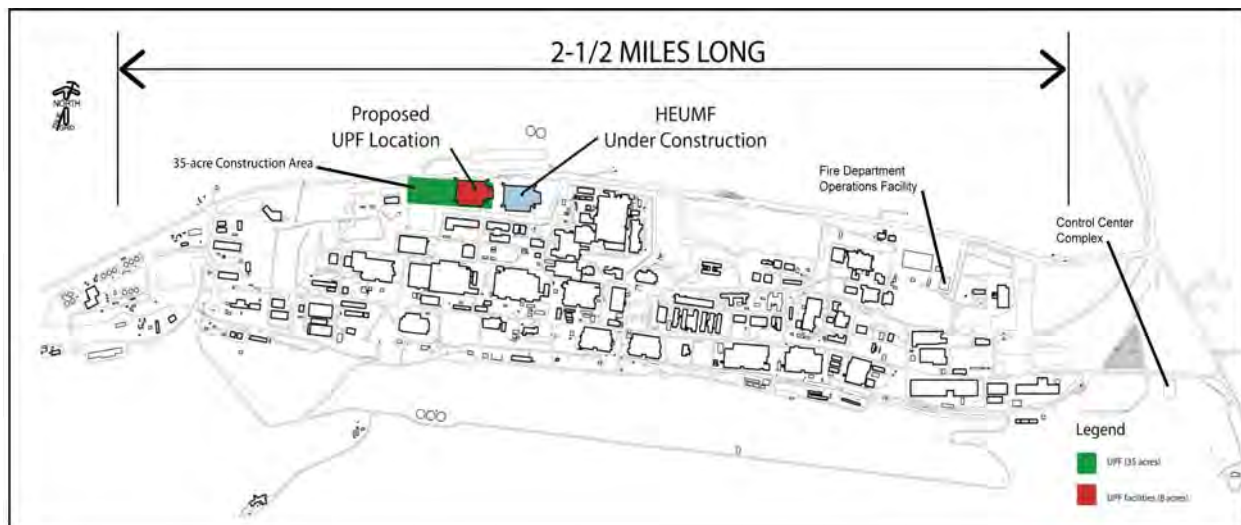

The proposed UPF would replace multiple existing enriched uranium and other processing facilities. The current operating and support areas occupy approximately 633,000 square feet in multiple buildings, while the UPF would result in approximately a 33 percent reduction, to approximately 400,000 square feet in one building. Figure S.3.4.2-1 shows an artist's rendering of the proposed UPF. Figure S.3.4.2-2 shows the proposed location of the UPF relative to other buildings at Y-12.

Source: NNSA 2005c.

Figure S.3.4.2-1—Artist’s Rendering of the UPF Adjacent to the HEUMF

The design service life of a UPF would be 50 years. The preliminary schedule for the project assumes that site preparation would begin in approximately 2010 should NNSA decide to construct this facility. Under this proposed schedule, a UPF would be completed by approximately 2016, and operations would begin by 2018. As shown on Figure S.3.4.2-2, construction of the UPF would require approximately 35 acres of land, which includes acreage for a construction laydown area and temporary parking. Once constructed, the UPF facilities would occupy approximately 8 acres.

Source: NNSA 2007.

Figure S.3.4.2-2—Location of the UPF at Y-12

S.3.4.3 Upgrade Existing Enriched Uranium Facilities at Y-12

NNSA could upgrade the existing Y-12 enriched uranium (EU) facilities. In that case, there would be no UPF and the current high-security area would not be reduced. The upgrade projects would be internal modifications to the existing facilities and would improve worker health and safety and extend the life of existing facilities. If a UPF were not constructed at Y-12, major investments above and beyond normal maintenance would be required for continued operations in the existing facilities, including structural upgrades; heating, ventilating, and air conditioning replacements; and fire protection system replacement/upgrades. The projects would improve airflow controls between clean, buffer, and contamination zones; upgrade internal electrical distribution systems; and upgrade a number of building structures to comply with current natural phenomena requirements (DOE-STD-1023-95).

S.3.5 Programmatic Alternative 2: Consolidated Centers of Excellence

NNSA also evaluates an alternative in this SPEIS involving consolidated centers of excellence (CCE). The CCE alternative would consolidate the three major SNM functions (plutonium, uranium, and weapon assembly/disassembly) involving Category I/II quantities of SNM into a consolidated nuclear production center (CNPC) at one site or into consolidated nuclear centers (CNC) at two sites. The requirements and assumptions for the CCE are:

- A CCE alternative would be sized and configured to support the U.S. nuclear weapons stockpile projected to exist after full implementation of the *Moscow Treaty*. The upper bound of the capacities would support delivery of 125 weapon assemblies per year in five-day, single-shift operations. Multiple shift operation and extended work weeks would yield up to 200 weapon assemblies per year.
- The CCE alternative includes three major facilities: the CPC, consolidated uranium center (CUC), and the A/D/HE Center. As explained in Section S.3.5.2, there is an option to separate the weapon A/D/HE mission to allow NNSA to consider an alternative that locates the nuclear production facilities at a different site than the weapons A/D/HE mission.
- All Category I/II SNM required by NNSA would be stored at the CCE facilities to support future NNSA needs.
- CCE facilities would be designed to have a useful service life of at least 50 years without major facility renovation.
- CCE facilities could be located at one or more of the following sites: Los Alamos, Pantex, NTS, SRS, and Y-12.
- A modular arrangement of facilities (a campus) is assumed for the CCE options rather than separate operational wings in a single large facility. The facilities making up the CCE campus could be configured so that they can be constructed sequentially. A single building to house the CCE functions was not considered to be reasonable due to the need

to bring facilities on-line in a sequential manner and the fundamental differences in uranium, plutonium, and assembly/disassembly operations.³¹ The assumed schedule for the CCE functional facilities is shown in Table S.3.5-0:

Table S.3.5-0—Schedule for Consolidated Centers of Excellence Facilities

Facility	Start Detailed Facility Design	Begin Operations
CUC	2009	2018
CPC	2012	2022
A/D/HE Center	2015	2025

- A CCE would consist of a central core area that includes all operations involving Category I/II quantities of SNM, as well as all support facilities that require lower levels of security protection. This core area would be surrounded by a perimeter intrusion detection and assessment system (PIDAS). A buffer area would provide an unobstructed view of the area surrounding the PIDAS. The land requirements for the operation of a CNPC and CNC are shown in Tables S.3.5-1 and S.3.5-2 respectively.

Table S.3.5-1—Land Requirements to Operate a CNPC

Operation (acres)	Total Area: 545 Acres*	
	PIDAS	Non-PIDAS
Total: 235	Total: 310	
<ul style="list-style-type: none"> • CPC: 40 • CUC: 15 • A/D/Pu Storage: 180 	<ul style="list-style-type: none"> • Non-SNM component production: 20 • Administrative Support: 70 • Explosives Area: 120 • Buffer Area: 100 	

*Total land area for CNPC at Y-12 would be reduced by approximately 27 acres due to existing uranium production facilities, including the HEUMF.

Table S.3.5-2—Land Requirements to Operate a CNC

Operation (acres)	Total Area: 195*	
	PIDAS	Non-PIDAS
Total: 55	Total: 140	
<ul style="list-style-type: none"> • CPC: 40 • CUC: 15 	<ul style="list-style-type: none"> • Non-SNM component production: 20 • Administrative Support: 70 • Buffer Area: 50 acres 	

*Total land area for CNC at Y-12 would be reduced by approximately 27 acres due to existing uranium production facilities, including the HEUMF.

³¹ The facilities that would constitute a CCE would be separate buildings in a campus because they have different and unique safety and operational requirements, and it would not be technically feasible to make them part of a single large facility without having separate systems for the operation of the three facilities and other physical features (blast wall separation, etc.) to keep them separate. They would be built in sequence because they are very complex facilities and the potential realities of construction logistics, cash flow, and start-up management would not support a single facility. Building them in sequence reduces the construction management risk and allows lessons learned from one to benefit the others. The CUC would be first because the existing uranium facilities at Y-12 (except the HEUMF) are aging. The CPC would be built second because the LANL facilities can handle the immediate need for pits. The weapons A/D/HE facilities would be built last because there is less programmatic urgency than for the CUC and CPC.

S.3.5.1 *Consolidated Nuclear Production Center (CNPC) Option*

This option would consolidate the three major SNM functions (plutonium, uranium, and weapon assembly/disassembly) involving Category I/II quantities of SNM into a single campus at one site. Depending on the site selected for the CNPC, this option could result in the cessation of NNSA weapons operations at Y-12 and/or Pantex. Under this option, NNSA would construct and operate a CNPC at SRS, Y-12, Pantex, NTS, or Los Alamos. The CNPC would comprise three major facilities: CPC, CUC, and the A/D/HE Center. The description of the CPC is contained in Section S.3.4.1 and is not repeated below. The sections below describe the other major CNPC facilities: the CUC (Section S.3.5.1.1) and the A/D/HE Center (Section S.3.5.1.2). In addition, Section S.3.5.1.3 describes the transport of plutonium and HEU to the CNPC. Finally, Section S.3.5.1.4 discusses site-specific characteristics of the candidate sites for a CNPC. These characteristics affect the manner in which a CNPC might be implemented. For example, a CNPC located at Pantex would not require the construction of the A/D/HE Center, as Pantex currently performs those missions in existing facilities that would not require major renovations in the reasonably foreseeable future. Section S.3.5.1.4 also identifies the reference locations for the CNPC at each site alternative. A generic layout of the CNPC is shown in Figure S.3.5.1-1.

S.3.5.1.1 **Consolidated Uranium Center**

The CUC would have a nuclear facility located within a PIDAS, and non-nuclear support facilities outside of it. The nuclear facility would consist of a UPF and a storage facility for HEU.³² The nuclear facility would process HEU, produce nuclear weapon secondary components, provide the capability to perform HEU R&D in support of LANL and LLNL, and store HEU. The non-nuclear facilities would contain the production operations and support functions. The non-nuclear facilities would also contain the chemical processes, fabrication operations, support functions associated with the production of lithium-hydride and lithium-deuteride components, and general manufacturing capabilities. For this analysis, it is assumed that the CUC could be built at any of the sites on approximately the same timeframe that a UPF could be built at Y-12. The CUC would be constructed over a six year period, beginning in approximately 2010, with completion by approximately 2016, and operations beginning by approximately 2018. The land requirements for the CUC are shown in Table S.3.5-3.

Table S.3.5-3—Land Requirements for CUC*

Construction (acres)	50	
Operation (acres)	Total Area: 35**	
	PIDAS	Non-PIDAS
	15	20

* At Y-12, a UPF would be constructed (see Section S.3.4.2). The UPF would require a total area of 8 acres rather than the 35 acres for a CUC.

** Includes a buffer area that would provide unobstructed view of the area surrounding the PIDAS.

³² A CUC at Y-12 would not require construction of a new HEU storage facility because NNSA recently completed construction of a modern storage facility (the HEUMF) at that site.

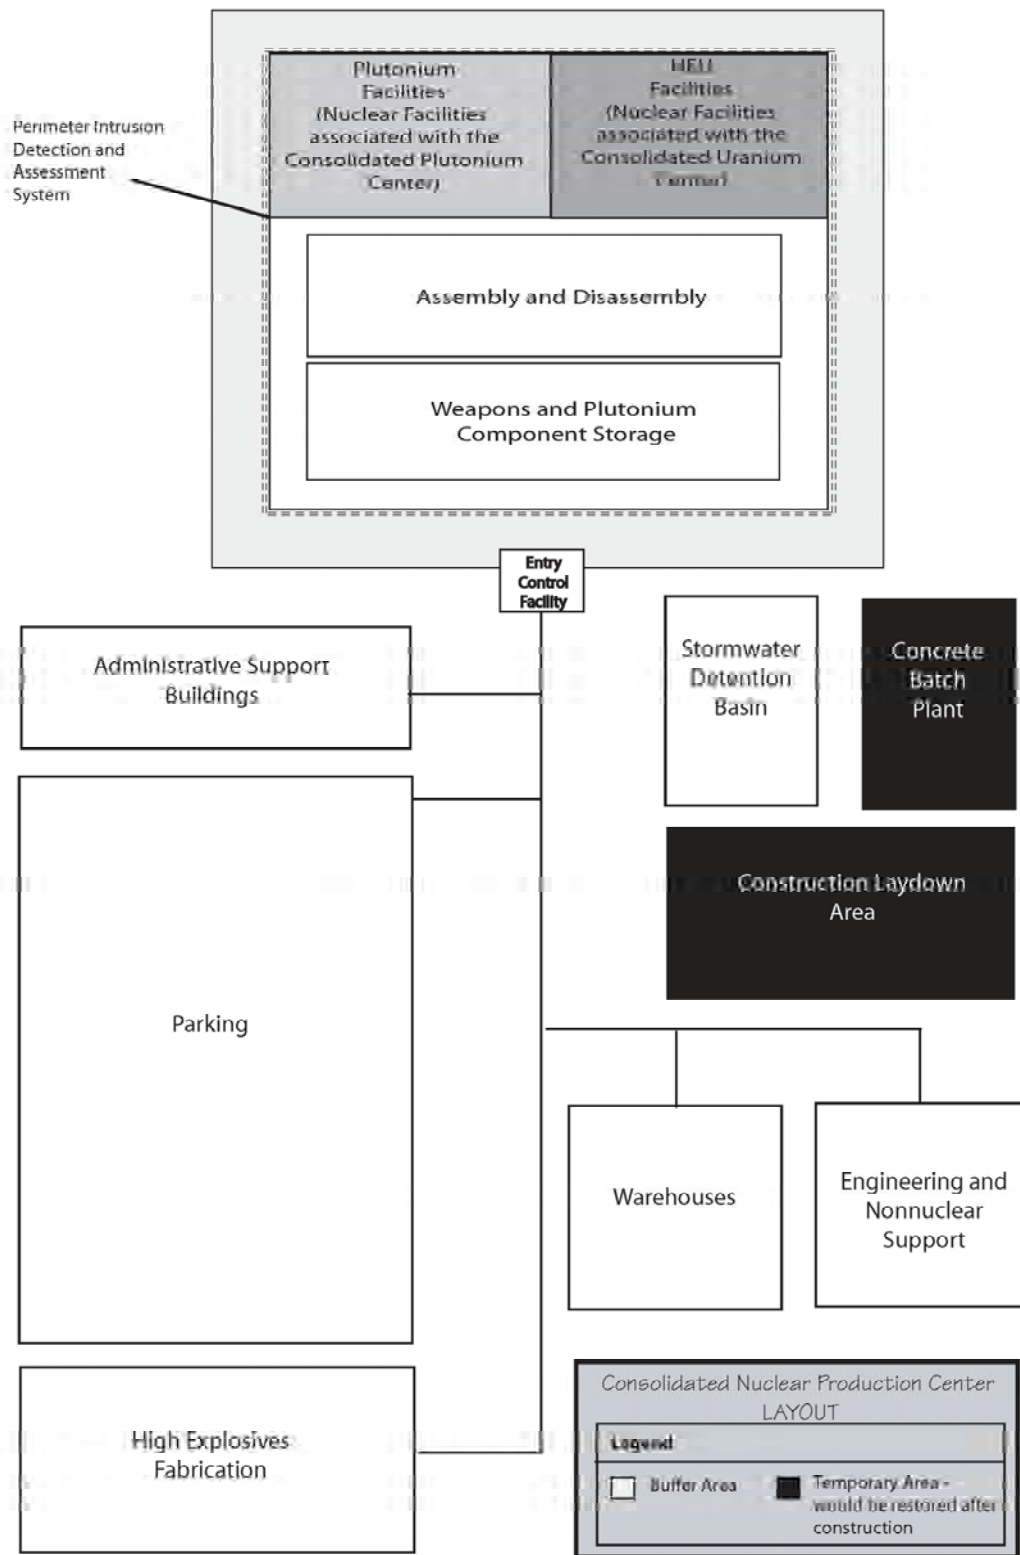

Figure S.3.5.1-1—Generic Layout of the Consolidated Nuclear Production Center

S.3.5.1.2 Assembly/Disassembly/High Explosives Center

The A/D/HE Center would carry out the following major missions:

- Assemble warheads;
- Dismantle weapons that are surplus to the strategic stockpile and sanitize,³³ store, or dispose of their components;
- Develop and fabricate explosive components; and
- Conduct surveillance related to certifying weapon safety and reliability.

The A/D/HE Center would contain nuclear facilities located within the PIDAS, and non-nuclear facilities outside the PIDAS. The nuclear facilities would contain the cells and bays in which maintenance, modification, disassembly, and assembly operations are conducted. The facilities would be designed to mitigate the effects of the unlikely accidental detonation of the weapon’s explosive components.

As shown in Table S.3.5-4, an area of 180 acres would be provided in the PIDAS for weapons assembly and disassembly facilities, and for weapons and component storage. Located outside the PIDAS would be a buffer zone and non-nuclear facilities for HE fabrication, administrative support, and disposal of explosive materials. This area would be approximately 120 acres. The A/D/HE Center would be constructed over a six-year period beginning in approximately 2020, with completion by approximately 2025, and operations beginning by approximately 2025.

Table S.3.5-4—Land Requirements for A/D/HE Center*

Construction (acres)	300	
Operation (acres)	Total Area: 300**	
	PIDAS	Non-PIDAS
	Weapons A/D/Pu Storage: 180	Administrative and High Explosives Area: 120

* At NTS, an A/D/HE Center would require 200 acres, due to use of existing infrastructure.

** Includes a buffer area that would provide unobstructed view of the area surrounding the PIDAS.

S.3.5.1.3 Transport of Plutonium and HEU to a CNPC

If NNSA were to construct and operate a CNPC, plutonium and HEU would be consolidated at the CNPC. This would entail three potential movements of these materials: (1) transfer of LANL’s Category I/II plutonium to the CNPC, if LANL is not selected as the host site for the CNPC; (2) transfer of Pantex’s non-excess Category I/II plutonium to the CNPC, if Pantex is not selected as the host site for the CNPC; and (3) transfer of Y-12’s Category I/II HEU to the CNPC, if Y-12 is not selected as the host site for the CNPC. Each of these movements is discussed below.

- Transfer of LANL’s Category I/II inventories of nuclear material essential to the programmatic mission of NNSA would be transferred to the eventual CNPC Site. This would involve approximately 4 shipments of material.

³³ Sanitization involves the obliteration and demilitarization of classified weapons parts.

- Transfer of Pantex's non-excess Category I/II plutonium to the CNPC would involve:
 - Less than 60 metric tons of plutonium, mostly in pit form;
 - Approximately 470 shipments would be required, beginning in approximately 2025 and lasting 5 years.

- Transfer of Y-12's Category I/II HEU to the CNPC would involve:
 - Up to 252 metric tons of HEU;
 - Approximately 540 shipments would be required, beginning after approximately 2023 and lasting 5 years.

S.3.5.1.4 Site-Specific Features Relevant to a CNPC

This section describes implementation of a CNPC at each candidate site. While the CNPC requirements would be the same at each site, the means of achieving them would vary depending upon the existing facilities and infrastructure at a site. This section also identifies the reference location for a CNPC at each site.

S.3.5.1.4.1 Los Alamos

A CNPC located at Los Alamos would require the construction of a CPC (which could either be a "Greenfield CPC" or an upgrade to existing LANL facilities), a CUC, and an A/D/HE Center. There would not be enough acreage at TA-55 to locate an entire CNPC. Thus, a CNPC at LANL could be divided between two TAs (TA-55 [which could be the site for the CPC and the CUC], and TA-16 [A/D/HE Center]) or completely located at TA-16. Figure S.3.5.1-2 identifies the reference locations for the CPC, CUC, and the A/D/HE Center at LANL. Because the CPC, CUC, and A/D/HE Center would be constructed sequentially, construction requirements for these three facilities would not create simultaneous impacts and are analyzed as sequential actions in this SPEIS.

S.3.5.1.4.2 NTS

A CNPC located at NTS would require the construction of a CPC, a CUC, and an A/D/HE Center (which would be an upgrade to the existing Device Assembly Facility, as described in this section). Figure S.3.5.1-3 shows the reference locations for the CPC, CUC, and the A/D/HE Center at NTS.

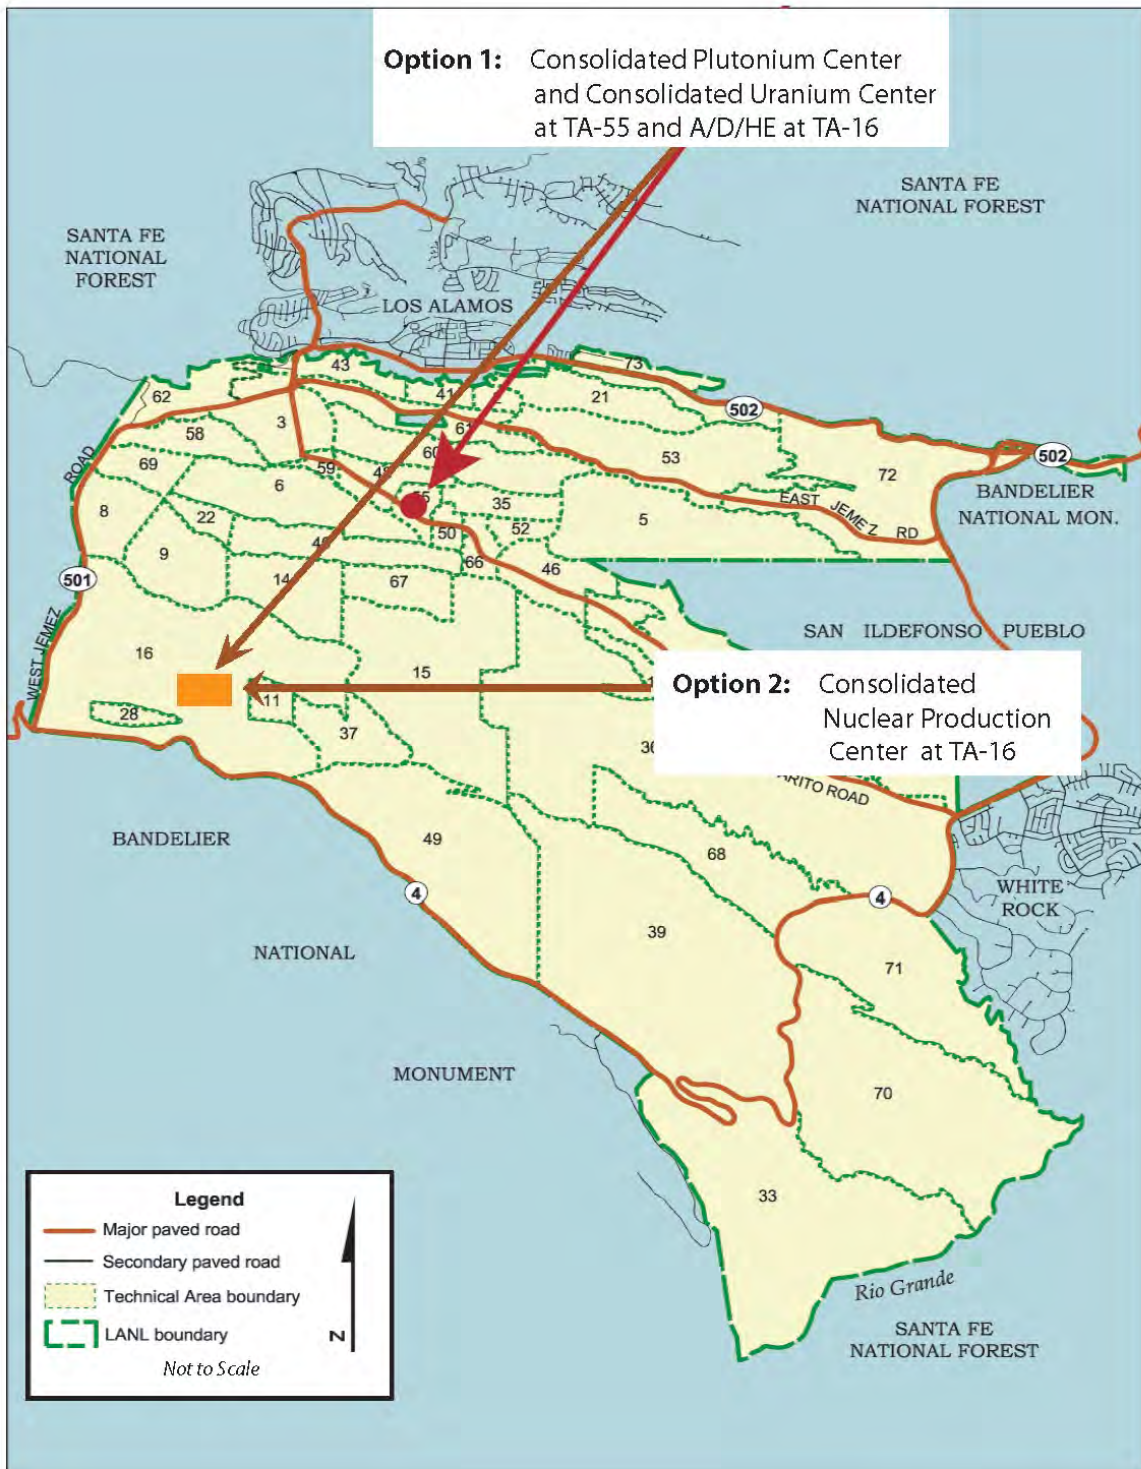

Figure S.3.5.1-2—Los Alamos Consolidated Nuclear Production Center Reference Locations

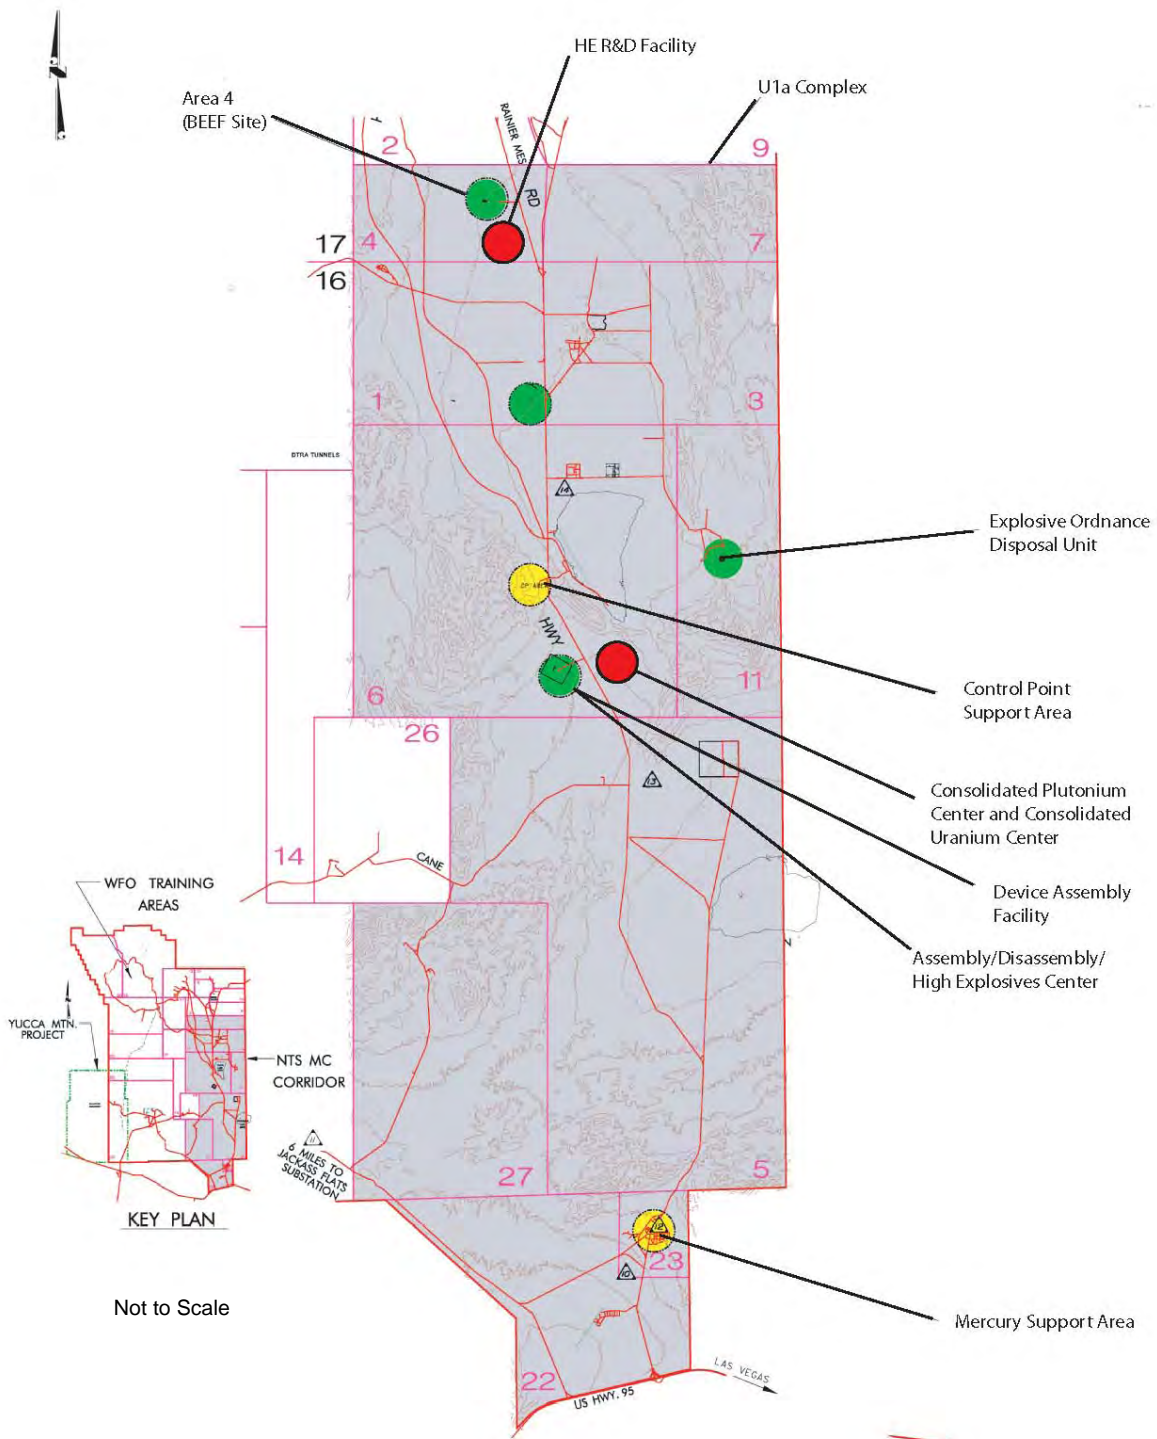

Figure S.3.5.1-3—NTS Consolidated Nuclear Production Center Reference Locations

An A/D/HE Center could make use of the existing capabilities at NTS such that construction requirements would be reduced compared to an A/D/HE Center located at other sites (other than Pantex). An A/D/HE Center at NTS could maximize use of existing facilities at the Device Assembly Facility (DAF), the underground complex of tunnels at U1a, the Big Explosive Experimental Facility (BEEF), the Explosives Ordnance Disposal Unit, existing site infrastructure, and the support areas of Mercury, the Control Point, and Area 6 Construction (Figure S.3.5.1-3). By utilizing these existing assets, the need for additional construction would be minimized.

S.3.5.1.4.3 Pantex

A CNPC located at Pantex would not require the construction of an A/D/HE Center, as Pantex currently performs these missions in existing facilities. As such, a CNPC at Pantex would involve construction of a CPC and a CUC. Figure S.3.5.1-4 identifies the reference location for a CPC and CUC at Pantex.

S.3.5.1.4.4 SRS

A CNPC at SRS would require the construction of a CPC, a CUC, and an A/D/HE Center. Figure S.3.5.1-5 identifies the reference location for a CNPC at SRS.

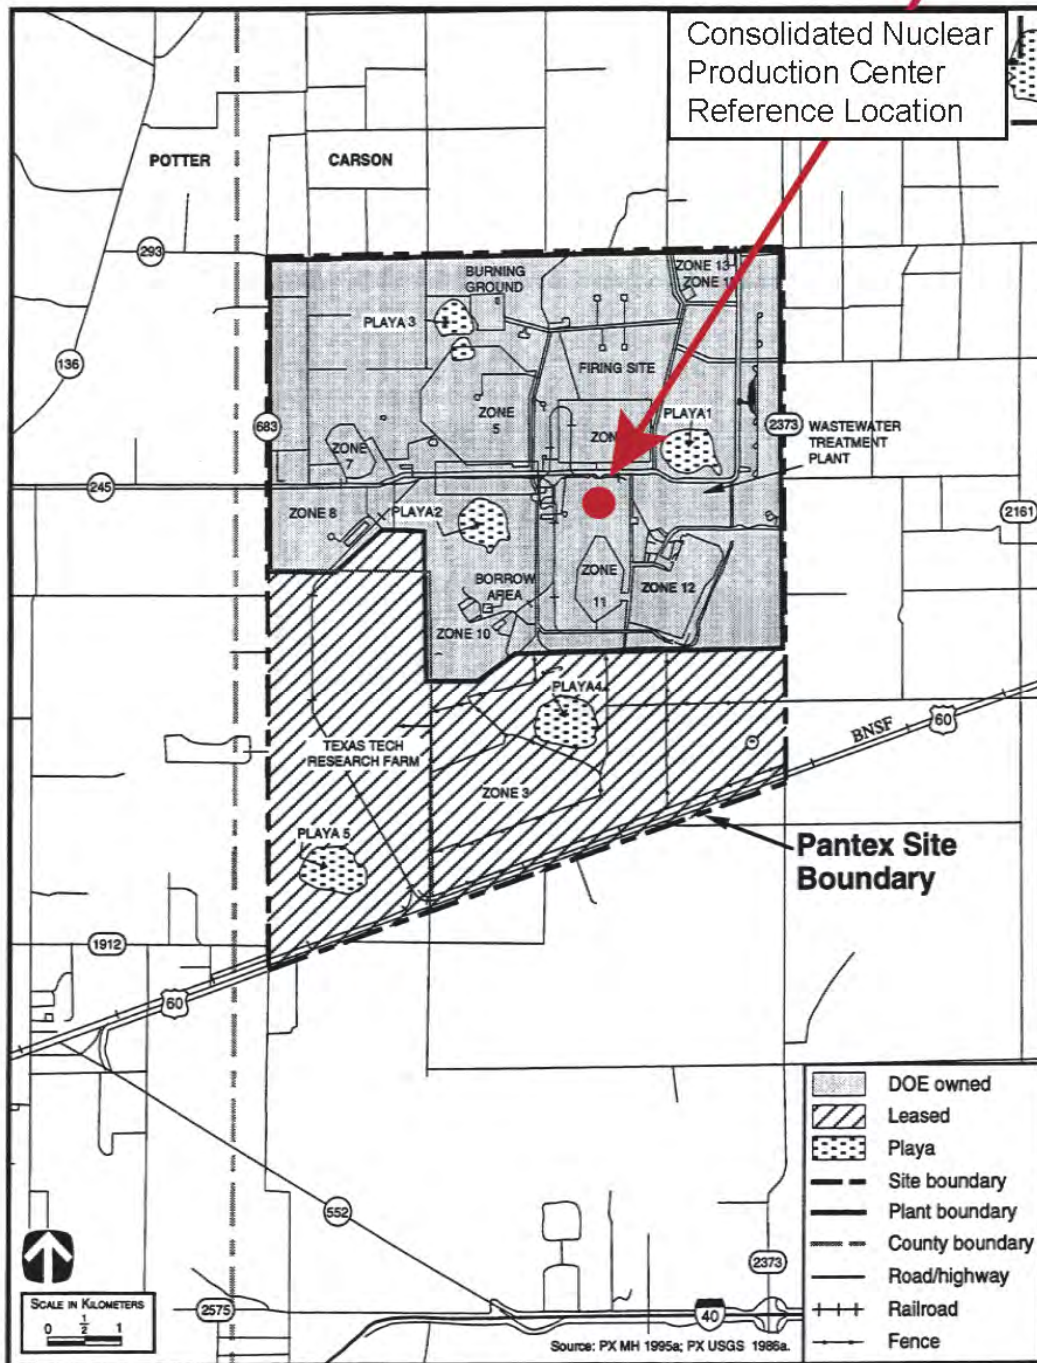

Figure S.3.5.1-4—Pantex CNPC Reference Location

Figure S.3.5.1-5—SRS CNPC Reference Location

S.3.5.1.4.5 Y-12

A CNPC located at Y-12 would require the construction of a CPC, a UPF, and an A/D/HE Center. A CUC at Y-12 would not require construction of a new HEU storage facility because NNSA is already building a modern storage facility there (the HEUMF). Figure S.3.5.1-6 identifies the reference locations for a CPC, UPF, and the A/D/HE Center at Y-12. The HE component of the A/D/HE Center would be located on the ORR approximately 4.5 miles west of Y-12 due to buffer requirements and available real estate.

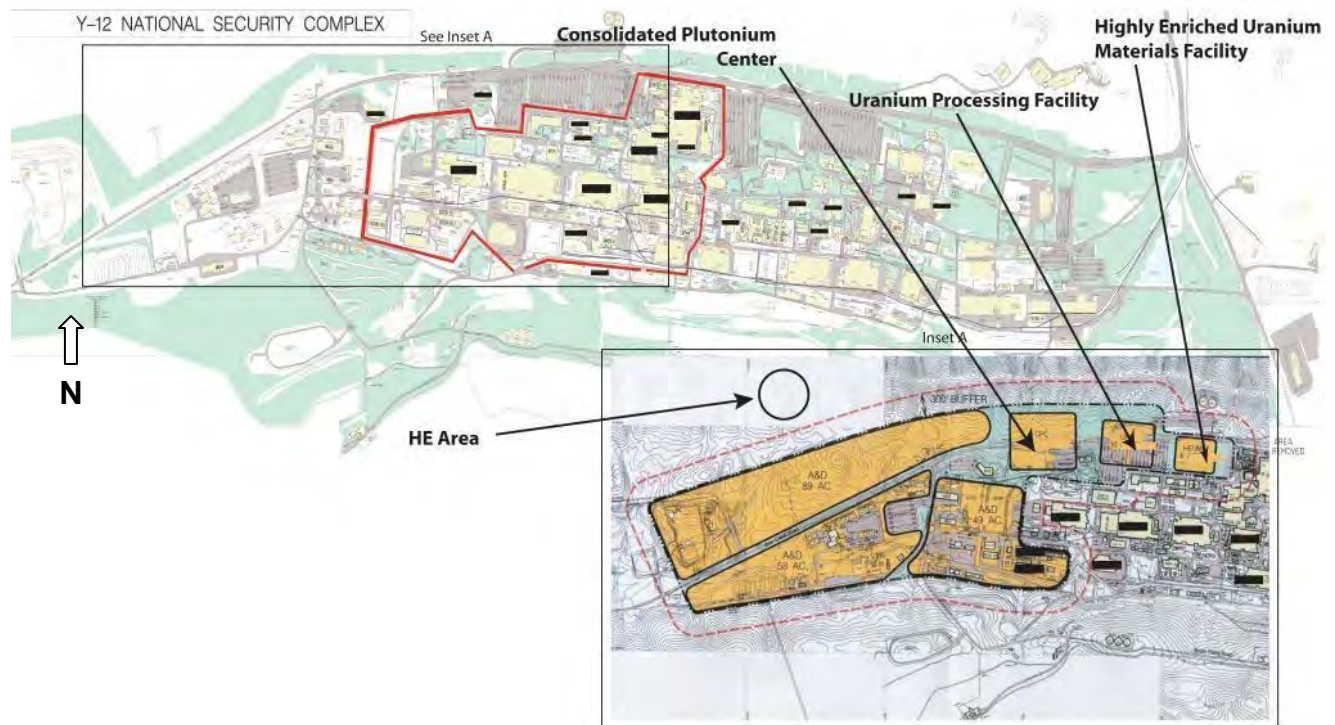

Figure S.3.5.1-6—Y-12 CNPC Reference Location

S.3.5.2 Consolidated Nuclear Center Option

This option would separate the weapon A/D/HE mission to allow NNSA to consider an alternative that locates the nuclear production facilities at a different site from the weapons A/D mission. Under this option, NNSA would construct and operate a CPC and CUC at one site and an A/D/HE Center at either Pantex or NTS. A generic layout of a CNC is shown in Figure S.3.5.2-1.

The descriptions of the facilities that constitute a CNC are contained in Section S.3.5.1. Operationally, the major difference between a CNPC and a CNC is the need for transportation between the nuclear production facilities and an A/D/HE Center. For example, once steady-state operations are achieved in a CNPC, all nuclear missions would occur at a single site and there would be virtually no radiological transportation within the Complex (with the exception of nuclear weapon and waste shipments).

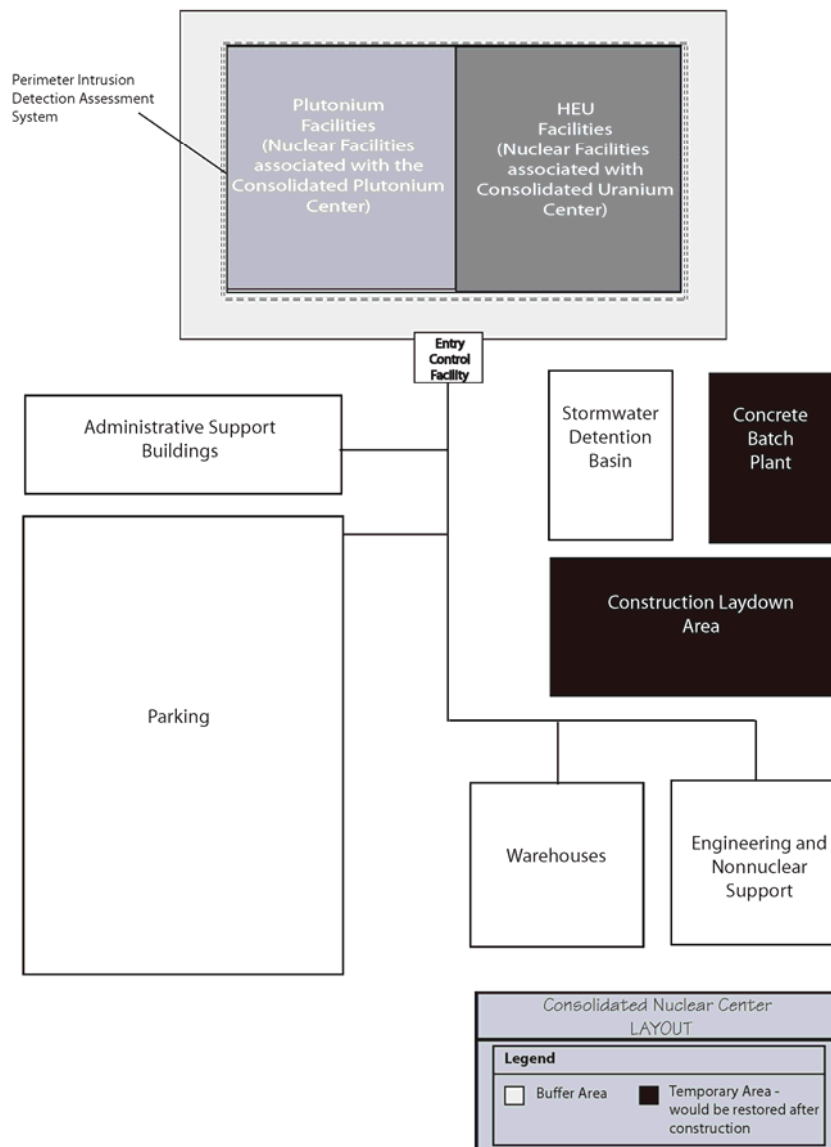

Figure S.3.5.2-1—Generic Layout of the Consolidated Nuclear Center

Under a CNC option, radiological transportation would be required between the nuclear production facilities and the A/D/HE Center. This SPEIS assesses the radiological transportation impacts of the alternative configurations shown in Table S.3.5.2-1.

Table S.3.5.2-1—Alternative Configurations of the CNC

If A/D/HE Center is at:	Then CNC would be located at one of the following locations:			
	SRS	NTS	Los Alamos	Y-12
Pantex	X	X	X	X
NTS	X		X	X

S.3.6 Programmatic Alternative 3: Capability-Based Alternative

The nuclear weapons stockpile and the Complex have undergone profound changes since the end of the Cold War. Since that time, more than 12,000 United States nuclear weapons have been dismantled, no new-design weapons have been produced, three former nuclear weapons plants (Mound, Pinellas, and Rocky Flats) have been closed, nuclear material production plants (Hanford, K-25 at ORR, most of SRS, and Fernald) have stopped production and are being decontaminated, and the United States is observing a moratorium on nuclear testing.

In 2002, President Bush and President Putin signed the *Moscow Treaty*, which will reduce the number of operationally deployed strategic nuclear weapons to 1,700-2,200 by 2012. In 2004, President Bush issued a directive to cut the entire U.S. stockpile—both deployed and reserve warheads—in half by 2012. This goal was later accelerated and achieved 5 years ahead of schedule in 2007. As of the end of 2007, the total stockpile was almost 50 percent below what it was in 2001. On December 18, 2007, the White House announced the President's decision to reduce the nuclear weapons stockpile by another 15 percent by 2012. This means the U.S. nuclear stockpile will be less than one-quarter its size at the end of the Cold War—the smallest stockpile in more than 50 years (D'Agostino 2008).

As these actions illustrate, the Administration's goal is to achieve a credible nuclear deterrent with the lowest possible number of nuclear warheads consistent with national security needs. NNSA's analyses in this SPEIS are based on current national policy regarding stockpile size (1,700-2,200 operationally deployed strategic nuclear warheads) with flexibility to respond to future Presidential direction to change the size. NNSA also assumes that it must continue to maintain an arsenal of some number of nuclear weapons. Maintaining a stockpile requires the ability to detect aging effects in weapons (a surveillance program), the ability to fix identified problems without nuclear testing (the stockpile stewardship program), and the ability to produce replacement components and reassemble weapons (a fully capable set of production facilities). Currently, there are some elements of the Complex that are unable to safely or reliably perform their assigned production mission (e.g., CMR at LANL and Building 9212 at Y-12). Therefore, new facilities are required to perform the essential production missions of these facilities.

Although the size of the stockpile beyond 2012 is not known, the trend suggests a significantly smaller one. Consistent with this trend, NNSA developed a programmatic alternative, referred to as the "Capability-Based Alternative," to analyze the potential environmental impacts associated with a Complex that would support stockpiles smaller than those currently planned. NNSA has assumed that such a stockpile would be approximately 1,000 operationally deployed strategic nuclear warheads. The objective of this analysis is to identify the potential environmental impacts that are particularly sensitive to assumptions about the size of the future stockpile. In addition, analysis of this alternative enhances NNSA's understanding of the infrastructure that might be appropriate if the United States continues to reduce stockpile levels. Within the Capability-Based Alternative, NNSA has analyzed two options:

(1) A Capability-Based Alternative that would maintain a basic manufacturing capability to produce nuclear weapons, as well as laboratory and experimental capabilities to support the stockpile. It would reduce the operational capacity of production facilities to a throughput of

approximately 50 weapons per year. This alternative involves pit production at LANL of 50 pits per year and reductions of production capacities at Pantex, Y-12, and SRS. This alternative is described in detail in Section 3.6.1.

(2) A No Net Production/Capability-Based Alternative that would produce a limited number of components and assembly of weapons beyond those associated with supporting surveillance, but would not involve adding new types or increased numbers of weapons to the total stockpile. This alternative involves a minimum production (production of 10 sets of components or assembly of 10 weapons per year) to maintain capability and to support a limited Life Extension Program (LEP). This alternative, which NNSA added after considering public comments on the Draft SPEIS, is described in detail in Section 3.6.2.

The two options analyzed for the Capability-Based Alternative might not provide the optimum configuration of the Complex if the stockpile became much smaller. In such a situation, NNSA could make changes to the Complex beyond those described by the two options analyzed for the Capability-Based Alternative. Consequently, this SPEIS discusses further changes to the Complex that might be reasonable if the stockpile were reduced even further (to hundreds of weapons). That discussion focuses on how the programmatic alternatives considered in this SPEIS could be adapted to such a small stockpile. NNSA acknowledges, however, that any decision to reduce the stockpile to those levels could result in a need to reassess the transformation options for the Complex.

S.3.7 Category I/II SNM Consolidation Actions Included in the No Action Alternative or Common to All of the Programmatic Action Alternatives

Category I/II quantities of SNM are stored at six NNSA sites: LLNL, LANL, NTS, Pantex, SRS (not associated with NNSA weapons activities), and Y-12. NNSA is seeking to reduce security costs and increase safety through SNM consolidation. As a result, the future complex is expected to have fewer sites and fewer locations within sites with Category I/II quantities of SNM. This section describes actions related to Category I/II SNM consolidation that are either included in the No Action Alternative or common to each of the programmatic action alternatives.

S.3.7.1 *Transfer Category I/II SNM from LLNL to Other Sites and Phase-out Operations at Superblock Involving Category I/II Quantities of SNM*

NNSA is assessing the removal of Category I/II SNM from LLNL by approximately 2012, and the phase-out of operations at the Superblock involving Category I/II quantities of SNM. Although the exact quantities of Category I/II SNM are classified, the Category I/II SNM at LLNL can be divided up into three basic categories, in the percentages indicated, along with the receiver site for this material, and the number of trips required (see Table S.3.7-1).

Table S.3.7-1—Category I/II SNM at LLNL

Category I/II SNM Category	Percentage	Receiver Site	# Trips
SNM Excess to Programmatic Missions ³⁴	56	SRS	10
SNM Required for Programmatic Missions	28	LANL ³⁵	5
Waste	6	WIPP	3

Source: NNSA 2007.

The LLNL SWEIS (DOE 2005) assesses the environmental impacts of transporting SNM to and from LLNL and other DOE sites as part of the proposed action. The Record of Decision for the LLNL SWEIS (70 FR 71491) authorized operations for the Proposed Action Alternative, which allows approximately 538 shipments annually of hazardous and radioactive materials and wastes. As such, the transportation activities identified in Table S.3.7-1 are included in the existing No Action Alternative³⁶. For completeness, however, this SPEIS assesses the environmental impacts associated with:

- Packaging and Unpackaging Category I/II SNM
- Transporting Category I/II SNM from LLNL to Receiver Sites
- Storage of Category I/II SNM at Receiver Sites
- Phasing out Category I/II SNM Operations from LLNL.

S.3.7.2 *Transfer Category I/II SNM from Pantex Zone 4 to Zone 12*

Under this alternative, which could be carried out under any of the programmatic action alternatives, NNSA would transfer pits currently stored at Pantex in Zone 4 to Zone 12. There are two options under this alternative. Under option one, NNSA would transfer the more than 10,000 pits stored in Zone 4 to Zone 12. Because there is insufficient storage space in existing Zone 12 facilities, NNSA would need to build a new storage facility capable of storing approximately 60 metric tons (MT) of plutonium. Transfer of the pits from Zone 4 to Zone 12 would enable all Category I/II SNM at Pantex to be consolidated at a central location, close to the assembly, modification, and disassembly operations. This new facility would permit the storage of all surplus and non-surplus pits in Zone 12 in the event there is a delay in the completion of the Pit Disposition and Conversion Facility (PDCF) at SRS. This would reduce the area at Pantex requiring a high level of security. Under option two, NNSA would transfer only

³⁴ In 2007, DOE prepared a Supplement Analysis (SA) that evaluated the potential environmental impacts of consolidation at SRS of surplus, non-pit, weapons-usable plutonium from Hanford, LLNL and LANL. The SA concluded that this consolidation would not produce a significant change to the potential environmental impacts identified in previous NEPA reviews (DOE 2007b). Subsequently, DOE decided to transfer surplus non-pit weapons-usable plutonium from LLNL to SRS for consolidated storage. Nonetheless, for completeness, this SPEIS includes an analysis of the transportation impacts associated with disposition of all surplus plutonium from LLNL to SRS.

³⁵ This analysis also evaluates NTS as an interim storage location for the LLNL Category I/II SNM required for programmatic missions. Under this option, NNSA would transfer the material to NTS for interim storage in the Device Assembly Facility until eventual transfer to LANL.

³⁶ The LLNL SWEIS (DOE 2005) assesses the environmental impacts of transporting SNM to and from LLNL and other NNSA sites, SRS, and WIPP. That analysis includes consideration of transportation activities involving greater quantities of SNM and more shipments than are proposed in this SPEIS. As such, the transportation activities associated with consolidating SNM from LLNL are included in the existing No Action Alternative and can proceed without additional NEPA analysis. For completeness, however, this SPEIS includes the environmental impacts associated with such actions.

the non-surplus pits from Zone 4 to Zone 12. The surplus pits would be shipped directly to SRS from Zone 4 for processing in the PDCF, which is to be constructed SRS and is currently projected to be operational in 2019. Because there is insufficient storage space in existing Zone 12 facilities for even this reduced quantity, NNSA would need to build a new smaller storage facility to store approximately 30 MT of plutonium.

ALTERNATIVES to RESTRUCTURE R&D and TESTING FACILITIES

S.3.8 High Explosives R&D

Energetic materials (high explosives [HE], propellant and pyrotechnic powders) provide specific quantities of energy needed for a nuclear weapon to function. Stewardship of the stockpile requires a broad spectrum of energetic material R&D. In the nuclear portion of a weapon system, HE is used for the main charge and associated triggering systems. More specifically, HE R&D is required to assure stability and dependability of HE in nuclear weapons. HE R&D is conducted at LLNL, LANL, SNL/NM, NTS, and Pantex. The project-specific alternatives for HE R&D are shown in Table S.3.8-1.

Table S.3.8-1—High Explosives R&D Alternatives

- **No Action** — continue operations at LLNL, LANL, SNL/NM, NTS, and Pantex
- **Minor Consolidation** — multiple options to consolidate or transfer some operations, but operations would continue at all sites
- **Major Consolidation** — multiple options to consolidate or transfer operations to fewer sites, and discontinue operations at sites that transfer missions

S.3.9 Tritium R&D

Tritium, a radioactive isotope of hydrogen, is an essential component (used to increase the yield) of every warhead in the current and projected U.S. nuclear weapons stockpile. Because warheads depend on tritium to perform as designed, an understanding of the properties of tritium is essential, and there is a need for tritium R&D. Within the Complex, tritium R&D involves activities such as: storage, purification, separation, engineering and physics performance, aging, analysis of surveillance data, diagnostics, enhanced surveillance, modeling and simulation, and compatibility testing. Over the past 15 years there has been substantial consolidation of tritium facilities. However, there are still opportunities for further reductions and/or consolidations. The alternatives for tritium R&D are shown in Table S.3.9-1.

Table S.3.9-1—Tritium R&D Alternatives

- **No Action** — continue operations at LLNL, LANL, SRS, and SNL/NM¹
- **Consolidate Tritium R&D at SRS** — move gas transfer system R&D support from LLNL² and LANL to SRS
- **Consolidate Tritium R&D at LANL** — move gas transfer system R&D support from LLNL to LANL
- **Reduce Tritium R&D In Place** — LLNL, LANL, and SRS would reduce operations

¹Tritium Operations at SNL/NM are primarily associated with the Neutron Generator Production Facility, which would be unaffected under all alternatives.

²Does not include National Ignition Facility (NIF) target R&D and filling NIF targets. Those operations would remain at LLNL under all alternatives.

S.3.10 NNSA Flight Test Operations for Gravity Weapons

SNL manages Flight Test Operations for gravity weapons (bombs) to assure compatibility of the hardware necessary for the interface between the weapon and the delivery system, and to assess weapon system functions in realistic delivery conditions. The actual flight tests are conducted

with both the B83 and B61 weapons, which are pulled from the stockpile and converted into units called Joint Test Assemblies (JTAs). These tests are presently conducted at the TTR, a 280 square-mile site, located about 140 air-miles northwest of Las Vegas, Nevada. NNSA operates this facility under the terms of a land use agreement with the United States Air Force. This agreement expires in 2019.

Conversion of nuclear weapons into JTAs is a multi-step operation. Pantex denuclearizes nuclear weapons that become JTAs. These JTAs are not capable of producing nuclear yield. They may then be further modified at SNL. JTAs are then dropped from aircraft at various altitudes and velocities. Depleted uranium may be present in JTAs, but because there is no explosive event, the depleted uranium is contained within the weapon case and completely recovered after each test. There is no contamination of the soil as the result of a JTA flight test. In some cases, JTAs are flown at velocities and altitudes of interest and not dropped. In this case, the aircraft returns to its base with the JTA on-board. In an average year, 10 JTAs are tested at TTR.

The alternatives for NNSA flight testing are shown in Table S.3.10-1. The selection of any of the alternatives for flight test operations is unconnected to, and will not impact, the continuation of ongoing DOE environmental restoration activities and responsibilities at TTR resulting from past testing by the Atomic Energy Commission.

Table S.3.10-1—NNSA Flight Test Operations Alternatives

- **No Action.** Continue operations at TTR
- **Upgrade Alternative.** Continue operations at TTR and upgrade equipment with state-of-the-art mobile technology
- **Campaign Mode Operations.** Continue operations at TTR but reduce permanent staff and conduct tests with DOE employees from other sites. Three options are assessed:
 - Option 1—Campaign from NTS: Reduce mission staff and relocate remaining Sandia staff to NTS; Operation and Management (O&M) and Security taken over by NTS. Additional contract for technical support of equipment is needed for maintenance and upgrade.
 - Option 2—Campaign Under Existing Permit: Reduce mission staff at TTR; campaign additional staff for each test series; retain O&M responsibilities; permit would be retained in current form; security responsibilities would be transferred to the U.S. Air Force (USAF).
 - Option 3—Campaign Under Reduced Footprint Permit: Reduce mission staff at TTR; campaign additional staff for each test series; retain O&M responsibilities; permit would be potentially reduced to less than 1 square mile; security, emergency services, power line and road maintenance responsibilities transferred to the USAF.
- **Transfer to WSMR.** Move NNSA Flight Testing from TTR to WSMR
- **Transfer to NTS.** Move NNSA Flight Testing from TTR to NTS

S.3.11 Hydrodynamic Testing

Hydrodynamic testing (hydrotesting) consists of high-explosive experiments to assess the performance and safety of nuclear weapons. Hydrodynamic tests (except for some underground sub-critical experiments at the NTS) do not normally employ fissile materials. Data from experiments including hydrotesting, coupled with modeling and simulation using high performance computers, is used to certify the safety, reliability, and performance of the nuclear physics package of nuclear weapons without nuclear testing. Hydrotesting is conducted at

LLNL, LANL, NTS, Pantex, and SNL/NM. The alternatives for hydrotesting are shown in Table S.3.11-1.

Table S.3.11-1—Hydrodynamic Testing Alternatives

- **No Action** – continue hydrotesting at LLNL, LANL, NTS, Pantex, and SNL/NM
- **Downsize in Place**
 - Consolidate LLNL hydrotesting at Contained Firing Facility (CFF)
 - Consolidate LANL hydrotesting at Dual Axis Radiographic Hydrodynamic Test (DARHT) facility
 - Consolidate NTS hydrotesting at single confined and single open-air sites
 - Discontinue hydrotesting at Pantex and SNL/NM
- **Consolidate at LANL**
 - Integrate hydrotesting program at LANL
 - Construct new CFF-like facility at LANL
 - Discontinue hydrotesting at LLNL once CFF-like facility is operational
 - Maintain BEEF at NTS
 - Discontinue hydrotesting at Pantex and SNL/NM
- **Consolidate at NTS¹**
 - Integrate hydrotesting program at NTS
 - Construct new DARHT-like facility at NTS
 - Construct new CFF-like facility at NTS
 - Discontinue hydrotesting at LLNL, LANL, Pantex, and SNL/NM

¹The NTS Alternative is considered a “next generation” alternative because NNSA is not proposing these changes at this time.

S.3.12 Major Environmental Test Facilities

Environmental testing supports a primary NNSA mission of maintaining and demonstrating the safety, reliability, and performance of the nation’s nuclear weapons systems. The environmental testing facilities (ETFs) are divided into two categories – base ETFs and system ETFs. The base ETFs are those facilities and laboratory scale (or “table-top”) items used to evaluate components or subassemblies in the environments defined by the Stockpile-to-Target Sequence (STS) and the Military Characteristics requirements for each nuclear weapon type in the stockpile. Every laboratory within the NNSA complex has some base capability essential for day-to-day operations. The system ETFs are those facilities used to test full-scale weapons systems (with or without SNM) or those unique major facilities that are used for development and certification of components, cases, accessories, subsystems, and systems. This SPEIS focuses on a subset of base and system ETFs, referred to as “major” ETFs that are costly to maintain or have potentially significant environmental impacts. Major ETFs are located at SNL/NM, LANL, LLNL, and NTS. The alternatives for major ETFs are shown in Table S.3.12-1.

Table S.3.12-1—Major ETF Alternatives

- **No Action** — Maintain status quo at each site. All facilities would be maintained, or upgraded to meet current safety and security standards.
- **Downsize-in-Place** — No duplication of capability within a given site, but there may be duplication from site to site - phase out aging and unused facilities.
- **Consolidate ETF Capabilities at One Site (NTS or SNL/NM)** — Entails construction of new facilities at consolidation site. This alternative also includes an option to move LLNL Building 334 and the LLNL Site 300 Building 834 Complex ETF capabilities to Pantex.

S.3.13 Sandia National Laboratories, California (SNL/CA), Weapons Support Functions

Facilities at SNL/CA are used to perform non-nuclear component design and engineering work. The SNL/CA facilities at Livermore consist of 72 buildings including laboratory and offices. Major NNSA facilities include Building 910, Building 914, Building 916, Building 927, the Micro and Nano Technologies Laboratory (MANTL), the Distributed Information Systems Laboratory (DISL), and other weapon system engineering and support buildings. The alternatives for continuing the SNL/CA weapons support functions are shown in Table S.3.13-1. Acceptance of these activities at SNL/NM would be accommodated in existing facilities.

Table S.3.13-1—SNL/CA Weapons Support Functions Alternatives

- | |
|--|
| <ul style="list-style-type: none">• No Action — Maintain current non-nuclear component design and engineering work at SNL/CA with SNL personnel• Consolidate SNL/CA non-nuclear component design and engineering work to SNL/NM |
|--|

S.3.14 Alternatives Considered But Eliminated from Detailed Study

NNSA considered alternatives other than those presented in Sections S.3.3 through S.3.13. NNSA concluded, however, that these alternatives were not reasonable and eliminated them from detailed analysis. This section identifies the alternatives that were considered but eliminated from detailed study, and discusses the reasons why they were eliminated.

Consolidate the three nuclear weapons laboratories (LLNL, LANL and SNL). The three weapons laboratories possess most of the nation's core intellectual and technical competencies in nuclear weapons. The laboratories perform the basic research, design, engineering, testing, and certification of weapon performance. Two of the laboratories (LANL and LLNL) focus on the weapons physics package and the third (SNL) focuses on non-nuclear components and systems engineering. In 1995, President Clinton concluded that the continued vitality of all three laboratories was essential to the nation's ability to fulfill the requirements of stockpile stewardship in the absence of underground testing (White House 1995). More recently, the Secretary of Energy Advisory Board Task Force on the Nuclear Weapons Complex of the Future (SEAB 2005) affirmed that three design laboratories are currently needed to certify nuclear weapons without underground testing. As a result of the continuing challenges of certification without underground testing, the need for robust peer review, benefits of intellectual diversity from competing physics design laboratories, and uncertainty over the details future stockpiles, NNSA does not consider it reasonable to evaluate laboratory consolidation at this time. While this conclusion has not changed, NNSA continues to make the laboratories more efficient and effective, as indicated by the alternatives to consolidate, relocate, or eliminate duplicative facilities and programs.

Pursue dismantlement and refrain from designing and building new nuclear weapons. Dismantlement coupled with no capabilities to design and build new nuclear weapons was not evaluated because it is not consistent with maintaining a safe, secure, and reliable nuclear weapons stockpile over the long-term. This SPEIS assesses reasonable alternatives for maintaining a nuclear weapons stockpile. The alternatives include actions to continue dismantlement consistent with Presidential direction to reduce the nuclear weapons stockpile.

However, all of the alternatives would maintain weapons design, R&D, and manufacturing capabilities because these are necessary to maintain the stockpile.

This SPEIS includes two options for a Capability-Based Alternative (Sections 3.6.1 and 3.6.2) that would support a stockpile much smaller than currently planned, and a discussion of how the reasonable alternatives might be adapted if the President were to direct even further reductions in the stockpile (Section 3.6.3). The No Net Production/Capability-Based Alternative (Section 3.6.2) would require the production of a limited number of components and assembly of weapons beyond those associated with supporting surveillance, but would not result in the addition of new types or increased numbers of weapons to the total stockpile.

Curatorship Alternative. This programmatic alternative was proposed during public scoping meetings and later public meetings on the Draft SPEIS. Under this proposed approach, NNSA would rely upon the surveillance and non-nuclear testing program to determine when work on nuclear weapons is necessary. Only if there is compelling evidence that components have degraded, or will soon degrade, and could cause a significant loss of safety or reliability, would NNSA replace the affected parts with new ones that would be remanufactured as closely to their original design as possible. A core assumption of this approach is that absent detectable changes, the well designed and thoroughly tested warheads in the stockpile would remain as safe and reliable as the laboratories have certified them to be today. The No Net Production/Capability-Based Alternative includes many facets of a Curatorship Alternative, namely: (1) not adding new types or increased numbers of weapons to the total stockpile; (2) state-of-the-art testing and engineering capabilities to examine components and detect and appraise problems; and (3) the capability to replace components, as needed. While NNSA acknowledges that aspects of curatorship are an accurate description of how the SSP works, NNSA eliminated curatorship from detailed study as a stand-alone alternative because it does not define a programmatic alternative distinctly different from the range of alternatives analyzed in this SPEIS.

Smaller CNPC/CUC/CNC/A/D/HE Alternative. The SPEIS includes an analysis of Capability-Based Alternatives (Section 3.6) that would produce as few as 10-50 components and assemble 10-50 weapons per year to maintain capability and to support a limited life extension program. Additionally, for both the Distributed Centers of Excellence Alternative and Consolidated Centers of Excellence Alternative, the SPEIS considers production of as few as 80 pits per year. Similarly, NNSA also considered whether to assess a smaller CUC, CNC, or CNPC. In determining whether to assess a smaller CUC/CNC/CNPC alternative, NNSA considered three different perspectives — programmatic risk, cost effectiveness, and environmental impacts. That analysis (NNSA 2007) concluded that, among other reasons, the cost and environmental impacts of the CUC/CNC/CNPC would not be highly sensitive to capacity at these low production rates. Chapter 3, Section 3.15 presents a summary of that NNSA 2007 analysis.

Relative to the CPC, NNSA identified the following potential alternatives, but eliminated them from detailed study for the reasons set forth below:

New CPC with a Smaller Capacity. NNSA considered whether it would be reasonable to build a new CPC with a capacity of fewer than 125 pits per year (single shift). In a detailed report

published in September 2007 (NNSA 2007), NNSA concluded that if it constructed a new pit facility with a capacity to produce 80 pits per year, the reduction in square footage would be small (less than a few percent) compared to a new facility designed for 125 pits per year (single shift). The reason for this is that the reduction in the number of equipment processing stations is only 6 stations from the total estimated requirement of 132 major processing stations. Reductions in the processing stations based on a lower production requirement only decreases a small amount of equipment that would be needed to provide production assurances in the capacity increase from 80 pits per year to 125 pits per year (single shift). From a design perspective for a new facility, a 125 pits per year plant is an optimal minimum. The expected environmental impacts of construction and operation of a new CPC at 125 pits per year would not be significantly different from 80 pits per year and the larger capacity provides better assurance of meeting the purpose and need for production of pits. This conclusion would also be true for the Capability-Based Alternatives, which evaluates impacts for pit production at capacities of 10-50 pits per year.

Purchase Pits. While there is no national policy that prohibits purchase of defense materials such as pits from foreign sources, NNSA has determined that the uncertainties associated with obtaining them from foreign sources render this alternative unreasonable for an assured long-term supply.

Upgrade Building 332 at Lawrence Livermore National Laboratory. Building 332 at LLNL is located in what is known as the “Superblock”. This building is a plutonium R&D facility containing a wide variety of plutonium processing and fabrication technologies but offering minimal production capabilities. Activities in Building 332 include developing and demonstrating improved technologies for plutonium metal preparation, casting, fabrication, and assembly; fabrication of components for subcritical tests; surveillance of LLNL pits; support for LANL pit surveillance and specimen fabrication; and fundamental and applied research in plutonium metallurgy. Building 332 does not have a pit manufacturing mission and is small in comparison to the production facilities at LANL. Additionally, because of the significant population around LLNL, an upgrade alternative at LLNL is undesirable.

Consider Other Sites for the CPC. In order to determine the reasonable site alternatives for a CPC, all existing, major DOE sites were initially considered as a location for a CPC. Because one of NNSA’s main purposes is to consolidate Category I/II SNM, sites that do not maintain Category I/II SNM were eliminated from consideration. Likewise, NNSA eliminated sites that do not conduct major NNSA program activities, as these sites would further expand the NNSA Complex. Other NNSA sites were not considered reasonable locations because they do not satisfy certain criteria such as low surrounding population, mission compatibility, or synergy with the site’s existing mission. The NOI To Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030 stated that Los Alamos, NTS, Pantex, SRS, and Y-12 would constitute the range of reasonable site alternatives for a CPC (71 FR 61731).

Redesign Weapons to Require Less or No Plutonium. The pits in the enduring nuclear weapons stockpile were designed and built with plutonium, and in an era when nuclear testing was being conducted to verify these designs. Replacing these pits with new ones that would use

little or no plutonium (i.e., using HEU instead) for the sole reason of not building a long-term, assured plutonium pit production facility would not be reasonable. Nuclear testing would likely be required to verify performance of a design that uses uranium instead of plutonium. In addition, these new pits would require costly changes in the weapon delivery systems.

Do Not Produce New Pits. The latest studies on plutonium aging indicate that the pits currently in the stockpile may be viable for more than 85 years. However, it may become necessary to manufacture new pits for a number of reasons including: consequences of an aging phenomena not previously considered, new weapon design, or a change in other components in the weapon (for example a change in the HE to be used or unavailability of certain materials or components). Prudent management of NNSA's mission dictates that it has the capability to produce all components necessary for the stockpile. However, NNSA has considered a No Net Production/Capability-Based Alternative (Section 3.6.2) that would produce as few as 10 pits per year, which would be the minimum production needed to maintain capability and to support a limited LEP workload.

NNSA Flight Testing. In addition to WSMR, NNSA considered other existing DoD flight test ranges, including Eglin Air Force Base, the U.S. Navy's China Lake testing and training range, and the Utah Test and Training Range (UTTR). A team of NNSA officials visited these sites, discussed their availability and assets with the technical staff and management of these facilities, and evaluated their ability to conduct NNSA flight test operations. Although Eglin has many desirable assets, it was eliminated from further consideration because of the available terrain, geological features, and the short depth to groundwater. With respect to China Lake, although the technical assets were sufficient to support NNSA flight test operations, the geology and soils are not considered adequate. At UTTR, the existing assets, such as optical systems, radar, and communications are all dated and its management has no plans for upgrading or replacing them. Additionally, soil composition is moist and soft over the entire range and is not suitable.

Additionally, in response to public comments on the Draft SPEIS, NNSA considered additional alternatives that would not relocate NNSA's flight test operations from TTR, but would conduct tests at TTR on a campaign basis. This led to the development of three options that are presented in Section 3.10.3.

Tritium R&D. NNSA considered changes to the tritium missions at SNL/NM (related to neutron generator production), at SRS (for tritium production), and at LLNL (for NIF target loading), but determined that there were no reasonable alternatives for changing these missions (see Chapter 3, Section 3.15).

S.3.15 Considerations Related to a Reliable Replacement Warhead (RRW)

The current status of the RRW program is that a feasibility study has been completed, a design competition has been concluded, and the joint DoD/DOE Nuclear Weapons Council has selected a design concept. If authorized and funded by Congress, the design concept would undergo further study and refinement over the coming years and cost estimates would be prepared by the DoD and the NNSA. The RRW would not have a different military requirement than the warhead it would replace.

The possibility that NNSA might be directed to develop an RRW does not have significant ramifications on the alternatives analyzed or their potential impacts. Pit production and other production activities would be allocated between legacy weapons and RRWs – production capacity would not be increased if NNSA is directed to develop an RRW. Development of an RRW would not require significant changes to the activities and proposed facilities that are analyzed as part of the alternatives evaluated in this SPEIS. If an RRW were developed and produced, it is likely that this production would be in lieu of maintenance and production activities for legacy weapons.

S.3.15.1 *RRW and the Proposed Actions and Alternatives*

Consideration of an RRW would assist NNSA in making informed decisions on the capabilities that might be required in select facilities if a decision is made to proceed with an RRW. However, an RRW would not affect the SNM consolidation efforts or the action alternatives related to restructuring SNM facilities, nor the action alternatives related to the restructuring of R&D and testing facilities, nor Complex transformation in general.

- **Restructure SNM Facilities:** The proposed action is based on the current site configuration that houses a very large inventory of SNM that needs to be consolidated in more modern facilities independent of whether an RRW is developed.
- **Restructure R&D and Testing Facilities:** Tritium R&D, high-explosives R&D, hydrodynamic, environmental, and flight test facilities are needed to support the maintenance of the safety, security, and reliability of the existing stockpile as well as potential RRW warheads. The R&D and flight test facilities retained will be those necessary to support either a future legacy stockpile or an RRW-based stockpile.

S.3.15.2 *RRW and Complex Transformation*

One of the objectives of the RRW program was to simplify component and subassembly fabrication and warhead assembly/disassembly processes. In general, simplifying designs to ones with fewer, less complex parts would reduce production operations in the Complex. Coordination and cooperation between the design laboratories and production plants to achieve this objective were encouraged by NNSA in the design competition for RRW. However, the fact that more weight and volume are available to RRW designers provides greater flexibility to simplify the manufacture, assembly, disassembly, and maintenance of weapons. In addition to the potential benefits to the Complex of a design that would be easier to produce, the proposed reduction of hazardous and problematic materials in RRW designs could reduce environmental impacts from operation of the Complex. The proposed increase in safety (e.g., elimination of conventional high explosives for the main charge) and security features in RRW designs could reduce the cost of normal operations and severity of accidents.

S.3.15.3 *RRW and the Use of Radioactive and Hazardous Materials*

The environmental impacts of the action alternatives in this SPEIS are based on the manufacturing materials and processes needed to support legacy weapons with life extension

programs. An RRW is only in the feasibility study stage. However, the RRW design objectives are directed at reducing the use of radioactive and hazardous materials compared to legacy weapons. Because the environmental impacts in this SPEIS are based on legacy weapons, these impacts should be larger than the potential impacts of an RRW if it were to go into production.

S.3.16 Comparison of Impacts

This comparison of potential environmental impacts is based on the information in Chapter 4, Affected Environment, and analyses in Chapter 5, Environmental Impacts. Table S.3.16-1 presents a comparison of the environmental impacts for construction and operation associated with the No Action Alternative, DCE Alternative, CCE Alternative, and Capability-Based Alternative. The No Action Alternative is also presented in Table S.3.16-1 as a benchmark for comparison of the impacts associated with the action alternatives. Table S.3.16-1 focuses on those resources for which there is the greatest potential for significant environmental impact. For a more complete discussion of the impacts of the alternatives, the reader is directed to Chapter 3 (Table 3.16-1) and Chapter 5 of this SPEIS. With respect to the Category I/II SNM consolidation proposals that are common to the programmatic action alternatives, Table S.3.16-2 presents a summary comparison of the potential impacts associated with alternatives for Category I/II SNM Consolidation for LLNL and Table S.3.16-3 presents a summary comparison of impacts associated with Category I/II SNM Consolidation at Pantex.

In addition to the comparisons presented in Table S.3.16-1, Table S.3.16-2, and Table S.3.16-3, this section presents an overview of the major environmental impacts associated with the programmatic alternatives presented in the SPEIS. This presentation focuses on the major discriminators between the programmatic alternatives with respect to land use, employment, transportation, and accidents. A detailed analysis of the environmental impacts associated with all alternatives (by specific site) is presented in Chapter 5, Sections 5.1 through 5.9. A detailed transportation analysis is presented in Section 5.10.

A detailed analysis of the project-specific alternatives is contained in Section 5.13 (HE R&D), Section 5.14 (Tritium R&D), Section 5.15 (Flight Testing), Section 5.16 (Hydrodynamic Testing), Section 5.17 (Major Environmental Test Facilities), and Section 5.18 (Non-Nuclear Weapons Support Functions at SNL/CA). Tables S.3.16-3 through S.3.16-8 summarizes the differences in impacts for the project-specific alternatives.

S.3.16.1 Land Use for Programmatic Alternatives

For land use, both the No Action Alternative and the Capability-Based Alternative have the least impacts, in that the total area of the seven Complex sites analyzed in this SPEIS (LANL, LLNL, NTS, Pantex, SNL, SRS, and Y-12) remains the same at approximately 1,000,000 total acres.

For the DCE Alternative, the Complex would remain the same size, but a CPC would be constructed at one of five site alternatives. This would disturb an area of approximately 140 acres during construction, resulting in a 110-acre facility within the existing boundaries of one of these sites. For Los Alamos, the disturbed land area could be smaller because an alternative to use existing and planned facilities is being considered along with a Greenfield CPC alternative.

At Y-12, if the UPF were constructed, consolidation from existing facilities could ultimately reduce the areas associated with nuclear production activities requiring the highest levels of security from 150 acres to approximately 15 acres.

Under the CCE Alternative, the Complex's size could be reduced. Depending upon the option (Consolidated Nuclear Production Center [CNPC] or Consolidated Nuclear Centers [CNC]), this alternative would involve the construction of facilities at one or two sites, and could result in a 545-acre facility at one of five candidate sites. If Los Alamos, NTS, or SRS were selected as the site for CCE facilities, both Pantex and Y-12 could be closed. This would reduce the size of the Complex by 16,777 acres. If Pantex (but not Y-12) were selected for CCE facilities, Y-12 could close and the size of the Complex reduced by approximately 800 acres. If Y-12 (but not Pantex) were selected for CCE facilities, Pantex could close and the Complex would be reduced by 15,977 acres.

S.3.16.2 *Impacts on Complex Facilities for Programmatic Alternatives*

Under the No Action Alternative, NNSA would continue the trend of closing, replacing, and upgrading older facilities, consistent with decisions based on previous NEPA analyses and applicable regulatory requirements. Surplus facilities with no inherent value to DOE, NNSA, or the community would ultimately be dispositioned or undergo decontamination and decommissioning (D&D) consistent with overall modernization plans. For example, at Y-12, excess buildings and infrastructure have been closed over the past decade, and approximately 244 buildings, with more than 1.1 million square feet, have been demolished or removed. In the future, as part of the environmental cleanup strategic planning, DOE and NNSA are developing an Integrated Facility Disposition Project (IFDP). The IFDP is a strategic plan for disposing of legacy materials and facilities at Oak Ridge National Laboratory and Y-12 that uses an integrated approach. Under the IFDP, the D&D of approximately 188 facilities at Oak Ridge National Laboratory and 19 facilities at Y-12, as well as the remediation of soil and groundwater contamination, would occur over the next decade. The IFDP will be conducted as a remedial action under the *Comprehensive Environmental Response, Compensation, and Liability Act*. Similar activities at other NNSA sites are ongoing. For instance, at LLNL, approximately 20 facilities with a combined floor space of 234,443 square feet are being deactivated.

With respect to the Programmatic Alternatives, if a site other than Pantex and Y-12 is selected for a CNPC, Pantex and Y-12 could be closed. At Pantex, this would involve closing approximately 400 buildings totaling 1.8 million square feet. At Y-12, approximately 5.3 million square feet of floor space and approximately 390 facilities would be closed. For each of the programmatic action alternatives, moving plutonium storage to Zone 12 at Pantex would result in closing more than 74,200 square feet of storage facilities in Zone 4.

S.3.16.3 *Impacts on Complex Facilities for Project-Specific Alternatives*

With respect to potential cumulative impacts, project-specific actions could also affect the total number of facilities and square footage devoted to NNSA weapons activities. This could result in additional facility closures or transfer of facilities from the NNSA to another user. For example, if flight testing were moved from TTR, approximately 195 buildings and structures,

covering approximately 180,000 square feet, could be closed or transferred to another user. For the Hydrodynamic Testing Consolidation-in-Place Alternative, 29 facilities at LANL, LLNL, and SNL/NM, with a combined floor space of 56,475 square feet could be closed or transferred. For alternatives that move HE R&D from LLNL Site 300, up to 35,000 square feet of floor space could be closed or transferred. If NNSA were to ultimately close Site 300, up to 115 buildings with a floor space of approximately 340,000 square feet could be closed or transferred.

S.3.16.4 *Employment under the Programmatic Alternatives*

For employment, the No Action Alternative would have the least impacts with the workforce remaining at the current level of approximately 27,000 management and operating contractors supporting weapons activities at the major sites analyzed in this SPEIS.

For the DCE Alternative, a new CPC could be constructed at Los Alamos, NTS, Pantex, SRS, or Y-12. If constructed, approximately 850 construction jobs and an operational workforce of approximately 1,780 could be employed at the CPC. If Los Alamos is not selected for a new CPC, Los Alamos would lose about 610 jobs.

The CCE Alternative has the greatest potential for employment impacts. The construction of CCE facilities could require more than 4,000 construction jobs and an operational workforce of approximately 4,500 could be added to the selected site(s). If Pantex is not selected for CCE facilities, Pantex could be closed, resulting in a loss of approximately 1,650 jobs. If CCE facilities are not located at Y-12, Y-12 could be closed with a loss of approximately 6,500 jobs.

For the Capability-Based Alternative, the reduced level of production would entail the loss of approximately 3,000 jobs (400 at Pantex, 15 at SRS, and 2,600 at Y-12).

S.3.16.5 *Transportation under the Programmatic Alternatives*

For the No Action Alternative, there would be no impacts to the existing transportation requirements of the Complex. Pits would continue to be transported from LANL to Pantex, CSAs would continue to be transported from Y-12 to Pantex, tritium reservoirs would continue to be transported between SRS and Pantex, and other required parts and materials would be transported among various NNSA sites.

For the DCE Alternative, transportation related to pit production could increase if a CPC were located at a site other than Pantex. If the CPC were located at Pantex, no off-site transportation related to pit production would be required.

For the CCE Alternative, if facilities were located at sites other than Y-12 and Pantex, less than 60 tons of plutonium, mostly in pit form, presently being stored at Pantex would be transported to the CNPC, and up to 252 tons of HEU would be transported from Y-12 to the CNPC. For the CNPC option, annual transportation related to nuclear production would cease once the CNPC becomes operational. For the CNC option, there would be annual transportation related to pits and CSAs between the CPC, CUC, and an A/D/HE Center.

For the Capability-Based Alternative, transportation requirements would be the same as for the No Action Alternative, except that only 25 percent of the existing number of CSAs would need to be transported from Y-12 to Pantex, and tritium shipments could be reduced by approximately 50 percent.

S.3.16.6 *Accidents and Malicious Acts in Programmatic Alternatives*

For the No Action Alternative and the Capability-Based Alternative, accident risks and consequences would remain the same. For the DCE and CCE Alternatives, the construction of new facilities would, in general, tend to reduce the risks and consequences of accidents due to advances in building design features. In general, if missions were moved to locations with populations lower than the populations at the sites where those missions are currently conducted, potential consequences would likely decrease. For example, if a CNPC were located at NTS, potential consequences associated with the A/D/HE mission, the CUC mission, and the CPC mission would be reduced compared to the No Action Alternative because of the greater distance to the site boundary and the smaller population within the surrounding area.

NNSA has prepared a classified appendix to this SPEIS that evaluates the potential impacts of malevolent, terrorist, or intentional destructive acts. Substantive details of terrorist attack scenarios, security countermeasures, and potential impacts are not released to the public because disclosure of this information could be exploited by terrorists to plan attacks. Appendix B (Section B.12.3) discusses the methodology used to evaluate potential impacts associated with a terrorist threat and the methodology by which NNSA assesses the vulnerability of its sites to terrorist threats and then designs its response systems. As discussed in that section, NNSA's strategy for the mitigation of environmental impacts resulting from extreme events, including intentional destructive acts, has three distinct components: (1) prevent or deter successful attacks; (2) plan and provide timely and adequate response to emergency situations; and (3) progressive recovery through long-term response in the form of monitoring, remediation, and support for affected communities and their environment.

Depending on the intentional destructive acts, impacts would be similar to or exceed the impacts of accidents analyzed in the SPEIS. These analyses provide NNSA with information upon which to base, in part, decisions regarding transformation of the Complex. The classified appendix evaluates several scenarios involving intentional destructive acts for alternatives at the following sites (LANL, LLNL, NTS, SRS, Pantex, and Y-12) and calculates consequences to the noninvolved worker, maximally exposed individual, and population in terms of physical injuries, radiation doses, and LCFs. Although the results of the analyses cannot be disclosed, the following general conclusion can be drawn: the potential consequences of intentional destructive acts are highly dependent upon distance to the site boundary and size of the surrounding population – the closer and higher the surrounding population, the higher the consequences. In addition, it is generally easier and more cost-effective to protect new facilities, as new security features can be incorporated into their design. In other words, protection forces needed to defend new facilities may be smaller due to the inherent security features of a new facility. New facilities can, as a result of design features, better prevent attacks and reduce the impacts of attacks. Impacts from intentional destructive acts would be much lower for the project-specific

alternatives than for the programmatic alternatives due to the fact that the programmatic alternatives involve significant quantities of special nuclear materials.

S.3.16.7 *Infrastructure Demands for the Programmatic Alternatives*

Electricity. Under the No Action Alternative, all sites have an adequate existing electrical infrastructure to support current and planned activities.

LANL has adequate electricity to support all of the alternatives.

At NTS, the existing infrastructure would be adequate to support all construction requirements. However, to support operations for a CUC, CNC, or CNPC, NTS would need to procure additional power.

At Pantex, the existing infrastructure would be adequate to support all construction requirements. However, to support operations for a CUC or CNPC, Pantex would need to procure additional power.

At SRS and Y-12, the existing infrastructure would be adequate to support the construction and operation of all alternatives. Construction and operation would have a negligible impact on current site infrastructure.

Water. Under the No Action Alternative, all sites have an adequate existing water infrastructure to support current and planned activities.

LANL has adequate water rights to support a CPC, CUC, or A/D/HE Center. However, operation of multiple new facilities (CNPC) would exceed the current LANL water rights.

At NTS, the sustainable site capacity for water would be adequate to support the construction and operation of all alternatives.

At Pantex, the existing wellfield capacity would be adequate to support the construction and operation of all alternatives.

At SRS and Y-12, the existing water infrastructure would be adequate to support the construction and operation of all alternatives.

S.3.17 *Preferred Alternatives*

CEQ regulations require an agency to identify the alternative it prefers for achieving its purpose in a Final EIS (40 CFR 1502.14(e)). NNSA's preferred alternative is described below. It is based on NNSA's consideration of environmental impacts described in this Final SPEIS, as well as other factors such as mission and infrastructure compatibility, economic analyses, safety, safeguards and security, and workforce training and retention. **The preferred alternative described below reflects NNSA's current preference, but it is not a decision. NNSA will announce any decisions in one or more Records of Decision and may select an alternative other than the preferred alternative identified below.**

S.3.17.1 *Preferred Alternatives for Restructuring SNM Facilities*

- **Plutonium manufacturing and R&D:** Los Alamos would provide a consolidated plutonium research, development, and manufacturing capability within TA-55 enabled by construction and operation of the Chemistry and Metallurgy Research Replacement—Nuclear Facility (CMRR-NF). The CMRR-NF is needed to replace the existing Chemistry and Metallurgy Research (CMR) Facility (a 50-year old facility that has significant safety issues that cannot be addressed in the existing structure), to support movement of plutonium R&D and Category I/II quantities of SNM from LLNL, and consolidate weapons-related plutonium operations at Los Alamos. Until completion of a new Nuclear Posture Review in 2009 or later, the net production at Los Alamos would be limited to a maximum of 20 pits per year. Other national security actinide needs and missions would continue to be supported at TA-55 on a priority basis (e.g., emergency response, material disposition, nuclear energy).
- **Uranium manufacturing and R&D:** Y-12 would continue as the uranium center producing components and canned subassemblies, and conducting surveillance and dismantlement. NNSA has completed construction of the HEUMF and will consolidate HEU storage in that facility.³⁷ NNSA would build a Uranium Processing Facility (UPF) at Y-12 in order to provide a smaller and modern highly-enriched uranium production capability to replace existing 50-year old facilities. The site-specific impacts and candidate locations for a UPF will be analyzed in a new SWEIS for Y-12 that NNSA is currently preparing.
- **Assembly/disassembly/high explosives production and manufacturing:** Pantex would remain the Assembly/Disassembly/High Explosives production and manufacturing center. NNSA would consolidate non-destructive surveillance operations at Pantex.
- **Consolidation of Category I/II SNM:** NNSA would continue to transfer Category I/II SNM from LLNL under the No Action Alternative and phase out Category I/II operations at LLNL Superblock by the end of 2012. NNSA would consolidate Category I/II SNM at Pantex within Zone 12, and close Zone 4.

³⁷ The environmental impacts at HEUMF and its alternatives are analyzed in the 2001 Y-12 SWEIS (DOE 2001a).

S.3.17.2 *Preferred Alternatives for Restructuring R&D and Testing Facilities*

HE R&D. NNSA would reduce the footprint of its HE production and R&D related to nuclear weapons; and reduce the number of firing sites. Use of energetic materials (greater than 1 kg) for environmental testing conducted at SNL/NM would continue (e.g., acceleration or sled tracks, shock loading, or in explosive tubes) and is not included in HE R&D. NNSA would consolidate weapons HE R&D and testing within the following locations, without constraining transfer and operation of weapons programs firing sites to other NNSA, DoD, and national security sponsors, as follows

- Pantex would remain the HE production (formulation, processing, and testing) and machining center. All HE production and machining to develop nuclear explosive packages would continue at Pantex. HE experiments up to 22 kg HE would remain at Pantex;
- NTS would remain the testing center for large quantities of HE (greater than 10 kg);
- LLNL would be the HE R&D center for formulation, processing, and testing (processing capability to handle up to 15 kg and testing less than 10 kg) HE at the High Explosives Applications Facility (HEAF); formulation and processing of HE would be conducted either at a new HEAF Annex built adjacent to HEAF, or at existing Site 300 facilities (but using less space than currently used for these activities);
- SNL/NM would remain the HE R&D center for non-nuclear explosive package components (less than 1 kg of HE) at the Explosive Components Facility (ECF); and
- LANL would produce war reserve main charge detonators, conduct HE R&D experimentation and support activities, and move towards contained HE R&D experimentation.
- Each site would maintain one weapons program open-burn and one open-detonation area for safety and treatment purposes.

Tritium R&D. NNSA would consolidate tritium R&D at SRS. SRS would remain the site for tritium supply management and provide R&D support to production operations and gas transfer system development. Neutron generator target loading at SNL/NM and production of National Ignition Facility targets at LLNL, which involve small quantities of tritium, would continue and would not be included in this consolidation. NNSA would move bulk quantities of tritium from LANL to SRS by 2009; and remove tritium materials above the 30 gram level from the Weapons Engineering Tritium Facility (WETF) at LANL by 2014.

NNSA flight test operations. Campaign Mode Operation of Tonopah Test Range (TTR) (Option 3—Campaign under Reduced Footprint Permit). NNSA would reduce the footprint of TTR, upgrade equipment with mobile capability, and operate in campaign mode. NNSA expects it would not use Category I/II SNM in future flight tests.

Major Hydrodynamic Testing. By the end of fiscal year 2008, NNSA would contain the hydrodynamic testing (consisting of Integrated Weapons Experiments and Focused Experiments) at LLNL at the Contained Firing Facility (CFF) and at LANL at the Dual-Axis Radiographic Hydrodynamic Test (DARHT) facility. At LANL, firing site operations for weapon programs

required by NNSA's hydrodynamic test program would be moved to contained firing. In addition:

- Hydrotesting at LLNL Site 300 would be consolidated to a smaller footprint by 2015.
- The goal is to minimize open-air testing at LANL. Open-air hydrotests at LANL's DARHT, excluding SNM, would only occur if needed to meet national security requirements.
- NNSA would allow open-air firing at LANL TA-36 until adequate radiographic capabilities and associated supporting infrastructure are available for open-air firing at NTS.

Major Environmental Test Facilities. NNSA would consolidate major environmental testing at SNL/NM and, infrequently conduct operations requiring Category I/II SNM in security campaign mode there. NNSA would close LANL's and LLNL's major environmental testing facilities by 2010 (except those in LLNL Building 334 and the Building 834 Complex). NNSA would move environmental testing of nuclear explosive packages and other functions currently performed in LLNL Buildings 334 and 834 to Pantex by 2012.

Sandia National Laboratories, California Weapons Support Functions. NNSA would continue operations under the No Action Alternative.

As to any other programmatic and project-specific alternatives not mentioned above, NNSA's preferred alternative at this time is to continue with the No Action Alternatives. Section 5.20 of this Final SPEIS provides a summary of the environmental impacts of the preferred alternatives.

Table S.3.16-1—Comparison of Environmental Impacts among Programmatic Alternatives

SITE	NO ACTION ALTERNATIVE	Major New Restructured SNM Facilities in the DCE and CCE Alternatives					CAPABILITY BASED ALTERNATIVE*
		CPC	CUC (or UPF at Y-12)	A/D/HE	CNC Operation	CNPC Operation	
Land Use							
LANL	Current and planned activities would continue as required to accomplish assigned missions. LANL has approximately 2,000 structures with approximately 8.6 million square feet under roof, spread over an area of approximately 25,600 acres.	<i>Greenfield CPC:</i> Potential disturbance of 140 acres for construction and 110 acres for operation. <i>Upgrade:</i> Potential disturbance of 13 acres for construction and 6.5 acres for operation. <i>50/80:</i> Potential disturbance of 6.5 acres for construction and 2.5 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of LANL total land area.	Potential disturbance of 50 acres for construction and 35 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of LANL total land area.	Potential disturbance of 300 acres from construction and 300 acres from operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be approximately 1.2% of LANL total land area.	195 acres (includes 50 acre buffer area) needed to operate CNC. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be approximately 1% of LANL total land area.	545 acres (includes 100-acre buffer area) needed to operate CNPC. Land uses would remain compatible with surrounding areas and with land use plans. Two non-contiguous TAs would be used for the CNPC. Land required would be approximately 2.3% of LANL total land area. Y-12 and Pantex would close, reducing the size of the Complex by 16,777 acres.	Potential disturbance of 6.5 acres. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of LANL total land area.
NTS	Current and planned activities would continue as required to accomplish assigned missions. Approximately 45 percent of NTS is currently unused or provides buffer zones for ongoing programs or projects, while about 7-10 percent (60,000 – 86,500 acres) of the site has been disturbed.	Potential disturbance of 140 acres for construction and 110 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of NTS total land area.	Potential disturbance of 50 acres for construction and 35 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of NTS total land area.	Because NTS would use existing capabilities at the DAF, potential land disturbance for construction and operation would be approximately 200 acres. Land required would be less than 1% of NTS total land area.	195 acres (includes 50-acre buffer area) needed to operate CNC. Land uses would remain compatible with surrounding areas and with land use plans.	445 acres (includes 100-acre buffer area) needed to operate CNPC. Land uses would remain compatible with surrounding areas and with land use plans. Y-12 and Pantex would close, reducing the size of the Complex by 16,777 acres.	NTS would be unaffected by the Capability Based Alternative.
Pantex	Preferred Alternative: Current and planned activities would continue on the 15,977- acre site as required to accomplish assigned missions. No new land disturbance expected.	Potential disturbance of 140 acres for construction and 110 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of Pantex total land area.	Potential disturbance of 50 acres for construction and 35 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of Pantex total land area.	No A/D/HE Center is proposed at Pantex because the A/D/HE mission is part of the No Action Alternative.	Pantex performs the A/D/HE mission; therefore the impact of a CNC at this site is identical to the CNPC impact. See CNPC Operation in next column.	545 acres (includes 100-acre buffer area) needed to operate CNPC. Land uses would remain compatible with surrounding areas and with land use plans. Y-12 would close, reducing the size of the Complex by approximately 800 acres.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.

Table S.3.16-1—Comparison of Environmental Impacts among Programmatic Alternatives (continued)

SITE	NO ACTION ALTERNATIVE	Major New Restructured SNM Facilities in the DCE and CCE Alternatives					CAPABILITY BASED ALTERNATIVE*
		CPC	CUC (or UPF at Y-12)	A/D/HE	CNC Operation	CNPC Operation	
SRS	Current and planned activities would continue on the 198,420-acre site as required to accomplish assigned missions. Approximately 77 acres of additional land would be disturbed by construction of the Mixed-Oxide (MOX) Fuel Fabrication Facility which broke ground August 2007 and the Pit Disassembly and Conversion Facility (PDCF) scheduled to break ground in 2010.	Potential disturbance of 140 acres for construction and 110 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of SRS total land area.	Potential disturbance of 50 acres for construction and 35 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of SRS total land area.	Potential disturbance of 300 acres from construction and 300 acres from operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be less than 1% of SRS total land area.	195 acres (includes 50 acre buffer area) needed to operate CNC. Land uses would remain compatible with surrounding areas and with land use plans.	545 acres (includes 100 acre buffer area) needed to operate CNPC. Land uses would remain compatible with surrounding areas and with land use plans. Y-12 and Pantex would close, reducing the size of the Complex by 16,777 acres.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Y-12	Current and planned activities would continue on the 800-acre site located on the 35,000-acre Oak Ridge Reservation as required to accomplish assigned missions.	Potential disturbance of 140 acres for construction and 110 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be approximately 17.5% of Y-12 total land area.	Preferred Alternative: UPF could disturb approximately 35 acres for construction and 8 acres for operation at Y-12. Land uses would remain compatible with surrounding areas and with land use plans. UPF would enable protected area to be reduced by 90%.	Potential disturbance of 300 acres for construction and 300 acres for operation. Land uses would remain compatible with surrounding areas and with land use plans. Land required would be approximately 37.5% of Y-12 total land area.	Y-12 performs the CUC mission; therefore the impact of a CNC at this site is identical to the CPC impact.	518 acres (includes 100 acre buffer area) needed to operate CNPC. Land uses would remain compatible with surrounding areas and with land use plans. Pantex would close, reducing the size of the Complex by 15,977 acres.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Visual Resources							
LANL	Current and planned activities would continue as required resulting in no additional impacts.	Short-term, temporary visual impacts from construction. New facilities would be visible from higher elevations beyond LANL boundary; however, change would be consistent with currently developed areas. No change to VRM Classification.	Short-term, temporary visual impacts from construction. New facilities would be visible from higher elevations beyond LANL boundary; however, change would be consistent with currently developed areas. No change to VRM Classification. Short-term, temporary visual impacts from construction. The reference location is obstructed from off-site view. Changes to visual appearance would be consistent with currently developed areas. No change to VRM Classification.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Y-12	Current and planned activities would continue as required resulting in no additional impacts.	Short-term, temporary visual impacts from construction. Changes to visual appearance would be consistent with currently developed areas. No change to VRM Classification.	Changes to visual appearance would be consistent with currently developed areas. No change to VRM Classification.	Short-term, temporary visual impacts from construction. Changes to visual appearance would be consistent with currently developed areas. No change to VRM Classification.	Y-12 performs the CUC mission, therefore the impact of a CNC at this site is identical to the CPC impact.	Short-term, temporary visual impacts from construction. Changes to visual appearance would be consistent with currently developed areas. No change to VRM Classification.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Site Infrastructure							
LANL	Current and planned activities would continue as required resulting in no additional impacts. The current power pool peak power capacity is 150 megawatts-electric [MWe]). The available site capacity is 63 MWe.	Under all approaches, existing infrastructure would be adequate to support construction and operation requirements. Operation of a CPC would have the potential to use approximately 17.5% of the peak power capacity that is available.	Existing infrastructure would be adequate to support construction and operation requirements. Operation of a CUC would have the potential to use approximately 29.2% of the peak power capacity that is available.	Operation of A/D/HE Center would have the potential to use approximately 18.9% of the peak power capacity that is available.	Operation of a CNC would have the potential to use approximately 45.1% of the peak power capacity that is available.	Operation of a CNPC would have the potential to use approximately 65.6% of the peak power capacity that is available.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
NTS	Current and planned activities would continue as required resulting in no additional impacts. NTS would be	Existing infrastructure would be adequate to support construction and operation requirements. Power	Existing infrastructure would be adequate to support construction requirements. Power	Existing infrastructure would be adequate to support construction. Power requirements	Power requirements would be 288% of available site electrical energy capacity. For operations, NTS would	Power requirements would be 357% of available site electrical energy capacity. For operations, NTS would	NTS would be unaffected by the Capability Based Alternative.

Table S.3.16-1—Comparison of Environmental Impacts among Programmatic Alternatives (continued)

SITE	NO ACTION ALTERNATIVE	Major New Restructured SNM Facilities in the DCE and CCE Alternatives					CAPABILITY BASED ALTERNATIVE*
		CPC	CUC (or UPF at Y-12)	A/D/HE	CNC Operation	CNPC Operation	
	expected to continue using 101,377 MWh of electricity per year. Electrical usage is below current site capacity.	requirements would be 64% of available site electrical energy capacity.	requirements would be 224% of available site electrical energy capacity. For operations, NTS would need to procure additional power.	would be 69% of available site electrical energy capacity.	need to procure additional power.	need to procure additional power.	
Pantex	Current and planned activities would continue as required resulting in no additional impacts to site infrastructure. Pantex would be expected to continue using about 81,850 MWh of electricity per year.	Existing infrastructure would be adequate to support construction and operation requirements. Power requirements would be 40% of available site electrical capacity.	Existing infrastructure would be adequate to support construction requirements. During operations, power requirements would be 140% of available site electrical energy capacity. To support a CUC, Pantex would have to procure additional power.	No A/D/HE Center is proposed at Pantex because the A/D/HE mission is part of the No Action Alternative.	Pantex performs the A/D/HE mission; therefore the impact of a CNC at this site is identical to the CNPC impact. See CNPC Operation in next column.	During operations, power requirements would be 148% of available site electrical energy capacity. To support a CNPC, Pantex would have to procure additional power.	Planned activities would continue as required to support smaller stockpile requirements. Infrastructure needs would be reduced.
SRS	Current and planned activities would continue, with the increased electrical usage from the MOX/PDCF facilities for a electrical use of 405,000 MWh/yr (370,000 MWh/yr existing plus 35,000 MWh/yr for the MOX/PDCF facilities)	Existing infrastructure would be adequate to support construction and operation requirements. Construction and operation requirements would have a negligible impact on current site infrastructure.	Existing infrastructure would be adequate to support construction requirements. Construction and operation requirements would have a negligible impact on current site infrastructure.	Existing infrastructure would be adequate to support construction requirements. Construction and operation requirements would have a negligible impact on current site infrastructure.	Existing infrastructure would be adequate to support operation requirements. Operation would require 15% of available electrical site capacity. Operation requirements would have a negligible impact on current site infrastructure.	Existing infrastructure would be adequate to support construction requirements. Operation requirements would have a negligible impact on current site infrastructure.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Y-12	Current and planned activities would continue as required resulting in no additional impacts to site infrastructure. Y-12 would be expected to continue using about 350,000 MWh of electricity per year.	Existing infrastructure would be adequate to support construction and operation requirements. During operations, power requirements would be <1% of available site electrical capacity.	Existing infrastructure would be adequate to support construction and operation requirements. During operations, power requirements would be <1% of available site electrical capacity.	Existing infrastructure would be adequate to support construction requirements. During operations, power requirements would be 1.5% of available site electrical capacity.	By definition, there is no CNC at Y-12.	Existing infrastructure would be adequate to support operation requirements. During operations, power requirements would be 7.1% of available site electrical capacity.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Air Quality							
LANL	Current and planned activities would continue as required resulting in no additional impacts. The area encompassing LANL and Los Alamos County is classified as an attainment area for all six criteria pollutants. Simultaneous operation of	Construction activities would create temporary increase in air quality impacts, but would not result in violations of the National Ambient Air Quality Standards (NAAQS). Operations would result in incremental increases less	Construction activities would create temporary increased in air quality impacts similar to CPC. For operations, CUC contribution to nonradiological emissions would not cause any standard or guideline to be	Construction activities would create temporary increase in air quality impacts that could result in exceeding PM ₁₀ regulatory limits. Operations could have the potential to exceed the 24-	Operations would result in incremental increases less than 5% of baseline for most pollutants. The greatest increase would occur for total suspended particulates (TSP), which could increase by approximately 28%.	Operations could have the potential to exceed the 24-hour standard for nitrogen dioxide and the 24-hour standard for TSP.	The higher level of pit production would result in the annual emission of an additional 0.000019 curies per year of plutonium from the Plutonium Facility Complex.

Table S.3.16-1—Comparison of Environmental Impacts among Programmatic Alternatives (continued)

		CPC	CUC (or UPF at Y-12)	A/D/HE	CNC Operation	CNPC Operation	
	LANL's air emission sources at maximum capacity, as described in the Title V permit application, would not exceed any state or Federal ambient air quality standards.	than 5% of baseline for most pollutants. The greatest increase would occur for total suspended particulates (TSP), which could increase by approximately 28%.	exceeded.	hour standard for nitrogen dioxide and the 24-hour standard for TSP.			
NTS	Current and planned activities would continue as required resulting in no additional impacts. No emission limits for any criteria air pollutants or HAPS have been exceeded. Measured concentration of nonradiological criteria pollutants are below regulatory requirements. The estimated annual dose to the public from radiological emissions from current and past NTS activities is well below the 10 millirem per year dose limit.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	NTS would be unaffected by the Capability Based Alternative.
Pantex	Current and planned activities would continue as required resulting in no additional impacts. Pantex is in compliance with all National Ambient Air Quality standards.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	No A/D/HE Center is proposed at Pantex because the A/D/HE mission is part of the No Action Alternative.	Pantex performs the A/D/HE mission; therefore the impact of a CNC at this site is identical to the CNPC impact. See CNPC Operation in next column.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
SRS	Emissions from current and planned MOX/PDCF facilities would result in no additional impacts. SRS is in compliance with all National Ambient Air Quality standards.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for construction and operation. No NAAQS exceeded.	Negligible impacts to air quality for operations. No NAAQS exceeded.	Negligible impacts to air quality for operations. No NAAQS exceeded.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Y-12	Current and planned activities would continue, resulting in no additional impacts. Y-12 is designated non-attainment area for 8-hour ozone and is in compliance with all other National Ambient Air Quality standards.	Temporary increases in pollutant emissions due to construction activities are too small to result in violations of the NAAQS beyond the Y-12 site boundary, with the exception of PM-2.5 and PM-10 concentrations (which could be mitigated using dust	Temporary increases in pollutant emissions due to construction activities are too small to result in violations of the NAAQS beyond the Y-12 site boundary, with the exception of PM-2.5 and PM-10 concentrations	Temporary increases in pollutant emissions due to construction activities are too small to result in violations of the NAAQS beyond the Y-12 site boundary, with the exception of PM-2.5 and PM-10 concentrations	Y-12 performs the CUC mission, therefore the impact of a CNC at this site is identical to the CPC plus UPF impact.	Potential to exceed PM-10 and ozone levels due to high background levels.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.

		suppression), and the 8-hour ozone concentration. The 8-hour ozone concentration exceedance is not a result of Y-12-specific activities. No new hazardous air emissions would result from the facility operation. Additionally, 90 percent of emissions at Y-12 are from operation of the steam plant, which would be relatively unaffected by CPC operations.	(which could be mitigated using dust suppression), and the 8-hour ozone concentration. The 8-hour ozone concentration exceedance is not a result of Y-12-specific activities. No new hazardous air emissions would result from the facility operation. Additionally, 90 percent of emissions at Y-12 are from operation of the steam plant, which would be relatively unaffected by UPF operations.	(which could be mitigated using dust suppression), and the 8-hour ozone concentration. The 8-hour ozone concentration exceedance is not a result of Y-12-specific activities. No new hazardous air emissions would result from the facility operation. Additionally, 90 percent of emissions at Y-12 are from operation of the steam plant, which would be relatively unaffected by A/D/HE Center operations.			
Water Resources							
LANL	Current and planned activities would continue as required resulting in no additional impacts. Approximately 380 million gallons of groundwater are used at LANL. Discharges were in compliance with discharge permits.	For construction and operation of the Greenfield CPC, annual groundwater use would increase by approximately 21%. However, LANL water use would remain within water rights.	For construction and operation, the increase in groundwater consumption would be approximately 27.6%. LANL water use would remain within water rights.	For construction and operation, annual groundwater use would increase by approximately 34.2%. LANL water use would be within water rights.	Annual groundwater use would increase by approximately 48.6%. LANL groundwater use would exceed water rights by approximately 23 million gallons/year.	Annual groundwater use would increase by approximately 104%. LANL groundwater use would exceed water rights by approximately 233 million gallons/year.	Same a No Action Alternative.
NTS	Current and planned activities would continue with an expected demand for groundwater of 634 million gallons per year. The annual maximum production capacity of site potable supply wells is approximately 2.1 billion gallons per year while the sustainable site capacity is estimated to be approximately 1.36 billion gallons per year	For construction and operation, annual groundwater use would require approximately 7% of sustainable site water capacity. No impact on groundwater availability or quality is anticipated.	For construction and operation, annual groundwater use would require less than 8% of sustainable water capacity. No impact on groundwater availability or quality is anticipated.	For construction and operation, annual groundwater use would require approximately 10% of sustainable water capacity. No impact on groundwater availability or quality is anticipated.	Operation of the CNC would use approximately 14.2% of the sustainable site water capacity. No impact on groundwater availability or quality is anticipated.	Operation of the CNPC would use approximately 23.7% of the sustainable site water capacity. No impact on groundwater availability or quality is anticipated.	NTS would be unaffected by the Capability Based Alternative.
Pantex	Current and planned activities would continue as required with an expected demand for water of 130,000 million gallons per year. Pantex	For construction and operation, annual groundwater use would increase by 68% compared to existing use. No impact on	For construction and operation, annual groundwater use would increase by approximately 81% compared to existing	No A/D/HE Center is proposed at Pantex because the A/D/HE mission is part of the No Action Alternative.	Pantex performs the A/D/HE mission; therefore the impact of a CNC at this site is identical to the CNPC impact. See CNPC	CNPC operations would increase groundwater use by approximately 150% compared to existing use. CNPC would require total	Planned activities would continue as required to support smaller stockpile requirements

	obtains its water from the City of Amarillo, which obtains water from the Ogallala aquifer.	groundwater availability or quality is anticipated from construction activities. Pantex's total contribution to the depletion of the Ogallala Aquifer from operation of the CPC would be approximately 0.0003 percent of the estimated annual total depletion.	use. No impact on groundwater availability or quality is anticipated from construction activities. Pantex's total contribution to the depletion of the Ogallala Aquifer from operation of the CUC would be approximately 0.0004 percent of the estimated annual total depletion.		Operation in next column.	of approximately 315.5 million gallons/year. The Pantex wellfield has a water capacity of approximately 422.7 million gallons/ year. Pantex's total contribution to the depletion of the Ogallala Aquifer from operation of the CNPC would be less than 1 percent of the estimated annual total depletion.	resulting in no additional impacts.
SRS	Current and planned activities would continue as required with an expected demand for water (groundwater and surface water) of 3.5 billion gallons/yr plus a small increase for the operation of the MOX/PDCF facilities.	For construction and operation, annual water use would increase by approximately 2% compared to existing use.	For construction and operation, annual water use by 3% compared to existing use.	For construction and operation, annual water use would increase by approximately 4% compared to existing use.	Operation of CNC would increase water use by approximately 5% compared to existing use.	Operation of CNPC would increase water use by 9% compared to existing use.	Planned activities would continue as required to support smaller stockpile requirements resulting in no additional impacts.
Y-12	Current and planned activities would continue as required with an expected demand for water of approximately 2,000 million gallons per year.	For construction and operation, annual water use would increase by approximately 4% compared to existing use.	For construction and operation, annual water use would increase by approximately 5% compared to existing use.	For construction and operation, annual water use would increase by approximately 7% compared to existing use.	Y-12 performs the CUC mission, therefore the impact of a CNC at this site is identical to the CPC impact.	Operation of CNPC would increase water use by approximately 20% compared to existing use.	Planned activities would continue as required to support smaller stockpile requirements.
Biological Resources							
LANL	Current and planned activities would continue as required resulting in no additional impacts.	TA-55 contains core and buffer areas of environmental interest for the Mexican Spotted Owl. Potential impacts would be within previously and substantially developed areas.	TA-55 contains core and buffer areas of environmental interest for the Mexican Spotted Owl. Potential impacts would be within previously and substantially developed areas.	Potential impacts at TA-16 would be within previously and substantially developed areas.	Potential impacts would be within previously and substantially developed areas.	Same as CNC.	Same a No Action Alternative.
NTS	Current and planned activities would continue as required resulting in no additional impacts.	Construction would not impact biological resources because new facilities would be sited on previously disturbed land. Operations would not impact biological resources because activities would be located in previously disturbed or	Construction would not impact biological resources because new facilities would be sited on previously disturbed land.	Same as CUC.	Reference location is in highly developed area, impacts would be minimal.	Same as CNC.	NTS would be unaffected by the Capability Based Alternative.

		habitat sufficient to support biologically diverse species mix.					
Socioeconomic Resources							
LANL	Current and planned activities would continue as required resulting in no additional impacts. Employment at LANL is expected to continue to rise due to both increased pit production and increased remediation and D&D activities. If LANL's employment rate were to continue increasing at the same level experienced from 1996 through 2005 (2.2 percent annually), approximately 15,400 individuals could be employed at LANL by the end of 2011.	<i>Greenfield CPC:</i> 770 workers during the peak year of construction. Total of 2,650 jobs. 1,780 operational workers, total of 3,667 jobs <i>Upgrade 125:</i> 300 workers during peak year of construction. Total of 618 jobs. 1,780 operational workers, total of 3,667 jobs. <i>50/80:</i> 190 workers during peak year of construction. Total of 391 jobs 680 operational workers, total of 1,401 jobs. Under all approaches there would be no appreciable changes to regional socioeconomic characteristics expected.	1,300 workers during the peak year of construction. Total of 2,678 jobs. No appreciable changes to regional socioeconomic characteristics expected.	3,820 jobs during peak year of construction. Total 7,869 jobs. No appreciable changes to regional socioeconomic characteristics expected.	2,715 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	4,500 operational workers. No appreciable changes to regional socioeconomic characteristics expected. Pantex and Y-12 could be closed, resulting in a loss of approximately 8,150 jobs.	Employment at LANL is expected to continue to rise due to increased pit production.
LANL Plutonium Phaseout: If LANL is not selected as the site for the CPC or CNPC, NNSA proposes to phase-out NNSA plutonium operations and remove Category I/II SNM from LANL by approximately 2022. Phasing out the plutonium operations from TA-55 would result in a loss of approximately 610 jobs representing a decrease of 4.5 % of the workforce. The total loss of jobs in the economic area would be 1,260.							
NTS	Current level of NTS employment is expected to continue. Current and planned activities would continue as required resulting in no additional impacts.	850 workers during the peak year of construction. Total of 1,676 jobs. 1,780 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	1,300 workers during the peak year of construction. Total of 2,563 jobs. 935 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	525 jobs during peak year of construction. Total 1,560 jobs. 1,285 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	2,715 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	4,500 operational workers. No appreciable changes to regional socioeconomic characteristics expected. Pantex and Y-12 could be closed, resulting in a loss of approximately 8,150 jobs.	NTS would be unaffected by the Capability Based Alternative.
Pantex	Pantex is expected to continue present operations with an employment level of about 3,800 employees.	850 workers during the peak year of construction. Total of 1,527 jobs. 1,780 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	1,300 workers during the peak year of construction. Total of 2,336 jobs. 935 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	No A/D/HE Center is proposed at Pantex because the A/D/HE mission is part of the No Action Alternative.	Pantex performs the A/D/HE mission; therefore the impact of a CNC at this site is identical to the CNPC impact. See CNPC Operation in next column.	2,715 operational workers. Total of 5,319 jobs. No appreciable changes to regional socioeconomic characteristics expected. Y-12 could be closed,	Reduced operations would reduce the workforce from 1,644 to 1,230. This workforce, which currently represents

Table S.3.16-1—Comparison of Environmental Impacts among Programmatic Alternatives (continued)

		CPC	CUC (or UPF at Y-12)	A/D/HE	CNC Operation	CNPC Operation	
						resulting in a loss of approximately 6,500 jobs.	approximately 1.3% of area employment, would fall to 1.2%. No major impact would occur.
SRS	The current level of employment at SRS is about 15,000, which is expected to be increased by the construction of the MOX/PDCF facilities which would add an additional 1,968 construction workers and once operational an additional 1,120 employees.	850 workers during the peak year of construction. Total of 1,461 jobs. 1,780 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	1,300 workers during the peak year of construction. Total of 2,234 jobs. 935 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	3,820 workers during the peak year of construction. Total of 6,561 jobs. 1,785 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	2,715 operational workers. No appreciable changes to regional socioeconomic characteristics expected	4,165 operational workers. No appreciable changes to regional socioeconomic characteristics expected. Pantex and Y-12 could be closed, resulting in a loss of approximately 8,150 jobs.	Reduced operations would reduce the workforce by approximately 25 workers. This reduction would be inconsequential relative to the total site workforce.
Y-12	Y-12 is expected to continue present operations with an employment level of about 6,500 employees.	850 workers during the peak year of CPC construction. During operations, CPC would employ 1,780. No appreciable changes to regional socioeconomic characteristics expected.	Construction of UPF would require approximately 900 workers during the peak year of construction. During operations, UPF would employ 600. No appreciable changes to regional socioeconomic characteristics expected.	3,820 workers during the peak year of construction. Total of 19,864 jobs. 1,285 operational workers. No appreciable changes to regional socioeconomic characteristics expected.	Y-12 performs the CUC mission, therefore the impact of a CNC at this site is identical to the CPC impact.	4,500 operational workers. No appreciable changes to regional socioeconomic characteristics expected. Pantex could be closed, resulting in a loss of approximately 1,650 jobs.	Reduced operations would reduce the workforce from 6,500 to 3,900 workers. The loss of 2,600 direct jobs could result in the loss of up to 10,920 indirect jobs for a total of 13,520 jobs lost. This would represent 6.5 percent of the total ROI employment.
Environmental Justice							
LANL	Current and planned activities would continue as required resulting in no additional impacts.	Minority population: 57 percent within the census tracts containing LANL Low-Income population: 9.3 percent of ROI Construction or operation activities would not result in any disproportionately high or adverse effects on minority or low-income populations.	Construction or operation activities would not result in any disproportionately high or adverse effects on minority or low-income populations.	Same as CUC.	Operation activities would not result in any disproportionately high or adverse effects on minority or low-income populations.	Same as CNC.	Same a No Action Alternative.
NTS	Current and planned activities	Minority population: 50	Construction activities	Same as CUC.	Operation activities would	Same as CNC.	NTS would be

Facility Accidents							
LANL	Current and planned activities would continue as required resulting in no additional impacts. Under all alternatives analyzed in the LANL SWEIS, the facility accident with the highest radiological risk to the offsite population would be a lightning strike fire at the Radioassay and Nondestructive Testing Facility located in TA-54. If this accident were to occur, there could be 6 additional LCFs in the offsite population.	Accident with the highest consequences to the offsite population is the beyond evaluation basis earthquake and fire. Approximately 26 LCFs in the offsite population could result from such an accident. Offsite maximally exposed individual (MEI) would receive a dose of 87.5 rem. Statistically, MEI would have 1 chance in 19 of LCF. When probabilities are taken into account, the accident with the highest risk is the explosion in a feed casting furnace. For this accident, the LCF risk to the MEI would be approximately 9×10^{-4} , or approximately 1 in 1,000. For the population, the LCF risk would be 0.19, or approximately 1 in 5.	Accident with the highest consequences to the offsite population is the fire in the EU warehouse. Approximately 0.06 LCFs in the offsite population could result from such an accident. Offsite MEI individual would receive a maximum dose of 0.249 rem. Statistically, the MEI would have 1 chance in 7,000 of an LCF. When probabilities are taken into account, the accident with the highest risk is the design-basis fire for HEU storage. For this accident, the maximum LCF risk to the MEI would be approximately 1.6×10^{-7} , or less than one in a million. For the population, the LCF risk would be 7.2×10^{-5} , or approximately 1 in 10,000.	Accident with the highest consequences to the offsite population is the explosive driven plutonium and tritium dispersal from an internal event. Approximately 3 LCFs in the offsite population could result from such an accident. Offsite MEI would receive a dose of 73.8 rem. Statistically, this MEI would have 1 chance in 23 of an LCF. When probabilities are taken into account for this accident, the LCF risk to the MEI would be approximately 9×10^{-6} , or approximately 1 in 100,000. For the population, the LCF risk would be 3×10^{-4} , meaning that an LCF would statistically occur once every 3,000 years in the population.	See CPC and CUC.	See CPC and CUC and A/D/HE.	Same as No Action Alternative.
<p>LANL Plutonium Phaseout: If LANL is not selected as the site for the CPC or CNPC, NNSA proposes to phase-out NNSA plutonium operations and remove Category I/II SNM from LANL by approximately 2022. Phasing out the plutonium operations from TA-55 would result in a decrease in the potential accident impacts to LANL employees and the population surrounding LANL.</p>							
NTS	Current and planned activities would continue as required resulting in no additional impacts. The maximum reasonably foreseeable accident at the NTS would be a non-nuclear explosion	Accident with the highest consequences to the offsite population is the beyond evaluation basis earthquake and fire. Approximately 0.5 LCFs in the offsite population could result from such an	Accident with the highest consequences to the offsite population is fire in the EU warehouse. Approximately 0.0008 LCFs in the offsite population could result from such an accident. An	Accident with the highest consequences to the offsite population is the explosive driven plutonium and tritium dispersal from an internal event. Approximately	See CPC and CUC. 	involving high explosives in a storage bunker, which has a probability of occurrence of 1 in 10,000,000. The following consequences are estimated if such an accident occurs: MEI dose of 34 rem, which would result in a 0.02 probability of an LCF; population dose of 5,800 to 110,000 person-rem, which would result in 3-55 LCFs.	<p>accident. An offsite MEI would receive a dose of approximately 2 rem. Statistically, the MEI would have a 0.001 chance of developing a LCF (i.e., about 1 chance in 1,000 of an LCF).</p> <p>When probabilities are taken into account, the accident with the highest risk to the MEI is the explosion in a feed casting furnace. For this accident, the LCF risk to the MEI would be 6×10^{-6}, or approximately 1 in 150,000. For the population, the LCF risk would be approximately 2×10^{-3}, meaning that an LCF would statistically occur once every 400 years in the population.</p>	<p>offsite MEI would receive a maximum dose of 0.0037 rem. Statistically, the LCF risk to the MEI would be approximately 2×10^{-6}, or about 1 in half a million.</p> <p>When probabilities are taken into account, the accident with the highest risk is the design-basis fire for HEU storage. For this accident, the maximum LCF risk to the MEI would be approximately 2×10^{-9}, or about 1 in half a billion. For the population, the LCF risk would be approximately 9×10^{-7}, or about 1 in a million.</p>	<p>0.06 LCFs in the offsite population could result from such an accident. An offsite MEI would receive a dose of 0.29 rem. Statistically, this MEI would have a 2×10^{-4} chance of developing a LCF (i.e., about 1 chance in 57,000 of an LCF).</p> <p>When probabilities are taken into account for this accident, the LCF risk to the MEI would be approximately 2×10^{-8}, or less than 1 chance in a million. For the population, the LCF risk would be approximately 7×10^{-6}, or approximately 1 in 150,000.</p>			
Pantex	Current and planned activities would continue as required resulting in no additional impacts. Potential accident scenarios and impacts for the No Action Alternative would be the same as presented in the A/D/HE facility column.	<p>Accident with the highest consequences to the offsite population is the beyond evaluation basis earthquake and fire. Approximately 5.9 LCFs in the offsite population could result from such an accident. An offsite MEI would receive a dose of 23.1 rem. Statistically, the MEI would have a 0.01 chance of developing a LCF (i.e., about 1 chance in 100 of an LCF).</p> <p>When probabilities are taken into account, the accident with the highest risk to the MEI is the explosion in a feed casting furnace. For this accident, the LCF risk to the MEI would be approximately 8×10^{-5}, or approximately one</p>	<p>Accident with the highest consequences to the offsite population is the aircraft crash into the EU facilities. Approximately 0.02 LCFs in the offsite population could result from such an accident. An offsite MEI would receive a maximum dose of 0.07 rem. Statistically, this MEI would have a 0.00004 chance of developing a LCF, or about 1 in 25,000.</p> <p>When probabilities are taken into account, the accident with the highest risk is the design-basis fire for HEU storage. For this accident, the maximum LCF risk to the MEI would</p>	<p>Accident with the highest consequences to the offsite population is the explosive driven plutonium and tritium dispersal from an internal event. Approximately 0.9 LCFs in the offsite population could result from such an accident. An offsite MEI would receive a dose of 3.6 rem. Statistically, this MEI would have a 0.002 chance of developing a LCF (i.e., about 1 chance in 500 of an LCF).</p> <p>When probabilities are taken into account for this accident, the LCF risk to the MEI would be 2×10^{-7},</p>	Pantex performs the A/D/HE mission; therefore the impact of a CNC at this site is identical to the CNPC impact. See CNPC Operation in next column.	See CPC and CUC and A/D/HE.	Planned activities would continue as required to support smaller stockpile requirements. It is anticipated that performing an operation less frequently would have a linear reduction in the overall probability that an accident would occur.

* Data is presented for Capability-Based Alternative. The No Net Production/Capability-Based Alternative is discussed in Chapter 5, as appropriate for any potentially-affected site. The No Net Production Capability-Based Alternative would result in less weapons-related activities at NNSA sites. This would translate into smaller infrastructure demands, less waste generation, less dose to workers, and reductions in employment. Although these changes would vary differently at the NNSA sites (see Section 3.6.2), most reductions would be on the order of approximately 10 percent compared to the Capability-Based Alternative.

Table S.3.16-2—Summary of Impact Comparison of SNM Consolidation: Transfer SNM from LLNL

Resource	No Action Alternative	Remove Category I/II SNM from LLNL (Includes the impacts of phasing out Category I/II SNM operations from LLNL Superblock)—Preferred Alternative
Land	No land issues	No land impacts or issues
Noise	No noise impacts	No change
Air Quality	No changes to air quality	<ul style="list-style-type: none"> no emissions of radionuclides to air from Superblock; therefore, phasing out this facility would have no effect on radiological air quality no nonradiological changes expected
Socioeconomic	No change	<ul style="list-style-type: none"> if Superblock operated as Category III SNM facility: minor impacts to facility employment associated with security force reductions if Superblock closed and undergoes D&D: employment would be expected to increase because of the D&D work, but would likely not be significant, and would be offset by the transfer of some personnel to LANL.
Transportation	No change. LLNL is authorized to transport approximately 584 shipments annually.	<ul style="list-style-type: none"> less than 19 shipments of radiological material expected population dose for all shipments: < 3 person-rem LCF risk: <0.01
Human Health	There are no emissions of radionuclides from Superblock.	<ul style="list-style-type: none"> phasing out Category I/II SNM operations from Superblock would have no effect on population doses to the surrounding population. material-at-risk limit for Superblock reduced by 60%; bounding accident source term for Superblock reduced by 60% Superblock accident consequences reduced from 1.3 LCFs to 0.52 LCFs.
Waste Management	Small quantities of hazardous, and liquid and solid non-hazardous wastes	<ul style="list-style-type: none"> if Superblock operated as Category III SNM facility: wastes would drop to 10% of current quantities (to 10 TRU waste drums per year and 40 LLW drums per year) if Superblock closed and undergoes D&D: waste would increase in short-term; for bounding case, wastes could double to 200 TRU waste drums and 800 LLW drums per year for several years

Table S.3.16-3—Summary of Impact Comparison of SNM Consolidation: Transfer SNM from Pantex Zone 4 to Zone 12

Resource	No Action Alternative	Move Category I/II SNM Storage from Zone 4 to Newly Constructed Underground Storage Facility in Zone 12 at Pantex—Preferred Alternative
Land	No land issues	Would disturb 42-57 acres of brownfield land for construction; A maximum of 11 acres would be utilized once operational
Noise	No noise impacts	Minor increase in noise during construction of new 95,900-142,800 sq. ft. underground storage facility.
Water	Water use limited to personal consumption of employees	Would require an additional 1,500,000-2,950,000 gallons of water for 5-year construction period
Air Quality	No impacts to air from SNM storage	Minor fugitive dust emissions during construction of new underground storage facility
Socioeconomics	Currently employs 40 workers	No change
Transportation	No impacts	No impacts off site; all transportation on-site Human health impacts from transportation included under “Human Health”
Human Health	Average dose of 12 mrem to 10 radiological workers	Movement of material would entail an additional total dose of 1,100 person-rem, which would statistically translate into a maximum of approximately 0.657 LCFs
Waste Management	No waste generation	Once material moved D&D of old facility would be expected to generate: <ul style="list-style-type: none"> • 12,000 yd³ of solid waste • 700 yd³ of LLW

Table S.3.16-4—Summary of Impact Comparison of Tritium R&D Alternatives

Resource	No Action	SRS Consolidation— Preferred Alternative	LANL Consolidation	Downsize-in-Place
Land	Continue operations at LLNL, LANL, and SRS	No new land disturbed	No new land disturbed	No new land disturbed
Noise	Continue operations at LLNL, LANL, and SRS	No change	No change*	No change
Air Quality	Continue operations at LLNL, LANL, and SRS No change	<ul style="list-style-type: none"> • SRS tritium emissions increase by 1,000 Curies (2.4% increase over current tritium emissions) • LANL tritium emissions decrease by 1,000 Curies (42% decrease compared to current tritium emissions) • No change to nonradiological emissions 	No change*	No change
Socioeconomic	Continue operations at LLNL, LANL, and SRS No change	<ul style="list-style-type: none"> • 25 jobs restructured at LANL • 25 new jobs would be created at SRS 	No change*	No change
Human Health	Continue operations at LLNL, LANL, and SRS	<ul style="list-style-type: none"> • Average exposure to worker from tritium R&D would be approximately 4.3 mrem • Total worker dose: 0.11 person-rem • Worker LCF risk: 6.6×10^{-5} • MEI dose at SRS: increase by 0.0008 mrem/year; • 50-mile population dose: increase 0.041 person-rem. • LANL decreases would be similarly small 	No change*	No change
Waste Management	Continue operations at LLNL, LANL, and SRS	Wastes would change by less than 1%	No change*	No change

* Consolidation to LANL includes LLNL tritium R&D activities, which amount to one glovebox system.

Table S.3.16-5—Summary of Impact Comparison of Major HE R&D Alternatives*

Resource	No Action	Consolidate HE R&D to LANL	Consolidate HE R&D to LLNL	Consolidate HE R&D to Pantex	Consolidate HE R&D to SNL/NM	Consolidate HE R&D to NTS
Donor Sites	Not Applicable	SNL/NM, LLNL, Pantex	SNL/NM, LANL, Pantex	SNL/NM, LLNL, LANL	Pantex, LLNL, LANL	SNL/NM, LLNL, Pantex, LANL
Land	Continue operations at LANL, LLNL, SNL/NM, Pantex	5 acres disturbed at LANL in vicinity of the Two-Mile Mesa Complex (includes portions of TA-6, TA-22, and TA-40)	8-10 acres disturbed on main LLNL site near the HEAF	5.7 acres disturbed in vicinity of Zone 11 and Zone 12	13.5 acres disturbed in Technical Areas 2 or 3	15 acres disturbed in vicinity of the BEEF
Noise	Continue operations at LANL, LLNL, SNL/NM, Pantex	“thunder-like” explosives testing; noise occasional, not continuous; public, and sensitive wildlife receptors unlikely to be adversely impacted	None detectable outside of HEAF.	“thunder-like” explosives testing; noise occasional, not continuous; public, and sensitive wildlife receptors unlikely to be adversely impacted	“thunder-like” explosives testing; noise occasional, not continuous; public, and sensitive wildlife receptors unlikely to be adversely impacted	“thunder-like” explosives testing; noise occasional, not continuous; public, and sensitive wildlife receptors unlikely to be adversely impacted
Air Quality	Continue operations at LANL, LLNL, SNL/NM, Pantex	Short-term impacts from construction; Operation increases in pollutants would be less than 1% of site emissions. No radiological emissions.	Short-term impacts from construction; Operation increases in pollutants would be less than 1% of site emissions. No radiological emissions.	Short-term impacts from construction; Operation increases in pollutants would be less than 1% of site emissions. No radiological emissions.	Short-term impacts from construction; Operation increases in pollutants would be less than 1% of site emissions. No radiological emissions.	Short-term impacts from construction; Operation increases in pollutants would be less than 1% of site emissions. No radiological emissions.
Socioeconomic	Continue operations at LANL, LLNL, SNL/NM, Pantex	<ul style="list-style-type: none"> • 125 peak construction jobs; • LANL: +300 jobs • LLNL: -175 jobs • SNL/NM: -45 jobs • Pantex: -10 jobs 	<ul style="list-style-type: none"> • 150 peak construction jobs; • LLNL: +300 jobs • LANL: -150 jobs • SNL/NM: -45 jobs • Pantex: -10 jobs 	<ul style="list-style-type: none"> • 210 peak construction jobs; • Pantex: +160 jobs • LANL: -150 jobs • SNL/NM: -45 jobs • LLNL: -175 jobs 	<ul style="list-style-type: none"> • 220 peak construction jobs; • SNL/NM: +325 jobs • LANL: -150 jobs • LLNL: -175 jobs • Pantex: -10 jobs 	<ul style="list-style-type: none"> • 250-300 peak construction jobs; • NTS: +250 jobs • LLNL: -175 jobs • LANL: -150 jobs • SNL/NM: -45 jobs • Pantex: -10 jobs

Table S.3.16-5—Summary of Impact Comparison of Major HE R&D Alternatives (continued)

Resource	No Action	Consolidate HE R&D to LANL	Consolidate HE R&D to LLNL	Consolidate HE R&D to Pantex	Consolidate HE R&D to SNL/NM	Consolidate HE R&D to NTS
Human Health	Continue operations at LANL, LLNL, SNL/NM, Pantex	No change	No change	No change	No change	No change
Waste Management	Continue operations at LANL, LLNL, SNL/NM, Pantex	Construction solid waste: 4,930 cubic yards. Operational wastes minimal.	Construction solid waste: 6,200 cubic yards. Operational wastes minimal.	Construction solid waste: 1,550 cubic yards. Operational wastes minimal.	Construction solid waste: 2,650 cubic yards. Operational wastes minimal.	Construction solid waste: 4,650 cubic yards. Operational wastes minimal.

* Impacts of minor downsizing/consolidation alternatives are presented in Section 5.13.1 of Final SPEIS. Preferred alternative is presented in Section 5.20.

Table 3.16-6—Summary of Impact Comparison of Flight Testing Alternatives

Resource	No Action Alternative	Mobile Upgrade Alternative	Campaign Mode at TTR Alternative			Move to NTS Alternative	Move to WSMR Alternative
			OPTION 1	OPTION 2	OPTION 3 Preferred Alternative		
Noise Impacts	No noise impacts to public	Same as No Action	Same as No Action	Same as No Action	Same as No Action	Same as No Action	Same as No Action
Impact on Air Quality	No impacts to air	Same as No Action	Same as No Action	Same as No Action	Same as No Action	Temporary PM-10 emissions during construction	Temporary PM-10 emissions during construction
Socioeconomic Impacts	Currently employs 135 at Tonopah	No impact to jobs	Loss of 92 jobs at Tonopah with secondary impacts on community	Loss of 57 jobs at Tonopah with secondary impacts on community	Loss of 70 jobs at Tonopah with secondary impacts on community	Loss of 135 jobs at Tonopah with impacts to community and gain of 135 jobs at NTS	Loss of 135 jobs at Tonopah and gain of 135 jobs at WSMR
Human Health Impacts	No radiological emissions (note 1)	No radiological emissions (note 1)	No radiological emissions (note 1)	No radiological emissions (note 1)	No radiological emissions (note 1)	No radiological emissions (note 1)	No radiological emissions (note 1)
Waste Management Impacts	Small quantities of hazardous and liquid and solid non-hazardous	Same as No Action	Same as No Action	Same as No Action	Same as No Action	Same as No Action	Same as No Action

Note 1: Some Flight Test operations utilize depleted uranium in the Joint Test Assembly. There is no explosive event and the depleted uranium is contained within the weapon case. Following each flight test, the depleted uranium is removed.

Table S.3.16-7—Summary of Impact Comparison of Hydrodynamic Testing Alternatives

Resource	No Action Alternative	Downsize in Place Alternative—Preferred Alternative*	Consolidate at LANL Alternative—Preferred Alternative*	Consolidate at NTS Alternative—Preferred Alternative*
Impacts to Land	No land issues	Would not require additional land	Require 5-7 acres additional land	Require 17 acres additional land
Noise Impacts	Limited to workers at facilities	Limited to workers at closure and facility sites	Limited to workers at closure construction and work sites	Limited to workers at closure construction and work sites
Impact on Air Quality	Less than 100 pounds of NOX and CO emissions/year from DARHT & CFF	Same as No Action	Construction PM-10 Emissions	Construction PM-10 Emissions
Socioeconomic Impacts	None as facilities do not employ but are used and managed by other programs	Loss of 26 jobs at LLNL Loss of 5 jobs at LANL	Loss of 56 jobs at LLNL Gain of 5 jobs at LANL	Loss of 56 jobs at LLNL Gain of 5 jobs at LANL
Human Health Impacts	No human health issues	No impacts	No impacts	No impacts
Waste Management Impacts	Small quantities of hazardous waste generated by DARHT and CFF	Additional waste from facility closures	Additional waste from facility closures	Additional waste from facility closures

* Preferred alternative contains elements of the Downsize in-Place Alternative, Consolidate at LANL Alternative, and Consolidate at NTS Alternative.

Table S.3.16-8—Summary of Impact Comparison of Major Environmental Test Facilities Alternatives

Resource	No Action Alternative	Downsize in Place Alternative	Move All ETF to NTS	Move all ETF to SNL/NM—Preferred Alternative*
Impacts to Land	Currently has 558,311 sq ft of floor space at four sites	Reduce building floor space by 62,777 sq ft	Reduce building floor space by 537,385 sq ft but require 23.5 acres of land at NTS	Reduce building floor space by 159,268 sq ft but require 2.5 acres of land at SNL/NM
Noise Impacts	Limited to workers at work sites	Limited to workers at closure and work sites	Limited to workers at closure construction and work sites	Limited to workers at closure construction and work sites
Transportation	No transportation issues	No transportation issues	Closure D&D could cause traffic congest at LANL and Sandia	Closure D&D could cause traffic congestion at LANL
Impact on Air Quality	Small emissions from Bldg 836 at LLNL	Same as no action alternative	PM-10 issues during Construction	PM-10 issues during Construction
Socioeconomic Impacts	Currently employs 29 at LANL 6 at LLNL 224 at SNL/NM	Jobs Lost: 6 at LLNL 16 at SNL/NM	Jobs Lost: 29 at LANL 6 at LLNL 224 at SNL/NM	Jobs Lost: 29 at LANL 6 at LLNL 16 at SNL/NM
Human Health Impacts	No human health issues	Same as no action alternative	Same as no action alternative	Same as no action alternative
Waste Management Impacts	Small waste generation from DAF and SNL/NM	Additional waste from facility closures	Additional waste from facility closures	Additional waste from facility closures

*Preferred alternative includes the option of moving environmental testing of nuclear explosive packages currently performed in LLNL Building 334 and the Building 834 environmental conditioning functions to Pantex by 2012.
