Under the Reduced Operations Alternative, impacts on ecological resources would be the same as those for the No Action Alternative (see Section 5.5.1).

Key Facilities Impacts

Activity levels at certain Key Facilities would change. High explosives processing and testing would be reduced by 20 percent. LANSCE would cease operation and be placed into a safe shutdown mode. Operations would cease at the Pajarito Site (TA-18), and that facility would be shut down. As there would be no change in impacts on ecological resources associated with the closure of LANSCE or TA-18 facilities, this action is not addressed further.

High Explosives Testing Facilities

Under the Reduced Operations Alternative, high explosives testing at LANL would be reduced by 20 percent. Although animals may adjust to constant noise levels, they do not readily adjust to intermittently high noise levels. Startle or fright is the immediate behavioral reaction to transient, unexpected, or unpleasant noise such as explosives testing (EPA 1980). Thus, although testing would be reduced, animals residing near test sites would still experience stress with the occurrence of each test. The overall number of times per year that this stress would be experienced, however, would be lessened.

5.5.3 Expanded Operations Alternative

The Expanded Operations Alternative reflects proposals that would expand the overall operations level at LANL above those established for the No Action Alternative. Thus, this alternative includes the ecological resource impacts for those actions addressed under that alternative (see Section 5.5.1), as well as the potential impacts of a number of new projects. Not all new projects or activities would affect these resources because many would involve actions within or modifications to existing structures, or the construction of new facilities within previously developed areas of LANL. For example, an increase in pit production would not require new construction and hence would not affect ecological resources. Only those projects that would likely impact ecological resources are addressed below.

Los Alamos National Laboratory Site-Wide Impacts

There are two options (capping and removal) related to remediation of MDAs at LANL. Under the Capping Option, terrestrial resources would be disrupted as the MDAs are cleared of existing vegetation and then capped. Provision of material for the caps could result in the loss of some habitat adjacent to the active portion of the borrow pit in TA-61 due to the need to enlarge the existing borrow area. At most sites, however, capping would have minimal biota impact because the MDAs are grassy areas enclosed within a fence that excludes most wildlife species except birds and very small animals. Noise and human presence during remediation could disturb wildlife in adjacent areas, but proper equipment maintenance and restrictions preventing workers from entering adjacent undisturbed areas would lessen these impacts. The caps would be designed to prevent or reduce biointrusion, which would reduce the ecological risks associated with reintroduction of contaminants into the environment. Once capped and revegetated, the MDAs would provide habitat similar to that existing prior to remediation. This option would not directly impact any wetlands or aquatic resources at LANL.

Impacts of MDA and PRS remediation activities to the Mexican spotted owl, bald eagle, and southwestern willow flycatcher were evaluated in a biological assessment prepared by DOE. This assessment determined that, provided reasonable and prudent measures are implemented, remediation activities may affect, but are not likely to adversely affect, the Mexican spotted owl (within MDAs N, Z, A, and AB), bald eagle (within MDA D), and southwestern willow flycatcher (within MDAs G and L). Activities at other MDAs and PRSs at LANL should not impact these species (LANL 2006b). The USFWS has concurred with the findings of the biological assessment (see Chapter 6, Section 6.5.2). Since expansion of the borrow pit could result in the removal of undeveloped buffer and core habitat for the Mexican spotted owl, consultation with the USFWS would be required prior to this activity.

Impacts to ecological resources under the MDA Removal Option would be similar to those described for the Capping Option. While remedial actions would create a disruptive environment for local wildlife in the short term, long-term impacts would likely be beneficial in terms of ecological risk because wastes would be removed. In addition, there would be no restrictions on the types of plants that could be introduced, which would permit reestablishment of more natural conditions that would, in turn, provide habitat for area wildlife (see Appendix I).

Most actions associated with implementing the Security-Driven Transportation Modifications Project would have little or no impact on ecological resources; however, the construction of the two parking lots, a portion of the new road across TA-63, and the highway and pedestrian bridges over the Ten Site branch of Mortandad Canyon would affect undeveloped ponderosa pine forest, open land, and wildlife. Other project elements would largely take place in currently developed areas. As no wetlands exist within Pajarito Corridor West and aquatic resources are not present on the mesa, impacts to these resources would not occur.

The parking lot in TA-63, the road across the eastern edge of TA-63, and the pedestrian and highway bridges fall within buffer habitat of the Mexican spotted owl Areas of Environmental Interest; a portion of the parking lot is within core habitat. A biological assessment performed by DOE determined that up to 18.8 acres (7.6 hectares) of buffer and 1 acre (0.4 hectares) of core Mexican spotted owl habitat could be lost and that the project would generate excess noise or light. The biological assessment concluded that even if reasonable and prudent measures are implemented to mitigate impacts, project activities may affect, and are likely to adversely affect, the Mexican spotted owl (LANL 2006b). However, following review of the biological assessment, the USFWS concluded that impacts to the spotted owl from construction activities associated with the Security-Driven Transportation Modifications Project would be insignificant and discountable, and would not result in adverse effects (see Chapter 6, Section 6.5.2). Additional USFWS consultation would be needed, however, if a land bridge, rather than a span bridge, were constructed.

Land disturbed by the Security-Driven Transportation Modifications Project does not fall within Areas of Environmental Interest for either the bald eagle or southwestern willow flycatcher. However, because the bald eagle forages over all of LANL and some habitat degradation is associated with the project, the biological assessment concluded that provided appropriate reasonable and prudent measures are implemented, the project may affect, but is not likely to adversely affect, the bald eagle. Because the southwestern willow flycatcher Area of Environmental Interest is more than 2 miles (3.3 kilometers) from the project site, the biological assessment concluded that the proposed project would have no effect on this species

(LANL 2006b). The USFWS has concurred with the biological assessment as it relates to the bald eagle and southeastern willow flycatcher (see Chapter 6, Section 6.5.2).

Auxiliary Action A for the Security-Driven Transportation Modifications Project involves construction of a two-lane bridge within a 1,000-foot (300-meter)-wide corridor across Mortandad Canyon and a new two-lane road from the north end of the new bridge westward through TA-60 to connect TA-35 with TA-3. Auxiliary Action B involves construction of a new two-lane bridge that would be constructed within a 1,000-foot (300-meter)-wide corridor across Sandia Canyon and a new two-lane road from the new bridge to connect with East Jemez Road. Construction of the roadways would have minimal impacts on habitat because they generally would follow the existing rights-of-way that have already been disturbed. The road that would be constructed under the second action, however, would require clearing and grading approximately 1.3 acres (0.5 hectares) of ponderosa pine forest. No wetlands or aquatic resources would be directly affected by roadway construction.

Under both auxiliary actions, road and bridge construction would take place within the buffer zone of the Sandia-Mortandad Canyon and Los Alamos Canyon Mexican spotted owl Area of Environmental Interest. Additionally, they would pass through the core zone of the Sandia-Mortandad Canyon Mexican spotted owl Area of Environmental Interest. The biological assessment prepared by DOE determined that Auxiliary Action A would disturb up to 25.3 acres (10.2 hectares) of undeveloped core habitat and 0.1 acres (0.4 hectares) of undeveloped buffer habitat. Under Auxiliary Action B, construction would directly impact up to 37.1 acres (15 hectares) of undeveloped core habitat and 28.7 acres (11.6 hectares) of undeveloped buffer habitat. Further, under both actions construction would cause temporary increases in light and noise which would be permanent once the bridge was operational. The biological assessment concluded that even if reasonable and prudent measures are implemented to mitigate impacts, project activities may affect, and are likely to adversely affect, the Mexican spotted owl (LANL 2006b). Upon review of the biological assessment, the USFWS determined that it could not adequately analyze the affects of the proposed actions since the exact location and design of the bridges have not been determined. Instead the agency requested that DOE submit a request for consultation when plans are finalized (see Chapter 6, Section 6.5.2).

The biological assessment determined that with reasonable and prudent measures, the project may affect, but is not likely to adversely affect, the bald eagle. This determination was made based on the fact that some foraging habitat degradation would be associated with construction. Since the closest southwestern willow flycatcher Area of Environmental Interest is more than 2.3 miles (3.7 hectares) from the nearest construction area, the biological assessment determined that there would be no effect to this species (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to bald eagle and southeastern willow flycatcher (see Chapter 6, Section 6.5.2).

Technical Area Impacts

Two projects are planned that could impact ecological resources within TA-3 and TA-21. These are addressed below.

Technical Area 3

Construction related to the Replacement Office Building Project would involve clearing and grading 13 acres (5.3 hectares) of mixed conifer forest within TA-3, resulting in loss of less mobile wildlife such as reptiles and small mammals and displacing more mobile species such as birds or large mammals. Construction of the new buildings and parking lot would not impact wetlands because none are located in or near the construction zone. Potential impacts to the Mexican spotted owl were evaluated in a biological assessment prepared by DOE. This assessment noted that although 11.2 acres (4.5 hectares) of buffer habitat would be disturbed, if all reasonable and prudent measures are taken, actions associated with the construction may affect, but are not likely to adversely affect, the Mexican spotted owl. The Area of Environmental Interest for the bald eagle does not include any part of TA-3. However, since some bald eagle foraging habitat degradation could be associated with the project, the biological assessment concluded that provided reasonable and prudent measures are implemented, the project may affect, but is not likely to adversely affect, the bald eagle. The nearest southwestern willow flycatcher Area of Environmental Interest is more than 4.6 miles (7.4 kilometers) from the project site. Thus, the biological assessment concluded that the proposed project would have no effect on this species (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to these three species (see Chapter 6, Section 6.5.2).

Operation of the Replacement Office Building complex would likely have minimal impact on terrestrial resources within or adjacent to TA-3 (see Appendix G.2).

Technical Area 21

DD&D of structures at TA-21 would occur within the highly disturbed industrial portion of the TA, which contains little wildlife habitat. Demolition-related disturbances to wildlife would likely be intermittent and localized. After DD&D of the buildings and structures, the site would be contoured and revegetated. Revegetation would have only relatively short-term benefits to wildlife, however, because both the parcel conveyed to Los Alamos County and the parcel retained by DOE could be developed in the future. Elimination of two NPDES-permitted outfalls associated with TA-21 operations would reduce the quantity of surface water discharged to the adjacent canyons.

TA-21 falls within the Los Alamos Canyon Mexican spotted owl Area of Environmental Interest. Because TA-21 is highly disturbed, no suitable foraging or nesting habitat would be lost as a result of DD&D activities. Because noise levels would increase as a result of demolition activities the biological assessment prepared by DOE concluded that provided reasonable and prudent measures are implemented, DD&D activities may affect, but are not likely to adversely affect, the Mexican spotted owl. Since no bald eagle nesting or foraging habitat would be lost as a result of DD&D activities and the southwestern willow flycatcher Area of Environmental Interest is more than 2.6 miles (4.2 kilometers) from TA-21, the biological assessment determined that the proposed project would have no effect on either species (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to these three species (see Chapter 6, Section 6.5.2).

Key Facilities Impacts

Four projects related to Key Facilities at LANL are planned that could affect ecological resources.

Radiochemistry Facility

Although construction of some of the new facilities associated with the Radiological Sciences Institute would take place on previously disturbed land, it would be necessary to clear about 12.6 acres (5.1 hectares) of ponderosa pine forest at TA-48, which would directly and indirectly impact area wildlife. Construction of the Radiological Sciences Institute would not directly impact wetlands located in Mortandad Canyon or the small wetland situated between TA-48 and TA-55, and best management practices would reduce the potential for indirect impacts. There would be no impact to aquatic resources from construction and operation of the Radiological Sciences Institute.

Portions of TA-48 are located within core and buffer zones of the Sandia-Mortandad Canyon and Pajarito Canyon Mexican spotted owl Areas of Environmental Interest. However, only a small portion of the Radiological Sciences Institute may be built within buffer habitat. Thus, the biological assessment prepared by DOE concluded that with the application of reasonable and prudent measures, the project may affect, but is not likely to adversely affect, the Mexican spotted owl. Areas of Environmental Interest for the bald eagle do not include any part of TA-48 or TA-55. Since some bald eagle foraging habitat degradation is possible with construction of the Radiological Sciences Institute, the biological assessment concluded that with reasonable and prudent measures the project may affect, but is not likely to adversely affect, the bald eagle. The nearest southwestern willow flycatcher Area of Environmental Interest is over 3 miles (4.8 kilometers) from the project site. Thus, it was determined that there would be no effect on this species (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to these three species (see Chapter 6, Section 6.5.2).

Removal of existing buildings and structures at TA-48, as well as those to be replaced by the Radiological Sciences Institute, would generate increased noise and levels of human disturbance. These impacts would be temporary, however, and would likely have minimal effect on wildlife because these structures exist within previously disturbed areas and wildlife in adjacent areas is accustomed to human activity. As wetlands do not exist in the immediate area of any of the buildings to be replaced by the new Radiological Sciences Institute, there would be no direct impacts on this resource. Of the buildings to be demolished in connection with the Radiological Sciences Institute project, only those located in TA-35 are located in developed core habitat for the Mexican spotted owl. The removal of these buildings could produce increased noise levels in undeveloped core habitat. However, the biological assessment concluded that demolition may affect, but is not likely to adversely affect, the Mexican spotted owl, provided that reasonable and prudent measures are followed. DD&D activities would have no effect on the bald eagle and southwestern willow flycatcher (LANL 2006b). The USFWS has concurred with the biological assessment as it relates impacts to these three species (see Chapter 6, Section 6.5.2).

Radioactive Liquid Waste Treatment Facility

No impacts to terrestrial resources or wetlands would be expected from implementing any of the alternatives for the Radioactive Liquid Waste Treatment Facility upgrade because it is located within a highly developed industrial area of TA-50. However, the evaporation tanks and pipeline that are proposed as an auxiliary action to this project would be located in undeveloped core and buffer habitat of the Sandia-Mortandad Canyon Mexican spotted owl Area of Environmental Interest. The biological assessment prepared by DOE determined that the tanks and pipeline would remove 3.1 acres (1.3 hectares) of undeveloped buffer habitat and 2.3 acres (0.9 hectares) of undeveloped core habitat. It was also determined that construction of the Radioactive Liquid Waste Treatment Facility would likely raise noise levels in the core zone. The biological assessment concluded that with the application of reasonable and prudent measures the project may affect, but is not likely to adversely affect, the Mexican spotted owl. The bald eagle Area of Environmental Interest is not located near the proposed project site; however, because the entire LANL site is considered potential bald eagle foraging habitat there may be some habitat degradation associated with the project. Provided reasonable and prudent measures are implemented, the biological assessment concluded that construction may affect, but is not likely to adversely affect, the bald eagle. The proposed project is not within or upstream of the southwestern willow flycatcher Area of Environmental Interest; thus, the project would not effect this species (LANL 2006b). The USFWS has concurred with the DOE biological assessment as it relates to these three species (see Chapter 6, Section 6.5.2). Implementation of the evaporation tank option would likely reduce the extent of perennial and intermittent stream reaches, associated wetlands, and riparian habitat, which would reduce the abundance and diversity of prey species for the Mexican spotted owl. Significant adverse impacts to the Mexican spotted owl, however, are not expected.

Solid Radioactive and Chemical Waste Facilities

Under both the options proposed as part of Waste Management Facilities Transition activities within TA-54, including new construction and removal of the white-colored domes, all activities would occur within developed areas. Thus, there would be little to no impact on ecological resources. Although TA-54 includes a portion of the southwestern willow flycatcher Area of Environmental Interest, the area within which project related activities would take place is located about 450 feet (137 meters) from the core habitat. Provided reasonable and prudent measures are implemented, the biological assessment prepared by DOE concluded that the project may affect, but is not likely to adversely affect, the southwestern willow flycatcher. With respect to the bald eagle and Mexican spotted owl, the biological assessment determined that there would be no effect on either species as a result of implementing the proposed project. This is the case since the site does not include any portion of Areas of Environmental Interest for these species, foraging habitat would not be disturbed, and noise levels would be low (LANL 2006b). The USFWS has concurred with this assessment as it relates to these three species (see Chapter 6, Section 6.5.2).

The proposed TRU Waste Facility could be located within a generic area in the Pajarito Road corridor selected from among a number of TAs, and would disturb about 2.5 to 7 acres (1 to 2.8 hectares) of land. In most cases this would involve the removal of ponderosa pine forest or open field habitat; however, the generic site within TA-54 West is developed. Impacts to wetlands and aquatic resources from this project would not be expected.

At least some portion of either the core or buffer zone of Mexican spotted owl Areas of Environmental Interest would be affected by construction of the new facility within all generic sites except in TA-48, TA-51, and TA-54 West. For those generic sites where the new facility has the potential to affect the spotted owl, either directly or indirectly (for example, by excess noise or light), it would be necessary to conduct a biological assessment and initiate formal consultation with the USFWS. None of the generic sites are within Areas of Environmental Interest for the bald eagle or southwestern willow flycatcher.

Pajarito Site

DD&D of facilities at TA-18 would have little impact on wildlife habitat because the facilities are located within areas that are developed and fenced. Animals could be intermittently disturbed by activity and noise during the demolition period. Implementation of best management practices during demolition would prevent potentially sediment-laden runoff from reaching the wetland located at the eastern end of TA-18. Ultimately, previously disturbed areas would be restored using native species, which would benefit area wildlife.

DD&D of buildings and structures at TA-18 would not directly impact the Mexican spotted owl because all activities would take place within developed areas. However, the biological assessment performed by DOE noted that noise levels in the core zone would be elevated above background levels. The biological assessment concluded that with the implementation of reasonable and prudent measures, DD&D activities may affect, but are not likely to adversely affect, the Mexican spotted owl. With respect to the bald eagle, DD&D of TA-18 facilities would have no effect since the project would not remove any bald eagle foraging habitat. While the project would take place upstream from the southwestern willow flycatcher Area of Environmental Interest, it was determined that with the application of reasonable and prudent measures, the project may affect, but is not likely to adversely affect, the southwestern willow flycatcher (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to these three species (see Chapter 6, Section 6.5.2).

Biosciences Facilities

Construction of the Science Complex would involve clearing and grading approximately 5 acres (2 hectares) of ponderosa pine forest under the Northwest TA-62 and Research Park Site options, which would result in loss and displacement of wildlife. Indirect impacts from construction, such as noise or human disturbance, could also impact wildlife. Construction of the new buildings and parking structure would not impact wetlands because none are located in or near the construction zone under either option. Operation of the Science Complex would minimally impact terrestrial resources because wildlife residing in the area has already adapted to levels of noise and human activity associated with development in the general area. Impacts to ecological resources would be minimal under the South TA-3 option because the area is already partially developed and is within the more developed part of TA-3.

Under the Northwest TA-62 Option a portion of the project area falls within the core and buffer zone of the Los Alamos Canyon Area of Environmental Interest for the Mexican spotted owl. The biological assessment prepared by DOE determined that construction would remove some undeveloped core habitat and buffer habitat. Further, the project would potentially increase noise levels in the core zone. The biological assessment noted that provided all reasonable and prudent measures are implemented, the project may affect, but is not likely to adversely affect, the Mexican spotted owl. Areas of Environmental Interest for the bald eagle and southwestern willow flycatcher are not located near the proposed Northwest TA-62 Science Complex location. However, because the bald eagle forages over all of LANL and some habitat degradation associated with construction could occur, the biological assessment concluded that with reasonable and prudent measures, the project may affect, but is not likely to adversely affect, the bald eagle. The nearest southwestern willow flycatcher Area of Environmental Interest is not within or downstream of the project site; thus, there would be no effect on this species (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to these three species (see Chapter 6, Section 6.5.2). Although the Research Park Site Option was not addressed in the biological assessment, the site is not within an Area of Environmental Interest for the Mexican spotted owl, bald eagle, or willow flycatcher. Thus, impacts to these species under this option would not be expected.

Warehouse and Truck Inspection Station

The proposed project would include clearing and grading approximately 4 acres (1.6 hectares) of ponderosa pine forest and pinyon-juniper woodland, which would result in loss and displacement of wildlife. Indirect impacts from construction, such as noise or human disturbance, could also impact wildlife. Operation of the proposed Remote Warehouse and Truck Inspection Station would not likely pose significant adverse effects to area wildlife. The new facility would not be located within Areas of Environmental Interest for the Mexican spotted owl, bald eagle, or southwestern willow flycatcher. However, because the bald eagle forages over all of LANL and some habitat degradation associated with construction could occur, the biological assessment prepared by DOE concluded that with appropriate reasonable and prudent measures, the project may affect, but is not likely to adversely affect, the bald eagle. The biological assessment further concluded that there would be no effect on the Mexican spotted owl or southwestern willow flycatcher (LANL 2006b). The USFWS has concurred with this assessment (see Chapter 6, Section 6.5.2).

5.6 Human Health

5.6.1 Radiological Impacts on the Public

People can be exposed to radiation through a variety of ways. Airborne radioactive particles can be inhaled. Radioactive particles can be ingested if they are on the surface of food or if the food was produced in areas that are contaminated with radioactive material that can be taken up by plants and animals. The body can be directly exposed to radiation from radionuclides in air emissions or from proximity to radioactive materials that have been deposited on the ground. Radiation also can enter the body through skin breaks. Estimates were made of the amount of radioactive materials to which the public could be exposed due to LANL radioactive air emissions (see Section 5.4.2). Using these estimates, radiation doses from LANL operations to the public and at certain receptor locations were calculated (details can be found in Appendix C).

The total annual radiation dose received by an individual is a combination of the potential dose received from LANL operations and the doses received from other radiation sources such as naturally occurring background radiation, medical radiation, and radiation from other nuclear activities. A challenge in measuring dose is that no person has the same actual exposure rate as any other. Because of this, health impacts analyses often evaluate the upper bound for individual exposure, which is expressed as the potential dose to the hypothetical MEI. For this analysis, the MEI is a hypothetical person who is assumed to remain in place outdoors without shelter and without taking any protective action for the entire period of exposure. In reality, no one would receive a dose approaching that of an MEI, but the concept is useful as an expression of the upper bound of any possible dose to an individual.

Historical data and capabilities were reviewed for the *1999 SWEIS* to determine which LANL facilities would be analyzed as Key Facilities. For this new SWEIS, changes to those capabilities and past emissions determined which facilities would remain designated as Key Facilities. **Table 5–15** lists those Key Facilities used in the human health analyses of this SWEIS.

Table 5–15 List of Facilities Modeled for Radionuclide Air Emissions from Los Alamos National Laboratory

Key Facility Name	*Technical Area/Building*
Chemistry and Metallurgy Research Building	TA-3-29
Sigma Complex	TA-3-66
Machine Shops	TA-3-102
High Explosives Processing Facilities	TA-11
High Explosives Testing Facilities	TA-15/36
Tritium Facilities [a]	TA-16
Pajarito Site	TA-18
Radiochemistry Facility	TA-48
LANSCE	TA-53
Solid Radioactive and Chemical Waste Facilities [b]	TA-54
Plutonium Facility Complex	TA-55
Non-Key Facilities	TA-21

TA = technical area, LANSCE = Los Alamos Neutron Science Center.

[a] This facility includes the Weapons Engineering Tritium Facility (TA-16). The Tritium Science Fabrication Facility and Tritium System Test Assembly at TA-21 continue to have emissions while awaiting DD&D, and are included under the non-Key Facilities.

[b] Includes MDA G and the Decontamination and Volume Reduction System.

Some facilities that have historically low emission rates are unmonitored. These unmonitored point sources receive periodic confirmatory measurements by LANL personnel to verify that emissions remain low. The *1999 SWEIS* analyzed air emissions data from TA-50-1 (Radioactive Liquid Waste Treatment Facility) and confirmed that air emissions were “insignificant relative to other sources at LANL” (LANL 1997b), so the public dose from those emissions was not analyzed. For this new SWEIS, air emissions data from the Radioactive Liquid Waste Treatment Facility were again reviewed for the period from 1999 to 2004. This review of actual radiological air emissions showed a decreasing trend since 1992, with a low of 7.9×10^{-8} curies per year recorded in 2004. The six-year average for TA-50 emissions during that period

(1.1×10^{-7} curies) is far less than emissions from LANSCE (2,700 curies), the major contributor to the public dose. It is anticipated that air emissions data would remain the same for the purposes of analyses presented in this new SWEIS, and therefore would result in insignificant health-related impacts to the public compared to other sources.

To calculate these doses for this new SWEIS, the Clean Air Act Assessment Package – 1988 (CAP-88) software was used. CAP-88 is an EPA-approved computer model for calculating the effective dose equivalent to members of the public, as required by emission monitoring and compliance procedures for DOE facilities [40 CFR 61.93 (a)]. CAP-88 uses modified Gaussian plume equations to estimate the average dispersion of radionuclides released to the air from up to six emitting sources. The program computes radionuclide concentrations in air, rates of deposition on ground surfaces, concentrations in food, and intake rates to people from ingestion of food produced in the assessment area.

For this SWEIS, an estimated dose to the facility-specific MEI was calculated for each modeled facility. The location of each facility-specific MEI is where the dose from that facility's emissions to a member of the public would be largest, and is based on wind direction and meteorological data for that facility. **Table 5–16** shows the distance and direction from each facility to its facility-specific MEI. Doses from all modeled facilities were calculated at the facility-specific MEI location; thus, the dose to the facility-specific MEI represents the estimated dose to an individual from the specific facility and all other modeled facilities. The LANL site-wide MEI is the single highest facility-specific MEI; therefore, any other facility-specific MEI doses would be less than the LANL site-wide MEI for the alternative under analysis.

Table 5–16 Distance and Direction from Key Facilities to the Facility-Specific Maximally Exposed Individual

Key Facility	*MEI Distance Feet (meters)*	*MEI Direction*
Chemistry and Metallurgy Research Building (TA-3–29)	3,575 (1,090)	N
Sigma Complex (TA-3–66)	3,560 (1,085)	N
Machine Shops (TA-3–102)	3,380 (1,030)	N
High Explosives Processing Facilities (TA-11)	4,300 (1,311)	S
High Explosives Testing Facilities (TA-15/36)	7,415 (2,260)	NE
Tritium Facilities (TA-16)	2,885 (879)	SSE
Pajarito Site (TA-18)	2,820 (860)	NE
Radiochemistry Facility (TA-48)	2,920 (890)	NNE
LANSCE (TA-53)	2,625 (800)	NNE
Solid Radioactive and Chemical Waste Facilities (TA-54)	1,195 (364)	NE
Plutonium Facility Complex (TA-55)	3,690 (1,125)	N
Non-Key Facilities (TA-21)	1,050 (320)	N

MEI = maximally exposed individual, TA = technical area, LANSCE = Los Alamos Neutron Science Center.

Population dose estimates were made for the entire population within a 50-mile (80-kilometer) radius of LANL by summing the estimated doses to all people within that radius. The population dose from each facility was modeled independently for each alternative. The total dose from all facilities for one alternative represents the projected population dose from implementing that alternative.

In addition to dose, estimates of risk to the public and the MEI were calculated. Scientists and decisionmakers quantify relationships among risks by using mathematical probabilities. In this SWEIS, risks are defined in terms of the number of additional latent cancer fatalities (excess LCFs due to the estimated dose) from LANL operations. The number of additional LCFs is calculated as the product of the dose in units of person-rem and the risk factor (0.0006 LCF per person-rem). These estimates are intended to be conservative measures of the potential public health impacts of the three alternatives for use in the decisionmaking process; they do not necessarily accurately represent actual anticipated fatalities.

Tables 5–17 and **5–18** summarize the projected public doses resulting from normal operations under each alternative for both an MEI near LANL property and the general population within 50 miles (80 kilometers) of LANL. The potential impact from shutdown of LANSCE operations under the Reduced Operations Alternative would substantially decrease the dose to the general public and to the MEI. Under all of the alternatives, the MEI would receive a smaller dose than the exposure limits set by DOE and EPA.

Table 5–17 Summary of Projected Doses to the Maximally Exposed Individual from Normal Operations at Los Alamos National Laboratory (millirem per year)

	No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
LANL Site-Wide			
Dose from MDA remediation only to LANL Site-Wide MEI	Not applicable	Not applicable	less than 0.42 [b]
Key Facilities [a], includes contributions from:			
CMR Building	0.011	0.0034	0.011
Sigma Complex	0.0041	0.0060	0.0041
Machine Shops	0.00032	0.00045	0.00032
High Explosives Processing Facilities	1.3×10^{-6}	1.8×10^{-6}	1.3×10^{-6}
High Explosives Testing Facilities	0.25	0.72	0.25
Tritium Facilities	0.0036	0.0045	0.0036
Pajarito Site	0.0070	0.0080 [c]	0.0070 [c]
Radiochemistry Facility	0.00029	0.00050	0.00029
LANSCE [d]	7.5	0	7.5
Solid Radioactive and Chemical Waste Facilities	0.0012	0.0012	0.0012 [e]
Plutonium Facility Complex	0.012	0.024	0.012
Non-Key Facility (TA-21)	0.012	0.0071	0.012 [f]
Total LANL Site-Wide MEI Dose	7.8	0.78	Less than 8.2 [b]

MDA = material disposal area, MEI = maximally exposed individual, CMR = Chemistry and Metallurgy Research, LANSCE = Los Alamos Neutron Science Center, TA = technical area.

[a] Under the No Action and the Expanded Operations Alternatives, the LANL site-wide MEI would be located near LANSCE. Under the Reduced Operations Alternative, the LANL site-wide MEI would be located near the High Explosives Testing (Firing Sites) at TA-36.

[b] This dose could be smaller depending on which MDA is being remediated, whether the MDA is being capped or removed, the number of MDAs being remediated at one time, and whether exhumation occurs under an enclosure (see Appendix I).

[c] Dose would be zero following shutdown of Pajarito Site (TA-18) after about 2009.

[d] The maximum dose to the MEI as a result of emissions from LANSCE would be limited to 7.5 millirem per year using administrative controls.

[e] This dose could increase to 0.0018 millirem per year if the Decontamination and Volume Reduction System, the new TRU Waste Facility, and remote-handled transuranic waste retrieval and processing activities operated simultaneously (estimated to occur from 2012 through 2015).

[f] Dose would be zero following decontamination, decommissioning, and demolition of TA-21 after about 2009.

Table 5–18 Summary of Projected Doses to the General Public Within 50 Miles (80 kilometers) of Los Alamos National Laboratory from Normal Operations (person-rem per year)

	No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
LANL Site-Wide			
Dose from MDA remediation	Not applicable	Not applicable	Less than 6.2 [a]
Key Facilities, includes contributions from:			
CMR Building	0.43	0.11	0.43
Sigma Complex	0.16	0.16	0.16
Machine Shops	0.01	0.01	0.01
High Explosives Processing Facilities	0.00005	0.00004	0.00005
High Explosives Testing Facilities	6.4	5.2	6.4
Tritium Facilities	0.09	0.09	0.09
Pajarito Site	0.23	0.23 [b]	0.23 [b]
Radiochemistry Facility	0.01	0.01	0.01
LANSCE	22	0	22
Solid Radioactive and Chemical Waste Facilities	0.04	0.04	0.04 [c]
Plutonium Facility Complex	0.19	0.19	0.20
Non-Key Facility (TA-21)	0.09	0.09	0.09 [d]
Total Dose to General Population	**30**	**6.1**	**Less than 36.2 [a]**

MDA = material disposal area, CMR = Chemistry and Metallurgy Research, LANSCE = Los Alamos Neutron Science Center, TA = technical area.

[a] This dose could be smaller depending on which MDAs are being remediated, whether the MDA are being capped or removed, the number of MDAs being remediated at one time, and whether exhumation occurs under an enclosure (see Appendix I).

[b] Dose would be zero following shutdown of Pajarito Site (TA-18) after about 2009.

[c] This dose could increase to 0.06 person-rem per year if the Decontamination and Volume Reduction System, the new TRU Waste Facility, and remote-handled transuranic waste retrieval and processing activities operated simultaneously (estimated to occur from 2012 through 2015).

[d] Dose would be zero following decontamination, decommissioning, and demolition of TA-21 after about 2009.

5.6.1.1 No Action Alternative

Annual doses to the general public and the MEI under the No Action Alternative are generally projected to remain at levels similar to those projected in the *1999 SWEIS* Expanded Operations Alternative. The projected doses for the MEI and population are dominated by estimated emissions from operations at LANSCE. The projected doses also reflect the expected relocation of certain tritium capabilities from the Chemistry and Metallurgy Research Building to the Plutonium Facility Complex as well as the change in operating levels as the Tritium Facilities (TA-21) begin DD&D.

Los Alamos National Laboratory Site-Wide Impacts

The projected annual collective dose to the population living within a 50-mile (80-kilometer) radius of LANL could be as high as 30 person-rem for the No Action Alternative. Nearly all of this dose (greater than 99 percent) would result from Key Facilities operations; the remaining contribution would come from non-Key Facility operations. Overall, the projected dose of 30 person-rem would result in no additional fatalities in the affected population (0.018 LCFs). The doses to the general public and an MEI under the No Action Alternative are presented in

Table 5–19. To put the doses into perspective, comparisons with natural background radiation levels are included in the table.

Table 5–19 Annual Radiological Impacts on the Public from Los Alamos National Laboratory Operations under the No Action Alternative

	Population within 50 Miles (80 kilometers) [a]	*Maximally Exposed Individual*
Dose	30 person-rem	7.8 millirem (LANSCE MEI) [b]
Latent cancer fatality risk [c]	0.018	4.7×10^{-6}
Regulatory dose limit [d]	Not applicable	10 millirem
Dose as a percent of regulatory limit	Not applicable	78
Dose from background radiation [e]	135,000 person-rem	400 millirem
Dose as a percent of background dose	0.02	2

LANSCE = Los Alamos Neutron Science Center, MEI = maximally exposed individual.
[a] The population estimated to be living within 50 miles (80 kilometers) of each Key Facility is unique for each facility. The year 2000 estimates range from 271,568 to 404,913, depending on the facility used.
[b] As a mitigating measure, operational controls at LANSCE would limit the MEI dose to 7.5 millirem per year.
[c] Based on a risk estimate of 0.0006 LCF per person-rem.
[d] 40 CFR Part 61 establishes an annual limit of 10 millirem via the air pathway to any member of the public from DOE operations. There is no standard for a population dose.
[e] The annual individual dose from natural background radiation at LANL ranges from a low of about 300 to a high of about 500 millirem (see Appendix C).

Under this alternative, the LANL site-wide MEI would be located approximately 2,625 feet (800 meters) north-northeast of LANSCE. This is the location where the dose resulting from emissions from all Key Facilities would be the highest. The annual dose to the MEI under this alternative could be up to 7.8 millirem. This projected dose corresponds to an increased risk of the MEI developing a fatal cancer due to LANL operations under the No Action Alternative of about 1 in 213,000 (4.7×10^{-6}) per year.

Specific Receptors

In addition to potential impacts to the public from the air exposure pathway, the risk to individuals from ingestion of water, foodstuffs, and soils is analyzed in Appendix C. These three individual scenarios, collectively referred to as “specific receptors,” include a Los Alamos County resident whose entire diet consists of locally produced foodstuffs, a user of outdoor recreational resources, and a special pathways receptor who relies heavily on fish and wildlife for subsistence. Using the average consumption rates, **Table 5–20** presents the projected doses to these individuals and the associated risks of developing a fatal cancer. Doses from a high consumption rate were also analyzed and detailed in their respective tables in Appendix C. The total doses to each receptor as a result of the potential consumption at these higher rates would be increased by a factor of less than three.

Table 5–20 Annual Ingestion Pathway Dose for Average Consumption Rates by Specific Receptors

	Dose (millirem)	*Cancer Fatality Risk* [a]
Offsite county resident	2.7	1.6×10^{-6}
Recreational resources user	4.0	2.4×10^{-6}
Special pathways receptor	4.5	2.7×10^{-6}

[a] Based on a risk estimate of 0.0006 LCF per person-rem.

The associated LCF risks resulting from the doses shown in Table 5–20 would be about 1 in 230,000 for the offsite county resident, 1 in 180,000 for the recreational resources user, and 1 in 156,000 for the special pathways receptor per year. These doses from ingestion would be almost entirely due to naturally occurring radioactivity in the environment and contamination in water and soils from worldwide fallout and past LANL operations. The contribution to ingestion pathway doses from current and projected future LANL operations tends to be extremely small by comparison, largely due to the more stringent effluent control and waste management practices now in use. Accordingly, these ingestion pathway dose and risk values are expected to remain essentially unchanged for some time and would apply to all three alternatives.

Technical Area Impacts

No measurable doses to the population or the site-wide MEI are expected to result from TA impacts under the No Action Alternative outside those associated with Key Facilities operations (as discussed below).

Key Facility Impacts

Los Alamos Neutron Science Center

Nearly all of the calculated MEI dose (96 percent) under the No Action Alternative would be attributable to gaseous mixed activation products from operations at LANSCE. Because of the close proximity of the LANSCE facility to the LANL site boundary, gaseous mixed activation product emissions remain the largest source of offsite dose from the airborne pathway. As a mitigating measure, administrative controls have been established at LANSCE that regulate beam operations as emissions levels increase. These controls require operational changes to prevent the generation of excessive radioactive air emissions so that the maximum dose to the LANL site-wide MEI from air emissions at LANSCE is 7.5 millirem per year, or less. The remainder of the dose to the LANL site-wide MEI as a result of LANL operations at all other Key Facilities (0.3 millirem per year) is small compared to that from operations at LANSCE.

5.6.1.2 Reduced Operations Alternative

Under the Reduced Operations Alternative, a major decrease in doses to the public compared to those under the No Action Alternative would result from lack of radiological air emissions from LANSCE after potential shutdown. Doses lower than those under the No Action Alternative also would be expected from reductions in high explosives processing and testing operations, and from reduced emissions from the Chemistry and Metallurgy Research Building. In 2009, shutdown of Pajarito Site (TA-18) operations would further reduce doses to the public.

Los Alamos National Laboratory Site-Wide Impacts

The projected annual collective dose to the population living within a 50-mile (80-kilometer) radius of LANL, as shown in **Table 5–21,** could be as high as 6.1 person-rem under the Reduced Operations Alternative. Nearly all of this dose (greater than 98 percent) would come from Key Facilities operations, and the remaining contribution would come from non-Key Facility operations. Overall, the projected annual collective dose of 6.1 person-rem would produce no additional fatalities in the affected population (0.0038 LCFs).

Table 5–21 Annual Radiological Impacts on the Public from Los Alamos National Laboratory Operations under the Reduced Operations Alternative

	Population within 50 Miles (80 kilometers) [a]	*Maximally Exposed Individual*
Dose [b]	6.1 person-rem	0.78 millirem (TA-36 MEI)
Latent cancer fatality risk [c]	0.0037	4.7×10^{-7}
Regulatory dose limit [d]	Not applicable	10 millirem
Dose as a percent of regulatory limit	Not applicable	7.8
Dose from background radiation [e]	135,000 person-rem	400 millirem
Dose as a percent of background dose	0.005	0.2

TA = technical area, MEI = maximally exposed individual, MDA = material disposal area.

[a] The population estimated to be living within 50 miles (80 kilometers) of each Key Facility is unique for each facility. The year 2000 estimates range from 271,568 to 404,913, depending on the facility used.

[b] Shutdown of TA-18 in about 2009 would result in a decrease in the population dose of 0.23 person-rem and a negligible decrease in the MEI dose.

[c] Based on a risk estimate of 0.0006 LCF per person-rem.

[d] 40 CFR Part 61 establishes an annual limit of 10 millirem via the air pathway to any member of the public from DOE operations. There is no standard for a population dose.

[e] The annual individual dose from natural background radiation at LANL ranges from a low of about 300 to a high of about 500 millirem (see Appendix C).

The LANL site-wide MEI under this alternative would be located 7,415 feet (2,260 meters) northeast of the High Explosives Testing Facilities at TA-36. This is the location where the dose resulting from emissions from all Key Facilities would be the highest. The estimated dose to this MEI would be 0.78 millirem per year for the foreseeable future. This projected dose corresponds to an increased risk of the MEI developing a latent fatal cancer as a result of LANL operations under the Reduced Operations Alternative of about 1 in 2.1 million (4.7×10^{-7}) per year.

Specific Receptors

The risk to the public specific receptors from ingestion of foodstuffs and water under the Reduced Operations Alternative does not differ from that described under the No Action Alternative, as most of the risk is attributable to existing levels of contamination, not future operations at LANL.

Technical Area Impacts

No measurable doses to the population or the site-wide MEI are expected to result from TA impacts under the Reduced Operations Alternative other than those associated with Key Facilities operations (discussed below).

Key Facility Impacts

Los Alamos Neutron Science Center

Under this alternative, operations at LANSCE would not be active and high explosives processing and testing would be reduced by 20 percent, resulting in a 79 percent reduction in the total projected dose to the population compared to the dose for the No Action Alternative.

High Explosives Testing Facilities

Long-lived uranium isotope emissions from the reduced level of activities at the High Explosives Testing Facilities at TA-15 and TA-36 would produce the majority of the population dose (80 percent). Because the location of the LANL site-wide MEI under the Reduced Operations Alternative would change from the location of the MEI associated with the No Action Alternative, the dose contributions from each Key Facility to the new MEI location would be different. For instance, although there is a 20 percent reduction in high explosives testing under the Reduced Operations Alternative, the dose to the LANL site-wide MEI from operations at the High Explosives Testing Facilities under this alternative is projected to be 0.72 millirem per year, compared to a dose of 0.25 millirem from high explosives testing under the No Action Alternative. In fact, more than 90 percent of the dose to the MEI under the Reduced Operations Alternative would come from emissions of uranium isotopes produced at the High Explosives Testing Facilities.

Pajarito Site

After about 2009, a decrease in the population dose of 0.23 person-rem per year would result from permanent shutdown of operations at the Pajarito Site (TA-18). The population dose from the Reduced Operations Alternative would therefore decline by approximately 4 percent.

Chemistry and Metallurgy Research Building

Limited operation of the Chemistry and Metallurgy Research Building under this alternative would decrease the dose to the population surrounding LANL population by 0.32 person-rem, which is reflected in the estimated population dose of 6.1 person-rem per year.

5.6.1.3 Expanded Operations Alternative

Under the Expanded Operations Alternative, there would be increased levels of activities at certain facilities in addition to construction projects, as well as some reduced activities. Operations resulting from LANSCE's refurbishment could increase air emissions, including radiological emissions (and consequential dose), due to enhanced operational availability of the accelerator facilities. There also would be an increase in pit production within the Plutonium Facility Complex (TA-55), up to 80 pits per year, which would produce additional radiological air emissions. Under this alternative, there could be an additional temporary or one-time dose to the public from removal of waste from the MDAs, which would last until MDA exhumations are completed. Actions proposed under this alternative that would result in smaller doses include completion of DD&D of buildings at TA-21 and shutdown of SHEBA operations at TA-18.

Los Alamos National Laboratory Site-Wide Impacts

The projected annual collective dose to the population living within a 50-mile (80-kilometer) radius of LANL, as shown in **Table 5–22,** could be as high as 36 person-rem for the Expanded Operations Alternative; 30 person-rem of that total dose would come from operations at the Key Facilities and the remaining 6 person-rem from removal activities at the various MDAs. Overall, the projected dose of 36 person-rem would result in no additional fatalities in the affected population (0.022 LCFs).

Table 5–22 Annual Radiological Impacts on the Public from Los Alamos National Laboratory Operations under the Expanded Operations Alternative

	Population within 50 Miles (80 kilometers) [a]	***MEI***
Dose [b]	36 person-rem	8.2 millirem (LANSCE MEI) [c]
Latent cancer fatality risk [d]	0.022	4.9×10^{-6}
Regulatory dose limit [e]	Not applicable	10 millirem
Dose as a percent of regulatory limit	Not applicable	82
Dose from background radiation [f]	135,000 person-rem	400 millirem
Dose as a percent of background dose	0.027	2.1

LANSCE = Los Alamos Neutron Science Center, MEI = maximally exposed individual, MDA = material disposal area.

[a] The population estimated to be living within 50 miles (80 kilometers) of each Key Facility is unique for each facility. The year 2000 estimates range from 271,568 to 404,913, depending on the facility used.

[b] These reflect the additional doses to the public from remediation of the larger MDAs and the simultaneous operation of the Decontamination and Volume Reduction System, the new TRU Waste Facility, and remote-handled transuranic waste retrieval and processing activities. The shutdown of TA-18 and TA-21 in about 2009 would result in a decrease in population dose of 0.32 person-rem and a negligible decrease in MEI dose.

[c] As a mitigating measure, operational controls at LANSCE would limit the MEI dose to 7.5 millirem per year. Population and MEI doses are projected at 6.2 person-rem and 0.42 millirem respectively, and are attributable to MDA remediation.

[d] Based on a risk estimate of 0.0006 LCF per person-rem.

[e] 40 CFR Part 61 establishes an annual limit of 10 millirem via the air pathway to any member of the public from DOE operations. There is no standard for a population dose.

[f] The annual individual dose from natural background radiation at LANL ranges from a low of about 300 to a high of about 500 millirem.

Under this alternative, the LANL site-wide MEI would be located 2,625 feet (800 meters) north-northeast of LANSCE. This is the location where the dose resulting from emissions from all Key Facilities would be the highest. Including the additional dose from remediation activities at the MDAs under this Alternative could bring the MEI dose to about 8.2 millirem. This projected dose corresponds to an increased risk of developing a latent fatal cancer for the MEI from LANL operations under the Expanded Operations Alternative of about 1 in 203,000 (4.9×10^{-6}) per year.

The various effects of radiological air emissions from the major MDA remediation activities, canyon cleanups, and other Consent Order actions could range from small long-term to temporary short-term doses to the public under the Expanded Operations Alternative. Under the MDA Capping Option, although the waste would remain in place, the long-term doses to the public would be reduced. The potential for radionuclides to be dispersed into the air would be reduced by the improved covers, which also would reduce doses. The MDA Removal Option would result in lower long-term risks to the public because the bulk of the contamination would be removed from the site. In the short term, however, the release of radionuclides into the air during removal could result in higher radiological doses to the public. If that removal took place under an enclosure, radiological air emissions would be filtered before exiting the structure, resulting in lower short-term doses to the public.

Under the MDA Removal Option, various radiological air emissions could be released depending on the inventory of radionuclides at the MDA being remediated and whether the removal was performed under an enclosure. These removal activities would be completed within a finite time of a few months to several years, depending on the MDA. For that specified amount of time, there would be an additional dose to the public resulting from emissions released during the removal of the MDA. There are several large MDAs to be remediated. The total estimated dose to the public (6.2 person-rem per year) within 50 miles (80 kilometers) of operations at LANL under this alternative is based on a conservative assumption that all MDAs would be exhumed at the same time.

The same factors—the inventory of radionuclides present in a given MDA and whether or not an enclosure is used—would affect the dose to the MEI. In addition, the location of the MDA being remediated could affect the dose an MEI would receive. The impacts of remediating the MDAs on the LANL site-wide MEI were analyzed in Appendix I. Removal activities at each MDA could contribute to the dose received by the LANL site-wide MEI under the Expanded Operations Alternative, who is assumed to be located northeast of LANSCE near the East Gate. Assuming *all* the large MDAs were remediated at the same time, the portion of the estimated dose to the LANL site-wide MEI contributed by MDA removal activities would be no more than 0.42 millirem in any given year.

Specific Receptors

The risk to the public specific receptors from ingestion of foodstuffs and water under the Expanded Operations Alternative would not differ from that described under the No Action Alternative, as most of the risk is attributable to the existing levels of contamination, not future operations at LANL.

Technical Area Impacts

No measurable doses to the population or the site-wide MEI are expected to result from TA impacts under the Expanded Operations Alternative apart from those associated with Key Facilities operations (discussed below) or MDA remediation activities (discussed above).

Key Facility Impacts

Under the Expanded Operations Alternative, impacts to the public from activities at the Key Facilities, including both increases in some activities and decreases in others, would be similar to those under the No Action Alternative. The change in the location of emissions from the Chemistry and Metallurgy Research Building in TA-3 to the Chemistry and Metallurgy Research Replacement Facility in TA-55 would have little effect on doses to the public compared to impacts from operations at LANSCE. Increased pit production at the Plutonium Facility Complex in TA-55 would cause a small increase in emissions, but the resulting doses to the public would be relatively small compared to the contribution from activities at LANSCE. Similarly, if the evaporation tank auxiliary action were implemented under the Radioactive Liquid Waste Treatment Facility Upgrade, the doses that would result from the tank air emissions (primarily tritium) would be small and bounded by the impacts from other key facilities.

Los Alamos Neutron Science Center

Over 60 percent of the projected population dose (22.3 person-rem per year) would result from radiological air emissions from LANSCE (TA-53). Similar to the No Action Alternative, the majority of the dose to the LANL site-wide MEI under the Expanded Operations Alternative would result from emissions of gaseous mixed activation products from operations at LANSCE.

Because of the close proximity of LANSCE to the LANL site boundary, gaseous mixed activation product emissions remain the greatest source of offsite dose via the airborne pathway. If the LANSCE Refurbishment Project were implemented, the dose from air emissions at LANSCE to the LANL site-wide MEI could potentially increase. As described in the No Action Alternative (see Section 5.6.1.1), however, the dose to the LANL site-wide MEI from air emissions at LANSCE would be limited by operational controls to 7.5 millirem per year.

High Explosives Testing Facilities

An additional 18 percent of the dose (6.4 person-rem per year) to the public would come from operations at the High Explosives Testing Facilities (TA-15 and TA-36).

Solid Radioactive and Chemical Waste Facilities

Implementation of the Waste Management Facilities Transition Project would result in relatively small additional impacts to the population near LANL. From 2012 through 2015, there would be a potential for simultaneous operation of the Decontamination and Volume Reduction System, the new TRU Waste Facility, and remote-handled transuranic waste retrieval and processing activities. Resulting impacts to the population from operations of these systems during this time would be negligible (an additional 0.02 person-rem per year) and are included in Table 5–22. Long-term impacts to the public would include a reduction in dose due to eventual removal of stored wastes in Area G.

Plutonium Facility Complex

The higher level of activity at the Plutonium Facility Complex associated with increased pit production also would result in a small increase in the dose to the public to 0.20 person-rem per year. The higher level of activity at the Plutonium Facility Complex associated with increased pit production would cause a negligible increase in the dose to the LANL site-wide MEI (less than 0.001 millirem).

Pajarito Site and Tritium Facilities

The estimated population dose would decrease slightly (by 0.32 person-rem per year) due to the permanent elimination of emissions from activities at the Pajarito Site at TA-18 and the Tritium Facility at TA-21 which is expected to occur in about 2009. The lack of activity at the Pajarito Site (TA-18) and the Tritium Facility (TA-21) would have a small effect (a decrease of 0.02 millirem per year) on the dose to the MEI compared to the dose from operations at LANSCE (7.5 millirem per year).

5.6.2 Chemical Impacts on the Public

5.6.2.1 No Action Alternative

Key Facilities

The combined cancer risk due to all carcinogenic pollutants from all TAs, as analyzed in the *1999 SWEIS*, was dominated by chloroform emissions expected from the Bioscience Facilities (formerly the Health Research Laboratory) (see **Tables 5–23** and **5–24**). Assuming that 100 percent of the chloroform used was emitted (and assuming no change in other carcinogenic pollutant emissions compared to those evaluated), the estimated combined incremental cancer risk at the Los Alamos Medical Center would be slightly above the guideline value of 1 in a million (1.0×10^{-6}). In other words, one person in a population of a million would develop cancer if this population were exposed to this concentration over a lifetime, a level of concern established in the Clean Air Act. It is known, however, that less than 100 percent of the chloroform used is emitted as a toxic air pollutant (as much as 25 pounds per year [8 liters per year] were disposed of as liquid chemical waste); thus, the incremental cancer risk under the No Action Alternative would be less than the guideline value. In addition, recent use of chloroform has been about 30 percent of the use projected for the Expanded Operations Alternative described in the *1999 SWEIS*. Based on the information discussed above, toxic air pollutants released under this new SWEIS No Action Alternative are not expected to cause air quality impacts that would affect human health and the environment.

Table 5–23 Estimated Annual Emission Rates of Carcinogenic Pollutants that Could Be Released from the Health Research Laboratory of the Technical Area 43 Facilities

Pollutants	*Stack ID*	*Annual Average Emission Rates*	
		Pounds per Year	*Grams per Second*
Acrylamide	Building 247	0.00586	8.44×10^{-8}
	Building 124/126	0.00586	8.44×10^{-8}
	N. Side FH	0.00586	8.44×10^{-8}
	S. Side FH	0.00586	8.44×10^{-8}

Table 5–24 Results of the Dispersion Modeling Analysis of Carcinogenic Pollutants from the Health Research Laboratory at Technical Area 43

Carcinogenic Pollutants	*Estimated Annual Concentration (micrograms per cubic meter)*
Acrylamide	0.0000115
Chloroform	0.0304
Formaldehyde	0.0024
Methylene Chloride	0.00078
Trichloroethylene	0.00334

Source: DOE 1999a.

Public health consequences from emissions of beryllium, lead, and depleted uranium from the High Explosives Testing Facilities (see Table 5−9) were analyzed by calculating hazard indices for lead and depleted uranium and calculating the excess LCFs from beryllium. A hazard index equal to or above 1 is considered consequential from a human toxicity standpoint. Beryllium has no established EPA reference dose from which to calculate the hazard index. The worst-case hazard indices for lead and depleted uranium were less than 0.000015 and 0.000065, respectively. The excess LCFs from beryllium were estimated to be 1 in 2,780,000 (3.6×10^{-7}) (DOE 1999a). Use of foam to control emissions from the High Explosives Testing Facilities would further reduce these emissions and health effects by about 50 to 95 percent (LANL 2006a).

Emissions from beryllium sources currently at the Beryllium Technology Facility in the Sigma Complex (TA-3) and Plutonium Facility Complex (TA-55) (see Table 5–10) are controlled by HEPA filtration with a removal efficiency of 99.95 percent. The maximum cancer risk of beryllium releases from TA-3 using its unit risk factor is approximately 1 in 415 million (2.41×10^{-9}), which is below the guideline value of 1 in a million (1.0×10^{-6}). In other words, one person in a population of a million would develop cancer if this population were exposed to this concentration over a lifetime, a level of concern established in the Clean Air Act. The maximum combined cancer risk of beryllium releases from TA-55 using its unit risk factor is approximately 1 in 4.3 billion (2.35×10^{-10}), which is also below the guideline value of 1 in a million (1.0×10^{-6}) (DOE 1999a).

5.6.2.2 Reduced Operations Alternative

Key Facilities

Public risk resulting from chemical releases under the Reduced Operations Alternative would be approximately the same as those associated with the No Action Alternative. There would be a reduction in risks associated with high explosives processing and testing activities because these activities would be reduced by 20 percent under this alternative. There also would be minor reductions in risk to the public as a result of shutting down operations at LANSCE and the Pajarito Site (TA-18) under this alternative.

5.6.2.3 Expanded Operations Alternative

Key Facilities

Public risk resulting from chemical releases under the Expanded Operations Alternative would be approximately the same as those associated with the No Action Alternative, except for a small increase (2.5 percent) in risk due to high explosives processing activities.

5.6.3 Worker Health

Worker risks associated with continued operations at LANL include radiological (ionizing and non-ionizing) risks, chemical exposure risks, and risk of injury during normal operations. The consequences to worker health from implementing the No Action, Reduced Operations, and Expanded Operations Alternatives are discussed below.

DOE has developed new regulations to require non-nuclear DOE contractors to comply with relevant Occupational Safety and Health Administration safety and health standards. Noncompliance could result in monetary fines. This is the first DOE regulation to provide for the protection of non-nuclear contractor workers. This new rule, 10 CFR Part 851, goes into effect on February 7, 2007, to allow 1 year for contractor and site management compliance training (DOE 2006a).

5.6.3.1 No Action Alternative

Ionizing Radiation Consequences

Table 5–25 presents the projected worker exposure from normal operations under the No Action Alternative. This projection is larger than the average annual worker dose shown in Chapter 4, Section 4.6.2.1, because it includes the dose associated with achieving a production level of 20 pits per year at TA-55, as well as the dose from increased levels of activity associated with additional personnel working in the new Chemistry and Metallurgy Research Replacement Facility. This projected collective worker dose represents the dose to the LANL workforce for the foreseeable future under the No Action Alternative.

Table 5–25 Projected Worker Radiation Exposure under the No Action Alternative

Collective worker dose (person-rem per year)	280
Number of workers with measurable dose	2,018
Excess LCF risk per year among worker population	0.17 [a]
Average individual worker measurable dose (millirem)	139
Excess LCF risk per year for average individual worker	0.000083 [a]
DOE limit on annual worker radiation exposure (millirem)	5,000
LANL average individual worker dose as a percentage of DOE limit (percent)	2.8

LCF = latent cancer fatality.
[a] Based on a risk estimate of 0.0006 LCF per person-rem (see Appendix C).

Worker exposures to radiation and radioactive materials in radiological control areas would be controlled using established procedures that require doses to be kept as low as reasonably achievable (ALARA). Potential hazards would be evaluated as part of the radiation worker and occupational safety programs at LANL. Nonroutine construction activities may require special work permits and worker protection measures for specific locations and activities.

DOE limits set the standard for worker exposure at 5,000 millirem per year whole body dose equivalent. In 10 CFR Part 835, DOE requires the ALARA process to be applied to reduce worker exposure to ionizing radiation. DOE has set an administrative control level of 2,000 millirem per year for an individual worker exposure (DOE 1999e). This level can be intentionally exceeded only with higher-level management approvals.

Under the No Action Alternative, the average individual worker dose of 139 millirem per year represents an increased risk of developing a latent fatal cancer of approximately 1 in 12,000 (8.3×10^{-5}) per year of operations. In addition to the 2,018 workers expected to receive a measurable dose, under the No Action Alternative, over 11,000 LANL workers or approximately

85 percent of the workforce would not likely receive any measurable dose during a year of normal operations.

Non-ionizing Radiation Consequences

Under the No Action Alternative, negligible effects on LANL worker health from normal operations of non-ionizing radiation sources, infrared radiation from instrumentation and welding, lasers, magnetic and electromagnetic fields, and microwaves would likely continue.

Biohazardous Material Exposure Consequences

Under the No Action Alternative, there would be negligible effects on LANL worker health from normal operations of the existing Biosafety Level 1 and 2 facilities. As explained in Appendix C, workers are protected by a combination of microbiological safety practices, safety equipment acting as primary barriers, and facilities that provide secondary barriers to preclude contamination or infection by biohazardous material.

Chemical Exposure Consequences

Occasional reportable, but minor, chemical exposures could occur at the rate of one to three incidents annually due to worker exposure to airborne asbestos, lead paint particles, crystalline silica, fuming perchloric acid, hydrofluoric acid, or acids or alkalis (via skin contact).

Operation of the Beryllium Technology Facility in the Sigma Complex presents a potential risk of worker exposure to beryllium. Other uses of beryllium at LANL include metals applications, which present little risk. The annual worker risk associated with high-explosives-testing-related applications of beryllium (evaluated as a carcinogen in the *1999 SWEIS*) at LANL was estimated to be less than 1 in 2.7 million (3.6×10^{-7}). This estimate is still valid under the No Action Alternative of this SWEIS.

Occupational Injuries and Illness

Occupational injury and illness rates under the No Action Alternative are projected to follow the patterns observed from 1999 through 2005, as reported in Chapter 4, Section 4.6.2.1. Using LANL's average rates during this period, there would be 2.40 recordable cases and 1.18 cases when workers missed days or their activities were restricted or transferred due to an occupational injury or illness for every 200,000 hours worked. These rates are well below industry averages, which in 2004 were 4.8 recordable cases and 2.5 cases where days were missed as a result of an occupational injury or illness (BLS 2005). Assuming that LANL's employment levels remain at current levels as expected (see Section 5.8.1.1), there would be approximately 311 recordable cases of occupational injury and illness and approximately 153 cases that resulted in days away or restricted or transferred duties per year. No fatalities would be expected under this alternative.

5.6.3.2 Reduced Operations Alternative

Ionizing Radiation Consequences

As shown in **Table 5–26**, under the Reduced Operations Alternative, involved workers would be exposed to lower cumulative doses of ionizing radiation from normal operations at LANL than under the No Action Alternative due to the potential shutdown of LANSCE and TA-18 operations.

Table 5–26 Projected Worker Exposure to Radiation under the Reduced Operations Alternative

Collective worker dose (person-rem per year)	257
Number of workers with measurable dose	1,659
Excess LCF risk per year among worker population	0.15 [a]
Average individual worker measurable dose (millirem per year)	155
Excess LCF risk per year for average individual worker	0.000093 [a]
DOE limit on annual worker radiation exposure (millirem per year)	5,000
LANL average individual worker dose as a percentage of DOE limit (percent)	3.1

LCF = latent cancer fatality.
[a] Based on a risk estimate of 0.0006 LCFs per person-rem (see Appendix C).

The average dose received by workers is projected to increase slightly from 139 millirem per year to 155 millirem per year under the Reduced Operations Alternative compared to the No Action Alternative. This is due to a decrease in the number of workers who would receive less than the average dose under this alternative. The average individual worker dose of 155 millirem per year represents an increased risk of developing a latent fatal cancer of approximately 1 in 10,750 (9.3×10^{-5}) per year of operation. Similar to the No Action Alternative, 1,659 workers would be expected to receive a measurable dose, but over 11,000 LANL workers or over 87 percent of the workforce would not be expected to receive any measurable dose during a year of normal operations under the Reduced Operations Alternative.

Non-ionizing Radiation Consequences

Under the Reduced Operations Alternative, negligible effects on LANL worker health from non-ionizing radiation sources, infrared radiation from instrumentation and welding, lasers, magnetic and electromagnetic fields, and microwaves would likely continue.

Biohazardous Material Exposure Consequences

Under the Reduced Operations Alternative, effects on LANL worker health from normal operations would not be substantially different from those under the No Action Alternative.

Chemical Exposure Consequences

Under the Reduced Operations Alternative, chemical exposure consequences to workers would likely be small and not substantially different than those under the No Action Alternative.

Occupational Injuries and Illness

Under the Reduced Operations Alternative, the number of occupational injuries and illnesses would likely be smaller than those observed under the No Action Alternative due to a smaller projected workforce, as discussed in Section 5.8.1.2. Using LANL's average rates, there would be approximately 300 recordable cases of occupational injury and illness and approximately 147 cases that result in days away or restricted or transferred duties per year, compared to 311 and 153, respectively, under the No Action Alternative. No fatalities would be expected under this alternative.

5.6.3.3 Expanded Operations Alternative

Ionizing Radiation Consequences

As shown in **Table 5–27**, the expansion of certain radiologically intensive operations at LANL would increase cumulative worker dose and annual average worker exposure under the Expanded Operations Alternative. Operations expected to expand under this alternative include pit production, remediation of a number of large MDAs, and DD&D of a number of TAs. In the long run, DD&D of the TAs and closure of many facilities such as those associated with the MDAs at LANL and older waste management facilities in TA-54, Area G, should reduce workers' annual radiation exposures.

Table 5–27 Projected Worker Exposure to Radiation under the Expanded Operations Alternative

	With MDA Removal Option	*With MDA Capping Option*
Collective worker dose (person-rem per year)	543	407
Number of workers with measurable dose	3,849	2,344
Excess LCF risk per year among worker population	0.33 [a]	0.24 [a]
Average individual worker measurable dose (millirem per year)	141	174
Excess LCF risk per year for average individual worker	8.5×10^{-5} [a]	0.00010 [a]
DOE limit on annual worker radiation exposure (millirem per year)	5,000	5,000
LANL average individual worker dose as a percentage of DOE limit (percent)	2.8	3.5

MDA = material disposal area, LCF = latent cancer fatality.
[a] Based on a risk estimate of 0.0006 LCFs per person-rem (see Appendix C).

The largest factors affecting worker dose under this alternative are increased pit production at TA-55 from 20 plutonium pits per year to up to 80 pits per year and remediation of the MDAs. The contribution to the collective worker dose from production of 20 pits per year is 90 person-rem per year under the No Action Alternative compared to 220 person-rem from production of up to 80 pits per year under the Expanded Operations Alternative. Remediation of the MDAs under this alternative also is expected to add to the site-wide collective worker dose. If the MDA

Removal Option were pursued, it would add an average of 137 person-rem per year to the site-wide collective worker dose. If the MDA Capping Option were pursued, it would add an average of just over 1 person-rem per year to the site-wide collective worker dose. DD&D activities across the site would add another 6 person-rem per year to the site-wide collective worker dose. Conversely, cessation of SHEBA operations at TA-18 would reduce LANL's site-wide collective worker dose under the Expanded Operations Alternative by 10 person-rem per year.

Under the Expanded Operations Alternative – MDA Removal Option, the average individual worker dose of 141 millirem per year represents an increased risk of developing a latent fatal cancer of approximately 1 in 11,800 (8.5×10^{-5}) per year of operations. Under the Expanded Operations Alternative – MDA Capping Option, the average individual worker dose of 174 millirem per year represents an increased risk of developing a latent fatal cancer of approximately 1 in 10,000 (1.0×10^{-4}) per year of operations.

Waste management workers, who currently receive an average dose of approximately 163 millirem annually, would receive a lower annual dose under the Expanded Operations Alternative after 2015. By the end of 2015, all legacy transuranic waste would be removed from the site and shipped to the Waste Isolation Pilot Plant (WIPP). Direct penetrating radiation levels in Area G, which currently measure above background levels in certain areas, would decrease to within background levels by this time. Waste management workers would still process newly generated transuranic waste at the proposed new TRU Waste Facility (to be built in either TA-50 or TA-63), but their exposures would be smaller than those currently observed because management of the newly generated waste would not be as time-intensive as currently required. Workers associated with retrieval of remote-handled transuranic waste from below-ground storage between 2011 and 2015 could see increases in radiation exposure, but their exposures would be monitored and engineering and administrative controls would be used to ensure their exposures are ALARA and within administrative control levels.

Non-ionizing Radiation Consequences

Under the Expanded Operations Alternative, negligible effects on LANL worker health from non-ionizing radiation sources, infrared radiation from instrumentation and welding, lasers, magnetic and electromagnetic fields, and microwaves would likely continue.

Biohazardous Material Exposure Consequences

Under the Expanded Operations Alternative, effects on LANL worker health from normal operations would not be substantially different from those under the No Action Alternative.

Chemical Exposure Consequences

Under the Expanded Operations Alternative, chemical exposure consequences to workers would likely be small and not substantially different from those under the No Action Alternative.

Occupational Injuries and Illness

As shown in **Table 5–28**, the projected number of annual occupational injuries and illnesses would be higher under the Expanded Operations Alternative compared to the No Action Alternative. This is due to two main factors. First, the size of the workforce is expected to continue to grow under this alternative, as discussed in Section 5.8.1.3. Second, more construction, DD&D, and remediation work is expected under the Expanded Operations Alternative, and these activities have higher incidence rates of occupational injuries and illnesses than the other types of work being performed at LANL.

While both total recordable cases and cases resulting in days away or restricted or transferred duties would be 12 to 13 percent higher under the Expanded Alternative compared to the No Action Alternative, no fatalities are expected under this alternative.

Table 5–28 Annual Projected Occupational Injuries and Illnesses Under the Expanded Operations Alternative

	Total Recordable Cases	*Cases Resulting in Days Away, Restricted, or Transferred*
General Laboratory Operations [a]	291.4	143.2
Construction	21.3	10.4
Remediation (MDA Removal Option)	35.1	17.1
Decontamination, decommissioning, and demolition	2.4	1.2
Total	350.2	171.9

MDA = material disposal area.
[a] Based on LANL averages of 2.40 total recordable cases and 1.18 cases resulting in days away, restricted, or transferred per 200,000 hours worked.

5.7 Cultural Resources

Potential impacts to cultural resources were assessed under the No Action, Reduced Operations, and Expanded Operations Alternatives. Cultural resources include archaeological resources, historic buildings and structures, and traditional cultural properties. Information used for impact assessment was derived from the results of systematic cultural resource inventories on LANL.

The analysis of impacts to cultural resources addressed potential direct and indirect impacts at each site from construction and operation. Direct impacts included those resulting from groundbreaking activities associated with new construction, building modifications, and demolition, as appropriate. Indirect impacts included those associated with reduced access to resource sites, as well as with increased stormwater runoff, traffic, and visitation to sensitive areas. The locations of known cultural resources were compared to the areas of potential effect from LANL activities. The potential for these activities to impact cultural resources was then assessed.

A summary of impacts is presented in **Table 5–29**.

Table 5–29 Summary of Environmental Consequences on Cultural Resources

	No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
LANL Site			
	Land Conveyance and Transfer – Conveyance or transfer of known cultural resources out of the responsibility and protection of DOE. – Potential damage to cultural resources on conveyed or transferred parcels due to future development. – Potential impacts on protection and accessibility to American Indian sacred sites. *Trails Management Program* – Enhanced protection of cultural resources	Same as No Action Alternative	Same as No Action Alternative plus: *MDA Remediation Project* – No direct impacts expected for either Capping or Removal Options. – Potential indirect adverse effects on resources located in vicinity of some MDAs and PRSs. *Security-Driven Transportation Modifications Project* – No direct impacts. – Potential indirect adverse effects on historic site located in vicinity of TA-63 and the proposed bridge over Mortandad Canyon. – Pedestrian and vehicle bridges under all options could impact canyon views from traditional cultural properties.
Affected Technical Areas			
TA-3	No change in impacts to cultural resources.	Same as No Action Alternative	*Physical Science Research Complex* – Two historic buildings, one eligible for the National Register of Historic Places and one that will be assessed for eligibility, would be removed. *Replacement Office Buildings* – Potentially adverse effects on nearby historic trail.
TA-21	No change in impacts to cultural resources.	Same as No Action Alternative	*TA-21 Structure DD&D* – Adverse effects on National Register of Historic Place-eligible historic buildings and structures.
Key Facilities			
Chemistry and Metallurgy Research Building (TA-3, TA-48, and TA-55)	Resulted in excavation of an archaeological site in TA-50.	Same as No Action Alternative	Same as No Action Alternative
High Explosives Processing Facilities (TA-16)	Adverse effect from demolition and remodeling of historic buildings.	Same as No Action Alternative	Same as No Action Alternative
High Explosives Testing Facilities (TA-6, TA-22, and TA-40)	Adverse effects from demolition and remodeling of historic buildings.	Same as No Action Alternative	Same as No Action Alternative

	No Action Alternative	***Reduced Operations Alternative***	***Expanded Operations Alternative***
Pajarito Site (TA-18)	No change in impacts to cultural resources.	Same as No Action Alternative	Potentially adverse effect from demolition of historic buildings.
Radiochemistry Facility (TA-48)	No change in impacts to cultural resources.	Same as No Action Alternative	*Radiological Sciences Institute Project* – Potentially adverse effects on two archeological sites located near Radiochemistry Building. – Potentially adverse effect from demolition of Radiochemistry Building and other potentially historic buildings.
Radioactive Liquid Waste Treatment Facility (TA-50)	No change in impacts to cultural resources.	Same as No Action Alternative	– Changes to the existing Radioactive Liquid Waste Treatment Facility could alter its original appearance. – Minimal impact on historic buildings possibly requiring documentation to resolve adverse effects.
Solid Radioactive and Chemical Waste Facilities (TA-50 and TA-54)	No change in impacts to cultural resources.	Same as No Action Alternative	– Potential indirect effects on cultural resources located in vicinity of project associated activities in TA-54. – Removal of domes would positively impact views from traditional cultural properties located on adjacent lands of the Pueblo of San Ildefonso. – Potential impact to cultural resources from construction of TRU Waste Facility. – TRU Waste Facility could be visible from lands of the Pueblo of San Ildefonso.
LANSCE (TA-53)	No change in impacts to cultural resources.	Same as No Action Alternative	– Potentially adverse effect to LANSCE or other historic buildings experiencing internal modifications.
Radiography Facility (TA-55)	No change in impacts to cultural resources.	Same as No Action Alternative	– Same as No Action Alternative.
Bioscience Facilities	No change in impacts to cultural resources.	Same as No Action Alternative	*Science Complex Project* – Under all options, an eligibility assessment of the buildings to be replaced by the new Science Complex would be required. – Potentially adverse effects on three prehistoric archeological sites under Option 1. – No adverse effects to cultural resource sites under Options 2 and 3.
Remote Warehouse and Truck Inspection Station (TA-72)	No change in impacts to cultural resources.	Same as No Action Alternative	– Potentially adverse effects on three archeological sites.

MDA = material disposal area; PRS = potential release site; TA = technical area; DD&D = decontamination, decommissioning, and demolition; LANSCE = Los Alamos Neutron Science Center.

5.7.1 No Action Alternative

The No Action Alternative was analyzed in terms of the existing environment as it relates to cultural resources (see Chapter 4, Section 4.7), as well as several actions that are planned, but have may not been fully implemented. These actions were analyzed in the *1999 SWEIS* or in other NEPA compliance reviews issued since the *1999 SWEIS*. Impacts to cultural resources are described in terms of those projects that impact the site as a whole and those that affect specific TAs. Key Facilities are addressed separately.

Los Alamos National Laboratory Site-Wide Impacts

Two projects have been approved since publication of the *1999 SWEIS* that could impact cultural resources across a number of TAs. These projects involve the conveyance and transfer of certain parcels of land and the management of the trails system at LANL. Site-wide projects that have been determined to have no impact on cultural resources include electrical power system upgrades, the Wildfire Hazard Reduction Program, disposition of Cerro Grande Fire structures, and the Security Perimeter Project (DOE 1999d, 2000a, 2000e, 2002j, 2003a, 2003b; NNSA 2004a, 2005a). Continuing the LANL environmental restoration program that existed before the 2005 Consent Order is expected to have little or no impact on cultural resources. Management of construction fill would not be expected to have an impact on cultural resources because the fill would be stored in existing borrow areas at TA-16 or TA-61.

The conveyance and transfer of 10 tracts of land would have both direct and indirect impacts on cultural resources. To date, eight parcels have been entirely or partly conveyed or transferred (see Chapter 4, Table 4–2). Direct impacts have included the transfer of known cultural resources and historic properties out of the responsibility and protection of DOE, including resources eligible for the National Register of Historic Places. It should be noted that a data recovery plan was implemented to resolve the adverse effects of conveying three tracts to the County of Los Alamos for future development that include 49 archaeological sites that are eligible for the National Register of Historic Places. In addition, 34 archaeological sites are included within three protective easements at a single tract to be conveyed to the county for recreational purposes (LANL 2002b). The disposition of each of these tracts affects their protection and accessibility as Native American sacred sites that are needed for the practice of traditional religion. In addition, the disposition of the tracts would potentially affect the treatment and disposition of any human remains, funerary objects, sacred objects, and objects of cultural patrimony that may be discovered on the tracts. Indirect impacts of the conveyance and transfer of land include potential future development of 826 acres (334 hectares) and use of the tracts for recreational purposes. This action could result in the physical destruction, damage, or alteration of cultural resources located on the tracts and in adjacent areas, as well as disturbance of traditional religious practices (DOE 1999d).

The Trails Management Program would enhance protection of cultural resources at LANL. Management activities would be coordinated with LANL archaeologists in consultation with appropriate Native American Tribes to minimize damages to any cultural resources present along the trail reaches. Where activities associated with trail maintenance or use would adversely affect a trail, that trail could be closed to all or certain users until the involved segment of trail could be rerouted around the cultural resources. Alternatively, certain trail segments could be closed periodically for Native American use. If work necessary to close a trail to all user groups would adversely affect a cultural resource, a data recovery plan would be prepared and the State Historic Preservation Officer and appropriate Native American Tribes would be consulted before such work commenced. New trails would not be constructed in locations where the activities of trail users or maintenance workers would adversely affect cultural resources (DOE 2003b).

Technical Area Impacts

Technical Area 3

One project within TA-3, the installation of combustion turbine generators, underwent a NEPA compliance review since issuance of the *1999 SWEIS* and was not fully implemented. The analysis presented in the project-specific EA determined that there would be no impact on cultural resources from implementation of this project (DOE 2002l).

Technical Area 54

Within TA-54, the proposed implementation of corrective measures at MDA H underwent a NEPA compliance review since issuance of the *1999 SWEIS*. The analysis presented in the EA for MDA H remediation supported NNSA's determination that implementation of corrective measures would not significantly impact cultural resources (DOE 2004e).

Key Facilities Impacts

Since issuance of the *1999 SWEIS*, NEPA compliance documentation was prepared for three currently active projects related to Key Facilities: Chemistry and Metallurgy Research Replacement Facility construction at TA-55, Weapons Manufacturing Support Facility consolidation and refurbishment at TA-16, and Two-Mile Mesa Complex consolidation at TA-22. Each of these projects was determined to have some potential impacts on cultural resources.

Chemistry and Metallurgy Research Building

A NEPA compliance review determined that construction of the new Chemistry and Metallurgy Research Replacement Facility at TA-55 would have no adverse impacts on cultural resources (DOE 2003d). A parking lot associated with the complex to be located in TA-50 will impact an archaeological site, the "Romero Cabin Site," which was originally excavated in the 1980s. Implementation of a data recovery plan to resolve the adverse effects of construction of the parking lot at the cabin site was completed in 2005.

High Explosives Processing Facilities

The planned consolidation and refurbishment of the TA-16 Weapons Manufacturing Support Facility will not affect the one prehistoric archaeological site that is located in the area. Demolition and remodeling of various buildings, however, which is a part of the project, will adversely affect historic structures, many of which were constructed in the 1950s, that are eligible for the National Register of Historic Places. A Memorandum of Agreement between NNSA and the State Historic Preservation Officer to resolve these adverse effects will be prepared following the State Historic Preservation Officer's concurrence with the National Register of Historic Places eligibility assessment of these structures. The Advisory Council on Historic Preservation will be notified of the Memorandum of Agreement and will have an opportunity to comment (DOE 2002l).

The planned consolidation and construction that is part of the Two-Mile Mesa Complex Project at TA-22 will not impact any recorded prehistoric or historic sites. Demolition of various historic buildings as a part of that action, however, will adversely affect historic structures that are potentially eligible for the National Register of Historic Places. As noted above for the TA-16 Weapons Manufacturing Support Facility, a Memorandum of Agreement between NNSA and the State Historic Preservation Officer to resolve these adverse effects will be prepared following the State Historic Preservation Officer's concurrence with the National Register of Historic Places eligibility assessment. The Advisory Council on Historic Preservation will be notified of the Memorandum of Agreement and will have an opportunity to comment (DOE 2003e).

5.7.2 Reduced Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Under the Reduced Operations Alternative, the same impacts to cultural resources as those discussed under the No Action Alternative (see Section 5.7.1) would occur.

Key Facilities Impacts

Activity levels at certain Key Facilities would change. High explosives processing and testing would be reduced by 20 percent. LANSCE would cease operation and be placed into a safe shutdown mode, and buildings at the Pajarito Site (TA-18) would undergo safe shutdown as well. As a result, the Pajarito Site would be dropped from the list of Key Facilities. As there would be no change in cultural resources associated with the reduction in high explosives processing and testing or the closure of LANSCE and TA-18, these actions are not addressed further.

5.7.3 Expanded Operations Alternative

The Expanded Operations Alternative includes proposals that would expand overall operations levels at LANL above those established for the No Action Alternative. Thus, under the Expanded Operations Alternative, the same impacts to cultural resources as those discussed under the No Action Alternative (see Section 5.7.1) would occur. Additionally, some of the new projects proposed under the Expanded Operations Alternative would potentially impact cultural resources. Not all new projects or activities would affect these resources, however, because many would involve actions within or modifications to existing structures, or the construction of new facilities within previously developed areas of LANL. For example, an increase in pit production would not require new construction and hence would not affect cultural resources. Only those projects that could impact cultural resources are addressed below.

Los Alamos National Laboratory Site-Wide Impacts

There are two options (Capping and Removal) for remediation of MDAs at LANL. The cultural resources impacts for both options would be generally similar. The surfaces of the MDAs would be disturbed whether they are capped or contamination is removed. Because no archaeological resources are located within any of the MDAs, neither option would directly impact such sites. Risk of impacts to cultural resources during remediation of any of the hundreds of other PRSs at LANL would depend on the situation and the corrective measure implemented, if any. Unlike the MDAs, many of the PRSs (such as firing sites) contain only surface or near-surface contamination that could be recovered relatively easily.

Indirect impacts to cultural resources from remedial actions are possible due to increased erosion resulting from clearing, capping, removal, or contamination recovery operations; from locating temporary remediation support facilities near the remediation sites; and from workers or equipment in the work area. In those cases where archaeological resource sites and historic buildings and structures are located near work areas, site boundaries would be marked and the site would be fenced, as appropriate. As one example, a building eligible for the National Register of Historic Places is located within the solid waste management units comprising Firing Site R-44 in TA-15. If remediation of R-44 were required by the New Mexico Environment Department, however, it would take place in a manner that protects the building.

Most actions associated with implementing the Security-Driven Transportation Modifications Project would have little or no impacts on cultural resources because no known cultural sites are located within any of the areas to be disturbed. A historic site is situated near an area to be disturbed within TA-63; however, direct impacts would be unlikely. Prior to any disturbance, site boundaries would be marked and the site would be fenced, as appropriate. If previously unknown resources were identified during ground-disturbing activities, the procedures in *A Plan for the Management of the Cultural Heritage at Los Alamos National Laboratory, New Mexico* (*Cultural Heritage Management Plan*) would be followed (LANL 2006f). The proposed vehicle and pedestrian bridges over Ten Site Canyon would be highly visible from both nearby and distant locations. Thus, they may degrade views of the canyon from sites identified by Native American and Hispanic communities as traditional cultural properties.

Under Auxiliary Actions A and B of the Security-Driven Transportation Modifications Project, bridges would be built over Mortandad Canyon and Sandia Canyon, respectively. As the corridors where the bridges would be constructed do not contain any known cultural resource sites, it is unlikely that construction of the bridges (or associated roadways) would directly impact such resources. There are a number of prehistoric sites and one historic site located to the east and west of the proposed Mortandad Canyon bridge corridor. Due to the relative proximity of these resources to the bridge corridor, it may be necessary to mark and fence sites, as appropriate. No cultural resource sites are located near the Sandia Canyon bridge corridor. In the event that a previously unknown resource is identified during ground-disturbing activities associated with the proposed options, the procedures in LANL's *Cultural Heritage Management Plan* (LANL 2006f) would be followed. As noted above for the road and pedestrian bridges over Ten Site Canyon, construction of the bridges could degrade views of the canyon from sites identified by Native American and Hispanic communities as traditional cultural properties (see Appendix J).

Technical Area Impacts

Three projects are being proposed that would potentially impact cultural resources within TA-3 and TA-21. These projects are related to the Physical Science Research Complex and the Replacement Office Buildings in TA-3 and TA-21 Structure DD&D.

Technical Area 3

The proposed site of the Physical Science Research Complex is in an already-developed area of TA-3. Building TA-3-0028, a potentially significant historic building, would be removed. Prior to its demolition, it would be assessed for inclusion in the National Register of Historic Places. The current Administration Building (TA-3-0043) has been formally declared as eligible for the National Register of Historic Places and a Memorandum of Agreement has been signed regarding required documentation prior to its removal.

Although no cultural resource sites that are eligible for the National Register of Historic Places are located in TA-3 in the vicinity of the Replacement Office Buildings, a historic trail located to the south of the parking lot must be managed until formally determined otherwise. Due to its proximity to the proposed project, there could be potentially adverse effects to the trail from construction. Appropriate measures, such as fencing, would be implemented to resolve any potentially adverse effects.

Technical Area 21

Decontamination and demolition of buildings and structures at TA-21 would directly affect those associated with the Manhattan Project and Cold War years that are eligible for the National Register of Historic Places. In total, there are 15 historic buildings and structures in TA-21; however, a number of these are located within the parcel that was conveyed to Los Alamos County. Regarding those historic buildings and structures that would be affected, NNSA, in conjunction with the State Historic Preservation Officer, has developed documentation measures to resolve adverse effects to eligible properties. Prior to demolition, these measures would be incorporated into a formal Memorandum of Agreement between NNSA and the New Mexico Historic Preservation Division. The Advisory Council on Historic Preservation would be notified of the Memorandum of Agreement and would have an opportunity to comment.

Key Facilities Impacts

Four projects are proposed that are related to Key Facilities at LANL under the Expanded Operations Alternative.

Pajarito Site

Prehistoric resources (specifically, 40 cavates and a rock shelter) and historic resources (specifically the Ashley Pond Cabin) are located on the Pajarito Site (TA-18). These resources would continue to be protected during DD&D activities. Three LANL-associated buildings located within TA-18 have been identified as eligible for the National Register of Historic Places, including the Slotin Building (18-1) and two other buildings (18-2 and 18-5). However, there are additional buildings within the TA that have yet to be assessed for eligibility to the National

Register of Historic Places. Prior to any DD&D activities, these buildings would have to be evaluated. Those that are candidates for long-term retention would be protected during DD&D activities, whereas others would be documented to resolve the adverse effects. As noted previously, NNSA, in conjunction with the State Historic Preservation Officer, has developed documentation measures to resolve adverse effects on eligible properties at LANL. Appropriate measures would be defined in a Memorandum of Agreement between NNSA and the New Mexico Historic Preservation Division prior to any DD&D activities. The Advisory Council on Historic Preservation would be notified of the Memorandum of Agreement and would have an opportunity to comment.

Radiochemistry Building

Construction of the Radiological Sciences Institute would not directly impact prehistoric cultural resources because none are located within areas to be disturbed by construction. One prehistoric site, however, is located across the access road from the existing Radiochemistry Building, which is itself is considered a historic structure. New construction in the area of the prehistoric site would require the site boundaries to be marked and the site to be fenced.

Before demolition could begin on parts of the Radiochemistry Building or other structures to be replaced by the Radiological Sciences Institute, NNSA, in conjunction with the State Historic Preservation Officer, would implement documentation measures to resolve any adverse effects to eligible properties. These measures would be incorporated into a formal Memorandum of Agreement between NNSA and the New Mexico Historic Preservation Division. The Advisory Council on Historic Preservation would be notified of the Memorandum of Agreement and would have an opportunity to comment. Impacts from construction and operation of the Radiological Sciences Institute on traditional cultural properties are unlikely because most development would take place within previously disturbed portions of TA-48. Potential views of TA-48 from any traditional cultural properties located in the vicinity would remain largely unchanged (see Appendix G, Section G.3.3.2).

Radioactive Liquid Waste Treatment Facility

Under the construction options for upgrades to the Radioactive Liquid Waste Treatment Facility, one or more treatment buildings would be constructed near the existing facility and the East and North Annexes would be demolished. Effects to cultural resources would be minimal. Under one of the auxiliary actions, which could be applied to any of the options, evaporation tanks and pipelines would be constructed. Impacts to cultural resources in the vicinity of the pipeline and evaporation tanks would be avoided during the siting process. If the pipeline alignment were to encroach on archaeological sites near the evaporation tanks, however, the archaeological sites would require testing or excavation. These options would have minimal effects on historic buildings because removal of later annexes to Radioactive Liquid Waste Treatment Facility would not likely affect the original historic fabric of the building. Changes to the process area of Radioactive Liquid Waste Treatment Facility, however, would require historic documentation before any equipment is removed from the building. The environmental consequences to cultural resources would be the same if the upgraded treatment capabilities were housed in one or multiple structures.

The New Construction and Renovation Option for the Radioactive Liquid Waste Treatment Facility involves renovation of the existing facility in addition to construction of one or more treatment buildings. This option also would result in minimal adverse effects on cultural resources. If the auxiliary action of construction of evaporation tanks and pipeline were implemented, the impacts to cultural resources would be the same as described above. However, changes to the structure of the existing Radioactive Liquid Waste Treatment Facility would alter the original historic appearance of the building. Removal of equipment, modification of the building, and demolition of the annexes would require documentation and consultation with the New Mexico Historic Preservation Office. For all options, mitigation plans would have to be implemented before or during implementation of the project.

Solid Radioactive and Chemical Waste Facilities

Impacts to cultural resources from Waste Management Facilities Transition activities would be similar under both options: Option 1, Accelerated Actions for Meeting the Consent Order or Option 2, Interim Actions Necessary for Meeting the Consent Order. All activities taking place in TA-54, including new construction and removal of the domes, would occur within developed areas. Thus, there would be no direct impacts on cultural resources. But because a number of cultural resource sites are located nearby, a potential exists for indirect impacts to these resources. To ensure these resources would not be affected under either alternative, cultural resource site boundaries would be marked and fenced, as appropriate. Although archaeological resources are located in the generic area considered for the TRU Waste Facility, only those in TA-50, TA-54-West, and TA-66 have the potential to be directly affected by construction of the TRU Waste Facility. Direct and indirect impacts to archaeological resources would require notifying appropriate LANL personnel and implementing the requirements of the LANL Cultural Resources Management Plan (LANL 2006f). Mitigation measures, including avoidance, would be taken to ensure that construction activity, traffic and ground disturbances would not result in damage to the resources. These measures would be incorporated into a formal Memorandum of Agreement between DOE and the New Mexico Historic Preservation Division to resolve adverse effects. The Advisory Council on Historic Preservation would have an opportunity to comment on the Memorandum of Agreement. Construction of the TRU Waste Facility would not impact any National Register of Historic Places-eligible buildings or structures. However, if the TRU Waste Facility were built within generic sites in TA-51, TA-52, or TA-54-West, it would be visible from San Ildefonso Pueblo lands. Thus, impacts to traditional cultural properties are possible if the new facility were built within these TAs. Impact potential is reduced within TA-54-West because construction would take place within a developed area. Removal of the white-colored domes at TA-54 would positively impact views from Pueblo of San Ildefonso lands, which border the TA to the north.

Los Alamos Neutron Science Center

The LANSCE accelerator building has been determined to be eligible for the National Register of Historic Places. Although project-related modifications would not affect the external appearance of the structure, it would be necessary to determine the potentially adverse effects and document existing conditions, as appropriate. Additionally, any other significant historic buildings at TA-53 that could experience internal modifications would have to be evaluated for National Register of Historic Places eligibility status; these buildings must be considered potentially eligible until formally assessed.

Science Complex

Three archaeological sites are situated near the proposed Northwest TA-62 location, and each has been determined to be eligible for the National Register of Historic Places. These three sites are at risk of indirect adverse effects from construction of the Science Complex. Mitigation measures would be taken as appropriate to resolve any adverse effects in conjunction with the State Historic Preservation Office and Advisory Council on Historic Preservation. There would be no adverse effects on cultural resources from construction of the Science Complex under the Research Park Site or South TA-3 Site options. Under all options, the buildings to be replaced by the Science Complex would have to be evaluated for their historic importance prior to being demolished.

Remote Warehouse and Truck Inspection Station

The Remote Warehouse and Truck Inspection Station could impact the three recorded prehistoric archaeological sites at the proposed location. Mitigation measures would be taken in conjunction with the State Historic Preservation Office and Advisory Council on Historic Preservation, as appropriate, to ensure that construction activity, traffic, and ground disturbances do not damage the sites. The Mortandad Trail located east of the proposed project site leads to the Mortandad Cave Kiva National Historic Landmark and is closed to public access except for organized tours. Although the proposed project would not affect normal access to the trail, it would incorporate fencing around the perimeter of the Warehouse and Truck Inspection Station to protect sensitive areas, including the Mortandad Cave Kiva National Historic Landmark, from unauthorized increased visitation.

5.8 Socioeconomics and Infrastructure

This section discusses the environmental effects of LANL operations on the socioeconomic region of influence and LANL site infrastructure. The effects are described for each of the alternatives.

5.8.1 Socioeconomics

The primary (direct) and secondary (indirect) impacts of LANL activities on employment, salaries, and procurement are analyzed in this SWEIS. The primary impacts were determined by analyzing projected changes in employment (in terms of full-time equivalents at LANL). Changes in employment were projected based on information regarding changes in activities at the Key Facilities. Employment for the rest of LANL was assumed to remain the same.

Projected changes in employment were distributed among the tri-county area (the three counties closest to LANL: Los Alamos County, Rio Arriba County, and Santa Fe County). Employment changes would likely result in additional, secondary changes in employment, salaries, and expenditures in the area, as well as changes in demands for social services. These secondary impacts would occur within a regional economy because jobs added in a primary industry such as LANL would create local opportunities for new employment in supporting industries. Analysis of these secondary economic and social impacts of LANL activities across the alternatives was conducted using the multipliers developed by the U.S. Department of Commerce, Bureau of

Economic Analysis's Regional Input-Output Modeling System (RIMS II) for the tri-county area to predict total LANL socioeconomic impacts in the area (DOC 2006d)[4]. For example, if LANL were to expand employment by 100 full-time workers who resided in the tri-county area, the secondary effect would be the addition of approximately 106 new secondary jobs in the tri-county labor market. On the other hand, if LANL were to reduce employment by 100 full-time workers, the reverberating effect across the tri-county economy would be the loss of 106 other jobs.

The projected changes in employment were used to determine whether there would be significant impacts in the tri-county area on the need for housing units, construction requirements at LANL, changes in local government finances, and the need for public services.

Table 5–30 summarizes the expected socioeconomic changes for each of the proposed alternatives.

5.8.1.1 No Action Alternative

Los Alamos National Laboratory Site-Wide Impacts

LANL Employment

LANL continues to be a major economic force within the region of influence consisting of Santa Fe, Los Alamos, and Rio Arriba Counties (the tri-county area). Chapter 4, Table 4–28, shows the percentage of LANL employees residing in the region of influence. As shown in this table, approximately 11.5 percent of the total number of persons employed in the region of influence are affiliated with LANL, and this level has remained relatively steady over a number of years.

At the end of 2005, LANL employed 13,504 individuals, nearly 19 percent more than the employment projection of 11,351 presented in the *1999 SWEIS*. From 1996 through 2005, employment at LANL increased by approximately 2.2 percent per year. During the same period, employment in the region of influence increased by an average of 2.5 percent annually. Under the No Action Alternative, it is assumed that LANL employment levels would no longer increase but would remain steady at the 2005 level.

Assuming LANL continues to directly employ 13,504 employees, it is estimated that approximately 11,560 of these employees would live within the region of influence based on existing residence rates (LANL 2006g). The existence of these direct jobs would be expected to result in the creation of another 12,240 indirect jobs for a total number of jobs related to LANL operations in the region of influence of approximately 23,800 jobs; about 21 percent of the total number of people expected to be employed in the region of influence in 2007.

---

[4] The LANL site specific multiplier was developed using a weighted average of RIMS II detailed industry multipliers for the tri-county area made up of the following industries: scientific research and development, environmental and other technical consulting services, construction, and investigative and security services.

Table 5–30 Summary of Socioeconomic Consequences

No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
LANL Site		
LANL Employment		
2005 levels of employment assumed to remain steady at 13,504 employees, 11,560 of whom would be expected to reside in the region of influence creating another 12,240 indirect jobs in the region of influence.	A decrease of 500 employees from 2005 levels would be expected to result in the loss of about 530 indirect jobs in the region. Loss of 1,030 jobs in the region would be less than 1 percent of total civilian workforce.	An employment increase of 2.2 percent per year from 2007 to 2011 would result in an additional 600 to 1,890 employees working at LANL and creation of another 640 to 2,000 indirect jobs. This growth rate is consistent with the projected regional growth rate.
Housing		
No new housing units would be needed specific to changes in LANL's employment level.	Additional housing units could become available in the tri-county area as a result of the projected decrease in LANL's employment level. These would likely offset the need for additional housing units in the region because the population would still be expected to grow, though at a slower rate (about 1.5 percent versus 2.3 percent).	Additional housing units would be required in the tri-county area due to the projected increases in LANL's employment level and in the regional population. More LANL employees could be expected over time to reside in Rio Arriba, Santa Fe, or other surrounding counties, compared to Los Alamos County, where a shortage of available housing would likely continue. The number of housing units needed would depend on the number of workers relocating from outside the area. Overall, the number of units needed would likely be small compared to overall needs in the tri-county area.
Construction		
Completion of previously approved construction projects would likely draw workers already living in the region who historically work from job-to-job.	Same as No Action Alternative.	An increase in the number of construction projects would likely draw workers already in the region who historically work from job-to-job.
Local Government Finance		
Annual gross receipts tax yields would likely remain at current levels in real terms.	Annual gross receipts tax yields directly and indirectly associated with LANL employment could decrease by approximately 1.1 percent.	Annual gross receipts tax yields directly and indirectly associated with LANL employment are projected to increase by between 1.3 and 3.9 percent from 2007 through 2011 above 2005 levels in real terms due to increases in LANL's workforce during that timeframe.
Services		
Demand for services such as police, fire, and hospital beds would likely remain at current levels in proportion to LANL employment. The regional population is projected to increase even if LANL employment remains flat, so the demand for regional services would continue to increase, but the increase would not be driven by LANL employment growth.	Demand for services associated with LANL employment would likely decrease in proportion to the number of out-of-work LANL-related employees forced to leave the region. The regional population is still projected to increase, however, in spite of the small decreases in LANL employment envisioned in this alternative, so demand for services would likely increase as well, though at a slower pace than under the No Action Alternative.	Demand for services associated with LANL employment would likely increase in proportion to the number of additional LANL-related jobs added to the region. The number of additional school-age children associated with these increases is projected at between 440 and 1,400 in the tri-county area, resulting in an estimated need for increased public school funding from the state of $3.2 million to $11 million between 2007 and 2011. Most of the additional services would be required in Rio Arriba, Santa Fe, and other surrounding counties because the population in Los Alamos County is projected to increase by a very small rate compared to the other counties.

Completion of construction projects previously approved under completed NEPA compliance reviews would likely draw workers who already live in the region of influence and historically work from job-to-job in the region. Thus, this sector of employment associated with LANL is not expected to grow as a result of the No Action Alternative.

Housing

No new housing units beyond current regional trends are likely to be needed under the No Action Alternative, because LANL employment levels would be expected to stay at current levels.

Local Government Finance

Under this alternative, the tri-county area's annual gross receipts tax yields would be expected to grow at the same level as the population. Changes in tax rates are assumed to be driven by the need to increase service levels to meet public demand in the case of a tax increase or a determination that service levels can reduced in some way in the case of a tax cut.

Services

Annual school enrollment trends in the tri-county area would likely continue due to projected population growth that is unrelated to LANL. Demands for police, fire, and other municipal services directly resulting from LANL employment needs would be expected to remain at current levels, because LANL employment levels would be expected to stay at current levels.

5.8.1.2 Reduced Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

LANL Employment

Under the Reduced Operations Alternative, employment at LANL could decrease by approximately 3.7 percent, or 500 employees, as a result of closing LANSCE, reducing high explosives processing and testing by 20 percent, and cessation of TA-18 activities. This would equate to a projected employment level of about 13,000 in 2007 under this alternative. As a result of this decrease in employment at LANL, a loss of about 530 indirect jobs also is projected.

If all of these displaced workers remained in the region of influence in 2007 and were unable to find new employment immediately, regional unemployment rates would be expected to increase by approximately 0.8 percent. As these projected decreases are less than 1 percent of the total civilian labor force for the region of influence, the changes would not be expected to result in any significant change in the regional economy. Similar swings in LANL employment were seen recently with no apparent impacts on the regional economy. For example, employment levels at LANL decreased by approximately 3 percent from 1999 to 2000, while the number of persons employed in the region of influence increased by 4 percent during the same period. A similar decrease was seen from 2003 to 2004 when LANL employment decreased by 2.6 percent, while the number of persons employed in the region of influence increased by 1.2 percent.

Under this alternative, LANL would be expected to directly employ approximately 13,000 employees. It is estimated that approximately 11,140 of these employees would live within the region of influence based on existing residence rates (LANL 2006g). The existence of these direct jobs would be expected to result in another 11,790 indirect jobs for a total number of jobs related to LANL operations in the region of influence of approximately 22,920 jobs; about 20 percent of the total number of people expected to be employed in the region of influence in 2007. The anticipated construction impacts would be the same as under the No Action Alternative.

Housing

In the event all of the persons affected by the projected reduction in LANL's workforce moved out of the region, available housing units in the region of influence would likely increase. This would not be expected to have a significant adverse impact on the region, however, because the population is expected to grow at the same time, so available units would likely fill new demands. The immediate impacts on the housing market in Los Alamos County would likely be greater than in Santa Fe or Rio Arriba Counties because a greater percentage of LANL employees reside in Los Alamos County. Given the lack of available units in Los Alamos County, however, any available units would likely be desired by others who may have wanted to move into the county but were unable due to lack of available housing. Thus, any initial increase in available units would likely be offset by pent-up demand. (In 2000, only 5.5 percent of the housing units in Los Alamos County were vacant, compared to over 13 percent in the State of New Mexico and 9 percent across the United States [DOC 2006a]).

Local Government Finance

Under the Reduced Operations Alternative, the tri-county annual gross receipts tax yields associated with LANL operations (both direct and indirect) would be expected to decrease by approximately 1.1 percent if all of the affected employees relocated outside of the region. Any reduction in tax revenues associated with the potential loss of LANL employees, however, would likely be offset by the continued growth in the regional workforce outside of LANL, similar to the increases seen in 2000 and 2004.

Services

Annual school enrollment in the tri-county area could decrease due to out-migration of affected LANL employees and their families, as well as indirect personnel and their families. The potential loss would likely be offset by the continued influx of non-LANL employees into the region as the region is expected to continue to grow, though at a slower rate.

Demands for police, fire, and other municipal services are not expected to be impacted by the projected employment changes under this alternative because affected LANL employees and their families represent less than 1 percent of the regional demand.

5.8.1.3 Expanded Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

LANL Employment

Under the Expanded Operations Alternative, employment at LANL would continue to rise due to both increased pit production and increased remediation and DD&D activities. In addition, work at LANL would likely increase beyond current operations in areas that cannot be easily identified at this time, but could be tied to expanding research efforts such as homeland security. Similar increases have been seen in recent years.

If LANL's employment rate were to continue increasing at the same level experienced from 1996 through 2005 (2.2 percent annually), approximately 15,400 individuals could be employed at LANL by the end of 2011, as shown in **Table 5–31**, which would be an increase of about 1,890 above the 2005 level. In addition to direct employees associated with LANL, approximately 2,000 positions would likely be created indirectly as a secondary impact on the region's payrolls by the end of 2011.

Table 5–31 Projected Los Alamos National Laboratory Employment under the Expanded Operations Alternative

Year	*Projected LANL Employees*	*LANL Employees Residing in ROI*	*Number of Indirect Jobs in ROI Related to LANL Employment*	*Total Number of Jobs Related to LANL in ROI*	*ROI Employed*	*LANL as a Percent of ROI Employed*
2007	14,107	12,080	12,782	24,862	112,435	22.1
2008	14,418	12,347	13,065	25,412	115,207	22.1
2009	14,736	12,619	13,352	25,971	118,047	22.0
2010	15,061	12,898	13,648	26,546	120,957	21.9
2011	15,394	13,182	13,948	27,130	123,939	21.9

ROI = region of influence.

Under this alternative, LANL would be expected to directly employ between approximately 14,100 employees in 2007 and 15,400 employees in 2011. Between 12,080 and 13,182 of these employees would live within the region of influence based on existing residence rates (LANL 2006g). The existence of these direct jobs would be expected to result in another 12,782 to 13,948 indirect jobs for a total number of jobs related to LANL operations in the region of influence of approximately 24,862 to 27,130 jobs; about 22 percent of the total number of people expected to be employed in the region of influence from 2007 through 2011.

Under the Expanded Operations Alternative, construction and remediation efforts at LANL would increase; however, similar to the No Action Alternative, these projects would likely be staffed by workers who are already present in the region of influence and historically work construction jobs in the region. Thus, this sector of employment associated with LANL is expected to grow as a result of the Expanded Operations Alternative, but at a rate comparable with the operational growth rate.

Housing

An increase in LANL employment along with associated increase in indirect hires, would likely increase the need for housing in the region of influence. Although available housing is currently limited in Los Alamos County, construction of new housing is planned within the next year. These units would likely be filled quickly and a larger percentage of LANL-related housing needs would still need to be accommodated by workers relocating to Santa Fe, Rio Arriba, or other nearby counties, in keeping with the trend in recent years.

Additional housing needs would not be expected to exceed regional growth projections because the region is already expected to grow by approximately 2.3 percent annually between 2000 and 2010 (LANL 2004c).

Local Government Finance

Under this alternative, the tri-county area's annual gross receipts tax yields would be expected to increase by between 1.3 and 3.9 percent in real terms as a result of the addition of workers to LANL's workforce from 2007 through 2011. Any increases in tax revenues needed to offset the cost of additional services to support the associated increased population under the Expanded Operations Alternative would be covered by these new employees.

Services

Annual school enrollment in the tri-county area due to increases in LANL-related employment (direct and indirect) is projected to increase by between 435 and 1,360 students from 2007 to 2011 under the Expanded Operations Alternative. Additional annual funding assistance from the State of New Mexico of about $3.2 million to $11 million would be required for public school operations because of these enrollment increases, which would be part of an expected increase of about 6,000 to 10,000 in school-age children in the tri-county area during that period.

In Los Alamos County, the school district would likely be able to absorb the anticipated new enrollment levels because the levels would not be expected to change significantly from current levels due to the lack of available housing units. If Los Alamos County approves plans to build additional homes, the need for additional schools would need to be evaluated. In Rio Arriba County and the cities of Española and Santa Fe, this increase would be greater, as a larger portion of LANL's workforce would likely reside in these areas.

The demand for police, fire, and other municipal services would likely increase in proportion to the increase in population expected in each county.

5.8.2 Infrastructure

Site infrastructure includes the utility systems required to support construction and/or modification and operation of LANL facilities. It includes the capacities of the electric power transmission and distribution system, natural gas and liquid fuel (fuel oil, diesel fuel, and gasoline) supply systems, and the water supply system. The region of influence for utility infrastructure resources includes the LANL site, including the affected TAs and the individual facilities and utility systems (electric power, natural gas, and water) that serve LANL.

Descriptions of these utility systems, along with analyses of historic trends in LANL usage and other demands within the region of influence that supports this analysis, are provided in Chapter 4, Section 4.8.2.

In general, potential infrastructure impacts were assessed by comparing projections of utility resource requirements under each alternative against utility system capacities. While many LANL facilities do not meter utility use, annual site-wide demands are known and were used to make projections for each of the alternatives considered in this SWEIS. In addition, base trends in site-wide infrastructure requirements to date, as well as within the larger region of influence, were identified and extrapolated to make predictions for future years. The data were then adjusted for LANL project-specific actions within specific TAs and at Key Facilities considered under each alternative. Any projected demand for infrastructure resources exceeding its availability can be regarded as an indicator of impact. Where projected demand approaches or exceeds capacity, further analysis for that resource is warranted. It should be noted that utility projections include considerable inherent uncertainty as demands for electric power, natural gas, and water can be greatly affected by climate conditions from year to year. As such, the further into the future such projections are made, the greater the uncertainty in the projection.

Projected site utility infrastructure requirements under the Proposed Action and alternatives are summarized in **Table 5–32**.

5.8.2.1 No Action Alternative

Annual utility infrastructure requirements for current LANL operations and for other Los Alamos County users that rely upon the same utility system, along with current utility system capacities, are presented in **Table 5–33**. Values from 2005 are presented as a reference baseline for comparing projections for the three proposed alternatives in this SWEIS. Under the Expanded Operations Alternative analyzed in the *1999 SWEIS* (DOE 1999a) and selected in the subsequent ROD, LANL operations were projected to require 782,000 megawatt-hours of electricity (electrical energy) with a peak load demand of 113 megawatts, 1,840,000 decatherms of natural gas, and 759 million gallons (2.87 billion liters) of water annually. LANSCE alone was projected to require 437,000 megawatt-hours of electricity with a peak load demand of 63 megawatts, and 265 million gallons (1.03 billion liters) of water (DOE 1999a). LANSCE operations historically have accounted for up to one-quarter to one-half of LANL's total water and electrical power demand, respectively (LANL 2004c, 2006a). LANSCE projections in the *1999 SWEIS* included operation of the Low-Energy Demonstration Accelerator, which operated from late 1998 until it was shut down in December 2001 and later decommissioned (LANL 2006g). Operation of this facility was forecast to more than double LANSCE's electric peak load demand and its water demand for cooling tower operation (LANL 2006a), but it will not be a factor in future LANSCE operations. The *1999 SWEIS* did not project natural gas consumption for LANSCE or forecast utility infrastructure requirements for other Los Alamos County users.

Table 5–32 Summary of Environmental Consequences on Site Infrastructure

	No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
LANL Site			
Total Alternative (annual)	*Electricity requirements* 645,000 megawatt-hours total (495,000 megawatt-hours for LANL); 49 percent of system capacity. *Electric Peak Load* 111 megawatts total (91.2 megawatts for LANL); 74 percent of system capacity. *Natural gas requirements* 2,215,000 decatherms total (1,197,000 decatherms for LANL); 27 percent of system contract supply capacity. *Water requirements* 1,621 million gallons total (380 million gallons for LANL); 90 percent of system available water rights.	*Electricity requirements* 516,000 megawatt-hours total (366,000 megawatt-hours for LANL); 39 percent of system capacity. *Electric Peak Load* 80.6 megawatts total (60.4 megawatts for LANL); 54 percent of system capacity. *Natural gas requirements* 2,181,000 decatherms total (1,163,000 decatherms for LANL); 27 percent of system contract supply capacity. *Water requirements* 1,544 million gallons total (303 million gallons for LANL); 85 percent of system available water rights.	*Electricity requirements* 827,000 megawatt-hours total (677,000 megawatt-hours for LANL); 63 percent of system capacity. *Electric Peak Load* 144 megawatts total (124 megawatts for LANL); 96 percent of system capacity. *Natural gas requirements* 2,331,000 decatherms total (1,313,000 decatherms for LANL); 29 percent of system contract supply capacity. *Water requirements* 1,763 million gallons total (522 million gallons for LANL); 98 percent of system available water rights.
MDA Remediation (10-year total)	No change in utility demands	Same as No Action Alternative	Up to 70 million gallons of liquid fuels and 58 million gallons of water for remediation activities.
Security-Driven Transportation Modifications (project total)	No change in utility demands	Same as No Action Alternative	Up to 4.0 million gallons of liquid fuels and 20 million gallons of water for construction.
Affected Technical Areas			
TA-3	TA-3 Co-Generation Complex upgrades would have a positive incremental impact on site electrical energy and peak load capacity, but natural gas consumption could increase to support higher electricity generation. Negligible short-term increase in utility demands from constructing new office buildings, with no net increase in operational demands.	Same as No Action Alternative	Replacement Office Buildings–1.8 million gallons of liquid fuels and 9.6 million gallons of water for construction and an additional 0.356 million gallons of liquid fuels and 11.3 million gallons of water for DD&D; no net increase in utility demands for operations. Physical Science Research Complex–2.6 million gallons of liquid fuels and 14.4 million gallons of water for construction and an additional 0.129 million gallons of

	No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
			liquid fuels and 4.1 million gallons of water for DD&D; no net increase in utility demands for operations.
TA-18	No change in utility demands	Elimination of utility demands in TA-18 from Pajarito Site shutdown with a negligible decrease in site-wide demands.	DD&D of TA-18 Structures–activities are expected to require 0.273 million gallons of liquid fuels and 8.4 million gallons of water. As activities would be staggered over an extended period of time, overall increase in utility demands would be minimal.
TA-21	No change in utility demands	Same as No Action Alternative	DD&D of TA-21 Structures–activities are expected to require 0.043 million gallons of liquid fuels and 1.3 million gallons of water. As activities would be staggered over an extended period of time, overall increase in utility demands would be minimal.
TA-54	Negligible short-term increase in utility demands from MDA H closure activities.	Same as No Action Alternative	Same as No Action Alternative
TA-61	No change in utility demands	Same as No Action Alternative	Negligible temporary increase in utility demands, especially liquid fuels and water, from excavation.
Key Facilities			
Chemistry and Metallurgy Research Building (TA-3, TA-48, and TA-55)	Negligible short-term increase in utility demands from DD&D of old facility at TA-3 and construction of new facility at TA-55. Little or no change in utility demands from CMRR Facility operation when moved to TA-55.	No incremental change from transfer of nonnuclear activities to TA-55.	Same as No Action Alternative
Sigma Complex (TA-3)	No change in utility demands	Same as No Action Alternative	Same as No Action Alternative
Machine Shops	No change in utility demands	Same as No Action Alternative	Same as No Action Alternative
Materials Science Laboratory	No change in utility demands	Same as No Action Alternative	Same as No Action Alternative
Metropolis Center	No change in utility demands	Same as No Action Alternative	Moderate to major increase in electrical energy, peak load, and water demands over the No Action due to increased operational levels.
High Explosives Processing Facilities (TA-16)	Negligible short-term increase in utility demands from TA-16 Engineering Complex activities and demolition of structures.	Same as No Action Alternative	Potential negligible increase in operational utility demands.
High Explosives Testing Facilities (TA-6, TA-22, and TA-40)	Negligible to minor short-term increase in utility demands from construction of 15 to 25 new structures within the Twomile Mesa Complex and removal or demolition of vacated structures.	Same as No Action Alternative	Same as No Action Alternative

	No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
Pajarito Site (TA-18)	No change in utility demands	Elimination of utility demands in TA-18 from Pajarito Site shutdown with a negligible decrease in site-wide demands.	DD&D of TA-18 Structures–activities are expected to require 0.273 million gallons of liquid fuels and 8.4 million gallons of water. As activities would be staggered over an extended period of time, overall increase in utility demands would be minimal.
Tritium Facilities (TA-21)	No change in utility demands	Same as No Action Alternative	TA-21 Structures DD&D activities are expected to require 0.043 million gallons of liquid fuels and 1.3 million gallons of water. As activities would be staggered over an extended period of time, overall increase in utility demands would be minimal.
Target Fabrication Facility	No change in utility demands	Same as No Action Alternative	Same as No Action Alternative
Bioscience Facilities	No change in utility demands	Same as No Action Alternative	Science Complex–4.3 million gallons of liquid fuels and 23 million gallons of water for construction; no net increase in utility demands for operations.
Radiochemistry Facility (TA-48)	No change in utility demands	Same as No Action Alternative	Radiological Science Institute–4.2 million gallons of liquid fuels and 22.4 million gallons of water for construction and an additional 0.101 million gallons of liquid fuels and 3.1 million gallons of water for DD&D; no net increase in utility demands for operations.
Radioactive Liquid Waste Treatment Facility (TA-50)	No change in utility demands	Same as No Action Alternative	Radioactive Liquid Waste Treatment Facility–1.04 million gallons of liquid fuels and 7.5 million gallons of water for construction and related DD&D; no net increase in utility demands for operations.
LANSCE (TA-53)	Moderate increase in operational utility demands from increase in annual hours of operation.	Moderate to major decrease in infrastructure utility demands in TA-53 and sitewide due to shut down of operations with a minor reduction within the Los Alamos region.	LANSCE Refurbishment–Negligible, short-term increase in utility demands from refurbishment. Moderate increase in electrical energy, peak load, and water demands over the No Action due to increased operational levels.
Solid Radioactive and Chemical Waste Facilities (TA-50 and TA-54)	No change in utility demands	Same as No Action Alternative	Waste Management Facilities Transition–Up to 0.893 million gallons of liquid fuels and 4.9 million gallons of water for TRU Waste Facility construction; negligible incremental increase in utility demands for operations.

	No Action Alternative	***Reduced Operations Alternative***	***Expanded Operations Alternative***
Plutonium Facility Complex (TA-55)	No change in utility demands	Negligible increase in utility demands from transfer of nonnuclear activities at CMR Building to TA-55.	Plutonium Facility Complex Refurbishment Negligible short-term increase in utility demands for construction and related DD&D; minor incremental increase in utility demands for operations to support increased pit production. Radiography Facility–0.042 million gallons of liquid fuels and 0.234 million gallons of water for construction; no net increase in utility demands for operations.
Remote Warehouse and Truck Inspection Station (TA-72)	No change in utility demands	Same as No Action Alternative	Up to 0.420 million gallons of liquid fuels and 2.0 million gallons of water for construction; negligible incremental increase in utility demands for operations.

MDA = material disposal area; TA = technical area, DD&D = decontamination, decommissioning, and demolition; CMRR = Chemistry and Metallurgy Research Replacement; LANSCE = Los Alamos Neutron Science Center, CMR = Chemistry and Metallurgy Research.
Note: To convert gallons to liters, multiply by 3.78533.

Table 5–33 Baseline Infrastructure Requirements and System Capacities for the Los Alamos National Laboratory Region of Influence

Resource	*System Capacity*	*Current Requirement (2005 [a])*		*Total Requirement*
		LANL	*Other Los Alamos County Users*	
Electricity				
Energy (megawatt-hours per year)	1,314,000 [b]	421,413	129,457	550,870
Peak load demand (megawatts)	150 [b]	69.5	18.3	87.8
Fuel				
Natural gas (decatherms per year)	8,070,000 [c]	1,187,855	943,559	2,131,414
Water (million gallons per year)	1,806 [d]	359	1,034	1,393

[a] Electric and fuel data for 2005 are fiscal year basis while water data are calendar year basis (see Sections 4.8.2.1, 4.8.2.2, and 4.8.2.3).
[b] Electrical energy and peak load capacity reflect the current import capacity of the electric transmission lines that deliver electric power to the Los Alamos Power Pool, as well as completion of upgrades at the TA-3 Co-Generation Complex, which will add 40 megawatts (350,400 megawatt-hours) of generating capacity. Values do not reflect completion of a new transmission line and other ongoing electrical power system upgrades.
[c] Reflects contractually limited capacity of the natural gas system serving the Los Alamos area (see Section 4.8.2.2).
[d] Equivalent to the total water rights from the regional aquifer managed by Los Alamos County.
Note: A decatherm is equivalent to 1,000 cubic feet.
Sources: Arrowsmith 2006, LANL 2006g.

While demand for key infrastructure resources (electricity, natural gas, and water) within the region of influence has generally followed an upward trend, there are notable exceptions. For electricity, total LANL demand increased by approximately 14 percent between 1999 and 2005, while other Los Alamos County user demands increased by 22 percent. In contrast, LANL natural gas consumption declined by nearly 17 percent between 1999 and 2005, but demand within the County increased by about 8 percent over roughly the same period. The decline at LANL is attributable to warmer-than-normal seasonal temperatures that have persisted since the early 1990s and a switch from district heating plants to more efficient systems at individual LANL facilities. Total LANL demand for water also decreased by nearly 21 percent between 1999 and 2005, but this was offset by an approximately 18 percent increase in demand among other Los Alamos County users, who account for the largest portion of total water use in the region of influence.

Los Alamos National Laboratory Site-Wide Impacts

Projected annual utility infrastructure requirements under the No Action Alternative are presented in **Table 5–34**. The No Action Alternative represents a future baseline that includes projects that have already been implemented to some degree (and may already be reflected in the current baseline values), are in the process of being implemented, or would be implemented fully between now and 2011. These projects are independent of subsequent project decisions at LANL, and their ongoing activities add to the overall increasing trend in utility infrastructure demand in the Los Alamos area as a whole.

Table 5–34 Projected Site Infrastructure Requirements under the No Action Alternative

Resource	LANL Requirements	Other Requirements [a]	Total Requirements	Percent of Capacity [b]
Electricity				
Energy (megawatt-hours per year)	495,000	150,000	645,000	49
Peak load demand (megawatts)	91.2	20.2	111	74
Fuel				
Natural gas (decatherms per year)	1,197,000	1,018,000	2,215,000	27
Water (million gallons per year)	380	1,241	1,621	90

[a] Projections through 2011 for electrical energy, peak load, natural gas, and water also include projected usage for other Los Alamos County users that rely upon the same utility system as LANL.
[b] A calculation based on the system capacity as shown in Table 5–33.
Note: A decatherm is equivalent to 1,000 cubic feet.
Sources: Projections based on Arrowsmith 2005, 2006, Glasco 2005, DOE 2002i, LANL 2000f, 2001e, 2002e, 2003h, 2004c, 2005f, 2006a, 2006g.

These infrastructure resource projections are made for operations levels at LANL Key Facilities actually approaching the operational levels forecast in the *1999 SWEIS* and associated ROD. The levels of operations forecast in the *1999 SWEIS* have not been realized to date, however, and LANL operational demands have trended well below the *1999 SWEIS* projections as a result (see Table 5–34). Some of the discrepancy between forecast and actual trends in infrastructure demands also reflect the rather conservative bounding approach used in the original estimates. As such, the projections made in this SWEIS, to the extent possible, account for those key factors that would prevent LANL operations from practically realizing the infrastructure resource demands forecast in the *1999 SWEIS*. Factors considered for LANSCE operations were previously discussed. While funding shortfalls have limited hours of operation at LANSCE and thus reduced utility demands, aging equipment physically limits the total operational availability of LANSCE such that the levels of operations forecast in the *1999 SWEIS* would not be reasonably foreseeable under the No Action Alternative for this SWEIS. Nonetheless, projections under the No Action Alternative do assume that easing of budgetary constraints and resumption of isotope production (as occurred in 2005) would result in an overall increase in annual hours of operation, with LANSCE utility demands approaching those recorded in years immediately prior to release of the *1999 SWEIS*.

No infrastructure capacity constraints are expected from implementation of the No Action Alternative in the short term because LANL operational and Los Alamos area demands on key infrastructure resources (electricity, natural gas, and water) have trended below previously forecasted levels. Under this alternative, total annual electricity, electric peak load, natural gas, and water requirements would be about 49 percent, 74 percent, 27 percent, and 90 percent, respectively, of the capacity of the utility systems that serve LANL.

Total peak load demand is projected to require 74 percent of the Los Alamos Power Pool's peak load capacity by 2011. This projection includes the generating capacity of the TA-3 Co-Generation Complex with an electric generating capacity of at least 40 megawatts after a new turbine became operational in September 2007. Ongoing upgrades to the electrical power transmission and distribution system, including construction of a third transmission line, would allow the import of additional power and support a higher electric peak load.

Natural gas is abundant in New Mexico, and the region has a high import capacity. Ongoing upgrades to the natural gas distribution system by the Public Service Company of New Mexico should ensure the adequacy and reliability of natural gas (see Chapter 4, Section 4.8.2.2). Completion of upgrades to the TA-3 Co-Generation Complex could make its use more attractive for electrical energy production by LANL than in the past; thus, the Complex could support an increase in natural gas consumption over time. Regardless, maintenance of an adequate capacity margin is forecast under the No Action Alternative.

Total water demand within the region of influence could approach 90 percent of Los Alamos County-managed rights to withdraw water from the regional aquifer, although projections indicate that LANL operational demands would remain within the site's annual water use ceiling quantity (542 million gallons [2,050 million liters]) under the No Action Alternative (see Chapter 4, Section 4.8.2.3). As described in Section 4.8.2.3, Los Alamos County has completed feasibility studies for accessing up to 391 million gallons (1,500 million liters) of water per year from the San Juan-Chama Transmountain Diversion Project; however, the earliest that this water could be made available for use would be 2010 (Glasco 2005).

Technical Areas Impacts

Under the No Action Alternative, construction and related DD&D requirements for electricity, fuels and water in the affected TAs are expected to be negligible, including those for Replacement Office Building construction, continued upgrades to the Co-Generation Complex in TA-3, and MDA H remediation and closure activities in TA-54. In the short term, these activities would entail short-term spikes in utility infrastructure resource demands on a TA basis, but would have negligible impacts on the capacities of affected utility systems and on the overall trend in utility resource demands.

Technical Area 3

New facility operations in TA-3 would likely have a negligible impact on overall trends in infrastructure resource requirements because the new facilities generally would replace older, less resource-efficient facilities. Further, upgrades at the TA-3 Co-Generation Complex would positively impact the Los Alamos Power Pool's electric power availability by increasing LANL's onsite generating capacity and improving the reliability of the complex, as discussed above. The completed upgrades, however, could contribute to higher natural gas consumption if the facility were required to provide more electricity in the future, as previously discussed.

Key Facilities Impacts

Completion of programmed construction projects and related DD&D activities, including the Chemistry and Metallurgy Research Replacement Facility at TA-55, the Weapons Manufacturing Support Facility at TA-16, and new Dynamic Experimentation Complex facilities within the Twomile Mesa Complex (part of TA-6, TA-22, and TA-40), would entail short-term spikes in utility resource demands. These activities would have a negligible impact on the capacity of affected utility systems and on the overall trend in utility resource demands.

Operation of these new facilities would not be expected to cause a measurable overall increase in utility infrastructure demands because modern facilities would replace antiquated, less resource-efficient facilities, creating an economy of scale in operational efficiency. For example, completing construction of the 15 to 25 new buildings within the Two-Mile Mesa Complex would replace about 59 structures currently used for such operations.

5.8.2.2 Reduced Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Projected annual utility infrastructure requirements under the Reduced Operations Alternative are presented in **Table 5–35**. Utility infrastructure demand resulting from actions under the No Action Alternative would continue, with certain operational reductions, under this alternative. Reductions in the levels of high explosives processing and testing activities would have negligible-to-minor impacts on overall utility infrastructure requirements, but most other ongoing projects and activities included under the No Action Alternative also would move forward under the Reduced Operations Alternative. The entire LANSCE complex and TA-18 Pajarito Site, however, would be placed into safe shutdown mode under this alternative, although not all activities and associated utility demands would cease. LANSCE accelerator and support operations currently demand a relatively large share (about 22 and 15 percent in 2005) of LANL's electricity and water, respectively. As such, shutdown of LANSCE as part of the Reduced Operations Alternative would measurably reduce site-wide infrastructure resource demands compared to both the No Action Alternative and current operations. Under this alternative, total annual electricity, electric peak load, natural gas, and water requirements would be reduced to about 39 percent, 54 percent, 27 percent, and 85 percent, respectively, of the capacity of the utility systems that serve LANL.

Table 5–35 Projected Site Infrastructure Requirements under the Reduced Operations Alternative

Resource	*LANL Requirements*	*Other Requirements* [a]	*Total Requirements*	*Percent of Capacity* [b]
Electricity				
Energy (megawatt-hours per year)	366,000	150,000	516,000	39
Peak load demand (megawatts)	60.4	20.2	80.6	54
Fuel				
Natural gas (decatherms)	1,163,000	1,018,000	2,181,000	27
Water (million gallons per year)	303	1,241	1,544	85

[a] Projections through 2011 for electrical energy, peak load, natural gas, and water also include projected usage for other Los Alamos County users that rely on the same utility system as LANL.
[b] A calculation based on the system capacity as shown in Table 5–33.
Note: A decatherm is equivalent to 1,000 cubic feet.
Sources: Projections based on Arrowsmith 2005, 2006, Glasco 2005, DOE 2002i, LANL 2000f, 2001e, 2002e, 2003h, 2004c, 2005f, 2006a, 2006g.

Technical Area Impacts

Operational demands on utility infrastructure under this alternative would be similar to those under the No Action Alternative on a TA basis (except for TA-53) because base requirements would not be appreciably reduced due to high explosives processing and testing reductions.

Key Facilities Impacts

Los Alamos Neutron Science Center

Shutdown of LANSCE operations is projected to result in a moderate-to-major reduction in electrical energy, electric peak load demand, and water use at TA-53 compared to the demand under the No Action Alternative. This would specifically represent reductions of approximately 125,000 megawatt-hours in total electricity, 30.3 megawatts in electric peak load, and 73 million gallons (276 million liters) in water demand annually at LANSCE as compared to operational levels projected for the No Action Alternative. This action alone would result in a minor overall reduction in utility demands within the region of influence. Natural gas demand within the region would not be measurably affected on a percentage basis because LANSCE's operational demand for natural gas is a small percentage of that used by LANL as a whole and usage by LANL and other Los Alamos County users is affected more by weather and onsite electricity generation needs.

Pajarito Site

Shutdown of the Pajarito Site (TA-18) would result in a negligible site-wide decrease in operational utility needs.

5.8.2.3 Expanded Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Projected annual utility infrastructure requirements under the Expanded Operations Alternative are presented in **Table 5–36**. On a site-wide basis, numerous additional projects involving new facility construction, facility renovation, facility DD&D, and site closure activities affecting many TAs would occur under this alternative. Infrastructure requirements for these actions would be additive to those for actions identified as part of the No Action Alternative. Although these new activities collectively would result in a spike in utility resource demands, principally for liquid fuels and water, their contribution to the overall trend in site-wide or Los Alamos area demands would be minor due to the extended timeframe over which projects such as the MDA Remediation Project would be implemented. Liquid fuels, mainly diesel fuel and gasoline, would be required to operate heavy equipment, vehicles, and other worksite equipment; however, unlike natural gas, which is the principal heating fuel used at LANL, liquid fuels are not considered limiting resources because they can be procured from offsite sources and supplied at the point of use as needed.

For a number of new projects at LANL that involve DD&D of existing facilities whose capabilities would be replaced by newly constructed facilities, an economy of scale in operational efficiency would be achieved, resulting in a net decrease in utility demands. This economy of scale would tend to moderate the overall trend toward increasing utility demands at LANL and by Los Alamos County users that rely upon the same utility systems. Still, other projects would entail operational expansions that would result in a minor-to-moderate overall increase in demand for electricity, particularly in electric peak load demand, as well as water compared to projected demand under the No Action Alternative. Only minor increases in natural gas demand are forecast. Under the Reduced Operations Alternative, total annual electricity, electric peak load, natural gas, and water requirements would be about 63 percent, 96 percent, 29 percent, and 98 percent, respectively, of the capacity of the utility systems that serve LANL.

Table 5–36 Projected Site Infrastructure Requirements under the Expanded Operations Alternative

Resource	*LANL Requirements*	*Other Requirements* [a]	*Total Requirements*	*Percent of Capacity* [b]
Electricity				
Energy (megawatt-hours per year)	677,000	150,000	827,000	63
Peak load demand (megawatts)	124	20.2	144	96
Fuel				
Natural gas (decatherms)	1,313,000	1,018,000	2,331,000	29
Water (million gallons per year)	522	1,241	1,763	98

[a] Projections through 2011 for electrical energy, peak load, natural gas, and water also include projected usage for other Los Alamos County users that rely upon the same utility system as LANL.
[b] A calculation based on the system capacity as shown in Table 5–33.
Note: A decatherm is equivalent to 1,000 cubic feet.
Sources: Projections based on Arrowsmith 2005, 2006, Glasco 2005, DOE 2002i, LANL 2000f, 2001e, 2002e, 2003h, 2004c, 2005f, 2006a, 2006g.

The electric peak load capacity of the Los Alamos Power Pool could be approached due to increased operational demands at LANL combined with the trend of increasing demand that is forecast to persist for other Los Alamos County users. The predicted spike in electric peak load demand at LANL is primarily attributable to the Metropolis Center Increase in Levels of Operations and the proposed LANSCE Refurbishment Projects. Under the Expanded Operations Alternative, LANSCE operations would potentially require 208,000 megawatt-hours of electricity annually with a peak load demand of 51 megawatts, as compared to about 139,000 megawatt-hours of electricity with a peak load demand of 34 megawatts under the No Action Alternative. The Metropolis Center would require about 131,400 megawatt-hours of electricity annually with a peak load demand of 18 megawatts, as compared to about 44,000 megawatt-hours of electricity with a peak load demand of 6 megawatts under the No Action Alternative. As discussed for the No Action Alternative, ongoing upgrades to the electrical power transmission and distribution system, including construction of a third transmission line, would allow the import of additional power and support a higher electric peak load.

As previously described, heating demand and associated natural gas consumption at LANL has steadily declined in recent years despite higher overall activity levels at the site, mainly due to higher-than-normal seasonal temperatures. While this trend could be partly reversed by implementing the Expanded Operations Alternative for this SWEIS, including operation of the TA-3 Co-Generation Complex for electric power generation, the capacity of the Los Alamos area natural gas delivery system is expected to be adequate for the foreseeable future.

In recent years, combined LANL and county water demands have consumed between 80 and 90 percent of the currently developed water rights. Under the Expanded Operations Alternative, increased operations at LANL, combined with projected growth in the rest of Los Alamos County, could approach the county-managed rights to withdraw water from the regional aquifer. LANSCE operations would potentially require 119 million gallons (450 million liters) of water annually, as compared to up to about 77 million gallons (291 million liters) under the No Action

Alternative. The Metropolis Center could require up to 51 million gallons (193 million liters) of water annually, as compared to about 19 million gallons (72 million liters) under the No Action Alternative. Nevertheless, LANL operational demands are projected to remain within the site's annual water use ceiling quantity (542 million gallons [2,050 million liters]) under the Expanded Operations Alternative. As discussed under the No Action Alternative (see Section 5.8.2.1) and detailed in Chapter 4, Section 4.8.2.3, supplementing the Los Alamos County water supply system with San Juan-Chama water will be essential to ensuring that the region has adequate water supplies under this alternative and in the future.

Technical Area Impacts

Construction and related DD&D requirements for utility infrastructure resources, including electricity, fuels, and water, are expected to be negligible to minor for most actions, including construction of the Physical Science Research Complex and Replacement Office Buildings projects in TA-3 and the TA-18 and TA-21 Structure DD&D Projects. Implementation of the TA-21 Structure DD&D Project, which would include the natural-gas fired TA-21 steam plant, also would result in a negligible-to-minor reduction in LANL natural gas consumption because the plant's natural gas demand historically was smaller than 10 percent of site-wide demand and has decreased appreciably in recent years as NNSA missions in TA-21 have been relocated or discontinued.

Key Facilities Impacts

A number of project actions undertaken as part of this alternative would enhance the operational capabilities of Key Facilities, causing a net increase in infrastructure resource demands to support the increased level of operations. Specifically, the Metropolis Center Increase in Levels of Operations and LANSCE Refurbishment Projects would result in a minor-to-moderate increase in LANL infrastructure resource requirements and requirements within the region of influence to support higher levels of operations as described above. Increased pit production at TA-55 under this alternative would cause a minor increase in LANL infrastructure requirements because existing Plutonium Facility Complex operations currently constitute a relatively small percentage (generally 3 to 5 percent) of LANL's total demands. A very conservative estimate is that increased pit production at TA-55 could require an additional 8,500 megawatt-hours of electricity, 1.4 megawatts in electric peak load, 28,000 decatherms of natural gas, and 8.2 million gallons (31 million liters) of water annually.

5.9 Waste Management

Waste management impacts were evaluated based on the quantities of waste generated by Key Facilities, non-Key Facilities, and LANL's environmental restoration activities. Waste generation rates were used to measure the impacts on the LANL waste management infrastructure and local environment. Other impacts associated with waste management are addressed in the following sections: Air Quality (Section 5.4); Worker Health (Section 5.6.3); Transportation (Section 5.10); and Facility Accidents (Section 5.12). Waste management practices related to handling, treating, storing, and preparing for transport and disposal are described in Chapter 3 of this SWEIS.

Waste quantities were compiled by waste type and included process wastewaters (sanitary liquid waste, high-explosives-contaminated liquid waste, and industrial effluents); solid waste; and radioactive (including radioactive liquid) and chemical wastes. Due to the large number of construction and demolition projects now underway or planned at LANL, additional categories of construction and DD&D waste were included in the impacts analysis. LANL's environmental restoration wastes are presented as a separate category in this SWEIS.

Impacts associated with waste management were evaluated in the *1999 SWEIS* based on historical waste generation rates, projections of future waste generation, and the infrastructure in place to manage the wastes. With the exception of liquid waste, solid (sanitary) waste, and low-level radioactive waste, all LANL wastes were assumed to be disposed of offsite. For purposes of the transportation analysis (see Section 5.10) all wastes are assumed to be disposed of offsite.

In this analysis, the *1999 SWEIS* projections were reviewed and adjusted as needed to develop bounding values for the waste quantities associated with each alternative. As discussed in Chapter 4, Section 4.9, the *1999 SWEIS* projections adequately covered waste generated through facility operations; exceedances were the result of one-time events such as chemical cleanouts, maintenance, remediation, and cleanup following the Cerro Grande Fire.

In addition to wastes generated onsite, LANL historically has received small quantities of low-level radioactive and transuranic waste from offsite locations. Some of these wastes are generated by LANL activities at other locations and some by other DOE facilities that do not have the capability to manage the wastes. Receipt of these wastes by LANL is expected to continue at the historical rate of 5 to 10 waste shipments per year. The expected quantities of offsite waste would be small compared to the onsite waste generated and would be easily accommodated by the existing LANL waste management infrastructure.

In the sections that follow, waste generation rates for each facility are evaluated for the three alternatives. Bounding waste generation rates were projected for the No Action Alternative, considering the actions covered by the *1999 SWEIS* and any subsequent actions that have received independent NEPA analysis. Under the Reduced Operations Alternative, waste projections were selectively reduced to correspond to a lower level of operations. For the Expanded Operations Alternative, planned additional activities were considered and waste projections were increased as necessary to adequately bound the impacts. **Table 5–37** summarizes the waste management impacts associated with each of the alternatives.

5.9.1 No Action Alternative

Los Alamos National Laboratory Site-Wide Impacts

The types and quantities of wastes expected to be generated by LANL operations under the No Action Alternative are generally the same as those presented for the Expanded Operations Alternative in the *1999 SWEIS*, but modified for a lower level of pit production.

Table 5–37 Summary of Total (Operations, Decontamination, Decommissioning, and Demolition, and Remediation) Waste Generation Projections by Alternative (Cumulative 2007 through 2016)

Waste Type	*No Action Alternative*	*Reduced Operations Alternative*	*Expanded Operations Alternative*
Low-Level Radioactive Waste [a, b]			
Bulk low-level radioactive waste (cubic yards)	39,000	39,000	196,000 to 884,000
Packaged low-level radioactive waste (cubic yards)	33,000 to 128,000	33,000 to 110,000	80,000 to 183,000
High activity low-level radioactive waste (cubic yards)	–	–	0 to 347,000
Remote-handled low-level radioactive waste (cubic yards)	–	–	480 to 1,700
Mixed low-level radioactive waste (cubic yards)	1,800 to 2,800	1,800 to 2,800	3,900 to 183,000
Transuranic Waste			
Contact-handled (cubic yards) [a]	3,500 to 5,900	3,500 to 5,900	5,300 to 33,000
Remote-handled (cubic yards)	–	–	11 to 61
Construction and demolition debris [c] **(cubic yards)**	198,000	197,000	642,000 to 722,000
Chemical waste [d] **(pounds)**	19,000,000 to 37,000,000	19,000,000 to 36,000,000	64,000,000 to 129,000,000
Liquid Radioactive Waste			
Liquid transuranic waste (gallons)	300,000	300,000	500,000
Liquid low-level radioactive waste (at TA-50) (gallons)	40,000,000	40,000,000	50,000,000
Liquid low-level radioactive waste (at TA-53) (gallons)	1,400,000	50,000 [e]	1,400,000

TA = technical area.

[a] Operations waste volumes are assumed to be contact-handled transuranic waste and packaged low-level radioactive waste, although small volumes of other types could be generated.

[b] The subcategories of low-level radioactive waste do not necessarily meet precise definitions, but are used to assist in the analysis of disposal and transportation options and impacts.
- Bulk low-level radioactive waste = wastes that can be transported in large volumes in soft-sided containers.
- Packaged low-level radioactive waste = typical low-level radioactive waste packaged in drums or boxes.
- High-activity low-level radioactive waste = waste exceeding 10 CFR 61.55 Class A concentrations (greater than 10 nanocuries per gram of transuranic nuclides) and therefore is not accepted at certain facilities.
- Remote-handled low-level radioactive waste = waste with a dose rate exceeding 200 millirem per hour at the surface of the container.

[c] Construction and demolition debris includes uncontaminated wastes such as steel, brick, concrete, pipe, and vegetative matter from land clearance.

[d] Chemical waste includes wastes regulated under the Resource Conservation and Recovery Act, Toxic Substance Control Act, or state hazardous waste regulations.

[e] Under the Reduced Operations Alternative, operations at LANSCE would cease. Approximately 5,000 gallons (20,000 liters) of radioactive liquid waste per year from TA-50 would continue to be treated at TA-53.

Note: To convert cubic yards to cubic meters, multiply by 0.76456; gallons to liters, multiply by 3.78533; for pounds to kilograms, multiply by 0.45359. Values have been rounded to the nearest hundred, thousand, or million.

Wastewaters are collected and managed in systems designed for each specific category of wastewater – sanitary liquid waste, high explosives-contaminated liquid waste, and industrial effluent. Sanitary wastes from across the LANL facility are delivered by dedicated pipeline to the Sanitary Wastewater System Plant at TA-46. The Sanitary Wastewater System Plant design capacity of 600,000 gallons (2.3 million liters) per day (DOE 1999a) is expected to be adequate for demand under the No Action Alternative. The treated wastewater is pumped to TA-3 for recycling in the Steam Plant cooling towers or is discharged into Outfall 001. Reuse of treated sanitary wastewater is expected to continue. Sludge from the treatment of sanitary wastewater will continue to be disposed of offsite as a New Mexico special waste. Offsite disposal capacity is expected to be adequate. (See Chapter 4, Section 4.9.1, for more details on sanitary wastewater treatment.)

Wastewaters containing high explosives compounds are generated by high explosives testing and processing activities. The High Explosives Wastewater Treatment Facility, located in TA-16, treats process waters containing high explosives compounds. Under the No Action Alternative, the High Explosives Wastewater Treatment Facility is expected to continue to operate within the 170,000-gallon (640,000-liter) projection for annual discharges included in the *1999 SWEIS* (DOE 1999a). (See Chapter 4, Section 4.9.1.3, for additional discussion of high explosives treatment.)

Industrial effluent is discharged to a number of NPDES-permitted outfalls across LANL. Currently, LANL facilities discharge wastewater to a total of 21 outfalls, down from the 55 identified in the *1999 SWEIS* (LANL 2005h). LANL's projected industrial effluent discharges would be approximately 280 million gallons (1.1 billion liters) per year under the No Action Alternative (see Section 5.3.1). (See Chapter 4, Section 4.9.1.4, for more details on industrial effluents.)

Sanitary waste generated at LANL is generally managed at a transfer station, where solid waste is sorted and consolidated for transport to an offsite landfill (LANL 2005a, 2006a. LANL conducts an aggressive waste minimization and recycling program, which greatly reduces the amount of sanitary waste requiring disposal (LANL 2004l). Sanitary solid waste includes both routine and nonroutine wastes. Routine waste is waste produced from any type of periodic or recurring work, including waste produced from production operations; analytical, and/or research and development laboratory operations; and treatment, storage, and disposal facility operations. Under the No Action Alternative, routine sanitary waste quantities are expected to be bounded at 5,000 tons (4,500 metric tons) per year.

Nonroutine waste is defined as one-time operations waste, including waste produced from construction, environmental restoration, and DD&D activities (LANL 2003e). Nonroutine waste quantities are projected for construction, DD&D, and environmental restoration wastes in the sections that follow. (Solid wastes from environmental restoration may be sent directly to an offsite facility rather than being processed through the transfer station.) Under the No Action Alternative, three major construction projects would generate significant quantities of construction wastes: TA-16 Refurbishment, Chemistry and Metallurgy Research Replacement Facility at TA-55, and consolidation of certain activities at the Dynamic Experimentation Complex at TA-6, TA-22, and TA-40. Construction wastes associated with these projects are expected to total about 12,000 cubic yards (9,200 cubic meters) (DOE 2002l, 2003d, 2003e). Generally, construction wastes may be disposed of in a solid waste landfill or a construction and demolition debris landfill; offsite disposal capacity is expected to be adequate.

Under the No Action Alternative, DD&D wastes would be generated by six projects, as detailed in **Table 5–38**. Although large quantities of demolition debris and low-level radioactive waste could be generated under this alternative, most wastes could be disposed of offsite and offsite capacity is expected to be sufficient. Chemistry and Metallurgy Research Building DD&D would likely not occur until after 2015, after the new Chemistry and Metallurgy Research Replacement Facility is operational. Waste generated by the demolition process for that structure would likely involve both onsite and offsite disposal capacity.

Table 5–38 Wastes from Decontamination, Decommissioning, and Demolition Activities – No Action Alternative (cubic yards)

Decontamination, Decommissioning, and Demolition Project	*Bulk Low-Level Radioactive Waste*	*Packaged Low-Level Radioactive Waste*	*Mixed Low-Level Radioactive Waste*	*Demolition Debris*	*Chemical Waste [a] (pounds)*
TA-16	8	3	–	5,800	51,000
Los Alamos Site Office	–	–	–	10,000	486,000
General Excess Facilities	13,900	4,600	26	128,000	246,000
Dynamic Experimentation Buildings [b]	–	20	–	21,000	781,000
Chemistry and Metallurgy Research Building [c]	12,000	4,000	280	20,000	280,000
LANSCE Area A [d]	4,000	–	89	520	3,000
Total [e]	30,000	8,700	400	186,000	1,847,000

TA = technical area, RCRA = Resource Conservation and Recovery Act, TSCA = Toxic Substances Control Act, LANSCE = Los Alamos Neutron Science Center.

[a] Chemical waste includes RCRA hazardous waste and TSCA waste (asbestos).

[b] Values from *Dynamic Experimentation EA* (DOE 2003e).

[c] Values from the *Chemistry and Metallurgy Research Building Replacement EIS* (DOE 2003d) and *Preliminary Chemistry and Metallurgy Research Building Disposition Study* (LANL 2003a).

[d] Values from the *1999 SWEIS* (DOE 1999a) and *National Environmental Policy Act Review LAN-05-018* (LANL 2006a).

[e] Totals may not add due to rounding.

Note: To convert cubic yards to cubic meters, multiply by 0.76456.

Wastes generated by LANL's environmental restoration activities are presented separately from operational wastes. These nonroutine waste quantities vary widely from year to year and could differ significantly from projections due to selection of remedies and actual site-specific conditions encountered during field activities. Low-level radioactive waste generated by LANL's environmental restoration activities could be disposed of onsite at TA-54 Area G or offsite at a commercial or DOE disposal facility. Chemical waste quantities generated by LANL's environmental restoration activities are expected to be substantial (LANL 2004g); however, offsite capacity for all waste types is expected to be sufficient.

The expected impacts of waste generation are discussed below for each category of chemical and radioactive waste. Projections of chemical and radioactive waste quantities are presented in **Table 5–39**. The information presented is based on the *1999 SWEIS* projections, which were updated with information from the *Waste Volume Forecast* prepared in June 2003 (LANL 2003e) and updated in September 2004 (LANL 2004g) and information from LANL staff (LANL 2006a). The *Forecast* integrates historical generation data with near- and long-term program plans (LANL 2003e). To aid the analysis, waste categories were further characterized as routine or nonroutine.

Table 5–39 Radioactive and Chemical Waste Projections from Routine Operations – No Action Alternative

Key and Non-Key Facilities	Waste Projections (cubic yards per year) [a]			
	Low-Level Radioactive Waste	Mixed Low-Level Radioactive Waste	Transuranic Waste	Chemical Waste (pounds per year)
Chemistry and Metallurgy Research Building [b]	2,400 [b]	25	55 [b]	24,000
Sigma Complex	1,300	5	0	22,000
Machine Shops	790	0	0	1,045,000
Materials Science Laboratory	0	0	0	1,300
Metropolis Center [c]	0	0	0	0
High Explosives Processing Facilities	20	<1	0	29,000
High Explosives Testing Facilities	1,200	10 [d]	<1	78,000
Tritium Facilities	630	4	0	3,800
Pajarito Site	190	2	0	8,800
Target Fabrication Facility	13	<1	0	8,400
Bioscience Facilities	45	4	0	29,000
Radiochemistry Facility	350	5	0	7,300
Radioactive Liquid Waste Treatment Facility [e]	330	3	13	880
Los Alamos Neutron Science Center	1,400	1	0	37,000
Solid Radioactive and Chemical Waste Facilities [f]	300 [g]	10 [g]	35	2,000
Plutonium Facility Complex	990	20	440	19,000
Non-Key Facilities	2,000 [h]	40	30 [h]	1,435,000
TOTAL [i]	12,000	130	570	2,749,000

[a] Projected values from *1999 SWEIS* ROD, as documented in the *2004 SWEIS Yearbook* (LANL 2005f), unless otherwise noted. Projections are based upon expected, routine facility operations and do not include wastes from nonroutine events such as chemical cleanouts and construction projects.
[b] Values reflect a pit production level of 20 pits per year.
[c] Value was not projected in the *1999 SWEIS* ROD. The Metropolis Center was not a designated Key Facility at that time. No wastes are projected for this facility.
[d] Value adjusted upward from *1999 SWEIS* projection based on projected waste volumes resulting from hydrotesting activities (LANL 2006a).
[e] Values adjusted from *1999 SWEIS* projections based on historical generation rates and new projections (LANL 2006a).
[f] This Key Facility includes the Legacy Transuranic Waste Retrieval Program and the Off-Site Source Recovery Project.
[g] Value adjusted upward from *1999 SWEIS* ROD projection based on projections in the 2004 revision to the *Waste Volume Forecast* (LANL 2004g).
[h] Value adjusted upward from *1999 SWEIS* projection based on historical generation rates and projections in the 2004 revision to the *Waste Volume Forecast* (LANL 2004g). Low-level radioactive waste increases are attributable to heightened activities and new construction. Transuranic waste increases are attributable to waste generated by the Off-Site Source Recovery Project; because this waste comes from shipping and receiving, it is attributed to non-Key Facilities (LANL 2006g).
[i] Totals may not add because all values have been rounded.

Note: To convert pounds to kilograms, multiply by 0.45359; for cubic yards to cubic meters, multiply by 0.76456. Values have been rounded to the nearest hundred, thousand, or million.

Low-Level Radioactive Wastes—Routine low-level radioactive waste generation has been declining (LANL 2003e) and is expected to continue in this direction under the No Action Alternative. Some fluctuations in facility-specific generation rates are expected. For example, the High Explosives Testing Key Facilities, due to increased numbers of hydrotests, are projected to double their average low-level radioactive waste generation (LANL 2004g). In addition, relocating the actinide processing and recovery capability to the Chemistry and Metallurgy Research Replacement Facility may increase low-level radioactive waste quantities by up to 24 cubic yards (18 cubic meters) per year (DOE 2003d). Table 5–39 presents the projected annual low-level radioactive waste quantities from routine operations at Key and non-Key Facilities. The TA-54 Area G expansion into Zone 4 is designed to provide 40 years of disposal capacity for operational low-level radioactive waste, assuming a disposal rate of about 3,900 cubic yards (3,000 cubic meters) per year. In addition, offsite disposal capacity is available and, together with onsite capacity, is expected to be adequate for wastes generated under the No Action Alternative.

Mixed Low-Level Radioactive Wastes—The pattern for mixed low-level radioactive waste generation is similar to that for low-level radioactive waste, with routine generation declining and LANL's environmental restoration-generated quantities varying widely (LANL 2004g). Table 5–39 presents the projected annual mixed low-level radioactive waste quantities from routine operations at Key and non-Key Facilities.

Transuranic and Mixed Transuranic Wastes—In the *Waste Volume Forecast*, transuranic and mixed transuranic categories have been combined for discussion; both waste categories are managed for disposal at WIPP. Higher generation rates, up to about 1600 cubic yards (1,200 cubic meters) per year LANL-wide, are projected for the short term (2005 through 2007), primarily due to activities under the Legacy Transuranic Waste Retrieval Program and several nuclear materials programs (LANL 2004g). The Nuclear Materials Technology vault cleanout would contribute nonroutine transuranic wastes for the short term. Pit production activities (up to 20 pits per year) are expected to yield quantities of transuranic and mixed transuranic wastes at the Plutonium Facility Complex. Relocating the actinide processing and recovery capability to the Chemistry and Metallurgy Research Replacement Facility may increase transuranic waste quantities by 8 cubic yards (6.1 cubic meters) per year (DOE 2003c). After 2007, most transuranic wastes would be generated through routine activities (LANL 2003e). The WIPP capacity attributed to newly-generated transuranic waste from LANL is about 14,000 cubic yards (10,800 cubic meters) (DOE 2002f), which is expected to be adequate for wastes generated under the No Action Alternative. Table 5–39 presents the projected annual transuranic quantities from routine operations at Key and non-Key Facilities.

Chemical Wastes—Routine chemical waste generation has been trending downward (LANL 2003e) and is expected to continue in this direction under the No Action Alternative. Bulk chemical wastes generated by LANL operations and environmental restoration activities make up approximately 90 percent of the chemical and hazardous waste generated across LANL (LANL 2003e). Although LANL's environmental restoration waste quantities are highly variable, operational bulk chemical waste is generated primarily at the Sanitary Wastewater Systems Plant in steady quantities. Nonbulk chemical and hazardous wastes are generated by a wide range of operations at LANL (LANL 2004g). Approximately half of the nonbulk chemical waste is not regulated as hazardous by the State of New Mexico, but this waste does not meet waste acceptance criteria for disposal at a solid waste landfill (LANL 2003e). Generation rates for nonbulk chemical and hazardous wastes from operations are expected to remain steady under the No Action Alternative (LANL 2003e). Scheduled cleanouts of outdated or unused chemicals periodically could increase annual quantities for specific facilities (LANL 2004g). Table 5–39 presents the projected annual chemical waste quantities from routine operations at Key and non-Key Facilities.

Radioactive Liquid Waste Treated at LANL—Radioactive liquid waste is treated at three locations, TA-21, TA-50 and TA-53. Treatment at TA-21 would continue only until all DD&D activities at this TA are complete. The Radioactive Liquid Waste Treatment Facility at TA-50 continues to treat the majority of radioactive liquid wastes generated at LANL. Treated radioactive liquid waste quantities at the Radioactive Liquid Waste Treatment Facility, including acid and caustic radioactive liquid waste treated in Room 60, are projected in **Table 5–40**. If hydrotesting activities at the High Explosives Testing Facilities continue to use foam as a containment matrix, up to 66,000 gallons (250,000 liters) of additional radioactive liquid waste annually may be treated at the Radioactive Liquid Waste Treatment Facility, but these quantities are well within projected treatment volumes. Quantities of radioactive liquid wastes at TA-53 are also included in Table 5–40.

Table 5–40 Radioactive Liquid Waste Treated at Los Alamos National Laboratory – No Action Alternative

Waste Treatment Activity	*Projection*
Pretreatment of radioactive liquid waste at TA-21	(a)
Pretreatment of transuranic liquid waste from TA-55 in Room 60	30,000 gallons (110,000 liters) per year
Solidification of transuranic sludge at TA-50	16 cubic yards (12 cubic meters) per year
Radioactive liquid waste treated at TA-50	4,000,000 gallons (15,000,000 liters) per year
Secondary treatment of radioactive liquid waste at TA-50	260,000 gallons (1,000,000 liters) per year
De-water low-level radioactive waste sludge at TA-50	70 cubic yards (50 cubic meters) per year
Radioactive liquid waste treated at TA-53	140,000 gallons (520,000 liters) per year [b]
Transport evaporator bottoms to Tennessee	66,000 gallons (250,000 liters) per year
Receive solidified evaporator bottoms from Tennessee [c]	25 cubic yards (20 cubic meters) per year

TA = technical area, LANSCE = Los Alamos Neutron Science Center.

[a] No new radioactive liquid waste is being generated at TA-21, and all inventory that existed in tanks and equipment was processed or transported to TA-54 in 2006.

[b] Radioactive liquid waste treated at TA-53 includes waste volumes from LANSCE plus approximately 5,000 gallons (20,000 liters) per year from TA-50.

[c] This is solid low-level radioactive waste that is disposed of at TA-54.

Source: LANL 2006a.

Summary—Waste management impacts from LANL operations under the No Action Alternative are expected to remain within the capacity of the LANL waste management infrastructure. **Table 5–41** summarizes the waste quantities estimated for operations, DD&D, and environmental restoration activities under the No Action Alternative. Although the summary table provides waste projections only through 2016, impacts from operations are expected to continue at comparable rates for the longer term. For operational waste, waste projections are presented as a range, with the lower end of the range representing the quantity projected in the *Waste Volume Forecast* (LANL 2004g) and the upper end representing the *1999 SWEIS* projection, except as noted. For this summary table, the transuranic and low-level radioactive waste categories have been further subdivided (contact- and remote-handled transuranic) to facilitate identification of offsite disposal options and analysis of transportation impacts.

Table 5–41 Summary of Waste Types by Generator Category – No Action Alternative (Cumulative 2007 through 2016) (in cubic yards)

Waste Type	*Operational Waste* [a]	*DD&D Waste* [b]	*Remediation Waste* [c]	*Total*
Low-Level Radioactive Waste [d]				
Bulk low-level radioactive waste	–	30,000	8,800	39,000
Packaged low-level radioactive waste	25,000 to 120,000	8,700	–	33,000 to 128,000
High Activity low-level radioactive waste	–	–	–	–
Remote-handled low-level radioactive waste	–	–	–	–
Mixed Low-Level Radioactive Waste	270 to 1,300	400	1,100	1,800 to 2,800
Transuranic Waste				
Contact-handled	3,300 to 5,700	0	210	3,500 to 5,900
Remote-handled	–	–	–	–
Construction and Demolition Debris [e]	12,000 [f]	186,000	–	198,000
Chemical Waste [g] **(pounds)**	9,997,000 to 27,000,000	1,847,000	7,513,000	19,000,000 to 37,000,000

DD&D = decontamination, decommissioning, and demolition; TA = technical area; LANSCE = Los Alamos Neutron Science Center; MDA = material disposal area; CMRR = Chemistry and Metallurgy Research Replacement.

[a] Operations waste volumes are represented as a range, with the lower end represented by best-estimate values documented in the Waste Volume Forecasts (LANL 2003e, 2004g), and the upper end represented by the bounding *1999 SWEIS* projections (DOE 1999a), adjusted as detailed in Table 5–39. These wastes are assumed to be contact-handled transuranic waste and packaged low-level radioactive waste, although small volumes of other types could be generated.

[b] DD&D waste quantities were estimated for the following projects: TA-16 Refurbishment, Los Alamos Site Office Building Replacement, General Excess Facilities, CMRR Facility, LANSCE Area A Renovation, and consolidation of certain activities at the Dynamic Experimentation Complex at TA-6, TA-22, and TA-40.

[c] Details of LANL's environmental restoration activities and resulting wastes are provided in Appendix I.

[d] The subcategories of low-level radioactive waste do not necessarily meet precise definitions, but are used to assist in the analysis of disposal and transportation options and impacts.
- Bulk low-level radioactive waste = wastes that can be transported in large volumes in soft-sided containers.
- Packaged low-level radioactive waste = typical low-level radioactive waste packaged in drums or boxes.
- High-activity low-level radioactive waste = waste exceeding 10 CFR 61.55 Class A concentrations (greater than 10 nanocuries per gram of transuranic nuclides), which is not accepted at certain facilities.
- Remote-handled low-level radioactive waste = waste with a dose rate exceeding 200 millirem per hour at the surface of the container.

[e] Construction and demolition debris includes uncontaminated wastes such as steel, brick, concrete, pipe, and vegetative matter from land clearance.

[f] Construction debris quantities were estimated for the following projects: TA-16 Refurbishment, Chemistry and Metallurgy Research Replacement Facility, and consolidation of certain activities at the Dynamic Experimentation Complex at TA-6, TA-22, and TA-40.

[g] Chemical waste includes wastes regulated under Resource Conservation and Recovery Act, Toxic Substance Control Act, or state hazardous waste regulations.

Note: To convert cubic yards to cubic meters, multiply by 0.76456; for pounds to kilograms, multiply by 0.45359. Totals may not add because values have been rounded to the nearest hundred, thousand, or million.

Most wastes, with the exception of some low-level radioactive waste, are disposed of offsite at permitted facilities designed for specific categories of wastes. The expansion of TA-54 Area G into Zone 4 is expected to provide onsite low-level radioactive waste disposal capacity for operations waste through the 2016 timeframe and beyond. Because of the difficulties in accurately predicting the volumes of wastes generated by LANL's environmental restoration activities, some variances from projections are possible in future years. The waste management infrastructure at LANL has adequate staffing and facilities to manage the quantities of waste expected to be generated under the No Action Alternative.

5.9.2 Reduced Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Many of the waste management impacts under the Reduced Operations Alternative would be the same as those under the No Action Alternative. Wastewaters, including sanitary liquid waste, high explosives-contaminated liquid waste, and industrial effluent, would be collected and managed in systems designed for each category of waste. High explosive-contaminated waste quantities would be reduced by about 20 percent as operations are scaled back at the High Explosives Processing and Testing Facilities. Sanitary waste generated at LANL would generally be managed at a transfer station, where solid waste is sorted and consolidated for transport to an offsite landfill (LANL 2005a). (Solid waste from environmental restoration may be sent directly to an offsite facility rather than through the transfer station.) As discussed under the No Action Alternative, waste minimization and recycling activities would reduce the quantities of solid waste disposed of. Waste management impacts associated with construction and DD&D activities would be similar to those for the No Action Alternative. Construction waste from the Chemistry and Metallurgy Research Replacement Facility would be about 500 cubic yards (382 cubic meters) smaller than that for the No Action Alternative, and DD&D of the Chemistry and Metallurgy Research Building may be further delayed beyond 2015.

Under the Reduced Operations Alternative, smaller quantities of some radioactive and chemical wastes would be generated due to shutdown of the Pajarito Site and LANSCE, as well as reductions in high explosives processing and testing. Projections of chemical and radioactive waste quantities from routine operations at Key and non-Key Facilities are presented in **Table 5–42**.

Radioactive liquid waste treatment would be the same as under the No Action Alternative, with the exception of limited treatment at TA-53 as LANSCE operations are halted; some liquid wastes with high tritium content from TA-50 could continue to be processed at TA-53. Radioactive liquid waste treatment quantities are presented in **Table 5–43**.

Table 5–42 Radioactive and Chemical Waste Projections from Routine Operations – Reduced Operations Alternative

Key and Non-Key Facilities	Waste Projections (cubic yards per year) [a]			
	Low-Level Radioactive Waste	Mixed Low-Level Radioactive Waste	Transuranic Waste	Chemical Waste (pounds per year)
Chemistry and Metallurgy Research Building [b]	2,400	25	55	24,000
Sigma Complex	1,300	5	0	22,000
Machine Shops	790	0	0	1,045,000
Materials Science Laboratory	0	0	0	1,300
Metropolis Center [c]	0	0	0	0
High Explosives Processing Facilities	15 [d]	<1 [d]	0	23,000 [d]
High Explosives Testing Facilities	980 [d]	8	<1 [d]	62,000 [d]
Tritium Facilities	630	4	0	3,800
Pajarito Site [f]	0	0	0	0
Target Fabrication Facility	13	<1	0	8,400
Bioscience Facilities	45	4	0	29,000
Radiochemistry Facility	350	5	0	7,300
Radioactive Liquid Waste Treatment Facility [g]	330	3	13	880
Los Alamos Neutron Science Center [h]	5	1	0	0
Solid Radioactive and Chemical Waste Facilities [i]	300 [j]	10 [j]	35	2,000
Plutonium Facility Complex	990	20	440	19,000
Non-Key Facilities	2,000 [k]	40	30 [k]	1,435,000
Total [l]	10,000	130	570	2,682,000

[a] Projected values are from the *1999 SWEIS* ROD, as documented in the *2004 SWEIS Yearbook* (LANL 2005f), unless otherwise noted. Projections are based upon expected, routine facility operations and do not include wastes from nonroutine events such as chemical cleanouts and construction projects.
[b] Values reflect a pit production level of 20 pits per year.
[c] Value was not projected in *1999 SWEIS* ROD. The Metropolis Center was not a designated Key Facility at that time.
[d] A 20 percent reduction from No Action levels is projected, based on a 20 percent reduction in operations.
[e] Value adjusted upward from 1999 SWEIS projection based on projected waste volumes from hydrotesting activities (LANL 2006a).
[f] No wastes would be generated at TA-18 as activities are ceased.
[g] Values adjusted from *1999 SWEIS* projections based on historical generation rates and new projections (LANL 2006a).
[h] Only small quantities of waste would be generated as LANSCE operations are halted and the facility is maintained in standby mode.
[i] This Key Facility includes the Legacy Transuranic Waste Retrieval Program and the Off-Site Source Recovery Project.
[j] Value adjusted upward from *1999 SWEIS* ROD projection based on projections in the 2004 revisions to the *Waste Volume Forecast* (LANL 2004g).
[k] Value adjusted upward from *1999 SWEIS* projection based on historical generation rates and projections in the 2004 revisions to the *Waste Volume Forecast* (LANL 2004g). Low-level radioactive waste increases are attributable to heightened activities and new construction. Transuranic waste increases are attributable to waste generated by the Off-Site Source Recovery Project; because this waste comes from shipping and receiving, it is attributed to non-Key Facilities.
[l] Totals may not add due to rounding. Values have been rounded to the nearest hundred, thousand, or million.
Note: To convert cubic yards to cubic meters, multiply by 0.76456; for pounds to kilograms, multiply by 0.45359.

Table 5–43 Radioactive Liquid Waste Treated at Los Alamos National Laboratory – Reduced Operations Alternative

Waste Treatment Activity	*Projection*
Pretreatment of radioactive liquid waste at TA-21	(a)
Pretreatment of transuranic liquid waste from TA-55 in Room 60	30,000 gallons (110,000 liters) per year
Solidification of transuranic sludge at TA-50	16 cubic yards (12 cubic meters) per year
Radioactive liquid waste treated at TA-50	4,000,000 gallons (15,000,000 liters) per year
Secondary treatment of radioactive liquid waste at TA-50	260,000 gallons (1,000,000 liters) per year
De-water low-level radioactive waste sludge at TA-50	70 cubic yards (50 cubic meters) per year
Radioactive liquid waste treated at TA-53	5,000 gallons (20,000 liters) per year [b]
Transport evaporator bottoms to Tennessee	66,000 gallons (250,000 liters) per year
Receive solidified evaporator bottoms from Tennessee [c]	25 cubic yards (20 cubic meters) per year

TA = technical area.
[a] No new radioactive liquid waste is being generated at TA-21, and all inventory that existed in tanks and equipment was processed or transferred to TA-54 in 2006.
[b] Under the Reduced Operations Alternative, operations at the LANSCE facility would cease. Approximately 5,000 gallons (20,000 liters) of radioactive liquid waste per year from TA-50 would continue to be treated at TA-53.
[c] This is solid low-level radioactive waste that is disposed of at TA-54.
Source: LANL 2006a.

Summary—Waste management impacts from LANL operations under the Reduced Operations Alternative are expected to be similar to those under the No Action Alternative, with some reductions in waste quantities due to the closure of LANSCE and the Pajarito Site and reduced operational levels at the High Explosives Facilities. **Table 5–44** summarizes the waste quantities estimated for operations, DD&D, and environmental restoration activities under the Reduced Operations Alternative. Although the summary table provides waste projections only through 2016, impacts from operations are expected to continue at comparable rates for the longer term. For operational waste, waste projections are presented as a range, with the lower end of the range representing the quantity projected in the *Waste Volume Forecast* (LANL 2004g) and the upper end representing the *1999 SWEIS* projection, except as noted. The waste management infrastructure at LANL has adequate staffing and facilities to manage the quantities of waste expected to be generated under the Reduced Operations Alternative.

5.9.3 Expanded Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Many of the waste management impacts under the Expanded Operations Alternative would be the same as under the No Action Alternative although certain waste volumes would periodically increase. Wastewaters, including sanitary liquid waste, high explosives-contaminated liquid waste, and industrial effluent, would be collected and managed in systems designed for each category of waste. Sanitary waste generated at LANL would generally be managed at a transfer station where solid waste is sorted and consolidated for transport to an offsite landfill (LANL 2005a). (Large quantities of solid wastes from construction, DD&D, and environmental restoration may be shipped directly to an offsite disposal facility rather than being processed through the transfer station.) Waste minimization and recycling activities would reduce the quantities of solid waste disposed of.

Table 5–44 Summary of Waste Types by Generator Category – Reduced Operations Alternative (Cumulative 2007 through 2016) (in cubic yards)

Waste Type	*Operational Waste* [a]	*DD&D Waste* [b]	*Remediation Waste* [c]	*Total*
Transuranic Waste				
Contact-handled	3,300 to 5,700	–	210	3,500 to 5,900
Remote-handled	–	–	–	–
Low-Level Radioactive Waste [d]				
Bulk low-level radioactive waste	–	30,000	8,800	39,000
Packaged low-level radioactive waste	25,000 to 101,000	8,700	–	33,000 to 110,000
High-activity low-level radioactive waste	–	–	–	–
Remote-handled low-level radioactive waste	–	–	–	–
Mixed Low-Level Radioactive Waste	270 to 1,300	400	1,100	1,800 to 2,800
Construction and Demolition Debris [e]	12,000 [f]	186,000	–	198,000
Chemical Waste [g] **(pounds)**	9,997,000 to 27,000,000	1,847,000	7,513,000	19,000,000 to 36,000,000

DD&D = decontamination, decommissioning, and demolition.

[a] Operations waste volumes are represented as a range, with the lower end represented by best-estimate values documented in the *Waste Volume Forecasts* (LANL 2003e, 2004g) and the upper end represented by the bounding *1999 SWEIS* projections (DOE 1999a), adjusted as detailed in Table 5–42. These wastes are assumed to be contact-handled transuranic waste and packaged low-level radioactive waste, although small volumes of other types could be generated.

[b] DD&D waste quantities are the same as those under the No Action Alternative.

[c] Environmental restoration-related waste quantities are the same as those under the No Action Alternative. These waste estimates do not include an additional 600 cubic yards of chemical waste, and 4,800 cubic yards of bulk low-level radioactive waste may be generated by a removal action.

[d] The subcategories of low-level radioactive waste do not necessarily meet precise definitions, but are used to assist in the analysis of disposal and transportation options and impacts.
- Bulk low-level radioactive waste = wastes that can be transported in large volumes in soft-sided containers.
- Packaged low-level radioactive waste = typical low-level radioactive waste packaged in drums or boxes.
- High-activity low-level radioactive waste = waste exceeding 10 CFR 61.55 Class A concentrations (greater than 10 nanocuries per gram of transuranic nuclides), which is not accepted at certain facilities.
- Remote-handled low-level radioactive waste = waste with a dose rate exceeding 200 millirem per hour at the surface of the container.

[e] Construction and demolition debris includes uncontaminated wastes such as steel, brick, concrete, pipe, and vegetative matter from land clearance.

[f] Construction debris quantities are about 500 cubic yards (382 cubic meters) smaller than those for the No Action Alternative.

[g] Chemical waste includes wastes regulated under RCRA, TSCA, or state hazardous waste regulations.

Note: To convert cubic yards to cubic meters, multiply by 0.76456; for pounds to kilograms, multiply by 0.45359. Totals may not add because values have been rounded to the nearest hundred, thousand, or million.

Waste management impacts associated with DD&D activities would increase under the Expanded Operations Alternative, as detailed in **Table 5–45**. Large quantities of demolition debris and bulk low-level radioactive waste wastes are expected from DD&D actions, along with smaller quantities of transuranic and mixed low-level radioactive waste and sanitary, asbestos, and hazardous wastes. Most of the waste would be disposed of offsite. Demolition debris may be sent to any solid waste landfill permitted to accept it. Low-level radioactive waste may be disposed of at TA-54 Area G or sent offsite to DOE or commercial facilities. Additional construction waste would be generated as new facilities are constructed under this alternative. **Table 5–46** summarizes the quantities of construction wastes associated with major new construction under the Expanded Operations Alternative.

Table 5–45 Wastes from Decontamination, Decommissioning, and Demolition Activities – Expanded Operations Alternative (cubic yards)

DD&D Project	*Contact-Handled Transuranic Waste*	*Bulk Low-Level Radioactive Waste*	*Packaged Low-Level Radioactive Waste*	*Mixed Low-Level Radioactive Waste*	*Demolition Debris*	*Chemical Waste [a] (pounds)*
No Action Total [b]	–	30,000	8,700	400	186,000	1,847,000
Physical Science Research Complex	–	13,000	4,300	< 1	177,000	314,000
Replacement Office Buildings	–	23	8	–	6,900	–
Radiological Sciences Institute	1,100 [c]	72,000	23,000 [c]	1,000	77,000	988,000
Radioactive Liquid Waste Treatment Facility Upgrade [d]	230	7,700	2,600	150	1,800	212,000
Plutonium Refurbishment	340	970	320	220	2,100	2,000
TA-18 Closure	–	4,700	–	5	17,000	75,000
TA-21 Structure	1	26,000	8,600	65	47,000	422,000
Waste Management Facilities Transition	–	23,000	7,600	8	54,000	566,000
Total [e]	1,700	177,000	56,000	1,900	569,000	4,425,000

DD&D = decontamination, decommissioning, and demolition; RCRA = Resource Conservation and Recovery Act; TSCA = Toxic Substances Control Act.

[a] Chemical waste includes RCRA hazardous waste and TSCA waste (asbestos).

[b] Details of the DD&D waste volumes generated under the No Action Alternative are provided in Table 5–38.

[c] In addition to these volumes, DD&D associated with the Radiological Sciences Institute is expected to generate 479 cubic yards of remote-handled low-level radioactive waste and 11 cubic yards of remote-handled transuranic waste.

[d] Waste volumes reflect the option that generates the most waste.

[e] Totals may not add because all values have been rounded to the nearest hundred, thousand, or million.

Note: To convert cubic yards to cubic meters, multiply by 0.76456.

Table 5–46 Construction Wastes [a] – Expanded Operations Alternative

Construction Project	*Waste Generated (cubic yards)*
No Action Total	12,000
Physical Science Research Complex	1,600
Replacement Office Buildings	1,700
Radiological Sciences Institute	2,800
Radioactive Liquid Waste Treatment Facility Upgrade	1,200
TA-55 Radiography Facility	24
Plutonium Facility Complex Refurbishment	690
Science Complex	3,300
Remote Warehouse and Truck Inspection Station	610
Waste Management Facilities Transition	500
Security-Driven Transportation Modifications	1,500
Total	26,000

TA = technical area.

[a] Construction debris includes uncontaminated wastes such as steel, brick, concrete, pipe and vegetative matter from land clearance.

Note: Totals may not add because values have been rounded to the nearest hundred, thousand, or million.

The type and extent of many environmental restoration activities that would be required by the New Mexico Environment Department are not yet known. To assess impacts under this uncertainty, LANL's MDA remediation activities were analyzed under two scenarios, the Capping Option and the Removal Option. The waste management impacts associated with both scenarios are presented here.

MDA remediation wastes would be generated under the Capping Option, with substantial quantities of demolition and low-level radioactive waste expected. Variations in actual versus projected waste quantities are expected for these wastes due to the difficulty in predicting selected environmental remedies and waste types and quantities. In addition, no credit was taken for waste volume reduction techniques, such as sorting.

Much greater quantities of MDA remediation wastes would be generated under the Removal Option than under the No Action Alternative because of the substantial quantities of demolition debris and low-level radioactive waste expected. The closure of some TA-54 Area G facilities and the subsequent remediation of the area would generate large quantities of demolition debris and low-level radioactive waste. Industrial, hazardous, and low-level radioactive liquid wastes also would be generated by remedial actions. These liquid wastes would be treated onsite at existing LANL facilities.

Under the Expanded Operations Alternative, larger quantities of some radioactive and chemical wastes would be generated due to increased levels of operations at various facilities. Expanded actinide activities at the Chemistry and Metallurgy Research Replacement Facility, increased pit production (up to 80 pits per year) at the Plutonium Facility Complex, and increased recovery of sealed sources under the Off-Site Source Recovery Project would result in larger quantities of transuranic and low-level radioactive wastes. Increased pit production is projected to annually result in about 240 cubic yards (180 cubic meters) of additional contact-handled transuranic waste. In addition, activities at TA-55 in support of mixed oxide fuel fabrication could generate additional quantities of transuranic waste (LANL 2004g). Projections of chemical and radioactive waste quantities from routine operations at Key and non-Key Facilities are presented in **Table 5–47**.

Radioactive liquid waste treatment volumes are expected to increase under the Expanded Operations Alternative due to increased pit production and activities in support of mixed oxide fuel fabrication. The TA-21 demolition work is expected to generate about 8,400 gallons (32,000 liters) of low-level radioactive liquid waste, which would be treated at the Radioactive Liquid Waste Treatment Facility in TA-50. Radioactive liquid waste treatment quantities are presented in **Table 5–48**.

Table 5–47 Radioactive and Chemical Waste Projections from Routine Operations – Expanded Operations Alternative

Key and Non-Key Facilities	*Waste Projections (cubic yards per year)* [a]			
	Low-Level Radioactive Waste	***Mixed Low-Level Radioactive Waste***	***Transuranic Waste***	***Chemical Waste (pounds per year)***
Chemistry and Metallurgy Research Building	2,600 [b]	30 [b]	90 [b]	25,000 [b]
Sigma Complex	1,300	5	0	22,000
Machine Shops	790	0	0	1,045,000
Materials Science Laboratory	0	0	0	1,300
Metropolis Center [c]	0	0	0	0
High Explosives Processing Facilities	20	<1	0	29,000
High Explosives Testing Facilities	1,200	10 [d]	<1	78,000
Tritium Facilities	630	4	0	3,800
Pajarito Site	190	2	0	8,800
Target Fabrication Facility	13	<1	0	8,400
Bioscience Facilities	45	4	0	29,000
Radiochemistry Facility	350	5	0	7,300
Radioactive Liquid Waste Treatment Facility [e]	390	3	18	1,100
Los Alamos Neutron Science Center	1,400	1	0	37,000
Solid Radioactive and Chemical Waste Facilities [f]	300 [g]	10 [g]	35	2,000
Plutonium Facility Complex	1,400 [h]	20	690 [i]	19,000
Non-Key Facilities	2,000 [j]	40	30 [j]	1,435,000
Total [k]	13,000	140	860	2,750,000

[a] Projected values are from the *1999 SWEIS* ROD, as documented in the *2004 SWEIS Yearbook* (LANL 2005f), unless otherwise noted. Projections are based upon expected, routine facility operations and do not include wastes from nonroutine events such as chemical cleanouts and construction projects.
[b] Value taken from *CMRR EIS* (DOE/EIS-0350).
[c] Values not projected in *1999 SWEIS* ROD. The Metropolis Center was not a designated Key Facility at that time.
[d] Value adjusted upward from *1999 SWEIS* projection based on projected waste volumes resulting from hydrotesting activities (LANL 2006a).
[e] Values adjusted from *1999 SWEIS* projections are based on historical generation rates and new projections (LANL 2006a).
[f] This Key Facility includes the Transuranic Waste Retrieval Project and the Off-Site Source Recovery Project.
[g] Value was adjusted upward from *1999 SWEIS* projection based on projections in *Waste Volume Forecast* (LANL 2004g).
[h] Projections for transuranic and low-level radioactive waste assume pit production of up to 80 pits per year, based on *1999 SWEIS* projections (DOE 1999a) and more recent waste estimates (LANL 2005d).
[i] Projections for transuranic and low-level radioactive waste assume pit production of up to 80 pits per year, based on *1999 SWEIS* projections (DOE 1999a) and more recent waste estimates (LANL 2005d). In addition, 46 cubic yards of transuranic waste per year are projected due to activities in support of mixed oxide fuel fabrication (LANL 2004g).
[j] Value was adjusted upward from the *1999 SWEIS* projection based on historical generation rates and projections in the *Waste Volume Forecast* (LANL 2004g). Low-level radioactive waste increases are attributable to heightened activities and new construction. Transuranic waste increases are attributable to waste generated by the Off-Site Source Recovery Project; because this waste comes from shipping and receiving, it is attributed to non-Key Facilities.
[k] Totals may not add because values have been rounded to the nearest hundred, thousand, or million.

Note: To convert cubic yards to cubic meters, multiply by 0.76456; for pounds to kilograms, multiply by 0.45359.

Table 5–48 Radioactive Liquid Waste Treated at Los Alamos National Laboratory – Expanded Operations Alternative

Waste Treatment Activity	*Projection* [a]
Pretreatment of radioactive liquid waste at TA-21	(a)
Pretreatment of transuranic liquid waste from TA-55 in Room 60	50,000 gallons (190,000 liters) per year
Solidification of transuranic sludge at TA-50	22 cubic yards (17 cubic meters) per year
Radioactive liquid waste treated at TA-50	5,000,000 gallons (20,000,000 liters) per year
Secondary treatment of radioactive liquid waste at TA-50	320,000 gallons (1,200,000 liters) per year
De-water low-level radioactive waste sludge at TA-50	80 cubic yards (60 cubic meters) per year
Radioactive liquid waste treated at TA-53	140,000 gallons (520,000 liters) per year [b]
Transport evaporator bottoms to Tennessee	80,000 gallons (300,000 liters) per year
Receive solidified evaporator bottoms from Tennessee [c]	30 cubic yards (23 cubic meters) per year

TA = technical area, LANSCE = Los Alamos Neutron Science Center.
[a] No new radioactive liquid waste is being generated at TA-21, and all inventories that existed in tanks and equipment was processed or transferred to TA-54 in 2006.
[b] Radioactive liquid waste treated at TA-53 includes waste volumes from LANSCE plus approximately 5,000 gallons (20,000 liters) per year from TA-50.
[c] This is solid low-level radioactive waste that is disposed of at TA-54.
Source: LANL 2006a.

Summary—**Table 5–49** summarizes the waste quantities estimated for operations, DD&D, and LANL's environmental restoration activities under the Expanded Operations Alternative. Although the summary table provides waste projections only through 2016, impacts from operations are expected to continue at comparable rates for the longer term. For this summary table, the transuranic and low-level radioactive waste categories have been further subdivided (for example, contact- and remote-handled transuranic) to facilitate identification of offsite disposal options and analysis of transportation impacts. In addition, for the Operational Waste and Remediation Waste categories, the quantities are presented as ranges rather than discrete values. For Operational Waste, the lower end of the range represents the quantity projected in the *Waste Volume Forecast* (LANL 2004g) and the upper end represents the *1999 SWEIS* projection, except as noted.

Waste management impacts from LANL operations under the Expanded Operations Alternative are expected to increase compared to those under the No Action Alternative due to heightened operations at the Plutonium Facility Complex and increased characterization and management activities associated with legacy waste retrieval. Although operational transuranic waste quantities are higher under the Expanded Operations Alternative, waste disposal capacity at WIPP is expected to be adequate, assuming the best estimates are realized. Operational low-level radioactive waste quantities also are expected to increase under this alternative, and use of both onsite and offsite disposal options can be used to manage this waste. As detailed in Appendix H, Section H.3, improvements to the LANL waste management infrastructure would be implemented to ensure safe and efficient management of wastes.

Table 5–49 Summary of Waste Types by Generator Category – Expanded Operations Alternative (Cumulative 2007 through 2016) (in cubic yards)

Waste Type	*Operational Waste* [a]	*DD&D Waste* [b]	*Remediation Waste* [c]	*Total*
Transuranic Waste				
Contact-handled	3,300 to 8,600	1,700	280 to 22,000	5,300 to 33,000
Remote-handled	–	11	0 to 50	11 to 61
Low-Level Radioactive Waste [d]				
Bulk low-level radioactive waste	–	177,000	20,000 to 710,000	196,000 to 884,000
Packaged low-level radioactive waste	25,000 to 127,000	56,000	–	80,000 to 183,000
High-activity low-level radioactive waste	–	–	0 to 347,000	0 to 347,000
Remote-handled low-level radioactive waste	–	480	0 to 1,200	480 to 1,700
Mixed Low-Level Radioactive Waste	270 to 1,400	1,900	1,800 to 180,000	3,900 to 183,000
Construction and Demolition Debris [e]	26,000	569,000	47,000 to 126,000	642,000 to 722,000
Chemical Waste [g] **(pounds)**	9,997,000 to 27,500,000	4,425,000	50,000,000 to 97,000,000	64,000,000 to 129,000,000

DD&D = decontamination, decommissioning, and demolition; RCRA = Resource Conservation and Recovery Act; TSCA = Toxic Substances Control Act.

[a] Operations waste volumes are represented as a range, with the lower end represented by best-estimate values documented in the *Waste Volume Forecasts* (LANL 2003e, 2004g) and the upper end represented by the bounding *1999 SWEIS* projections (DOE 1999a), adjusted as detailed in Table 5–47. These wastes are assumed to be contact-handled transuranic waste and packaged low-level radioactive waste, although small volumes of other types could be generated.

[b] DD&D waste quantities include those under the No Action Alternative, as well as all DD&D wastes estimated to arise from new projects under the Expanded Operations Alternative, as detailed in Table 5–45.

[c] The low and high ends of the ranges correspond to the MDA Capping Option and Removal Option, respectively. See Appendix I for details.

[d] The subcategories of low-level radioactive waste do not necessarily meet precise definitions, but are used to assist in the analysis of disposal and transportation options and impacts.
– Bulk low-level radioactive waste = wastes that can be transported in large volumes in soft-sided containers.
– Packaged low-level radioactive waste = typical low-level radioactive waste packaged in drums or boxes.
– High-activity low-level radioactive waste = waste exceeding 10 CFR 61.55 Class A concentrations (greater than 10 nanocuries per gram of transuranic nuclides), which is not accepted at certain facilities.
– Remote-handled low-level radioactive waste = waste with a dose rate exceeding 200 millirem per hour at the surface of the container.

[e] Construction and demolition debris includes uncontaminated wastes such as steel, brick, concrete, pipe, and vegetative matter from land clearance.

[f] Construction debris quantities include those under the No Action Alternative, as well as all construction wastes estimated to arise from new projects under the Expanded Operations Alternative, as detailed in Table 5–46.

[g] Chemical waste includes waste regulated under RCRA, TSCA, or state hazardous waste regulations.

Note: To convert cubic yards to cubic meters, multiply by 0.76456; for pounds to kilograms, multiply by 0.45359. Totals might not add because values have been rounded to the nearest hundred, thousand, or million.

DD&D activities also are expected to generate large quantities of waste, particularly low-level radioactive waste and uncontaminated debris. The quantities of low-level radioactive waste would exceed the Area G capacity and some portion would require offsite disposal. Uncontaminated debris would be sent offsite for disposal.

For remediation waste, the range is intended to reflect the uncertainty associated with site cleanups. Final decisions on cleanup of MDAs and other PRSs will be made after DOE and LANL investigate the sites and propose remedies to the New Mexico Environment Department, which will then solicit public comment on the proposed remedies and decide what remedies will be implemented. For many of LANL's MDAs and PRSs, investigation is still ongoing and the remedy selection process has not begun. Thus, the remediation process, including the amount of waste generated as a result of the process, is not clearly defined. To adequately address impacts, the remediation process was analyzed under a Capping Option, which would produce relatively small amounts of waste, and a Removal Option, which would involve significant excavations and would produce significantly more waste. These two options, Capping and Removal, represent the lower and upper values, respectively, in the remediation waste summary.

Under the MDA Capping Option, remedial actions would take place at PRSs such as high explosives testing sites and outfalls. Actions at most MDAs would be limited to installing an engineered cover, with the wastes remaining in place. Under this option, moderate quantities of bulk low-level radioactive waste, uncontaminated debris, and chemical wastes would be expected, as well as small quantities of transuranic waste. Offsite disposal of most waste could occur, although some portion of low-level radioactive waste could be disposed of onsite depending upon available capacity and disposal priorities.

Under the MDA Removal Option, the same remedial activities as those under the MDA Capping Option would take place, with one important addition: all MDAs would be exhumed, which would generate very large quantities of waste including transuranic, low-level radioactive, mixed low-level radioactive, uncontaminated debris, and chemical waste. For the uncontaminated debris (managed as solid waste) and chemical waste categories, offsite disposal capacity is expected to be adequate. Quantities of low-level radioactive waste would exceed the planned annual rate of disposal at Area G; decisions regarding onsite or offsite disposal would depend on available capacity, decisions about changes to disposal operations, if any, and disposal priorities.

The transuranic waste volumes projected for the MDA Removal Option involve waste, most of which DOE buried before 1970. These projected volumes are conservative, and may be smaller than that assumed depending on future regulatory decisions by the New Mexico Environment Department. Also, no credit was taken for use of waste volume reduction techniques such as sorting. It was assumed for this SWEIS that all transuranic waste would be disposed of at WIPP. WIPP disposal capacity is expected to be sufficient for disposal of all retrievably stored waste and all newly generated transuranic waste from the DOE complex over the next few decades, but not sufficient for this waste and all transuranic waste buried before 1970 across the complex (63 FR 3624). Decisions about disposal of transuranic waste generated by remediation at LANL, will be based on the needs of the entire DOE complex. If necessary, any transuranic waste that is generated without a disposal pathway would be safely stored until disposal capacity becomes available.

The large quantities of waste resulting from the Removal Option may exceed LANL's waste handling and processing capacity. As needed, additional, augmented, or mobile waste management equipment or facilities could be developed similar to those described in Appendix H, Section H.3.2.2, and Appendix I, Section I.3.3.2.8, of this SWEIS. Modular mobile facilities could be sited at appropriate LANL locations, and moved between remediation sites as needed. These modular facilities could include capacity for safety inspections of removed waste, waste processing and temporary storage, radioactive and chemical analyses, or other support services.

5.10 Transportation

This section summarizes the potential impacts associated with shipping materials to and from LANL to various locations (such as waste disposal sites and other DOE or commercial sites) under both incident-free and accident conditions. For incident-free transportation, the potential human health impacts from the radiation field surrounding the radioactive packages were estimated for transportation workers and populations along the route (off-traffic, or off-link), people sharing the route (in-traffic or on-link), and people at rest areas and stops along the route. The RADTRAN 5 computer program (Neuhauser and Kanipe 2003) was used to estimate the impacts for transportation workers and populations, as well as the impact to an MEI (for example, a person stuck in traffic, a gas station attendee, or an inspector), who may be a worker or a member of the public.

Human heath impacts could result from transportation accidents. The impact of a specific radiological accident is expressed in terms of probabilistic risk, which is defined as the accident probability (accident frequency) multiplied by the accident consequences. The overall risk is obtained by summing individual risks from all reasonably conceivable accidents. The analysis of accident risks accounts for a spectrum of accidents ranging from high-probability accidents of low severity (a fender bender) to hypothetical high-severity accidents that have a corresponding low probability of occurrence. Only as a result of a severe fire or a powerful collision, which are of extremely low probability, could a transportation package of the type used to transport radioactive material be damaged to the extent that radioactivity could be released to the environment with significant consequences.

In addition to calculating the radiological risks that would result from all reasonably conceivable accidents during transportation of radioactive wastes, NNSA assessed the consequences of maximum reasonably foreseeable accidents with a probability greater than 1×10^{-7} (1 in 10 million) per year. These latter consequences were determined for the atmospheric conditions that would likely prevail during accidents. The analysis used the RISKIND computer program to estimate doses to individuals and populations (Yuan et al. 1995).

Incident-free radiological health impacts are expressed as additional LCFs. Radiological accident health impacts are also expressed as additional LCFs, and nonradiological accident risks are expressed in terms of additional immediate (traffic) fatalities. LCFs associated with radiological exposure were estimated by multiplying the occupational (worker) and public dose by 6.0×10^{-4} LCFs per person-rem of exposure. Transportation impacts of radioactive wastes were calculated assuming that all wastes are transported by truck.

In determining the transportation risks, per-shipment risk factors were calculated for the incident-free and accident conditions using the RADTRAN 5 computer program (Neuhauser and Kanipe 2003) in conjunction with the Transportation Rating Analysis Geographic Information System (TRAGIS) computer program (Johnson and Michelhaugh 2003) to choose transportation routes in accordance with U.S. Department of Transportation regulations. The TRAGIS program provides population estimates based on the 2000 census along the routes for determining the population radiological risk factors. For incident-free operations, the affected population includes individuals living within 0.5 miles (800 meters) of each side of the road. For accident conditions, the affected population includes individuals living within 50 miles (80 kilometers) of the accident, and the MEI is assumed to be an individual located 330 feet (100 meters) directly downwind from the accident.

For determining traffic accident fatalities from offsite commercial truck transportation, separate accident rates and accident fatality risks were used for rural, suburban, and urban population zones. These accident and fatality rates were taken from data provided in *State-Level Accident Rates for Surface Freight Transportation: A Reexamination*, ANL/ESD/TM-150 (Saricks and Tompkins 1999). The values selected were the "mean" accident and fatality rates given in ANL/ESD/TM-150 for "interstate," "primary," and "total." These values were assigned to rural, suburban, and urban population zones, respectively. Accident rates are generically defined as the number of accident involvements (or fatalities) in a given year per unit of travel in that same year. Therefore, the rate is a fractional value, with accident involvement count as the numerator of the fraction and vehicular activity (total travel distance in truck-kilometers) as its denominator. The accident rates for rural, suburban, and urban zones were 3.15, 3.52, and 3.66 per 10 million truck-kilometers, respectively; and the fatality rates were 0.88, 1.49, and 2.32 per 100 million truck kilometers, respectively.

For determining traffic accident fatalities from safe secure trailer (SST) transport, DOE operational experience between 1984 and 1999 was used. The mean probability of an accident requiring towing of a disabled trailer truck was about 6 per 100 million kilometers (DOE 2000g). The number of historical SST accidents is too small to support allocating this overall rate among the various types of routes (interstate, primary, others) used in the accident analysis. Therefore, data for the relative rate of accidents on these route types, or influence factor, as provided in *Determination of Influence Factor and Accident Rates for Armored Tractor/Safe Secure Trailer* (Phillips, Clauss, and Blower 1994), were used to estimate accident frequencies for rural, urban, and suburban transports. Traffic accident fatalities for the SST transports were estimated using the commercial truck transport fatality per accident ratios within each zone.

For determining traffic accident fatalities from local and regional transportation of industrial and hazardous waste, New Mexico State accident and fatality rates, which also are given in ANL/ESD/TM-150, were used. The rates used were 1.13 accidents per 10 million truck-kilometers and 1.18 fatalities per 100 million truck-kilometers. For assessment purposes, the total number of expected accidents or fatalities was calculated by multiplying the total shipment distance for a specific waste by the accident or fatality rate. Additional details on the analysis approach and on modeling and parameter selection are provided in Appendix K.

In summary, at LANL, radioactive materials (special nuclear material, low-level radioactive waste, transuranic waste, etc.) are transported both onsite (between the TAs) and offsite to multiple locations. Onsite transportation constitutes the majority of activities that are part of routine operations in support of various programs. The radioactive materials transported onsite between TAs are mainly limited quantities that are transported over short distances and mostly on closed roads. The impacts of these activities are part of the impacts of normal operations at these areas. For example, worker dose from handling and transporting radioactive materials is included as part of the worker dose from operational activities. Specific analyses performed in the *1999 SWEIS* (DOE 1999a) indicated that the projected collective radiation dose for LANL drivers from a projected 10,750 onsite shipments was 10.3 person-rem per year, or on average, less than 1 millirem per transport. A review of recent onsite radioactive materials transportation indicates a much smaller number of shipments than those projected in the *1999 SWEIS*. Therefore, the *1999 SWEIS* projection of impacts would envelop the impacts for routine onsite transportation. The impacts of nonroutine onsite transportation activities, such as waste transportation associated with facility DD&D or MDA remediation, were evaluated and are presented in this SWEIS where applicable.

Offsite transportation of radioactive materials would occur using both trucks and airfreight. Materials transported by airfreight would be similar in number, type, and forms to those considered in the *1999 SWEIS*, and hence would result in similar impacts. The aircrew dose from airfreight radioactive transportation was estimated at 2.4 person-rem per year (DOE 1999a).

Truck (both commercial and DOE SST) transportation is analyzed further in this SWEIS. The *1999 SWEIS* provides a comprehensive list of various radioactive material types, forms, origins and destinations, and quantities, as well as a projected number of shipments. The radioactive materials transported included tritium, plutonium, uranium (both depleted and enriched), offsite source recovery materials, medical isotopes, small quantities of activation products, low-level radioactive waste, and transuranic waste. The specific origins and destinations, except for Rocky Flats, are expected to be applicable to future transports. For analyses purposes in this SWEIS, the destinations were limited to those that could be significantly affected, namely offsite waste disposal sites (such as the Nevada Test Site, a commercial waste disposal site in Utah, and WIPP in New Mexico) and the DOE and NNSA sites supporting nuclear weapons production and mixed oxide fuel fabrication (such as the Pantex Plant in Texas, Oak Ridge National Laboratory and Y-12 Complex in Tennessee, Lawrence Livermore National Laboratory in California, and Savannah River Site in South Carolina). Impacts from the transportation of other radioactive materials would remain similar to those projected in the *1999 SWEIS*.

Table 5–50 provides the estimated number of material shipments under each alternative over a 10-year period. This table also provides the estimated number of shipments resulting from activities for proposed MDA remediation options such as removal or capping, and those from activities related to increasing pit production from 20 to up to 80 pits per year.

Table 5–50 10-Year Total Number of Offsite Shipments under Each Alternative and Selected Activities

Alternative (Activities)	*Number of Shipments*

LSA = low specific activity, DD&D = decontamination, decommissioning, and demolition, LLW = low-level radioactive waste, RH = remote handled, TRU = transuranic waste, SNM = special nuclear material, PuO_2 = plutonium dioxide.

[a] Low-level radioactive waste transported in drums or Type A, B-25 boxes. The values here also include shipments of evaporator bottoms from Radioactive Liquid Waste Treatment Facility to an offsite location and the returned dried wastes.

[b] High activity low-level radioactive waste containing more than 10 nanocuries per gram of transuranic waste transported in Type A, B-25 boxes. This waste is comparable to Class B or Class C of 10 CFR Part 61 waste classification. This waste is generated during MDA waste retrieval, and from decontamination and demolishing of some of the buildings. The shipments also include one shipment of strontium-90 radioisotope thermoelectric generators under all alternatives.

[c] Remote-handled low-level radioactive waste transported in 55-gallon (208-liter) drums.

[d] The sum of remote-handled and contact-handled transuranic waste shipments.

[e] Others include industrial, sanitary, and asbestos wastes.

[f] The range of values represent the estimated number of shipments for options of capping and remediation and removal and remediation of all MDAs.

[g] Expanded Operations with baseline MDA remediation (without capping or removal).

[h] The range values represent the estimated number of shipments for options of capping and removal of all MDAs.

[i] The waste shipment values presented are based on the differences between the No Action Alternative and the Expanded Operations Alternative projected waste volumes for routine operation.

Table 5–51 summarizes the total transportation impacts, as well as the transportation impacts on two nearby LANL transportation routes: LANL to Pojoaque, New Mexico, the route segment that trucks from LANL use, and Pojoaque to Santa Fe, New Mexico, the route segment that all trucks using Interstate-25 (such as trucks traveling to WIPP) use. For analysis purposes in this SWEIS, two sites, the DOE Nevada Test Site and a commercial facility in Utah, were selected as possible disposal sites for all low-level radioactive wastes should the decision be made to dispose low-level radioactive waste offsite rather than onsite. The differences in distance from LANL and the affected population along the different transportation routes between these two sites result in a range of impacts under each alternative. Transuranic waste was assumed to be disposed of at WIPP.

NTS = Nevada Test Site, MDA = material disposal area.

[a] Under this option, low-level radioactive waste would be shipped to either the Nevada Test Site or a commercial site in Utah. Transuranic wastes would be shipped to WIPP. Pantex, Y-12, Oak Ridge, Nevada Test site, Lawrence Livermore and the Savannah River Site would ship or receive special nuclear materials. Also note that the number of shipments along the Pojoaque to Santa Fe segment would be lower when the commercial site in Utah is used as an offsite disposal option for low-level radioactive waste.

[b] Risk is expressed in terms of latent cancer fatalities, except for the nonradiological risk, where it refers to the number of traffic accident fatalities.

[c] Shipments of low-level radioactive waste to a commercial disposal site in Utah would not pass along the Pojoaque to Santa Fe segment of highway.

Note: The values in this table are rounded in comparison to those provided in Appendix K.

The following conclusions can be drawn from the results presented in Table 5–51. The maximum total 10-year dose to the public would be 287 person-rem from all shipments under the Expanded Operations Alternative – MDA Removal Option with all low-level radioactive waste being sent to the Nevada Test Site for disposal. The expected excess LCFs among the exposed population would be less than 1 (0.17 LCF). The total dose to the public along the LANL to Pojoaque route under this option would be 8.1 person-rem, with less than 1 excess LCF (0.0049 LCF) among the exposed population. The total dose to the public along the Pojoaque to Santa Fe route would be up to 13.3 person-rem, with less than 1 excess LCF (0.008 LCF) among the exposed population. The maximum dose to the transportation crew (truck drivers) would be 910 person-rem over 10 years, with a potential of less than 1 (0.55) LCF among the exposed crew. It should be noted that DOE regulations limit the maximum annual dose to a transportation worker to 100 millirem per year unless the individual is a trained radiation worker, which would have an administrative control annual dose limit of 2 rem (DOE 1999e). The potential for a trained radiation worker to develop a fatal latent cancer from the maximum annual exposure is 0.0012. Therefore, an individual transportation worker would not be expected to develop a lifetime latent fatal cancer from exposures during these activities.

Table 5–51 also presents the risk of traffic accident fatalities for each of the alternatives. The risk of a traffic accident fatality is greater than the risk of an excess LCF for each of the alternatives. For instance, excess LCFs among the exposed population from all shipments under the Expanded Operations Alternative-MDA Removal Option with all waste being sent to the Nevada Test Site for disposal would be less than 1 (0.17 LCF), while the number of traffic accident fatalities from these shipments would be nearly 3 (2.66).

Onsite traffic patterns were reviewed with respect to traffic flowing through the main access points onto the site. Based on the average traffic flows recorded in 2004 and 2005, an estimate of the daily number of trips per employee was made, assuming that 90 percent of all trips were related to employee trips and the remaining 10 percent were related to truck trips in support of normal LANL activities, not including construction or DD&D-related activities, which were calculated separately. The alternatives were then analyzed and traffic flows were assumed to fluctuate consistent with the employment levels estimated in Section 5.8.1. For example, under the Reduced Operations Alternative, employment at LANL is projected to decline; therefore, the number of daily trips associated with LANL activities are also projected to decline. Similarly, under the Expanded Operations Alternative, LANL employment is projected to increase; consequently, traffic would likely increase as well.

As shown in **Table 5–52**, local traffic flows would likely remain at current levels under the No Action Alternative because employment levels would stay at current levels. Under the Reduced Operations Alternative, a small decline in traffic through LANL would be expected mainly because of the projected decrease in employment under this alternative. Under the Expanded Operations Alternative, traffic would likely increase substantially due to the projected increases in employment and construction and remediation activities. This would be particularly true for Pajarito Road as remediation activities start on MDA G. The Expanded Operations Alternative – MDA Removal Option would have a larger traffic increase relative to the MDA – Capping Option due to the more numerous truck trips associated with MDA remediation and the greater number of remediation workers needed to implement this option.

Table 5–52 Summary of Changes in Annual Traffic Flow at the Entrances to Los Alamos National Laboratory

Alternative	*Average Daily Vehicle Trips*				
	Diamond Drive Across Los Alamos Canyon	*Pajarito Road at NM 4*	*East Jemez Road at NM 4*	*West Jemez Road at NM 4*	*DP Road at Trinity Drive*
No Action	24,545	4,984	9,502	2,010	1,255
Reduced Operations - Estimated Daily Trips - Percent Change from No Action (%)	 23,600 -4	 4,800 -4	 9,100 -4	 1,900 -5	 1,200 -4
Expanded Operations – MDA Removal Option – Estimated Daily Trips - Percent Change from No Action (%)	26,000 +6	9,200 +85	10,700 +13	2,200 +9	1,700 +35

MDA = material disposal area.

5.10.1 No Action Alternative

Los Alamos National Laboratory Site-Wide Impacts

Under this alternative, about 13,600 offsite shipments of radioactive materials would be made between 2007 and 2016 to the Nevada Test Site (or a commercial site in Utah), WIPP, and the

NNSA sites supporting nuclear weapons. Maximum transportation impacts would be realized if low-level radioactive waste were shipped to either the Nevada Test Site or a commercial site in Utah instead of being disposed of onsite. Transuranic waste would be shipped to WIPP, and special nuclear material would be shipped mainly between LANL and Pantex. The total projected (one-way) distance traveled on public roads transporting radioactive materials to various locations would range from about 8.5 million to 10 million miles (13.75 million to 16 million kilometers).

Impacts of Incident-free Transportation

The dose to the transportation crew from all offsite transportation activities under this alternative was estimated to range from about 147 person-rem for disposal at the commercial low-level radioactive waste disposal site in Utah to about 164 person-rem for disposal at the Nevada Test Site. The dose to the general population would range from 53 to 58 person-rem for the commercial site in Utah and the Nevada Test Site options, respectively. Accordingly, incident-free transportation would result in a maximum of 0.098 excess LCFs among the transportation workers and 0.035 excess LCFs in the affected population. The estimated dose associated with disposal of low-level radioactive waste at the Nevada Test Site is higher because of the longer distance traveled and larger affected population. The differences in estimated doses under either option are very small, however, as shown above.

It should be noted that DOE regulations limit the maximum annual dose to a transportation worker to 100 millirem per year unless the individual is a trained radiation worker. Trained radiation workers have an administrative control dose level of 2 rem per year (DOE 1999e). The potential for a trained radiation worker to develop a fatal latent cancer from an annual dose at the maximum annual exposure is 0.0012. Therefore, an individual transportation worker would not be expected to develop a lifetime fatal latent cancer from exposure during these activities.

The doses to the general populations along the routes from LANL to Pojoaque and from Pojoaque to Santa Fe were estimated to be a maximum of 1.8 and 3.3 person-rem, respectively. These doses would result in 0 (0.0011 and 0.0020) excess LCFs among the exposed populations.

Impacts of Accidents during Transportation

As stated earlier, two sets of analyses were performed for the evaluation of transportation accident impacts: impacts of maximum reasonably foreseeable accidents (accidents with probabilities greater than 1 in 10 million per year [1×10^{-7}]) and impacts of all conceivable accidents (total transportation accidents).

For radioactive materials transported under this alternative, the maximum reasonably foreseeable offsite truck transportation accident with the greatest consequence would involve a truck carrying contact-handled transuranic waste. The probability of such an accident occurring would be about 1 in 5.3 million (1.9×10^{-7}) per year in an urban area. If such an accident were to occur, the consequences in terms of general population dose would be 310 person-rem. Such an exposure could result in 0.19 excess LCFs among the exposed population. This accident, if it occurred, would result in a dose of 6.2 millirem to a hypothetical MEI located at a distance of 330 feet (100 meters) and exposed to the accident plume for 2 hours, with a corresponding risk of developing a latent fatal cancer of about 1 in 270,000 (3.7×10^{-6}).

Under the No Action Alternative, estimates of the total offsite transportation accident risks for all projected accidents involving radioactive shipments, regardless of type, are a maximum radiological dose-risk[5] to the general population of 0.28 person-rem, resulting in 0.00017 LCFs, and a maximum nonradiological accident risk of 0 (0.30) fatalities.

The maximum radiological transportation accident dose-risk to the general populations along the LANL to Pojoaque and the Pojoaque to Santa Fe routes would be 0.0065 and 0.012 person-rem, respectively. These doses would result in 0 (3.9×10^{-6} and 7.1×10^{-6}) excess LCFs among the exposed populations. The maximum expected traffic accident fatalities along these routes would be 0 (0.0093 and 0.016, respectively).

Impacts of Construction, Operations, and Hazardous Material Transportation

The impacts of transporting various nonradiological materials were evaluated. These impacts are presented in terms of distance traveled and numbers of expected traffic accidents and fatalities. The transportation impacts under this alternative would be, for 3.4 million miles (5.5 million kilometers) traveled, 1 (0.62) traffic accident and 0 (0.07) fatalities.

Local Traffic

Under the No Action Alternative, the impacts of LANL activities on local traffic flow and roadway infrastructure would be approximately the same as current conditions, as described in Chapter 4, Section 4.10.1. Efforts being undertaken to enhance site security, such as the Security Perimeter Project, would be implemented as planned. These modifications would alter traffic patterns in and around LANL, but would likely have only minor impacts on traffic flow during normal security conditions. In the case of heightened security, traffic entering the site would be delayed as vehicles were subjected to greater scrutiny.

Management of construction fill could result in up to 15,000 round trips on LANL roads from LANL construction sites to borrow areas for storage or to sites using construction fill. This traffic could be mitigated by scheduling trips during off-peak hours, as appropriate.

5.10.2 Reduced Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Under this alternative, about 12,270 offsite shipments of radioactive materials would be made to the Nevada Test Site (or a commercial disposal site in Utah), WIPP, and the NNSA sites supporting nuclear weapons production between 2007 and 2016. Similar to the No Action Alternative, the maximum transportation impacts would result from shipments of low-level radioactive waste to either the Nevada Test Site or a commercial disposal site in Utah, transuranic waste to WIPP, and special nuclear material between LANL and Pantex. The total projected (one-way) distance traveled on public roads while transporting radioactive materials to

---

[5] Dose-risk includes the probability of an accident occurring. Here, these values are calculated by dividing the radiological risks in terms of LCFs given in Table 5–51 (column 9) by 0.0006, which is a risk of an LCF per person-rem of exposure.

various locations would range from 7.6 million to 8.9 million miles (12.3 million to 14.3 million kilometers).

Impacts of Incident-free Transportation

The dose to transportation workers from all offsite transportation activities under this alternative has been estimated to range from about 133 person-rem for the Utah commercial low-level radioactive waste disposal option to 147 person-rem for the Nevada Test Site disposal option. The dose to the general population would range from 49 to 53 person-rem for each option, respectively. Accordingly, incident-free transportation would result in a maximum of 0.088 excess LCFs among transportation workers and 0.032 excess LCFs in the affected population for the Nevada Test Site low-level radioactive waste disposal option because of the longer distance traveled and larger affected population.

The impact of this alternative on individual transportation workers would be the same as the impact discussed under the No Action Alternative. An individual transportation worker would not be expected to develop a lifetime latent fatal cancer from exposure during these activities.

The doses to the general populations along the routes from LANL to Pojoaque and from Pojoaque to Santa Fe under this alternative were estimated to be a maximum of 1.7 and 3.1 person-rem, respectively. These doses would respectively result in 0.0011 and 0.0019 excess LCFs among the exposed populations.

Impacts of Accidents during Transportation

Similar to the estimate forecast for No Action Alternative, for radioactive materials transported under this alternative, the maximum reasonably foreseeable offsite truck transportation accident with the highest consequence would involve a truck carrying contact-handled transuranic waste. The probability of such an accident occurring would be 1 in 5.3 million (1.9×10^{-7}) per year in an urban area. Should such an accident occur, the consequences would be similar to those projected for the No Action Alternative.

Under the Reduced Operations Alternative, the estimated maximum radiological dose-risk to the general population for all projected accidents involving radioactive shipments, regardless of type, would be about 0.25 person-rem, resulting in 0.00015 LCFs and a maximum nonradiological accident risk of 0 (0.27) fatalities.

The maximum radiological transportation accident dose-risk to the general populations along the LANL to Pojoaque and the Pojoaque to Santa Fe routes would be 0.0057 and 0.010 person-rem, respectively. These doses would result in 0 (3.4×10^{-6} and 6.2×10^{-6}) excess LCFs among the exposed populations. The maximum expected traffic accident fatalities along these routes would be 0 (0.009) and 0 (0.015), respectively.

Impacts of Construction, Operations, and Hazardous Material Transports

The impacts of transporting various nonradiological materials were evaluated. These impacts are presented in terms of distance traveled and numbers of expected traffic accidents and fatalities.

The transportation impacts under this alternative would be 1 (0.62) traffic accident and 0 (0.07) fatalities, for 3.4 million miles (5.5 million kilometers) traveled.

Local Traffic

Under the Reduced Operations Alternative, the impacts of LANL activities on local traffic flow and roadway infrastructure would be somewhat smaller than those expected under the No Action Alternative. The relatively small reduction in the number of employees associated with the reduction in high explosives processing and testing, cessation of TA-18 activities, and shutdown of LANSCE (see Section 5.8.1.2) would likely result in small decreases in local traffic flow and the impacts of site activities on local roadway infrastructure, as shown in **Table 5–53**.

Table 5–53 Estimated Changes in Traffic at the Entrances to Los Alamos National Laboratory under the Reduced Operations Alternative

Activity	*Average Daily Vehicle Trips*				
	Diamond Drive Across Los Alamos Canyon	*Pajarito Road at NM 4*	*East Jemez Road at NM 4*	*West Jemez Road at NM 4*	*DP Road at Trinity Drive*
No Action Alternative	24,545	4,984	9,502	2,010	1,255
Estimated Daily Vehicle Trips under Reduced Operations Alternative	23,600	4,800	9,100	1,900	1,200
Percent Change from Baseline	-4	-4	-4	-5	-4

5.10.3 Expanded Operations Alternative

The discussions in this section focus on the doses and risk impacts from activities under the Expanded Operations Alternative with the MDA Capping and Removal Options. For each receptor (transportation workers or population) a range of impacts is provided reflecting those activities associated with the MDA Capping and MDA Removal Options. Table 5–52 also provides similar information for the Expanded Operations Alternative without the MDA Capping or Removal Options; and those resulting from activities associated with the MDA Removal Option, the MDA Capping option, and increasing pit production from 20 to 80 pits per year.

Los Alamos National Laboratory Site-Wide Impacts

Under this alternative, under the MDA Capping and Removal Options respectively, approximately 28,820 to 122,440 offsite shipments of radioactive materials would be made between 2007 and 2016 to the Nevada Test Site (or a commercial disposal site in Utah), WIPP, and the NNSA sites supporting nuclear weapons production and mixed oxide fuel fabrication. Maximum transportation impacts would be realized if low-level radioactive waste were shipped to either the Nevada Test Site or a commercial site in Utah instead of being disposed of onsite. Transuranic waste would be shipped to WIPP, and special nuclear material would be shipped mainly between LANL and Pantex or Savannah River. The total projected (one-way) distance traveled on public roads while transporting radioactive materials to various locations would range from 18.9 million to 21.6 million miles (30.3 million to 34.7 million kilometers) under the MDA Capping Option, and 84.3 million to 93.2 million miles (135.6 million to 155 million kilometers) under the MDA Removal Option.

Impacts of Incident-free Transportation

The dose to transportation workers from all offsite transportation activities under this alternative would range from 223 to 770 person-rem for low-level radioactive waste disposal at a commercial facility in Utah, and from 256 to 910 person-rem for disposal at the Nevada Test Site for the MDA Capping and Removal Option. The corresponding dose to the general population would range from 82 to 274 person-rem for disposal at a commercial facility and from 89 to 287 person-rem for disposal at the Nevada Test Site. The doses for options involving disposal of low-level radioactive waste at the Nevada Test Site are larger because of the longer distances traveled and larger affected population. Accordingly, incident-free transportation would result in a maximum of 0.15 excess LCFs among transportation workers and 0.053 excess LCFs in the affected population for the MDA Capping Option, and a maximum of 0.55 LCFs among transportation workers and 0.17 excess LCFs in the affected population for the MDA Removal Option.

The impact of this alternative on individual transportation workers would be the same as the impact discussed under the No Action Alternative. An individual transportation worker would not be expected to develop a lifetime latent fatal cancer from exposure during these activities.

Under the MDA Capping Option, doses to the general populations along the LANL to Pojoaque and the Pojoaque to Santa Fe routes were estimated to be a maximum of 2.8 and 4.6 person-rem, respectively. These doses would result in 0 (0.0017 and 0.0028) excess LCFs among the exposed populations. Under the MDA Removal Option, doses to the general populations along the LANL to Pojoaque and the Pojoaque to Santa Fe routes were estimated to be a maximum of 8.1 and 13.3 person-rem, respectively. These doses would result in 0 (0.0049 and 0.0080) excess LCFs among the exposed populations.

Impacts of Accidents during Transportation

Similar to the projection under the No Action Alternative, for radioactive materials transported under this alternative, the maximum reasonably foreseeable offsite truck transportation accident with the highest consequence would involve a truck carrying contact-handled transuranic waste. The probability of such an accident occurring would be about 1 in 3.7 million (2.7×10^{-7}) per year in an urban area under the MDA Capping Option and 1 in 1.9 million (5.2×10^{-7}) per year in an urban area under the MDA Removal Option. If this accident occurred, the consequences would be similar to those projected for the No Action Alternative.

The estimated maximum radiological dose-risk to the general population for all projected accidents involving radioactive shipments, regardless of type, would be 0.42 person-rem, resulting in 0.00025 LCFs and a maximum nonradiological accident risk of 1 (0.66) fatality under the MDA Capping Option. Under the MDA Removal Option, the estimated maximum radiological dose-risk to the general population for all projected accidents involving radioactive shipments, regardless of type, would be 2.7 person-rem, resulting in 0.0016 LCFs, and a maximum nonradiological accident risk of 3 (2.96) fatalities.

The maximum radiological transportation accident dose-risk to the general populations along the LANL to Pojoaque and the Pojoaque to Santa Fe routes would be about 0.0095 and 0.016 person-rem under the MDA Capping Option, and about 0.053 and 0.078 person-rem under the MDA Removal Option. These doses would result in excess LCFs among the exposed populations of 0 under either MDA remediation option (5.7×10^{-6} and 9.8×10^{-6} for the MDA Capping Option and 3.2×10^{-5} and 4.7×10^{-5} for the MDA Removal Option). The maximum expected traffic fatalities along these routes would be 0 (0.021 and 0.026, respectively) under the MDA Capping Option. Under the MDA Removal Option, the maximum expected traffic accident fatalities along these routes also would be 0 (0.089 and 0.11, respectively).

Impacts of Construction, Operations, and Hazardous Material Transports

The impacts of transporting various nonradiological materials were also evaluated. These impacts are presented in terms of distance traveled and numbers of expected traffic accidents and fatalities. The transportation impacts under this alternative for the MDA Capping Option would be, for 15.2 million miles (24.5 million kilometers) traveled, 3 (2.8) traffic accidents and 0 (0.29) fatalities. For the MDA Removal Option, the nonradiological transportation impacts would be, for 17.4 million miles (28.1 million kilometers) traveled, 3 (3.2) traffic accidents and 0 (0.33) fatalities.

Local Traffic

Under the Expanded Operations Alternative, the impacts of LANL activities on local traffic flow and roadway infrastructure could be substantial without changes to current conditions. The potential addition of thousands of new employees combined with an increased number of trucks traveling to and from the site associated with increased construction, DD&D, and MDA remediation activities could impact local transportation. As shown in **Table 5–54**, a number of intersections could see large increases in daily traffic flow.

Table 5–54 Estimated Changes in Traffic at the Entrances to Los Alamos National Laboratory under the Expanded Operations Alternative

Activity	Average Daily Vehicle Trips				
	Diamond Drive Across Los Alamos Canyon	*Pajarito Road at NM 4*	*East Jemez Road at NM 4*	*West Jemez Road at NM 4*	*DP Road at Trinity Drive*
No Action Alternative	24,545	4,984	9,502	2,010	1,255
Estimated Daily Vehicle Trips under Expanded Operations Alternative	26,000	9,200	10,700	2,200	1,700
Percent Change from Baseline	+6	+85	+13	+9	+35

Areas of concern include increased truck traffic along East Jemez Road at NM 4 if it continues to be the route for trucks traveling to LANL or from the Los Alamos townsite. With the number of construction projects and MDA remediation efforts occurring along Pajarito Road that are expected to be underway in TA-18, TA-54, TA-55 and TA-3 under this alternative, it may be necessary to consider an alternate truck entry point for trucks working on these projects along Pajarito Road at NM 4 to alleviate some of the truck traffic on East Jemez.

Under the proposal to construct a new warehouse on East Jemez Road, a traffic study concluded that the level of service on East Jemez would lead to a breakdown in traffic flow during the afternoon rush hour without changes to the current road (LSC 2005). The study concluded that left turn lanes would be needed, as well as acceleration lanes for east- and west-bound traffic on

East Jemez Road (see Appendix G.9). These concerns would likely be further exacerbated by increased remediation activities under the Expanded Operations Alternative. For example, there would be a substantial increase in truck traffic into and out of the TA-61 borrow pit under the MDA Capping Option. Under this option, an average of about 60 truckloads of fill could be transported daily out of this borrow pit over a 10-year period. Trucks coming in and out of the pit would likely delay traffic flow on East Jemez Road and add to the noise level around this area.

The intersection of Trinity Drive and DP Road is already an area of concern. As discussed in Chapter 4, Section 4.10.2, the New Mexico Department of Transportation is planning improvements to this intersection that would improve the ability of trucks to leave DP Road and turn onto Trinity Drive. Expected increases in traffic during the period that TA-21 is undergoing DD&D and MDAs A, B, T, and U are being remediated would increase the need for these improvements. The concerns about additional trucks entering and leaving DP Road and the affect of increased truck traffic on the local road infrastructure may result in the need for another entry point to TA-21 during periods of heavy activity.

Large increases beyond those discussed under the No Action Alternative also are expected on Pajarito Road; however, usage of this road is much lower than that of other main access points into and out of LANL. Further traffic studies may be needed to determine whether any changes would be required if all of the planned projects progressed on the current schedules set under the Expanded Operations Alternative. Pajarito Road would experience the largest increase in traffic once remediation efforts start at MDA G. It may be necessary to regulate traffic flow at its intersection with NM 4 during peak travel hours under this alternative.

Furthermore, although some of the traffic on Pajarito Road is associated with staff that work in technical areas along Pajarito Road, other traffic is through traffic – for instance, people traveling from White Rock to TA-3 or the Los Alamos townsite. Implementation of the proposed Security-Driven Transportation Modifications to the Pajarito Corridor would occasionally restrict private vehicles from this section of Pajarito Road, and result in increased traffic on other local roads such as the Truck Route (NM 501) and NM 502. Additional traffic information would be needed to fully assess the impacts that the Security Driven Transportation Modification would have on local traffic.

5.11 Environmental Justice

The environmental justice analysis assesses the potential for disproportionately high and adverse human health or environmental effects on minority and low-income populations that could result from normal operations resulting from implementing the alternatives considered in this SWEIS. In assessing the impacts, the following definitions of minority individuals and populations and low-income population were used:

- *Minority individuals:* Individuals who identify themselves as members of the following population groups: Hispanic or Latino, American Indian or Alaska Native, Asian, Black or African-American, Native Hawaiian or Other Pacific Islander, or two or more races (meaning individuals who identified themselves on the census form as being a member of two or more races, such as both Hispanic and Asian).

- *Minority populations*: Minority populations are identified where either: (1) the minority population of the affected area exceeds 50 percent, or (2) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis.

- *Low-income population*: Low-income populations in an affected area are identified using the annual statistical poverty thresholds from the Census Bureau's Current Population Reports, Series PB60, on Income and Poverty.

Consistent with the impact analysis for the public and occupational health and safety, the affected populations are defined as those minority and low-income populations that reside within a 50-mile (80-kilometer) radius centered on the LANL LANSCE Facilities at TA-53 and the High Explosives Testing Sites at TA-36 (see **Table 5–55**). A 50-mile (80-kilometer) radius was chosen because impacts are not typically significant beyond 50 miles (80 kilometers). If it is determined that impacts could be significant beyond a 50-mile (80-kilometer) radius, additional analysis would be performed. In the case of this LANL SWEIS, it was determined that impacts beyond a 50-mile (80-kilometer) radius were not expected to be significant. For example, projected radiation doses drop dramatically with increasing distance from the source. For LANL, the highest projected dose to the public would be to persons residing north-northeast of LANSCE as discussed in Section 5.6.1. Under this scenario, individuals residing 0.5 miles (0.8 kilometers) from LANSCE would receive a dose of approximately 7.5 millirem annually while those residing 50 miles (80 kilometers) away in the same direction would receive a dose of 0.035 millirem annually. For additional information on the analysis of impacts beyond a 50-mile (80-kilometer) radius see Appendix C, Section C.1.3.3.

Table 5–55 Potentially Affected Populations

Source Location	*Total Population*	*Total Minority Population*	*Hispanic Population*	*American Indian Population*	*Low-Income Population*
TA-53	283,766	155,261	127,641	17,811	35,826
TA-36	375,495	185,474	151,110	21,263	39,206

Based on the analysis of impacts for other resource areas, NNSA expects no high and adverse impacts from the continued operation of LANL under any of the alternatives. NNSA also analyzed the potential risk due to radiological exposure through the consumption patterns of special pathways receptors, including subsistence consumption of native vegetation (pinyon nuts and Indian Tea [Cota]), locally grown produce and farm products, groundwater, surface water, fish (game and nongame), game animals, other foodstuffs, and incidental consumption of soils and sediments (on produce, in surface water, and ingestion of inhaled dust); absorption of contaminants in sediments through the skin; and inhalation of plant materials. The special pathways receptors analysis is important to the environmental justice analysis because this consumption pattern may reflect the traditional or cultural practices of members of minority populations in the area. See Section 5.6.1.1 and Appendix C, Section C.1.4 for more information on special pathways receptors.

Subsistence Consumption of Fish and Wildlife

Section 4–4 of Executive Order 12898 directs Federal agencies "whenever practical and appropriate, to collect and analyze information on the consumption patterns of populations who principally rely on fish and/or wildlife for subsistence and that Federal governments communicate to the public the risks of these consumption patterns." In the *1999 SWEIS*, DOE considered whether there were any means for minority or low-income populations to be disproportionately affected by examining impacts to American Indian, Hispanic, and other traditional lifestyle special pathway receptors. Consideration of special pathways took into account the levels of contaminants in native vegetation (pinyon nuts and Indian Tea [Cota]), locally grown produce and farm products, groundwater, surface water, fish (game and nongame), game animals (including organ meats), and soils and sediments on or near LANL (DOE 1999a).

Based on recent monitoring results, concentrations of contaminants in native vegetation, produce, surface water, fish, game animals, other foodstuffs, soils and sediments in areas surrounding LANL have been quite low (at or near the threshold of detection) and seldom above background levels (see Appendix C, Section C.1.4). For a person whose diet and lifestyle reflect all of the special pathways considered, his or her annual dose would be expected to increase by between 4.5 millirem (0.0045 rem) and 10.7 millirem (0.0107 rem) annually. Using a risk estimator value of 0.0006 lifetime probability of fatal cancer per person-rem, an increased dose of between 4.5 millirem (0.0045 rem) and 10.7 millirem (0.0107 rem) per year would equate to an increased annual risk of developing a fatal cancer of between 1 in 370,000 (2.7×10^{-6}) and 1 in 156,000 (6.4×10^{-6}). By comparison, the average resident of New Mexico receives a dose of approximately 400 millirem (0.4 rem) per year from background sources. Therefore, for those individuals participating in all of the special pathways, their average annual dose and risk of developing a fatal cancer would increase by approximately 1.1 to 2.7 percent due to these special pathways.

Ingestion pathway calculations focused on concentrations of radionuclides in environmental media from natural background sources, weapons testing fallout, and previous radiological releases from LANL, as reported in LANL environmental surveillance reports for 2001 through 2004. The actual contribution from recent operations at LANL is only a small fraction of this value. The overall risk to the special pathway receptor would not differ among the alternatives considered in this new SWEIS because most of the risk would be attributed to the existing low levels of radiological contamination in water and soils in the area around LANL. Consequently, no disproportionately high and adverse human health impacts would be expected in special pathway receptor populations in the region as a result of subsistence consumption of fish and wildlife.

5.11.1 No Action Alternative

Los Alamos National Laboratory Site-Wide Impacts

There would be no disproportionately high and adverse environmental impacts on minority and low-income populations due to construction activities at LANL under the No Action Alternative. This conclusion is a result of investigations in this SWEIS that determined there were no significant impacts on human health, ecological, cultural, paleontological, socioeconomic, and other resource areas described in other subsections of this chapter.

Under the No Action Alternative, all current nuclear production operations would be conducted in existing or replacement facilities at LANL and no new nuclear operations would be conducted. As discussed in Sections 5.6.1 and 5.6.2, radiological and hazardous chemical risks to the public resulting from normal operations would be small and are not considered significant. In summary, implementation of the No Action Alternative would pose no disproportionately high and adverse health and safety risks to low-income or minority populations living in the potentially affected area surrounding LANL.

As shown in Table 5–18, the total population within 50 miles (80 kilometers) of LANL for the No Action Alternative is projected to receive an annual dose of about 30 person-rem. Because the majority of this dose results from operations at LANSCE, the environmental justice analysis for this alternative uses the 50-mile (80-kilometer) population centered on LANSCE in TA-53. As shown in **Table 5–56**, the dose from LANSCE along with the dose associated with High-Explosive Testing firing site operations ascribed to TA-36 would result in an annual dose of approximately 29.2 person-rem to the affected population and an average annual individual dose of 0.10 millirem. These two locations account for approximately 97 percent of the total estimated dose from all sites at LANL under the No Action Alternative.

Table 5–56 Comparison of Total Minority, Hispanic, American Indian and Low-Income Population and Average Individual Doses Under the No Action Alternative [a]

	Annual Dose in Person-rem	*Annual Dose in Millirem*
Total Population [b]	29.2	
Average Individual		0.10
White (non-Hispanic) Population	15.0	
Non-Minority Average Individual		0.11
Total Minority Population	14.1	
Minority Average Individual		0.088
Hispanic Population [c]	11.3	
Hispanic Average Individual		0.086
American Indian Population [d]	1.8	
American Indian Average Individual		0.092
Non-Low-Income Population	25.9	
Non-Low-Income Average Individual		0.10
Low-Income Population	3.0	
Low-Income Average Individual		0.082

[a] The total population dose displayed in this table, accounts for the estimated dose from LANSCE at TA-53 and the High-Explosive Testing firing site operations at TA-36 for the No Action Alternative.

[b] The total population dose for this environmental justice analysis differs by 3 percent from that in Table 5–18. This difference is due to different models used to estimate the populations; both estimates are based on data drawn from the 2000 decennial census. The SECPOP computer program used for the analysis for Table 5–18 does not allow for the identification of minority and low-income populations. Therefore an alternate method that uses a more refined distribution of the population is used for this analysis. The minor differences do not affect the conclusions supported by the analyses.

[c] The Hispanic population includes all Hispanic persons regardless of race.

[d] The American Indian population may include persons who also indicated that they were of Hispanic ethnicity in the 2000 census.

Similar population doses are estimated for the following populations: white (non-Hispanic), all (total) minorities, American Indians, and Hispanic of any race. The white (non-Hispanic) population would be expected to receive the largest annual collective dose (15 person-rem) and annual average individual dose (0.11 millirem). This compares to a total minority annual collective dose of 14.1 person-rem and an average annual dose of 0.088 millirem to a member of the minority population. American Indians living within 50 miles (80 kilometers) of LANL would receive a collective dose of 1.8 person-rem annually and an average annual individual dose of 0.092 millirem. The Hispanic population would receive a collective dose of 11.3 person-rem annually; the annual average dose to a member of the Hispanic population would be 0.086 millirem.

Population doses to persons living below the poverty level are also analyzed in Table 5–56. Low-income populations surrounding LANL would receive an annual dose of 3.0 person-rem and an annual average individual dose of 0.082 millirem. Persons living above the poverty level would receive an annual collective dose of 25.9 person-rem and an annual average individual dose of 0.10 millirem. These data show that the total minority, American Indian, Hispanic, and low-income populations would not be subjected to disproportionately high and adverse dose impacts from normal operations at LANL under the No Action Alternative.

As shown in Table 5–17, the MEI for the No Action Alternative is projected to receive a dose of 7.8 millirem (0.0078 rem). As explained in Chapter 4, Section 4.6.1.2, the offsite MEI is a hypothetical member of the public who would receive the largest dose from LANL operations. For this SWEIS, that person would be located at LANL's East Gate along NM 502. Since no one actually resides at this location, the MEI dose is considered a conservative estimate with all members of the public expected to receive a dose that would be smaller than the estimated MEI dose. Therefore, doses to members of minority or low-income populations would not be considered significant because the dose to the MEI under this Alternative is not considered significant. As discussed earlier in Section 5.11, the average resident of New Mexico receives a dose of approximately 400 millirem (0.4 rem) per year from background sources. Therefore, for any individual under the No Action Alternative, his or her average annual dose and risk of developing a fatal cancer from the dose received would be expected to increase by a maximum of approximately 2.0 percent as a result of LANL operations.

As discussed in Section 5.6.2.1, the maximum public risk of developing a cancer as a result of chemical releases under the No Action Alternative would be below the guideline value of 1 in a million (1.0×10^{-6}) for the major carcinogenic pollutants that could be released from LANL under normal operations. In other words, one person in a population of a million would develop cancer if this population were exposed to this concentration over a lifetime, a level of concern established in the Clean Air Act. Therefore, the impact of potential chemical releases on minority or low-income individuals under this alternative would not be considered significant.

For nonradiological air quality impacts, as shown in Table 5–8, the concentrations of criteria pollutants as a result of LANL operations under the No Action Alternative would remain well below the ambient standards established to protect human health. Therefore, the impact of potential nonradiological air pollutant releases on minority or low-income individuals under this alternative would not be considered significant.

As shown in Table 5–62, the accident with the highest risk to the offsite MEI is a lightning strike at the Radioassay and Nondestructive Testing Facility in TA-54 that leads to a catastrophic fire. This accident represents the highest risk to an offsite MEI for all alternatives under consideration including the No Action Alternative. Under this accident scenario, the risk to the MEI of developing a fatal cancer as a result of radiation exposure from this accident is conservatively estimated to be 1 chance in 17 per year (0.06). For this accident, the MEI would be at the site boundary on the San Ildefonso Pueblo; however, the likelihood of an individual being at this location at the time of the accident would be highly unlikely since no one resides in the area adjacent to LANL. The accident with the highest risk to the offsite public for all alternatives under consideration, shown in Table 5–78, is a wildfire that would consume the waste storage domes in TA-54. Under this accident, the risk to the public is estimated to be 3 (2.7) latent cancer fatalities in the general public. Given the proximity of the more heavily populated areas of Los Alamos and White Rock to TA-54, these areas would be the most heavily impacted in the event of such an accident. Since neither of these is a minority or low-income community, this accident would not have a disproportionate high and adverse impact on low income or minority populations. For more information on the demographics of Los Alamos County, see Chapter 4, Section 4.8.1.2.

Key Facilities Impacts

Routine normal operations at Key Facilities would not be expected to cause fatalities or illness among the general population, including minority and low-income populations living within the potentially affected area.

The annual radiological risks to the offsite population that could result from the maximum potential accident at a Key Facility is estimated to be smaller than 0.76 LCFs (see Table 5–62). Thus, the risk of an excess LCF in the entire offsite population would be less than 1 under the No Action Alternative.

5.11.2 Reduced Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Implementation of the Reduced Operations Alternative would pose no disproportionately high and adverse health and safety risks to low-income or minority populations living in the potentially affected area surrounding LANL. Under the Reduced Operations Alternative, the risks of disproportionately high and adverse environmental impacts on minority and low-income populations in the vicinity of LANL would be no higher than those described under the No Action Alternative; in some cases, they would be lower.

As shown in Table 5–18, the total population within 50 miles (80 kilometers) of LANL for the Reduced Operations Alternative is projected to receive an annual dose of about 6.4 person-rem. Because the majority of this dose results from operations at the High Explosive Testing firing sites in TA-36, the environmental justice analysis for this alternative uses the 50-mile (80-kilometer) population centered on TA-36. As shown in **Table 5–57**, the dose from High Explosive Testing would result in an annual dose of approximately 4.9 person-rem to the affected population and an average annual individual dose of 0.013 millirem. The High Explosive

Testing firing site operations account for approximately 77 percent of the total estimated dose from all sites at LANL under the Reduced Operations Alternative.

Table 5–57 Comparison of Total Minority, Hispanic, American Indian and Low-Income Population and Average Individual Doses Under the Reduced Operations Alternative [a]

	Annual Dose in Person-rem	*Annual Dose in Millirem*
Total Population [b]	4.9	
Average Individual		0.013
White (non-Hispanic) Population	2.7	
Non-Minority Average Individual		0.014
Total Minority Population	2.2	
Minority Average Individual		0.012
Hispanic Population [c]	1.9	
Hispanic Average Individual		0.012
American Indian Population [d]	0.20	
American Indian Average Individual		0.0094
Non-Low-Income Population	4.4	
Non-Low-Income Average Individual		0.013
Low-Income Population	0.44	
Low-Income Average Individual		0.011

[a] The collective population dose displayed in this table, accounts for the estimated dose from the High Explosive Testing firing site operations at TA-36 for the Reduced Operations Alternative.
[b] The collective population doses for this environmental justice analysis differs by 6 percent from that in Table 5–18. This difference is due to different models used to estimate the populations; both estimates are based on data drawn from the 2000 decennial census. The SECPOP computer program used for the analysis for Table 5–18 does not allow for the identification of minority and low-income populations. Therefore an alternate method that uses a more refined distribution of the population is used for this analysis. The minor differences do not affect the conclusions supported by the analyses.
[c] The total Hispanic population includes all Hispanic persons regardless of race.
[d] The American Indian population may include persons who also indicated that they were of Hispanic ethnicity in the 2000 census.

The white (non-Hispanic) population would be expected to receive the largest annual collective dose (2.7 person-rem) and annual average individual dose (0.014 millirem). This compares to a total minority annual collective dose of 2.2 person-rem and an average annual dose of 0.012 millirem to a member of the minority population. American Indians living within 50 miles (80 kilometers) of LANL would receive a collective dose of 0.20 person-rem annually and an annual average individual dose of 0.0094 millirem. The Hispanic population would receive a collective dose of 1.9 person-rem annually; the annual average dose to a member of the Hispanic population would be 0.012 millirem.

Population doses to persons living below the poverty level are also presented in Table 5–57. Low-income populations surrounding LANL would receive an annual dose of 0.44 person-rem and an average annual individual dose of 0.011 millirem. Persons living above the poverty level would receive an annual collective dose of 4.4 person-rem and an average annual individual dose of 0.013 millirem. These data show that the total minority, American Indian, Hispanic, and low-income populations would not be subjected to disproportionately high and adverse dose impacts from normal operations at LANL under the Reduced Operations Alternative.

As shown in Table 5–17, the MEI for the Reduced Operations Alternative is projected to receive a dose of 0.79 millirem (0.00079 rem), about 10 times smaller than the dose projected for the

MEI under the No Action Alternative. As discussed in Section 5.11.1, doses to members of minority or low-income populations would not be considered significant because the dose to the MEI under the No Action Alternative is not considered significant and this remains true for the Reduced Operations Alternative. As discussed earlier in Section 5.11, the average resident of New Mexico receives a dose of approximately 400 millirem (0.4 rem) per year from background sources. Therefore, for the MEI under the Reduced Operations Alternative, his or her average annual dose and risk of developing a fatal cancer from the dose received would be expected to increase by a maximum of approximately 0.2 percent as a result of LANL operations.

As discussed in Section 5.6.2.2, the maximum public risk of developing a cancer as a result of chemical releases under the Reduced Operations Alternative would be approximately the same as those cited for the No Action Alternative and below the guideline value of 1 in a million (6.4×10^{-6}) for the major carcinogenic pollutants that could be released from LANL under normal operations. In other words, one person in a population of a million would develop cancer if this population were exposed to this concentration over a lifetime, a level of concern established in the Clean Air Act. Therefore, the impact of potential chemical releases on minority or low-income individuals under this alternative would not be considered significant.

For nonradiological air quality impacts, as discussed in Section 5.4.1.2, the concentrations of criteria pollutants as a result of LANL operations under the Reduced Operations Alternative would likely be smaller than those expected under the No Action Alternative and would remain well below the ambient standards established to protect human health. Therefore, the impact of potential nonradiological air pollutant releases on minority or low-income individuals under this alternative would not be considered significant.

The impact of potential accidents on the minority or low-income populations under the Reduced Operations Alternative would be the same as those discussed above for the No Action Alternative in Section 5.11.1.

5.11.3 Expanded Operations Alternative

Los Alamos National Laboratory Site-Wide Impacts

Based on the analysis of impacts for other resource areas in this chapter, there would be no high and adverse impacts from continued operation of LANL under the Expanded Operations Alternative. No disproportionately high and adverse environmental impacts on minority or low-income populations would occur due to construction activities at LANL or to the project-specific activities discussed in Appendices G, H, I, and J under this alternative. As stated in other subsections of this chapter, environmental impacts from construction under this alternative would be small and would not be expected to be significant and adverse beyond the LANL site boundary.

No disproportionately high and adverse environmental impacts on minority or low-income populations would occur under this alternative. This conclusion results from analyses presented in this SWEIS that determined there would be no significant impacts on human health, ecological, cultural, paleontological, socioeconomic, and other resource areas described in other subsections of this chapter.

As shown in Table 5–18, the total population within 50 miles (80 kilometers) of LANL for the Expanded Operations Alternative is projected to receive an annual dose of about 36 person-rem. Because the majority of this dose results from operations at LANSCE, the environmental justice analysis for this alternative uses the 50-mile (80-kilometer) population centered on LANSCE in TA-53. As shown in **Table 5–58**, the dose from LANSCE along with the dose associated with High Explosive Testing firing site operations ascribed to TA-36 would result in an annual dose of 29.2 person-rem to the affected population and an average annual individual dose of 0.10 millirem. These two locations account for approximately 81 percent of the total estimated dose from all sites at LANL under the Expanded Operations Alternative.

Table 5–58 Comparison of Total Minority, Hispanic, American Indian and Low-Income Population and Average Individual Doses Under the Expanded Operations Alternative [a]

	Annual Dose in Person-rem	*Annual Dose in Millirem*
Total Population [b]	29.2	
Average Individual		0.10
White (non-Hispanic) Population	15.0	
Non-Minority Average Individual		0.11
Total Minority Population	14.1	
Minority Average Individual		0.088
Hispanic Population [c]	11.3	
Hispanic Average Individual		0.086
American Indian Population [d]	1.8	
American Indian Average Individual		0.092
Non-Low-Income Population	25.9	
Non-Low-Income Average Individual		0.10
Low-Income Population	3.0	
Low-Income Average Individual		0.082

[a] The total population dose displayed in this table, accounts for the estimated dose from LANSCE at TA-53 and the High-Explosive Testing firing site operations at TA-36 for the Expanded Operations Alternative.
[b] The total population dose for this environmental justice analysis differs by 3 percent from that in Table 5–18. This difference is due to different models used to estimate the populations; both estimates are based on data drawn from the 2000 decennial census. The SECPOP computer program used for the analysis for Table 5–18 does not allow for the identification of minority and low-income populations. Therefore an alternate method that uses a more refined distribution of the population is used for this analysis. The minor differences do not affect the conclusions supported by the analyses.
[c] The total Hispanic population includes all Hispanic persons regardless of race.
[d] The American Indian population may include persons who also indicated that they were of Hispanic ethnicity in the 2000 census.

The white (non-Hispanic) population would be expected to receive the largest annual collective dose (15 person-rem) and annual average individual dose (0.11 millirem). This compares to a total minority annual collective dose of 14.1 person-rem and an average annual dose of 0.088 millirem to a member of the minority population. American Indians living within 50 miles (80 kilometers) of LANL would receive a collective dose of 1.8 person-rem annually and an annual average individual dose of 0.092 millirem. The Hispanic population would receive a collective dose of 11.3 person-rem annually; the annual average dose to a member of the Hispanic population would be 0.086 millirem.

Population doses to persons living below the poverty level are also analyzed in Table 5–58. Annually, low-income populations surrounding LANL would receive a collective dose of

3.0 person-rem and an average individual dose of 0.082 millirem. Persons living above the poverty level would receive an annual collective dose of 25.9 person-rem and an annual average individual dose of 0.10 millirem. These data show that the total minority, American Indian, Hispanic, and low-income populations would not be subjected to disproportionately high and adverse dose impacts from normal operations at LANL under the Expanded Operations Alternative.

As discussed in Sections 5.6.1 and 5.6.2, radiological and hazardous chemical risks to the public resulting from normal operations would be small and not considered significant. As shown in Table 5–17, the MEI for the Expanded Operations Alternative is projected to receive a dose of approximately 8.2 millirem (0.00082 rem), about a 5 percent increase in the dose projected for the MEI under the No Action Alternative. This increase in the MEI dose would not be considered significant and therefore doses to members of minority or low-income populations that would be lower than the increase in dose to the MEI would not be considered significant. As discussed earlier in Section 5.11, the average resident of New Mexico receives a dose of approximately 400 millirem (0.4 rem) per year from background sources. Therefore, for the MEI under the Expanded Operations Alternative, his or her average annual dose and risk of developing a fatal cancer from the dose received would be expected to increase by a maximum of approximately 2.1 percent as a result of LANL operations.

As discussed in Section 5.6.2.3, the maximum public risk of developing a cancer as a result of chemical releases under the Expanded Operations Alternative would be approximately the same as those cited for the No Action Alternative with the exception of a small increase in high explosives processing that would not be expected to substantially change the risks. Therefore, the impact of potential chemical releases on minority or low-income individuals under this alternative would not be considered significant.

For nonradiological air quality impacts, as discussed in Section 5.4.1.3, the concentrations of criteria pollutants as a result of LANL operations under the Expanded Operations Alternative would likely be larger than those expected under the No Action Alternative but would remain below the ambient standards established to protect human health. Therefore, the impact of potential nonradiological air pollutant releases on minority or low-income individuals under this alternative would not be considered significant.

The impact of potential accidents on the minority and low-income populations under the Expanded Operations Alternative would be the same as those discussed above for the No Action Alternative in Section 5.11.1.

Key Facilities Impacts

Routine normal operations at Key Facilities would not be expected to cause fatalities or illness among the general population, including minority and low-income populations living within the potentially affected area.

Annual radiological risk to the offsite population that could result from the maximum potential accident at a Key Facility is estimated to be less than 0.76 LCFs (see Table 5–65). Thus, the risk of an excess LCF in the entire offsite population under the Expanded Operations Alternative would be less than 1.

5.12 Facility Accidents

The estimated impacts of potential accidents are described in this section for the No Action, Reduced Operations, and Expanded Operations Alternatives. A summary of the risks from radiological and chemical operations, potential seismic events, and a potential wildfire is provided in **Table 5–59**. Radiological impacts from facility accidents are addressed in Section 5.12.1. Chemical impacts from facility accidents are addressed in Section 5.12.2. Impacts from postulated earthquake events that could simultaneously affect multiple facilities are addressed in Section 5.12.3. Wildfire, another natural event that can also impact multiple facilities, is addressed in Section 5.12.4. Additional accident analysis details are provided in Appendix D. For all accident scenarios, the noninvolved worker is a hypothetical individual located 110 yards (100 meters) from the site of the accident, the MEI is a hypothetical individual located at the nearest site boundary, and the population includes residents within 50 miles (80 kilometers) of the site of the accident.

Table 5–59 Summary of Worker and Public Radiological Risks and Chemical Consequences from Potential Accidents

Maximum Potential Accident	*No Action Alternative*	*Reduced Operations Alternative*	*Expanded Operations Alternative*
Facility Radiological Release		Same as No Action Alternative	Same as No Action Alternative
• Offsite Population (LCF per year)	0.8		
• MEI (LCF per year)	0.06		
• Noninvolved Worker (LCF per year)	0.1		
Facility Chemical Release [a]		Same as No Action Alternative	Same as No Action Alternative
• Concentrations above which life-threatening health effects could result (ERPG-3 [t] limit)	5 parts per million		
• ERPG-3 distance	962 yards		
• Distance to the site boundary	537 yards		
Site-Wide Seismic Event Radiological		Same as No Action Alternative	Same as No Action Alternative
• Offsite Population (LCF per year)	0.009		
• MEI (LCF per year)	0.0003		
• Noninvolved Worker (LCF per year)	0.001		
Site-Wide Seismic Event Chemical [a]		Same as No Action Alternative	Same as No Action Alternative
• Concentrations above which life-threatening health effects could result (ERPG-3 [t] limit)	25 parts per million		
• ERPG-3 distance	122 yards		
• Distance to the site boundary	13 yards		
Wildfire Radiological		Same as No Action Alternative	Same as No Action Alternative
• Offsite Population (LCF per year)	2.7		
• MEI (LCF per year)	0.05		
• Noninvolved Worker (LCF per year)	0.05		
Wildfire Chemical [a]		Same as No Action Alternative	Same as No Action Alternative
• Concentrations above which life-threatening health effects could result (ERPG-3 [t] limit)	25 parts per million		
• ERPG-3 distance	97 yards		
• Distance to the site boundary	13 yards		

LCF = latent cancer fatality, MEI = maximally exposed individual, ERPG = Emergency Response Planning Guideline.

[a] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2005e).

Note: To convert yards to meters, multiply by 0.9144.

5.12.1 Facility Radiological Impacts

Estimated radiological accident consequences and risks associated with the No Action, Reduced, and Expanded Alternatives are shown in Tables 5–60 through 5–65.

5.12.1.1 No Action Alternative

The accident with the highest estimated consequences to the offsite population, as shown in **Table 5–60**, is a lightning strike fire at the Radioassay and Nondestructive Testing Facility.[6] If this accident were to occur, there could be 6 additional LCFs in the offsite population. The accident with the highest estimated consequences to the MEI and a noninvolved worker is a waste storage dome fire at TA-54 as shown in Tables 5–60 and **5–61**. If this accident were to occur as modeled, the noninvolved worker and the MEI would receive large radiation doses. Depending on the specific radionuclides released and the route of human exposure, radiation doses of this magnitude would result in near-term health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose to the exposed individual, mitigating health impacts, or both. In addition to the conservative assumptions used to develop the source term (amount of radioactive material released) for this accident, the calculated doses are based on the assumptions that no protective action is taken during the entire time of exposure and that no subsequent medical intervention occurs. The MEI for all of the scenarios is located at the nearest site boundary.

The potential exists for exposures in excess of the above in the vicinity of the Chemistry and Metallurgy Research Building because of public access to Diamond Drive, which is approximately 50 meters from the building. The Chemistry and Metallurgy Building is expected to be operational until transition to the Chemistry and Metallurgy Research Replacement Facility is completed. The consequences to an individual at this Diamond Drive location during the HEPA Filter Fire would be 8.1 rem, resulting in an increased individual LCF risk of 0.0049 (approximately 1 in 210). Appendix D, Section D.3.2.1, contains further discussion of the Chemistry and Metallurgy Research Building exposures.

After accounting for the frequency of the postulated accidents (see Appendix D), the estimated highest risk accident would be a Radioassay and Nondestructive Testing Facility lightning strike fire (TA-54-38). **Table 5–62** shows the annual risk of an increased likelihood of an LCF for this accident to be 0.059 (about 1 in 17 years) for the MEI. The offsite population annual risk of additional LCFs is estimated to be 0.76 for an LCF in any one member of the total offsite population. Table 5–62 shows the annual risk of an increased likelihood of an LCF for this accident to be 0.12 (about 1 in 8 years) for a noninvolved worker.

---

[6] *The lightning fire accident scenario conservatively assumes that any lightning striking the Radioassay and Nondestructive Testing Facility would result in a fire that affects and releases radioactive material located inside the facility regardless of the lightning energy or the specific location at the facility subject to the lightning strike.*

Table 5–60 Radiological Accident Offsite Population Consequences for the No Action and Reduced Operations Alternatives

Accident Scenario	Maximally Exposed Individual		Population to 50 Miles (80 kilometers)	
	Dose [a] (rem)	Latent Cancer Fatality [b]	Dose (person-rem)	Latent Cancer Fatalities [c, d]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	410	0.49	11,000	6 (6.3)
Weapons Engineering Tritium Facility Fire (TA-16-205)	5.9	0.0036	190	0 (0.11)
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	46	0.055	4,800	3 (2.9)
Waste Storage Dome Fire (TA-54)	420	0.50	4,200	3 (2.5)
Onsite Transuranic Waste Fire (TA-54)	190	0.22	5,700	3 (3.4)
Plutonium Facility Material Staging Area Fire (TA-55-4)	73	0.087	9,000	5 (5.4)
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	20	0.012	190	0 (0.11)
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	320	0.39	6,100	4 (3.7)
SHEBA Hydrogen Detonation (TA-18-168) [e]	0.88	0.00053	69	0 (0.041)
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.77	0.00046	200	0 (0.12)

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, HEPA = high-efficiency particulate air (filter).

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Increased number of LCFs for the offsite population, assuming the accident occurs; value in parentheses is the calculated result.

[d] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-69), 343,100 (TA-54-38, TA-54-412, Domes), 301,900 (TA-55-4).

[e] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations Alternative.

Table 5–61 Radiological Accident Onsite Worker Consequences for the No Action and Reduced Operations Alternatives

Accident Scenario	Noninvolved Worker at 110 Yards (100 meters)	
	Dose [a] (rem)	Latent Cancer Fatality [b]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	1,900	1.0 [c]
Weapons Engineering Tritium Facility Fire (TA-16-205)	8.92	0.00535
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	1,100	1.0 [c]
Waste Storage Dome Fire (TA-54)	2,000	1.0 [c]
Onsite Transuranic Waste Fire (TA-54)	760	0.91
Plutonium Facility Material Staging Area Fire (TA-55-4)	1,600	1.0 [c]
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	51	0.062
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	890	1.0 [c]

Accident Scenario	Noninvolved Worker at 110 Yards (100 meters)	
	Dose [a] (rem)	Latent Cancer Fatality [b]
SHEBA Hydrogen Detonation (TA-18-168) [d]	15	0.0092
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	5.4	0.0032

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, HEPA = high-efficiency particulate air (filter).
[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.
[b] Increased risk of an LCF to an individual, assuming the accident occurs.
[c] The indicated dose yields a risk value greater than 1.0. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For this reason, a value of 1.0 is shown.
[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations Alternative.

Table 5–62 Radiological Accident Offsite Population and Worker Risks for the No Action and Reduced Operations Alternatives

Accident Scenario	Frequency (per year)	Onsite Worker	Offsite Population	
		Noninvolved Worker at 110 Yards (100 meters) [a]	Maximally Exposed Individual [a]	Population to 50 Miles (80 kilometers) [b, c]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	0.12 [d]	0.12	0.059	0.76
Weapons Engineering Tritium Facility Fire (TA-16-205)	1.1×10^{-5}	5.9×10^{-8}	4.0×10^{-8}	1.3×10^{-6}
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	0.14 [d]	0.14	0.0077	0.4
Waste Storage Dome Fire (TA-54)	0.001	0.001	0.0005	0.0025
Onsite Transuranic Waste Fire (TA-54)	0.001	0.00091	0.00022	0.0034
Plutonium Facility Material Staging Area Fire (TA-55-4)	0.01	0.01	0.00087	0.054
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	0.02	0.0012	0.00024	0.0022
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	0.001	0.001	0.00039	0.0037
SHEBA Hydrogen Detonation (TA-18-168) [e]	0.0054	0.00005	2.8×10^{-6}	0.00022
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.01	0.000032	4.6×10^{-6}	0.0012

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, HEPA = high-efficiency particulate air (filter).
[a] Increased risk of an LCF to an individual per year.
[b] Increased number of LCFs for the offsite population per year.
[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-69), 343,100 (TA-54-38, DVRS, Domes), 301,900 (TA-55-4).
[d] The lightning strike fire accident scenarios conservatively assumes that any lightning strike on the facility would result in a source term equivalent to a structure fire.
[e] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations Alternative.

5.12.1.2 Reduced Operations Alternative

The accident impacts from the Reduced Operations Alternative are the same as those from the No Action Alternative and are presented in Tables 5-60 through 5-62. Activities at TA-18, including operation of SHEBA, would cease under this alternative. Inspection of the tables shows that SHEBA operations are a small component of the facility impacts at LANL; its elimination would not significantly alter the overall risk profile of individual facility operations. All other impacts in the tables are equally applicable for this alternative.

5.12.1.3 Expanded Operations Alternative

Accident impacts under the Expanded Operations Alternative are shown in **Tables 5–63** through **5–65**. SHEBA operations would cease under the Expanded Operations Alternative, so its impacts, although relatively small, have been eliminated from the tables below. Additional or replacement risks from accident impacts would result from expanded waste management activities. Transuranic waste storage would be consolidated in a new facility, the TRU Waste Facility located in TA-50 or a generic site along the Pajarito Road corridor. The impacts from this new facility would be smaller than those of the existing facilities because of its new location and because less material would be stored and the rest would be moved offsite. The entries in Tables 5–63 through 5–65 reflect present Decontamination and Volume Reduction System and waste storage domes operations because they would bound the impacts of the new facility. Accident impacts for the new facility are described in Appendix H.

MDA cleanup is a component of the Expanded Operations Alternative. A number of scenarios were considered for this activity and an explosion or fire during removal operations that breaches the MDA enclosure and bypasses the HEPA filtration was chosen. MDA G, because of its relatively large inventory, bounds the accident impacts from MDA removal. The consequences and risks from this scenario are included in Tables 5–63 through 5–65. As with the No Action Alternative, TA-54 operations generally dominate the accident risks from Expanded Operations. Possible removal of MDA G in TA-54 adds a component to this risk. Appendix I includes more details about MDA cleanup accident impacts.

The accident with the largest consequences to the offsite population is a fire at Chemistry and Metallurgy Research Building involving sealed sources, as shown in Table 5–63. If this accident were to occur, there could be 7 additional LCFs in the offsite population. The accident with the highest consequences to the MEI and the noninvolved worker is a waste storage dome fire at TA-54.

The potential exists for exposures in excess of those above at the Chemistry and Metallurgy Research Building because of public access to Diamond Drive, approximately 50 meters from the facility. The Chemistry and Metallurgy Research Building is expected to be operational until the transition to the Chemistry and Metallurgy Research Replacement Facility is completed. The consequences to an individual at this Diamond Drive location during a fire impacting sealed sources (applicable to only the Expanded Operations Alternative) or a HEPA filter fire would be 4.3 rem and 8.1 rem, respectively. These doses would result in an increased risk of a latent fatal cancer during the lifetime of the individual of 0.0026 (approximately 1 in 390) and 0.0049 (approximately 1 chance in 210), respectively. Appendix D, Section D.3.2.1, contains further discussion of the Chemistry and Metallurgy Research Building exposures.

Table 5–63 Radiological Accident Offsite Population Consequences for the Expanded Operations Alternative

Accident Scenario	Maximally Exposed Individual		Population to 50 Miles (80 kilometers)	
	Dose [a] (rem)	LCF [b]	Dose (person-rem)	LCF [c, d]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	410	0.49	11,000	6 (6.3)
Weapons Engineering Tritium Facility Fire (TA-16-205)	5.9	0.0036	190	0 (0.11)
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	46	0.055	4,800	3 (2.9)
Waste Storage Dome Fire (TA-54)	420	0.50	4,200	3 (2.5)
Onsite Transuranic Waste Fire (TA-54)	190	0.22	5,700	3 (3.4)
Plutonium Facility Material Staging Area Fire (TA-55-4)	73	0.087	9,000	5 (5.4)
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	20	0.012	190	0 (0.11)
Explosion at Material Disposal Area G (TA-54)	55	0.066	770	0 (0.46)
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	320	0.39	6,100	4 (3.7)
Chemistry and Metallurgy Research Building Fire Involving Sealed Sources (TA-3-29)	0.099	0.000059	12,000	7 (7.0)
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.77	0.00046	200	0 (0.12)

LCF = latent cancer fatality, TA = technical area, HEPA = high-efficiency particulate air (filter).

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Increased number of LCFs for the offsite population, assuming the accident occurs; value in parentheses is the calculated result.

[d] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 271,600 (TA-21-155, -209), 302,000 (TA-50-69), 343,100 (TA-54-38, DVRS, Domes), 301,900 (TA-55-4).

After accounting for the frequency of the postulated accidents, the estimated highest risk accident would be a Radioassay and Nondestructive Testing Facility lightning strike fire (TA-54-38). Table 5–65 shows the annual risk of an increased likelihood of an LCF for this accident to be 0.059 (about 1 in 17 years) for the MEI. The offsite population annual risk of additional LCFs is shown to be 0.76 for any one member of the offsite population. Table 5–65 shows the annual risk of an increased likelihood of an LCF for this accident to be 0.12 (about 1 chance in 8 years) for a noninvolved worker.

Table 5–64 Radiological Accident Onsite Worker Consequences for the Expanded Operations Alternative

Accident Scenario	Noninvolved Worker at 110 Yards (100 meters)	
	Dose (rem) [a]	LCF [b]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	1,900	1.0 [c]
Weapons Engineering Tritium Facility Fire (TA-16-205)	8.9	0.0054
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	1,100	1.0 [c]
Waste Storage Dome Fire (TA-54)	2,000	1.0 [c]
Onsite Transuranic Waste Fire (TA-54)	760	0.91
Plutonium Facility Material Staging Area Fire (TA-55-4)	1,600	1.0 [c]
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	51	0.062
Explosion at Material Disposal Area G (TA-54)	410	0.49
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	890	1.0 [c]
Chemistry and Metallurgy Research Building Fire Involving Sealed Sources (TA-3-29)	1.2	0.00073
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	5.4	0.0032

LCF = latent cancer fatality, TA = technical area, HEPA = high-efficiency particulate air (filter).

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] The indicated dose yields a risk value greater than 1.0. This means that it is likely that an individual exposed to the indicated dose would develop a fatal latent cancer. For this reason, a value of 1.0 is shown.

Table 5–65 Radiological Accident Offsite Population and Worker Risks for the Expanded Operations Alternative

Accident Scenario	Frequency (per year)	Risk to Onsite Worker	Offsite Population	
		Noninvolved Worker at 110 Yards (100 meters) [a]	Maximally Exposed Individual [a]	Population to 50 Miles (80 kilometers) [b, c]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	0.12 [d]	0.12	0.059	0.76
Weapons Engineering Tritium Facility Fire (TA-16-205)	1.1×10^{-5}	6.0×10^{-8}	4.0×10^{-8}	1.3×10^{-6}
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	0.14 [d]	0.14	0.0077	0.4
Waste Storage Dome Fire (TA-54)	0.001	0.001	0.0005	0.0025
Onsite Transuranic Waste Fire (TA-54)	0.001	0.00091	0.00022	0.0034
Plutonium Facility Material Staging Area Fire (TA-55-4)	0.01	0.01	0.00087	0.054
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	0.02	0.0012	0.00024	0.0022
Explosion at Material Disposal Area G (TA-54)	0.01	0.0049	0.00066	0.0046
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	0.001	0.001	0.00039	0.0037
Chemistry and Metallurgy Research Building Fire Involving Sealed Sources (TA-3-29)	0.00024	1.7×10^{-7}	1.4×10^{-8}	0.0017

Accident Scenario	Frequency (per year)	Risk to Onsite Worker	Offsite Population	
		Noninvolved Worker at 110 Yards (100 meters) [a]	Maximally Exposed Individual [a]	Population to 50 Miles (80 kilometers) [b, c]
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.01	0.000032	4.6×10^{-6}	0.0012

TA = technical area, HEPA = high-efficiency particulate air (filter).

[a] Increased risk of an LCF to an individual per year.

[b] Increased number of LCFs for the offsite population per year.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-69), 343,100 (TA-54-38, DVRS, Domes), 301,900 (TA-55-4).

[d] The lightning strike fire accident scenarios conservatively assumes that any lightning strike on the facility would result in a source term equivalent to a structure fire.

5.12.2 Facility Hazardous Chemical Impacts

5.12.2.1 No Action Alternative

The chemicals of concern at LANL facilities under the No Action Alternative are shown in **Table 5–66**. They were selected from a database of chemicals used onsite based on their quantities, chemical properties, and human health effects. The table shows the Emergency Response Planning Guideline (ERPG) values. ERPG-2 and ERPG-3 values are the concentrations that, if an accident were to occur, could result in serious health effects or life-threatening implications for exposed individuals.

Table 5–66 also shows the risk of worker and public exposure in the event of a chemical release from site-wide events only (seismic- and wildfire-related releases are discussed in their respective sections). The cause of a chemical release could be mechanical failure, corrosion, mechanical impact, or natural phenomena. The estimated frequency of each accident is shown in the table. The direction traveled by the chemical plume, which would depend on meteorological conditions at the time of the accident, would determine what segment of the worker and offsite populations would be at risk of exposure.

For selenium hexafluoride located at TA-54-216, there is an annual risk of 0.0041 (1 in 240 years) that workers and the public within a distance of 962 yards (880 meters) of the release would be exposed to concentrations in excess of ERPG-3 values. The workers and the public within a distance of 3,062 yards (2,800 meters) of the release face the same risk of being exposed to concentrations in excess of ERPG-2 values.

For sulfur dioxide located at TA-54-216, there is an annual risk of 0.00051 (1 in 1,950 years) that workers and the public within a distance of 755 yards (690 meters) of the release would be exposed to concentrations in excess of ERPG-3 values. The workers and the public within a distance of 1,804 yards (1,650 meters) of the release face the same risk of being exposed to concentrations in excess of ERPG-2 values.

Table 5–66 Chemical Accident Risks under the No Action and Reduced Operations Alternatives

Chemical	Frequency (per year)	Quantity Released	ERPG-2 [a]		ERPG-3 [b]	
			Value (ppm)	Annual Risk	Value (ppm)	Annual Risk
Selenium hexafluoride from waste cylinder storage at TA-54-216	0.0041	19.8 gallons (75 liters)	0.6 [c]	1 chance in 240 years of workers or public within 3,062 yards (2,800 meters) of facility receiving exposures in excess of limit. Nearest public access is at 537 yards (491 meters).	5 [c]	1 chance in 240 years of workers or public within 962 yards (880 meters) of facility receiving exposures in excess of limit. Nearest public access is at 537 yards (491 meters).
Sulfur dioxide from waste cylinder storage at TA-54-216	0.00051	300 pounds (136 kilograms)	3	1 chance in 1,950 years of workers or public within 1,804 yards (1,650 meters) of facility receiving exposures in excess of limit. Nearest public access is at 537 yards (491 meters).	15	1 chance in 1,950 years of workers or public within 755 yards (690 meters) of facility receiving exposures in excess of limit. Nearest public access is at 537 yards (491 meters).
Chlorine gas released outside of Plutonium Facility Complex (TA-55-4)	0.063	150 pounds (68 kilograms)	3	1 chance in 15 years of workers within 1,181 yards (1,080 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,111 yards (1,016 meters).	20	1 chance in 15 years of workers within 416 yards (380 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,111 yards (1,016 meters).
Helium at TA-55-41	0.063	9,230,000 cubic feet (at STP) (261,366 cubic meters)	280,000 ppm [c]	1 chance in 15 years of workers within 203 yards (186 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,146 yards (1,048 meters).	500,000 ppm [c]	1 chance in 15 years of workers within 152 yards (139 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,146 yards (1,048 meters).

ERPG = Emergency Response Planning Guideline, ppm = parts per million, TA = technical area, STP = standard temperature and pressure.

[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action (DOE 2005e).

[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2005e).

[c] The Temporary Emergency Exposure Limit value is used. ERPGs have not been issued for this substance.

For chlorine gas located outside of TA-55-4, there is an annual risk of 0.063 (1 in 15 years) that workers within a distance of 416 yards (380 meters) of the release would be exposed to concentrations in excess of ERPG-3 values. Workers and the public within a distance of 1,181 yards (1,080 meters) of the release face the same risk of being exposed to concentrations in excess of ERPG-2 values.

For helium gas located at TA-55-41, there is an annual risk of 0.063 (1 in 15 years) that workers within 152 yards (139 meters) of the release would be exposed to concentrations in excess of ERPG-3 values. Workers within a distance of 203 yards (186 meters) of the release face the same risk of being exposed to concentrations in excess of ERPG-2 values.

5.12.2.2 Reduced Operations Alternative

The chemicals of concern that could be released in a facility accident are the same for the Reduced Operations Alternative as for the No Action Alternative. None of the chemicals identified for the latter is eliminated in this alternative. The information in Table 5–66, therefore, also applies to the Reduced Operations Alternative.

5.12.2.3 Expanded Operations Alternative

The chemicals of concern that could be released in a facility accident for the No Action Alternative apply equally to the Expanded Operations Alternative. In addition, MDA cleanup, a component of the Expanded Operations Alternative, also includes a potential for accidental releases of toxic chemicals. A fire during removal operations that breaches any MDA enclosure and bypasses the HEPA filtration was chosen for analysis. There is a great deal of uncertainty regarding how much and which chemicals were disposed of in the MDAs. For the most conservative analysis, MDA B, the MDA closest to the public (and thus with the potential for the greatest impact on the public), was chosen to represent the chemical accident impacts of MDA cleanup. Two chemicals, sulfur dioxide (a gas) and beryllium (assumed to be in powder form), were chosen based on their restrictive ERPG values to bound the impacts of an extensive list of possible chemicals disposed of in the MDAs. **Table 5–67** shows, if present in MDA B in the quantities assumed, both of these chemicals would dissipate to below the ERPG-3 value very close to the release, but would continue to be a risk to the public due to the short distance to the nearest public access point for this MDA. Appendix I includes more details about MDA cleanup chemical accident impacts.

5.12.3 Site-Wide Seismic Impacts

As addressed in more detail in Appendix D, Section D.4, two site-wide seismic events, referred to as Seismic 1 and Seismic 2, were postulated to estimate the potential effects of radiological and chemical releases during an earthquake. In the event of a site-wide seismic event, radiological and chemical hazardous materials could be simultaneously released. Seismic events are categorized by their performance category (PC), which is numbered from PC-0 through PC-4. A higher performance category has a smaller annual frequency of occurrence, but a larger associated ground acceleration. A higher performance category has more severe consequences and structures would require a more resilient engineering design to survive.

The seismic accident scenarios (Seismic 1 and 2) analyzed in the SWEIS were based on the February 24, 1995, *Seismic Hazards Evaluation of the Los Alamos National Laboratory*. Seismic 1 – the seismic event characterized by a peak horizontal ground acceleration of 0.22g (0.22 times the acceleration due to gravity) – had an estimated annual probability of exceedance of 0.001 (1 in 1,000). Seismic 2 – a more severe seismic event characterized by a peak ground acceleration of 0.31g – had an estimated annual probability of exceedance of 0.0005 (1 in 2,000).

Table 5–67 Chemical Accident Risks under the Expanded Operations Alternative

Chemical	Frequency (per year)	Quantity Released	ERPG-2 [a]		ERPG-3 [b]	
			Value	Annual Risk	Value	Annual Risk
Selenium hexafluoride from waste cylinder storage at TA-54-216	0.0041	19.8 gallons (75 liters)	0.6 ppm [c]	1 chance in 240 years of workers or public within 3,062 yards (2,800 meters) of facility receiving exposures in excess of limit. Public access is at 537 yards (491 meters).	5 ppm [c]	1 chance in 240 years of workers or public within 962 yards (880 meters) of facility receiving exposures in excess of limit. Nearest public access is at 537 yards (491 meters).
Sulfur dioxide from waste cylinder storage at TA-54-216	0.00051	300 pounds (136 kilograms)	3 ppm	1 chance in 1,950 years of workers or public within 1,804 yards (1,650 meters) of facility receiving exposures in excess of limit. Public access is at 537 yards (491 meters).	15 ppm	1 chance in 1,950 years of workers or public within 755 yards (690 meters) of facility receiving exposures in excess of limit. Nearest public access is at 537 yards (491 meters).
Chlorine gas released outside of Plutonium Facility Complex (TA-55-4)	0.063	150 pounds (68 kilograms)	3 ppm	1 chance in 15 years of workers within 1,181 yards (1,080 meters) of facility receiving exposures in excess of limit. Public access is at 1,111 yards (1,016 meters).	20 ppm	1 chance in 15 years of workers within 416 yards (380 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,111 yards (1,016 meters).
Helium at TA-55-41	0.063	9,230,000 cubic feet (261,366 cubic meters) (at STP)	280,000 ppm [c]	1 chance in 15 years of workers within 203 yards (186 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,146 yards (1,048 meters).	500,000 ppm [c]	1 chance in 15 years of workers within 152 yards (139 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,146 yards (1,048 meters).
Sulfur Dioxide (MDA B)	No frequency established; performed as an enveloping analysis	1 pound (0.45 kilogram)	3 ppm	Risk of workers or public within 90 yards (83 meters) of facility receiving exposures in excess of limit. Nearest public access is at 49 yards (45 meters).	15 ppm	Risk of workers or public within 37 yards (34 meters) of facility receiving exposures in excess of limit. Nearest public access is at 49 yards (45 meters).
Beryllium Powder (MDA B)	No frequency established; performed as an enveloping analysis	22 pounds [d] (10 kilograms)	0.025 milligram per cubic meter	Risk of workers within 25 yards (23 meters) of facility receiving exposures in excess of limit. Public access is at 49 yards (45 meters).	0.1 milligram per cubic meter	Risk of workers within 10 yards (9 meters) of facility receiving exposures in excess of limit. Nearest public access is at 49 yards (45 meters) and beyond this limit.

ERPG = Emergency Response Planning Guideline, TA = technical area, ppm = parts per million, MDA = material disposal area.

[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action (DOE 2005e).

[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2005e).

[c] The Temporary Emergency Exposure Limit value is used. ERPGs have not been issued for this substance.

[d] This quantity represents the total material at risk. A fraction of this solid (0.00006) would be released as respirable particles under the hypothesized scenario.

An updated probabilistic seismic hazard analysis providing an improved understanding of the seismic characteristics of LANL was completed in 2007 (LANL 2007a). The new study indicates that the seismic hazard is higher than previously understood; the annual probability of exceedance for the previously analyzed peak ground accelerations is now estimated to be about 1 in 700 (rather than 1 in 1,000) for the Seismic 1 event, and 1 in 1,250 (rather than 1 in 2,000) for the Seismic 2 event. The revised annual probabilities of exceedance are thus 0.0015 and 0.0008, respectively. Using these larger probabilities, however, the seismic accident risks for the MEI, the noninvolved worker, and the population are less than 1 percent of accident risks for other types of accidents in the SWEIS such as fires at the Radioassay and Nondestructive Testing Facility, the Waste Characterization, Reduction, and Repackaging Facility, and the TA-54 waste storage domes.

For many facilities involved in the SWEIS Seismic 1 and 2 accident scenarios, a conservative assumption was made that there was complete failure of structures, systems, and components (given the Seismic 1 and 2 ground shaking), thereby resulting in the maximum possible radioisotope or chemical release. Higher seismic accelerations at the same annual frequency of exceedance would result in identical consequences for these facilities. Therefore, the larger seismic peak ground accelerations associated with the updated probabilistic seismic hazard analysis would not increase the consequence of these accident scenarios.[7] Furthermore, structures are typically designed with considerable factors of safety that provide large margins before failure would occur. For those facilities that were not assumed to completely fail, it is not possible to state the impacts of different peak horizontal ground accelerations without detailed structural analyses of LANL facilities using the updated probabilistic seismic hazard analysis results. Therefore, a bounding analysis was used to estimate the maximum expected effect of the updated seismic hazard analysis on the SWEIS seismic accident risks.

Using the accident source terms that were developed for the SWEIS Seismic 1 and 2 accident scenarios, the effect of the revised estimates of annual probability of exceedance would be an increase in the radiological risk of 50 percent for Seismic 1 scenarios and 60 percent for Seismic 2 scenarios. For this assessment, no credit was taken for facilities for which complete failure was already assumed and therefore no larger accident source term would be expected at larger seismic ground accelerations. Furthermore, the number of LCFs calculated for these two postulated seismic events should be considered within the context of the nonradiological human health impacts expected from these seismic events, which would cause widespread failures of non-nuclear LANL structures and structures outside of LANL. A much larger number of fatalities and injuries from structure collapse would be expected for these seismic events in the area surrounding LANL.

Just as the updated probabilistic seismic hazards analysis used new data and advanced methods to calculate LANL seismic hazards, revised structural analysis methods tied to damage states

---

[7] *The facilities for which the consequences would be the same include: the Chemistry and Metallurgy Research Building, the Weapons Engineering Test Facility, the Tritium Science and Fabrication Facility, the Tritium System Test Assembly, and Radioactive Liquid Waste Treatment Facility, the Waste Characterization, Reduction, and Repackaging Facility, and the Radioassay and Nondestructive Testing Facility. Facilities for which the consequences of higher ground acceleration may be greater include: the Plutonium Facility, the TA-55 Storage Facility, the Decontamination and Volume Reduction System, Waste Storage Domes, and the Safe Secure Transport Facility.*

credited in safety assessment documents will be used to update the seismic structural integrity evaluation of LANL facilities. The effect of the higher values of peak horizontal ground acceleration on accident consequences and risks will be analyzed in future facility safety analyses and incorporated as appropriate into future NEPA documents. NNSA and the LANL management and operating contractor will undertake an evaluation of LANL facility performance in terms of the updated seismic hazard information. Until that revised analysis is completed, operations would be authorized based on NNSA approval of a contractor-prepared justification for continued operation.

The LANL management and operating contractor has developed and NNSA has accepted a site-wide justification for continued operation as a result of the estimates of increased seismic event frequency and acceleration associated with the updated probabilistic seismic hazards analysis. The justification for continued operation presents a qualitative evaluation of the effect of this increased seismic hazard on site-wide transportation and on the following LANL facilities: Chemistry and Metallurgy Research Building, Beryllium Technology Facility, Dual-Axis Radiographic Hydrodynamic Test Facility, Weapons Engineering Test Facility, Radioactive Liquid Waste Treatment Facility, Waste Characterization, Reduction, and Repackaging Facility, TA-53 underground spent resin tank, LANSCE, Area G waste operations, Radioassay and Nondestructive Testing Facility, Plutonium Facility, Safe and Secure Transport Facility, and the nuclear environmental sites (MDA A, MDA B, MDA C, MDA H, MDA T, MDA W, TA-35 Wastewater Treatment Plant, TA-35 Pratt Canyon, and MDA AB). The justification for continued operation determined that existing bounding seismic accident analyses; new facility safety analyses; compensatory measures of limiting radioactive material inventory, new programs, and procedures; and the low probability of a seismic event during the anticipated time period for detailed quantitative analysis of each facility's safety documentation provide the basis for an acceptable risk for continued operation of LANL (LANL 2007a, NNSA 2007c).

The Los Alamos Site Office directed the LANL management and operating contractor to develop a draft project execution plan to perform specific detailed facility seismic analyses; incorporate necessary changes to facility safety bases; and develop a list of potential facility modifications to address deficiencies identified in the seismic analyses (NNSA 2007c). If necessary, facility-specific justifications for continued operation will be developed as part of this process. This project will provide for the evaluation of each LANL facility using the updated probabilistic seismic hazard analysis seismic accelerations and frequencies and in accordance with appropriate LANL structural engineering standards for seismic events using all applicable industry, federal government, and international standards, codes, and criteria.

5.12.3.1 No Action Alternative

Site-Wide Seismic 1 – Radiological

Site-wide Seismic 1 is represented by a PC-2 seismic event. Referring to **Tables 5–68** through **5–70** and noting that all of the listed facilities could contribute to offsite population impacts, the facility with generally the highest contribution to worker and public risk is the Chemistry and Metallurgy Research Building. In the event of this seismic event, it is estimated that there would be four LCFs in the offsite population from a Chemistry and Metallurgy Research Building release. As a result of such a release, the noninvolved worker would receive a large radiation dose. There is also a potential for an individual at publicly accessible Diamond Drive, approximately 55 yards (50 meters) from the Chemistry and Metallurgy Research Building, to receive an exposure in excess of the offsite MEI exposure. The calculated dose to such an individual is 6,400 rem, or about 100 times the MEI dose. Depending on the specific radionuclides released and the route of human exposure, radiation doses calculated for the individual on Diamond Drive and the noninvolved worker would result in near-term health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose to the exposed individual, mitigating health impacts, or both. In addition to the conservative assumptions used to develop the source term (the amount of radioactive material released) for this accident, the calculated dose is based on the assumptions that no protective action is taken during the entire time of exposure and that no subsequent medical intervention occurs. Since the annual probability of this seismic event is 0.001, the increased risk of an additional LCF occurring in the population is estimated to be 0.0037 per year; the increased risk of a health effect for an individual on Diamond Drive or the noninvolved worker is estimated to be 0.001 or 1 chance in 1,000.

Table 5–68 Site-Wide Seismic 1 Radiological Accident Offsite Population Consequences for the No Action, Reduced Operations, and Expanded Operations Alternatives

	Maximally Exposed Individual		*Population to 50 Miles (80 kilometers)*	
Facility Impacted by Seismic 1 Event	***Dose (rem)***	***Latent Cancer Fatality*** [a]	***Dose (person-rem)***	***Latent Cancer Fatalities*** [b, c]
Chemistry and Metallurgy Research Building (TA-3-29)	62	0.075	6,100	4 (3.7)
SHEBA (TA-18-168) [d]	0.03	0.000018	0.77	0 (0.00046)
Tritium System Test Assembly (TA-21-155)	0.0015	8.8×10^{-7}	0.049	0 (0.00003)
Tritium Science and Fabrication Facility (TA-21-209)	0.013	7.5×10^{-6}	0.43	0 (0.00026)
Radioactive Liquid Waste Treatment Facility (TA-50-1)	3	0.0018	520	0 (0.31)
Radioassay and Nondestructive Testing Facility (TA-54-38)	64	0.077	1,100	1 (0.67)
Storage Facility (TA-55-185)	6	0.0036	590	0 (0.35)
Decontamination and Volume Reduction System (TA-54-412) (PC-2 Seismic)	2.8	0.0017	49	0 (0.03)
	Max 64	Max 0.077	Total or sum 8,400	Total 5 (5.01)

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Increased risk of an LCF to an individual, assuming the accident occurs.

[b] Increased number of LCFs for the offsite population, assuming the accident occurs.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-1), 343,100 (TA-54-38, DVRS).

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations and Expanded Operations Alternatives.

Table 5–69 Site-Wide Seismic 1 Radiological Accident Onsite Worker Consequences for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 1 Event	*Noninvolved Worker at 110 Yards (100 meters)*	
	Dose (rem) [a]	*Latent Cancer Fatality* [b]
Chemistry and Metallurgy Research Building (TA-3-29)	2,000	1.0 [c]
SHEBA (TA-18-168) [d]	1.1	0.00064
Tritium System Test Assembly (TA-21-155)	0.011	6.7×10^{-6}
Tritium Science and Fabrication Facility (TA-21-209)	0.097	0.000058
Radioactive Liquid Waste Treatment Facility (TA-50-1)	120	0.15
Radioassay and Nondestructive Testing Facility (TA-54-38)	580	0.69
Storage Facility (TA-55-185)	240	0.29
Decontamination and Volume Reduction System (TA-54-412) (PC-2 Seismic)	10	0.0061

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] The indicated dose yields a risk value greater than 1.0. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For this reason, a value of 1.0 is shown.

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations and Expanded Operations Alternatives.

Table 5–70 Site-Wide Seismic 1 Radiological Accident Offsite Population and Worker Risks for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 1 Event	*Frequency (per year)*	*Onsite Worker*	*Offsite Population*	
		Noninvolved Worker at 110 Yards (100 meters) [a]	*Maximally Exposed Individual* [a]	*Population to 50 Miles (80 kilometers)* [b, c]
Chemistry and Metallurgy Research Building (TA-3-29)	0.001	0.001	0.000075	0.0037
SHEBA (TA-18-168) [d]	0.001	6.4×10^{-7}	1.8×10^{-8}	4.6×10^{-7}
Tritium System Test Assembly (TA-21-155)	0.001	6.7×10^{-9}	8.8×10^{-10}	3×10^{-8}
Tritium Science and Fabrication Facility (TA-21-209)	0.001	5.8×10^{-8}	7.5×10^{-9}	2.6×10^{-7}
Radioactive Liquid Waste Treatment Facility (TA-50-1)	0.001	0.00015	1.8×10^{-6}	0.00031
Radioassay and Nondestructive Testing Facility (TA-54-38)	0.001	0.00069	0.000077	0.00067
Storage Facility (TA-55-185)	0.001	0.00029	3.6×10^{-6}	0.00035
Decontamination and Volume Reduction System (TA-54-412) (PC-2 Seismic)	0.001	6.1×10^{-6}	1.7×10^{-6}	0.00003
		Maximum 0.001	Maximum 0.000077	Total 0.0051

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Increased risk of an LCF to an individual per year; new seismic data increases the risk by about 50 percent.

[b] Increased number of LCFs for the offsite population per year; new seismic data increases the risk by about 50 percent.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-1), 343,100 (TA-54-38, DVRS).

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations and Expanded Operations Alternatives.

All site facilities containing hazardous radiological materials that are susceptible to structural failure during this event could potentially contribute to the exposure of LANL workers and the public in the event of a site-wide seismic event. As a result, the population risks given in Table 5–70 can be summed as shown to provide a meaningful estimate of worker and public impacts. The individual risks to the MEI and noninvolved worker cannot be summed, however, because the risk at a specific location depends on the meteorology during the event. The direction that the wind carries the release from each facility would not impact one location in the same manner for multiple accidents at the same time. As a result, Table 5–70 shows the maximum risk of the individual receptors. The total impact to these individuals could be somewhat greater than indicated if more than one release affects these locations. Table 5–70 only provides estimated impacts for facilities with the highest potential impacts. If all facilities were taken into account, the sum of offsite population impacts from all LANL facilities with radiological materials would be somewhat larger.

As discussed in Section 5.12.3, an updated seismic hazard analysis has been developed for the LANL site (LANL 2007a). Because it is not possible to state the impacts of the different peak horizontal ground accelerations indicated in the updated seismic hazard analysis without detailed structural analyses of LANL facilities, a bounding approach was used to estimate the expected effect of the updated seismic hazard analysis on the SWEIS seismic accident risks. The effect of the revised estimate on the annual probability of exceedance of the Seismic 1 accident would be an increase in radiological risk of 50 percent. This results in a maximum risk of an LCF of 0.00012 for the MEI, 0.0015 for the noninvolved worker, and 0.0077 for the population. These estimated higher seismic accident risks do not take credit for facilities in which complete failure has already been assumed (including the Chemistry and Metallurgy Research Building and Radioassay and Nondestructive Testing Facility in Tables 5–68 through 5–70) and therefore no larger accident source term would be expected at higher seismic ground accelerations. Although these seismic risks have increased due to the results of the updated seismic analysis, they remain less than 1 percent of the highest MEI, noninvolved worker, and population risks for other types of accidents analyzed in the SWEIS.

Site-Wide Seismic 2 – Radiological

Site-Wide Seismic 2 is represented by a PC-3 seismic event. Referring to **Tables 5–71** through **5–73** and noting that all of the listed facilities could contribute to offsite population impacts, the facility with the highest contribution to public consequence is the Plutonium Facility at TA-55. In the event of this seismic event, it is estimated that there would be 9 LCFs in the offsite population from this TA-55 release. The waste storage domes at TA-54 holding transuranic waste would result in the highest contribution to the MEI's radiological consequences. A TA-55 release would result in the highest contribution to the noninvolved worker's radiological consequences. As discussed above for the Seismic 1 scenario, depending on the specific radionuclides released and the route of human exposure, radiation doses calculated for the MEI and the noninvolved worker would result in near-term health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose to the exposed individual, mitigating health impacts, or both. In addition to the conservative assumptions used to develop the source term (the amount of radioactive material released) for this accident, the calculated dose is based on the assumptions that no protective action is taken during the entire time of exposure and that no subsequent medical intervention occurs. The risk of additional LCFs from the TA-55 release would be estimated at 0.0035 per year in the offsite population. The next highest risk of an LCF to the general population would be from the waste storage domes. The increased risk of an LCF for the MEI and noninvolved worker are estimated at 1 in 3,600 (0.00028) and 1 in 2,000 (0.0005) per year, respectively.

Table 5–71 Site-Wide Seismic 2 Radiological Accident Offsite Population Consequences for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 2 Event	Maximally Exposed Individual		Population to 50 Miles (80 kilometers)	
	Dose (rem) [a]	Latent Cancer Fatality [b]	Dose (person-rem)	Latent Cancer Fatality [c, d]
Chemistry and Metallurgy Research Building (TA-3-29)	62	0.075	6,100	4 (3.7)
Weapons Engineering Tritium Facility (TA-16-205)	17	0.01	110	0 (0.063)
SHEBA (TA-18-168) [e]	0.03	0.000018	0.77	0 (0.00046)
Tritium System Test Assembly (TA-21-155)	0.0015	8.8×10^{-7}	0.049	0 (0.00003)
Tritium Science and Fabrication Facility (TA-21-209)	0.013	7.5×10^{-6}	0.43	0 (0.00026)
Radioactive Liquid Waste Treatment Facility (TA-50-1)	3	0.0018	520	0 (0.31)
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	43	0.052	5,400	3 (3.1)
Radioassay and Nondestructive Testing Facility (TA-54-38)	64	0.077	1,100	1 (0.67)
Plutonium Facility (TA-55-4)	150	0.17	14,000	9 (8.6)
Storage Facility (TA-55-185)	6	0.0036	590	0 (0.35)

Waste Storage Domes (TA-54)	460	0.55	7,400	5 (4.5)
Safe, Secure Transport Facility (TA-55-355)	3.9	0.0024	290	0 (0.18)
	Max 460	Max 0.55	Total 36,000	Total 22

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Increased number of LCFs for the offsite population, assuming the accident occurs.

[d] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-1, -69), 343,100 (TA-54-38, 4-12, Domes), 301,900 (TA-55-4, -185, -355).

[e] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations and Expanded Operations Alternatives.

Table 5–72 Site-Wide Seismic 2 Radiological Accident Onsite Worker Consequences for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 2 Event	Noninvolved Worker at 110 Yards (100 meters)	
	Dose (rem) [a]	Latent Cancer Fatality [b]
Chemistry and Metallurgy Research Building (TA-3-29)	2,000	1.0 [c]
Weapons Engineering Tritium Facility (TA-16-205)	156	0.17
SHEBA (TA-18-168) [d]	1.1	0.00064
Tritium System Test Assembly (TA-21-155)	0.011	6.7×10^{-6}
Tritium Science and Fabrication Facility (TA-21-209)	0.097	0.000058
Radioactive Liquid Waste Treatment Facility (TA-50-1)	120	0.15
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	1,100	1.0 [b]
Radioassay and Nondestructive Testing Facility (TA-54-38)	580	0.69
Plutonium Facility (TA-55-4)	2,700	1.0 [c]

Facility Impacted by Seismic 2 Event	Noninvolved Worker at 110 Yards (100 meters)	
	Dose (rem) [a]	Latent Cancer Fatality [b]
Storage Facility (TA-55-185)	240	0.29
Decontamination and Volume Reduction System (TA-54-412) (PC-3 Seismic)	120	0.15
Waste Storage Domes (TA-54)	2,200	1.0 [c]
Safe, Secure Transport Facility (TA-55-355)	130	0.16

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.
[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.
[b] Increased risk of an LCF to an individual, assuming the accident occurs.
[c] The indicated dose yields a risk value greater than 1.0. This means that it is likely that an individual exposed to the indicated dose would develop a fatal latent cancer. For this reason a value of 1.0 is shown.
[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations and Expanded Operations Alternatives.

Table 5–73 Site-Wide Seismic 2 Radiological Accident Offsite Population and Worker Risks for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 2 Event	Frequency (per year)	Onsite Worker	Offsite Population	
		Risk to Noninvolved Worker at 110 Yards (100 meters) [a]	Maximally Exposed Individual [a]	Population to 50 Miles (80 kilometers) [b, c]

Tritium System Test Assembly (TA-21-155)	0.0005	3.3×10^{-9}	4.4×10^{-10}	1.5×10^{-8}
Tritium Science and Fabrication Facility (TA-21-209)	0.0005	2.9×10^{-8}	3.8×10^{-9}	1.3×10^{-7}
Radioactive Liquid Waste Treatment Facility (TA-50-1)	0.0005	0.000073	9.1×10^{-7}	0.00016
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	0.0001 [e]	0.0001	5.2×10^{-6}	0.00031
Radioassay and Nondestructive Testing Facility (TA-54-38)	0.0005	0.00035	0.000039	0.00034
Plutonium Facility (TA-55-4)	0.0004 [e]	0.0004	7×10^{-5}	0.0035
Storage Facility (TA-55-185)	0.0005	0.00014	1.8×10^{-6}	0.00018
Decontamination and Volume Reduction System (TA-54-412) (PC-3 Seismic)	0.0005	0.000074	0.00002	0.00018
Waste Storage Domes (TA-54)	0.0005	0.0005	0.00028	0.0022
Safe, Secure Transport Facility (TA-55-355)	0.0005	0.000077	1.2×10^{-6}	0.000088
		Maximum 0.0005	Maximum 0.00028	Total 0.009

TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.
[a] Increased risk of an LCF to an individual per year; new seismic data increases the risk by about 60 percent.
[b] Increased number of LCFs for the offsite population per year; new seismic data increases the risk by about 60 percent.
[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18, -168), 271,600 (TA-21-155, -209), 302,000 (TA-50-1, -69), 343,100 (TA-54-38, DVRS, Domes), 301,900 (TA-55-4, -185, -355).
[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduced Operations and Expanded Operations Alternatives.
[e] Different frequency than other seismic events due to assumption of other addition failures.

All site facilities containing hazardous radiological materials that are susceptible to structural failure during this event could potentially contribute to the exposure of LANL workers and the public in the event of a site-wide seismic event. As a result, the offsite population risks given in Table 5–73 can be summed as shown to provide a meaningful estimate of worker and public impacts. The individual risks to the MEI and noninvolved worker cannot be summed because the risk at a specific location depends on the meteorology during the event. The direction that the wind carries the release from each facility would not impact one location in the same manner as for multiple accidents at the same time. As a result, Table 5–73 shows the maximum risk of the individual receptors. The total impact to these individuals could be somewhat greater than indicated if more than one release were to affect these locations. Table 5–73 only provides estimated impacts for facilities with the highest potential impacts. If all facilities were taken into account, the sum of worker and offsite population risks from all LANL facilities with radiological materials could be somewhat higher.

As discussed in Section 5.12.3, an updated seismic hazard analysis has been developed for the LANL site (LANL 2007a). Because it is not possible to state the impacts of the different peak horizontal ground accelerations indicated in the updated seismic hazard analysis without detailed structural analyses of LANL facilities, a bounding approach was used to estimate the expected effect of the updated seismic hazard analysis on the SWEIS seismic accident risks. The effect of the revised estimate of the probability of exceedance of the Seismic 2 accident would be an increase in radiological risk of 60 percent. This results in a maximum risk of an LCF of 0.00045 for the MEI, 0.0008 for the noninvolved worker, and 0.014 for the population. These estimated higher seismic accident risks do not take credit for facilities in which complete failure has already been assumed (including the Chemistry and Metallurgy Research Building and Radioassay and Nondestructive Testing Facility in Tables 5–71 through 5–73) and therefore no larger accident source term would be expected at higher seismic ground accelerations. Although these seismic risks have increased due to the results of the updated seismic analysis, they remain less than 1 percent of the highest MEI, noninvolved worker, and population risks for other types of accidents analyzed in the SWEIS.

Site-Wide Seismic 1 – Chemical

The facilities and chemicals of concern under site-wide Seismic 1 conditions are shown in **Table 5–74**. There are numerous chemicals in small quantities onsite that may be released under these conditions. The listed chemicals were selected from a complete set of chemicals used onsite, based on their larger quantities, chemical properties, and human health effects. Exposure to concentrations in excess of the ERPG values could result in serious health effects or life-threatening implications to the exposed individuals.

Table 5–74 also shows the estimated annual risks for workers and the public in the event of an accidental release of each chemical. The annual frequency of this accident is 0.001 based on the *Seismic Hazards Evaluation of the Los Alamos National Laboratory (February 24, 1995)*. Based on the 2007 update of the seismic hazard analysis (LANL 2007a), the annual frequency is estimated to be 0.0015. Because this accident is a site-wide seismic event, all of the chemicals shown in the table would be released almost simultaneously. The annual risk of exposure to workers and the public to chemical concentrations in excess of ERPG-2 and ERPG-3 values is 1 in 1,000 based on the previous seismic hazard analysis and 1 in 700 based on the 2007 update of the seismic hazard analysis. The nearest public access relative to each facility is shown for each chemical. For some chemicals, the nearest public access point is beyond the distance at which concentrations would be at ERPG values. In these instances, there would likely be no serious health affects to the public in the event of an accident. For formaldehyde, as shown in Table 5–74, the nearest public access point is closer than the distance at which concentrations would be at the ERPG values. If this accident were to occur, members of the public could be exposed to harmful and possibly fatal concentrations of formaldehyde.

Table 5–74 Chemical Accident Risks under Seismic 1 Conditions for the No Action, Reduced Operations, and the Expanded Operations Alternatives

Chemical	Frequency [a] (per year)	Quantity Released	ERPG-2 [a, b]		ERPG-3 [a, c]	
			Value (ppm)	Annual Risk	Value (ppm)	Annual Risk
Hydrogen cyanide at TA-3-66 (Sigma Complex)	0.001	13.5 pounds (6.1 kilograms)	10	1 chance in 1,000 years of workers within 150 yards (137 meters) of facility receiving exposures in excess of limit. Nearest public access is at 260 yards (238 meters).	25	1 chance in 1,000 years of workers within 94 yards (86 meters) of facility receiving exposures in excess of limit. Nearest public access is at 260 yards (238 meters).
Phosgene at TA-9-21	0.001	1 pound (0.45 kilograms)	0.2	1 chance in 1,000 years of workers within 302 yards (276 meters) of facility receiving exposures in excess of limit. Nearest public access is at 900 yards (823 meters).	1	1 chance in 1,000 years of workers within 129 yards (118 meters) of facility receiving exposures in excess of limit. Nearest public access is at 900 yards (823 meters).
Formaldehyde at TA-43-1 (Bioscience Facilities)	0.001	3.7 gallons (14.1 liters)	10	1 chance in 1,000 years of workers or public within 195 yards (178 meters) of facility receiving exposures in excess of limit. Nearest public access is at 13 yards (12 meters).	25	1 chance in 1,000 years of workers or public within 122 yards (112 meters) of facility receiving exposures in excess of limit. Nearest public access is at 13 yards (12 meters).

ERPG = Emergency Response Planning Guideline, ppm = parts per million, TA = technical area.
[a] A conservative estimate of the frequency based on the 2007 probabilistic seismic hazard analysis (LANL 2007a) is 0.0015. The corresponding annual risk would be 1 chance in 700 years.
[b] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action (DOE 2005e).
[c] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2005e).

Site-Wide Seismic 2 - Chemical

The facilities and chemicals of concern under Site-Wide Seismic 2 conditions are shown in **Table 5–75**. There are numerous chemicals in small quantities onsite that could be released under these conditions. The listed chemicals were selected from a complete set of chemicals used onsite based on their larger quantities, chemical properties, and human health effects.

Table 5–75 Chemical Accident Risks under Seismic 2 Conditions for the No Action, Reduced Operations, and Expanded Operations Alternatives

Chemical	Frequency [a] (per year)	Quantity Released	ERPG-2 [a, b] Value (ppm)	ERPG-2 [a, b] Annual Risk	ERPG-3 [a, c] Value (ppm)	ERPG-3 [a, c] Annual Risk
Hydrogen cyanide at TA-3-66 (Sigma)	0.0005	13.5 pounds (6.1 kilograms)	10	1 chance in 2,000 years of workers within 150 yards (137 meters) of facility receiving exposures in excess of limit. Nearest public access is at 260 yards (238 meters).	25	1 chance in 2,000 years of workers within 94 yards (86 meters) of facility receiving exposures in excess of limit. Nearest public access is at 260 yards (238 meters).
Phosgene at TA-9-21	0.0005	1 pound (0.45 kilograms)	0.2	1 chance in 2,000 years of workers within 302 yards (276 meters) of facility receiving exposures in excess of limit. Nearest public access is at 900 yards (823 meters).	1	1 chance in 2,000 years of workers within 129 yards (118 meters) of facility receiving exposures in excess of limit. Nearest public access is at 900 yards (823 meters).
Formaldehyde at TA-43-1 (Bioscience Facilities)	0.0005	3.7 gallons (14.1 liters)	10	1 chance in 2,000 years of workers or public within 195 yards (178 meters) of facility receiving exposures in excess of limit. Nearest public access is at 13 yards (12 meters).	25	1 chance in 2,000 years of workers or public within 122 yards (112 meters) of facility receiving exposures in excess of limit. Nearest public access is at 13 yards (12 meters).
Chlorine gas released outside of Plutonium Facility Complex (TA-55-4)	0.0005	150 pounds (68 kilograms)	3	1 chance in 2,000 years of workers within 1,181 yards (1,080 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,111 yards (1,016 meters).	20	1 chance in 2,000 years of workers within 416 yards (380 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,111 yards (1,016 meters).
Nitric acid spill at Plutonium Facility Complex (TA-55-4)	0.0005	6,100 gallons (23,090 liters)	6	1 chance in 2,000 years of workers within 53.6 yards (49 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,111 yards (1,016 meters).	78	1 chance in 2,000 years of workers within 7.2 yards (6.6 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,111 yards (1,016 meters).
Hydrochloric acid spill at TA-55-249	0.0005	5,200 gallons (19,684 liters)	20	1 chance in 2,000 years of workers or public within 220 yards (185 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,221 yards (1,117 meters).	150	1 chance in 2,000 years of workers or public within 70 yards (64 meters) of facility receiving exposures in excess of limit. Nearest public access is at 1,221 yards (1,117 meters).
Beryllium at TA-3-141 (Beryllium Technology Facility)	0.0005	110 pounds (49 kilograms) (powder) [d]	0.025 [d]	1 chance in 2,000 years of workers or public within 309 yards (282 meters) of facility receiving exposures in excess of limit. Nearest public access is at 963 yards (880 meters).	0.1 [d]	1 chance in 2,000 years of workers or public within 127 yards (116 meters) of facility receiving exposures in excess of limit. Nearest public access is at 963 yards (880 meters).

ERPG = Emergency Response Planning Guideline, ppm = parts per million, TA = technical area.

[a] A conservative estimate of the frequency based on the 2007 probabilistic seismic hazard analysis (LANL 2007a) is 0.0008. The corresponding annual risk would be 1 chance in 1,250 years.

[b] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action (DOE 2005e).

[c] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2005e).

[d] Units for beryllium are in milligrams per cubic meter.

Table 5–75 also shows the estimated annual risks for workers and the public in the event of an accidental release of each chemical. The annual frequency of this accident is 0.0005 based on the *Seismic Hazards Evaluation of the Los Alamos National Laboratory (February 24, 1995)*. Based on the 2007 update of the seismic hazard analysis (LANL 2007a), the annual frequency is estimated to be 0.0008. As this accident is a site-wide seismic event, all of the chemicals shown in the table would be released almost simultaneously. The annual risk of exposure to workers and the public to chemical concentrations in excess of ERPG-2 and ERPG-3 values is 1 in 2,000 per year based on the previous seismic hazard analysis and 1 in 1,250 based on the 2007 update of the seismic hazard analysis. The nearest public access point relative to each facility is shown for each chemical. For some chemicals, the nearest public access point is beyond the distance at which concentrations would be at ERPG values. In these instances, there would likely be no serious health affects to the public in the event of an accident. As shown in Table 5–75, for formaldehyde at the Bioscience Facilities and chlorine gas at the Plutonium Facility Complex, the nearest public access points are closer than the distance at which concentrations would be at the ERPG values. If these accidents were to occur, members of the public could be exposed to harmful and possibly fatal concentrations of these chemicals.

5.12.3.2 Reduced Operations Alternative

Site-Wide Seismic 1 and 2 – Radiological

The site-wide Seismic 1 and 2 radiological accident impacts under the Reduced Operations Alternative are similar to those under the No Action Alternative, as shown in Tables 5–68 through 5–73. Activities at TA-18, including operation of SHEBA, would cease under this alternative. SHEBA operations are a small component of the site-wide seismic accident impacts at LANL; its elimination would not significantly alter the overall site risk profile from such an event. All other impacts in the tables are equally applicable for this alternative.

Site-Wide Seismic 1 and 2 – Chemical

The chemicals of concern that could be released in a site-wide Seismic 1 or 2 event are the same under the Reduced Operations Alternative as those under the No Action Alternative. None of the chemicals identified for the latter is eliminated in this alternative. The information in Tables 5–74 and 5–75, then, is applicable to the Reduced Operations Alternative.

5.12.3.3 Expanded Operations Alternative

Site-Wide Seismic 1 and 2 – Radiological

The Seismic 1 and 2 accident impacts under the Expanded Operations Alternative are similar to those under the No Action Alternative, as shown in Tables 5–68 through 5–73. SHEBA operations would cease under the Expanded Operations Alternative. Because the potential impacts are relatively small, deleting this accident does not change the overall risk profile of this alternative. Additional accident risks would result from expanded waste management activities. Transuranic waste storage would be consolidated in a new facility, the TRU Waste Facility, which would be located in TA-50 or a generic site along the Pajarito Road corridor. The TRU Waste Facility would carry fewer potential accident impacts than the existing facility because of its new location and because less material would be stored onsite. The entries in Tables 5–68 through 5–73 reflect present Decontamination and Volume Reduction System Facility operations because the system would be active for most of the period of interest. Present accident impacts bound the impacts of the replacement facility. The potential accident impacts for the new facility are described in Appendix H.

Site-Wide Seismic 1 and 2 – Chemical

The chemicals of concern that could be released in a site-wide Seismic 1 or 2 event are the same under the Expanded Operations Alternative as those under the No Action Alternative. No additional chemicals were identified under this alternative that would have impacts exceeding those under the No Action Alternative. The information in Tables 5–74 and 5–75, therefore, also applies to the Expanded Operations Alternative.

5.12.4 Wildfire Accident Impacts

Wildfire accident scenarios were postulated as a method of evaluating potential impacts to onsite workers and the offsite population. Details of these scenarios are provided in Appendix D, including a discussion of the LANL buildings that could be affected by wildfire, an inventory of hazardous radiological materials, and the source term factors and estimated source terms.

5.12.4.1 Wildfire – Radiological

The estimated radiological consequences of a wildfire to workers and the public are shown in **Tables 5–76** and **5–77** for each listed facility. The values shown assume that a wildfire has occurred and therefore do not reflect any credit for the probability of a wildfire occurrence. The estimated annual risks for each wildfire scenario are shown in **Table 5–78**. These values take credit for the probability of a wildfire's occurrence. The wildfire accident scenario consequences and risks in Table 5–76 through 5–78 apply to the No Action, Reduced Operations and Expanded Operations Alternatives.

As shown in Table 5–76, the results indicate that radiological releases from the TA-54 waste storage domes dominate the impacts to workers and the public. In the event of this accident, the consequence to the MEI is a likelihood of developing an LCF during his or her lifetime and an additional 55 LCFs for the population. As shown in Table 5–77, an onsite worker located 110 yards (100 meters) from the facility would be likely to develop an LCF as a result of this accident occurring at TA-54.

The risks for this accident, which takes credit for its low frequency of occurrence, are estimated to be about 1 chance in 20 (0.05) of an increased likelihood of an LCF per year for the MEI and an additional 2.7 LCFs per year of operations in the offsite population. An onsite worker located 110 yards (100 meters) from the facility would experience an increased likelihood of an LCF of about 1 chance in 20 (0.05) per year of operations. These risks assume that the receptors do not take evasive action in the event of a wildfire. Because releases from the TA-54 domes dominate the consequences and risks from a wildfire, they represent the total impacts on the offsite and worker populations.

Table 5–76 Radiological Accident Offsite Population Consequences for a Wildfire Accident for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Wildfire	Maximally Exposed Individual		Population to 50 Miles (80 kilometers)	
	Dose (rem)	Latent Cancer Fatality Risk [a]	Dose (person-rem)	Latent Cancer Fatalities [b, c]
Sigma Complex (TA-3-66/451)	0.0039	2.3×10^{-6}	4.8	0 (0.0029)
Weapons Engineering Tritium Facility (TA-16-205)	0.061	0.000036	110	0 (0.067)
Radiochemistry Facility (TA-48-1)	0.0011	6.4×10^{-7}	0.44	0 (0.00026)
Waste Storage Domes (TA-54)	1,900	1.0 [d]	91,000	55 (54.8)
Device Assembly (TA-16-411)	1.6×10^{-6}	8.9×10^{-10}	0.00017	0 (1×10^{-7})
Decontamination and Volume Reduction System (TA-54-412)	4.9	0.003	1,200	0 (0.7)
Radiography (TA-8-23)	0.00033	2×10^{-7}	0.56	0 (0.00034)
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	27	0.032	6,900	4 (4.2)

TA = technical area.
[a] Increased risk of an LCF to an individual, assuming the accident occurs.
[b] Increased number of LCFs for the offsite population, assuming the accident occurs; value in parentheses is the calculated result.
[c] Offsite population size is approximately 297,030 for TA-3-66/451; 404,913 for TA-16-205 and TA-16-411; 299,508 for TA-48-01; 343,069 for Domes, and TA-54-412; and 349,780 for TA-8-23.
[d] The indicated dose yields a risk greater than 1.0. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For this reason, a value of 1.0 is shown.

Table 5–77 Radiological Accident Onsite Worker Consequences for a Wildfire Accident for the No Action, Reduced Operations, and Expanded Operations Alternatives

Accident	Noninvolved Worker at 110 Yards (100 meters)	
	Dose (rem)	Latent Cancer Fatality [a]
Sigma Complex (TA-3-66/451)	0.076	0.000046
Weapons Engineering Tritium Facility (TA-16-205)	0.33	0.0002
Radiochemistry Facility (TA-48-1)	0.016	9.3×10^{-6}
Waste Storage Domes (TA-54)	8,700	1.00 [b]
Device Assembly (TA-16-411)	0.000017	1×10^{-8}
Decontamination and Volume Reduction System (TA-54-412)	16	0.0098
Radiography (TA-8-23)	0.0019	1.2×10^{-6}
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	440	0.53 [b]

TA = technical area.
[a] Increased risk of an LCF to an individual, assuming the accident occurs.
[b] The indicated dose yields a risk greater than 1.0. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For this reason, a value of 1.0 is shown.

Table 5–78 Radiological Accident Offsite Population and Worker Risks for a Wildfire Accident for the No Action, Reduced Operations, and Expanded Operations Alternatives

Accident	Frequency (per year)	Onsite Worker	Offsite Population	
		Noninvolved Worker at 110 Yards (100 meters) [a]	Maximally Exposed Individual [a]	Population to 50 Miles (80 kilometers) [b, c]
Sigma Complex (TA-3-66/451)	0.05	2.3×10^{-6}	1.2×10^{-7}	0.00014
Weapons Engineering Tritium Facility (TA-16-205)	0.05	1×10^{-5}	1.8×10^{-6}	0.0034
Radiochemistry Facility (TA-48-1)	0.05	4.7×10^{-7}	3.2×10^{-8}	1.3×10^{-5}
Waste Storage Domes (TA-54)	0.05	0.05	0.05	2.7
Device Assembly (TA-16-411)	0.05	5.2×10^{-10}	4.4×10^{-11}	5.2×10^{-9}
Decontamination and Volume Reduction System (TA-54-412)	0.05	0.00049	0.00015	0.035
Radiography (TA-8-23)	0.05	5.7×10^{-8}	1×10^{-8}	1.7×10^{-5}
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	0.01 [d]	0.0053	0.00032	0.042

TA = technical area.
[a] Increased risk of an LCF to an individual per year.
[b] Increased number of LCFs for the offsite population per year; value in parentheses is the calculated result.
[c] Offsite population size is approximately 297,030 for TA-3-66/451; 404,913 for TA-16-205 and TA-16-411; 299,508 for TA-48-01; 343,069 for Domes and TA-54-412; and 349,780 for TA-8-23.
[d] Assumes additional failures.

5.12.4.2 Wildfire – Chemical

The chemicals of concern at LANL facilities under wildfire conditions are shown in **Table 5–79**. They were selected from a database of chemicals used onsite based on their quantities, chemical properties, and human health effects. The table shows the ERPG-2 and ERPG-3 values for which, were an accident to occur, concentrations in excess of these values could result in serious health effects or life-threatening implications for exposed individuals.

Table 5–79 also shows the risks of worker and public exposure in the event of a chemical release, as well as the estimated frequency of each release. The direction traveled by the chemical plume would depend on the meteorological conditions at the time of the accident and would determine which segment of the worker and offsite populations would be at risk of exposure. The wildfire chemical accident impacts in Table 5–79 apply to the No Action, Reduced Operations, and Expanded Operations Alternatives.

For formaldehyde at TA-43-1, there is an annual risk of 0.05 (once in 20 years) that workers and the public within a distance of 97 yards (89 meters) of the release would be exposed to concentrations in excess of ERPG-3 values. The workers and public within a distance of 154 yards (141 meters) of the release would face the same risk of being exposed to concentrations in excess of ERPG-2 values.

Table 5–79 Chemical Accident Risks under Wildfire Conditions for the No Action, Reduced Operations, and Expanded Operations Alternatives

Chemical	Frequency (per year)	Quantity Released	ERPG-2 [a] Value (ppm)	ERPG-2 [a] Annual Risk	ERPG-3 [b] Value (ppm)	ERPG-3 [b] Annual Risk
Formaldehyde at TA-43-1	0.05	3.7 gallons (14.1 liters)	10	1 chance in 20 years of workers or public within 154 yards (141 meters) of facility receiving exposures in excess of limit. Nearest public access is at 13 yards (12 meters).	25	1 chance in 20 years of workers or public within 97 yards (89 meters) of facility receiving exposures in excess of limit. Nearest public access is at 13 yards (12 meters).
Hydrogen cyanide from TA-3-66	0.05	13.5 pounds (6.1 kilograms)	10	1 chance in 20 years of workers within 118 yards (108 meters) of facility receiving exposures in excess of limit. Nearest public access is at 260 yards (238 meters).	25	1 chance in 20 years of workers within 77 yards (70 meters) of facility receiving exposures in excess of limit. Nearest public access is at 260 yards (238 meters).

ERPG = Emergency Response Planning Guideline, ppm= parts per million, TA = technical area.

[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action (DOE 2005e).

[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2005e).

For hydrogen cyanide released from TA-3-66, there is an annual risk of 0.05 (once in 20 years) that workers within a distance of 77 yards (70 meters) of the release would be exposed to concentrations in excess of ERPG-3 values. The workers within a distance of 118 yards (108 meters) of the release would face the same risk of being exposed to concentrations in excess of ERPG-2 values. There would be no risk that the public would receive an exposure in excess of ERPG-2 or ERPG-3 values because the nearest public access is 260 yards (238 meters) from the location of this chemical release.

5.12.5 Construction Accidents

The construction of new facilities includes the risk of accidents that could impact workers. Because construction activities do not involve radioactive materials, there would be no radiological impacts. The presence of hazardous flammable, explosive, and other chemical substances, however, could initiate accident conditions that could impact the health and safety of workers. In addition, in the course of their work, construction and site personnel could receive serious or fatal injuries as a result of incidents that fall in the category of industrial accidents. DOE’s construction contractors are required to adhere to strict safety standards and procedures to promote a working environment that minimizes the possibility of such accidents.

5.12.6 Terrorist Incidents

The analysis of the impacts of terrorist incidents is described in a classified appendix to this SWEIS. The impacts of some terrorist incidents would be similar to the accident impacts described earlier in this section, while some terrorist incidents may have more severe impacts.

This section describes how NNSA assesses the vulnerability of its sites to terrorist threats and then designs its response systems.

5.12.6.1 Assessment of Vulnerability to Terrorist Threats

In accordance with DOE Order 470.3A, "Design Basis Threat Policy," and DOE Order 470.4, "Safeguards and Security Program," NNSA conducts vulnerability assessments and risk analyses of the facilities and sites under its management to evaluate the possible threats and the protection elements, technologies, and administrative controls used to protect against these threats. DOE Order 470.4 establishes the roles and responsibilities for the conduct of DOE's Safeguards and Security Program. DOE Order 470.3A establishes requirements designed to prevent unauthorized access, theft, diversion, or sabotage (including unauthorized detonation or destruction) of all nuclear weapons, nuclear weapons components, and special nuclear material under DOE's control. Among other provisions, the Order (a) specifies those national security assets that require protection; (b) outlines threat considerations for safeguards and security programs to provide a basis for planning, design, and construction of new facilities or modifications to existing facilities; and (c) provides an adversary threat basis for evaluating the performance of safeguards and security systems. NNSA also protects against espionage, sabotage, and theft of radiological, chemical, or biological materials; classified matter; non-nuclear weapon components; and critical technologies.

NNSA's safeguards and security programs and systems employ state-of-the-art technologies to:

- Deny access to nuclear weapons, nuclear test devices, and completed nuclear assemblies;
- Prevent theft, sabotage, or an unauthorized nuclear yield (criticality) of special nuclear materials and credible rollup quantities of special nuclear materials.
- Protect the public and employees from unacceptable impacts resulting from an adversary's use of radiological, chemical, or biological materials; and
- Protect classified matter and designated critical facilities and activities from sabotage, espionage, and theft.

NNSA's vulnerability assessments employ a rigorous methodology based on guidance from the *DOE Vulnerability Assessment Process Guide* (September 2004), and the Vulnerability Assessment Certification course. Typically, a vulnerability assessment involves analyses of modeling, simulation, and performance testing results by subject matter experts to determine the effectiveness of a safeguard and security system against an adversary's objectives. Vulnerability assessments generally include the following activities.

Characterizing the threat. Threat characterization provides a detailed description of a physical threat by a malevolent adversary to a site's physical protection systems. Usually the description includes information about potential adversary types, motivations, objectives, actions, physical capabilities, and site-specific tactical considerations. Much of the information required to develop a threat characterization is described in DOE Order 470.3A and the Adversary Capabilities List. DOE also issues additional site-specific threat clarification and guidance.

Determining the target. Target determination involves identifying, describing, and prioritizing potential targets among NNSA's security interests that meet the criteria outlined in DOE Order 470.3A. Target determination results are used to help characterize potential threats and target facilities, as well as protective force and neutralization requirements.

Defining the scope. The scope of a vulnerability assessment is determined by agreement among DOE Headquarters and Field staff and contractor personnel. In addition to defining the threat and applicable targets to be assessed, the scope establishes the key assumptions and interpretations that will guide the analyses, as well as the objectives, methods, schedule, personnel responsibilities, and format for documenting the results of the assessment.

Characterizing the facility or site. This activity requires defining and documenting aspects of the facility or site, particularly existing security programs (personnel security, information security, physical security, material control and accountability, etc.), to assist in identifying strengths and weaknesses. Results are used as inputs to the pathway analyses used to develop representative case scenarios for evaluating the security system. Facility and site characterization modeling tools include Analytical System and Software for Evaluating Safeguards and Security (ASSESS), Adversary Time-Line Analysis System (ATLAS), VISA, tabletop analysis, and others.

Characterizing the protective force. To assess a facility or site's vulnerability, analysts must accurately characterize the associated protective force's capabilities against a defined threat and objective, particularly the force's ability to detect, assess, respond to, interrupt, and neutralize an adversary. Specific data used for this activity include special nuclear materials categorization; configuration, flow, and movement of special nuclear materials within or from a facility or site; defined threats; detection and assessment times; and adversary delay and task time. The protective force's equipment, weapons, number, and locations also are considered in the characterization. The characterization information is validated and verified via observation, alarm response assessments, limited scope performance tests, force-on-force exercises, joint conflict and tactical simulations (JCATS), and tabletop analyses. The JCATS software tool is used for training, analysis, planning, and mission rehearsal, as well as characterization of the protective force. It employs detailed graphics and models of buildings, natural terrain features, and roads to simulate realistic operations in urban and rural environments.

Analyzing adversary pathways. This activity identifies and analyzes base case adversary pathways based on the results of threat, target, facility, and protective force characterization, as well as ancillary analyses such as explosives analysis. ASSESS and ATLAS are two primary tools that are used in this analysis. Analysts also conduct insider analysis as part of this activity.

Developing base case scenarios. Base case scenarios are developed for use in performance testing and to determine the effectiveness of the security system in place against a potential adversary's capabilities and objectives. As part of this activity, data from the base case adversary pathways analyses are used to identify applicable threats, threat strategies, and objectives, and combined with protective force strategies and capabilities to develop scenarios that include specific adversary resources, capabilities, and projected task times to successfully complete their objectives. Specialists also work with the vulnerability assessment team to develop realistic scenarios that provide a structured, intellectually honest analysis of the strengths and weaknesses of the terrorist adversary.

Determining the probability of neutralization. The probability of neutralization is a numeric value representing the probability that the protective force can prevent an adversary from achieving their objectives. The calculated number is derived from more than one source, one of which must be based on Joint Tactical Simulation, JCATS analysis, or force-on-force exercises.

Determining system effectiveness. System effectiveness is determined by applying an equation that reflects the capabilities of a multi-layered protection system. Analysis data derived from the various vulnerability assessment activities are used to calculate this equation, which reflects the security system's effectiveness against each of the scenarios developed for the vulnerability assessment. If system effectiveness is unacceptable for a scenario, the root cause of the weakness must be analyzed and security upgrades must be identified. The scenarios are reanalyzed with the upgrades, and the successful upgrades are documented in the vulnerability analysis report.

Implementation. The culmination of the vulnerability assessment is development of a report documenting the analyses and results and a plan for implementing any necessary upgrades to achieve the required security system effectiveness. NNSA verifies the results of the vulnerability assessment report and the conclusions of the implementation plan. NNSA also provides management oversight of the actual implementation of security system upgrades.

5.12.6.2 Terrorist Impacts Analysis

Substantive details of terrorist attack scenarios and security countermeasures are not released to the public because disclosure of this information could be exploited by terrorists to plan attacks. Depending on the malevolent, terrorist, or intentionally destructive acts, impacts may be similar to or could exceed bounding accident impact analyses prepared for the SWEIS. A separate classified appendix to this Final SWEIS has been prepared that considers the underlying facility threat assumptions with regard to malevolent, terrorist, or intentionally destructive acts. Based on these threat assumptions, the classified appendix evaluates the potential human health impacts using appropriate analytical models, similar to the methodology used in this SWEIS to analyze accident impacts. These data provide NNSA with information upon which to base, in part, decisions regarding activities at LANL.

5.13 Cumulative Impacts

In accordance with the Council on Environmental Quality regulations, a cumulative impact analysis includes, "the incremental impacts of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time," (40 CFR 1508.7).

The cumulative impact analysis for this SWEIS includes (1) an examination of cumulative impacts presented in the *1999 SWEIS*; (2) impacts since the *1999 SWEIS* was issued, which are presented in this chapter; and (3) a review of the environmental impacts of past, present, and reasonably foreseeable actions for other Federal and non-Federal agencies in the region.

Reasonably foreseeable future actions that are likely to occur at LANL are described in Chapter 3, Section 3.3 under the Expanded Operations Alternative. Additional DOE or NNSA actions that could impact LANL include consolidation of nuclear operations related to production of radioisotope power systems; proposed operation of a Biosafety Level 3 Facility; a potential advanced fuel cycle facility; implementation of NNSA's complex transformation planning; and a disposal facility for Greater-Than-Class C waste.

Consolidation of DOE plutonium-238 activities at the Idaho National Laboratory as proposed in the *Draft Environmental Impact Statement for the Proposed Consolidation of Nuclear Operations Related to Production of Radioisotope Power Systems* (DOE/EIS-0373D) (*Consolidation EIS*) (DOE 2005c) would reduce plutonium-238 operations at LANL. Regardless of the decision on the *Consolidation EIS*, some plutonium-238 operations would continue at LANL. Therefore, very small changes in the impacts from plutonium-238 activities at LANL would be realized.

If current plutonium-238 operations were continued at the LANL Plutonium Facility Complex, as described under the *Consolidation EIS* No Action Alternative, manufacturing of up to 80 pits per year could still be accomplished within the LANL Plutonium Facility Complex. This production rate would be accomplished by consolidating a number of plutonium processing and support activities (such as analytical chemistry and materials characterization at the Chemistry and Metallurgy Research Replacement Facility). The impacts of the 80-pit-per-year production rate and plutonium-238 processing (at levels far above the level identified in the *Consolidation EIS*) were evaluated in both the LANL *1999 SWEIS* and this new SWEIS. These evaluations indicate there would be no additional cumulative effects from these activities.

NNSA is preparing an *Environmental Impact Statement for the Operation of a Biosafety Level-3 Facility at Los Alamos National Laboratory, Los Alamos, New Mexico* (DOE/EIS-0388D). Operation of the Biosafety Level 3 Facility would be consistent with the land use designation of Research & Development for Experimental Science. The facility is visually compatible with surrounding structures, therefore there are no impacts to visual resources. There would be no impacts to geology and soils and water resources from operations. Air emissions from the Biosafety Level 3 Facility laboratories would be HEPA-filtered, resulting in very minor air quality effects. Noise impacts would be limited to sounds from heating, ventilation, and air conditioning operations, consistent with other buildings in the area. Facility operations would have no effect upon ecological resources or prehistoric, historic, traditional or paleontological resources in the area. Facility personnel would come primarily from the existing LANL workforce, resulting in no socioeconomic impacts. Operations would be well within LANL infrastructure capability to provide utilities requirements such as electricity, water, and natural gas. There would be no discernable effects on local traffic conditions. There have been no reported cases of illnesses in the United States due to the release of diagnostic specimens during transport (Cummings 2007).

There would be a low potential risk of illness to site workers or visitors from routine operations involving biohazardous material and no public human health effect. Accident conditions would result in minimal or no impact to the public primarily because there would be severely limited opportunity for transport of an infectious dose of a biohazardous material to the public. Biohazardous material would be handled in open cultures only in a biosafety cabinet, where a spill would be contained. In addition, biohazardous material would be handled in a liquid or solid culture container that would release very few organisms to the air if dropped or spilled. This means that one of the most critical risk factors, public exposure to an infectious dose from a biohazardous material, is greatly minimized, and therefore, the potential risk of disease would be very low. The EIS will evaluate slope stability at the Biosafety Level 3 Facility based on the recent update to the LANL probabilistic seismic hazard analysis (Cummings 2007, LANL 2007a).

DOE issued a Notice of Intent (NOI) to prepare the *Global Nuclear Energy Partnership Programmatic Environmental Impact Statement (GNEP PEIS)* (DOE/EIS-0396) on January 4, 2007 (72 FR 331). The Global Nuclear Energy Partnership (GNEP) would encourage expansion of domestic and international nuclear energy production while reducing nuclear proliferation risks, and reduce the volume, thermal output, and radiotoxicity of spent nuclear fuel before disposal in a geologic repository. The *GNEP PEIS* includes evaluation of a proposed advanced fuel cycle facility that would support research and development associated with the GNEP program. LANL is one of the DOE sites being considered for the research facility. The advanced fuel cycle facility would be a large shielded facility (approximately 1 million square feet [92,900 square meters]) (DOE 2008). Construction would begin in about 2014 with full operations planned for 2020. Potential cumulative impacts at LANL associated with the proposed advanced fuel cycle facility were addressed in the *Complex Transformation SPEIS* cumulative impacts analysis based on preliminary data (DOE 2007b). Where available, the cumulative impacts analyses in this SWEIS are based on more recent, but still preliminary data (DOE 2008). Impacts analyses for the *GNEP PEIS* are still underway so data for some resource areas are not available at this time and data that are included in this SWEIS could change prior to public release of the draft *GNEP PEIS*.

In 2006, NNSA outlined a comprehensive proposal, called Complex Transformation, for a smaller, more efficient nuclear weapons complex that would be better able and more suited to respond to future national security challenges (NNSA 2006b). On October 19, 2006, NNSA issued an NOI (71 FR 61731) to prepare a *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement - Complex 2030* (now called the *Complex Transformation Supplemental Programmatic Environmental Impact Statement* [*Complex Transformation SPEIS*]). This NOI also announced the cancellation of NNSA's previous proposal to build a modern pit facility for which NNSA issued a draft Supplemental EIS in June 2003 (68 FR 33487). LANL had been one of the sites under consideration for a modern pit facility. The NOI outlined some alternatives for transforming the nuclear weapons complex to better meet future national security requirements, including a proposal to construct and operate a consolidated plutonium center within the complex. Another proposal, to construct and operate a consolidated nuclear production center, was added during the scoping period, which ended in January 2007. Both of these proposals are analyzed in the Draft *Complex Transformation SPEIS* (DOE 2007b).

Implementation of the alternatives analyzed through the *Complex Transformation SPEIS* could result in changes to facilities and operations at LANL; for instance, NNSA is reconsidering construction of the nuclear facility portion of the Chemistry and Metallurgy Research Replacement project, and the impacts of not constructing that facility have been addressed in the Reduced Operations Alternative in this SWEIS. LANL is one of the sites under consideration for a consolidated plutonium center or a consolidated nuclear production center. The Preferred Alternative in the Draft *Complex Transformation SPEIS* is to site a consolidated plutonium center at LANL with a capacity of up to 80 pits per year, based on the use of the existing and planned infrastructure already described in the SWEIS Expanded Operations Alternative. This SWEIS cumulative impacts analysis addresses the impacts of construction and operation of a consolidated nuclear production center at LANL; the center would include primarily new plutonium, highly enriched uranium, and weapons assembly/disassembly facilities.

On July 23, 2007, DOE issued an NOI to prepare an *Environmental Impact Statement for the Disposal of Greater-Than-Class-C Low-Level Radioactive Waste (GTCC EIS)* (72 FR 40135). The *GTCC EIS* will address the disposal of low-level radioactive waste that contains radionuclides in concentrations exceeding 10 CFR Part 61 Class C limits, generated by activities licensed by the U.S. Nuclear Regulatory Commission or an Agreement State, as well as DOE waste having similar characteristics. Certain sealed sources that would be managed at LANL under the Off-Site Source Recovery Project would be addressed in the *GTCC EIS*. LANL is being considered as one of eight candidate DOE disposal sites for Greater-Than-Class C waste, along with generic commercial disposal facility options in arid and humid environments. In addition, DOE is evaluating several disposal technologies in the *GTCC EIS* including geologic repositories, intermediate depth boreholes, and enhanced near-surface disposal facilities. The alternatives in the *GTCC EIS* could result in changes to facilities or operations at LANL, but because the changes have yet to be developed and evaluated, they are not included in the cumulative impacts analysis.

Primary sources of information on LANL contributions to cumulative impacts, other than the current and the *1999 SWEIS*, are listed below:

- *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada*, DOE/EIS-0250 (DOE 2002b).

- *Waste Isolation Pilot Plant Disposal Phase Final Supplemental Environmental Impact Statement*, DOE/EIS-0026-S-2 (DOE 1997a).

- *Environmental Surveillance at Los Alamos during 2005*, LA-14304-ENV (LANL 2006h).

- *Draft Environmental Impact Statement for the Proposed Consolidation of Nuclear Operations Related to Production of Radioisotope Power Systems*, DOE/EIS-0373D (DOE 2005c).

- *Final Environmental Impact Statement for the Conveyance and Transfer of Certain Land Tracts Administered by the U.S. Department of Energy and Located at the Los Alamos National Laboratory, Los Alamos and Santa Fe Counties, New Mexico,* DOE/EIS-0293 (DOE 1999d).

- NOI to Prepare an Environmental Impact Statement for the Operation of a Biosafety Level 3 Facility at Los Alamos National Laboratory, Los Alamos, New Mexico, 70 FR 228, November 29, 2005.

- *Draft Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada*, DOE/EIS-0250F-S1D (*Draft Yucca Mountain SEIS*) (DOE 2007a)

- *Draft Complex Transformation Supplemental Programmatic Environmental Impact Statement*, DOE/EIS-0236-S4 (DOE 2007b).

It is also necessary to consider activities implemented by other Federal, state, and local agencies and individuals outside LANL, but within the its region of influence, including state or local development initiatives; new residential development; new industrial or commercial ventures; clearing land for agriculture; new utility or infrastructure construction and operation; and new waste treatment and disposal activities.

Sandia National Laboratories' main facility in Albuquerque is located approximately 60 miles from LANL. Due to this distance, cumulative impacts other than air emissions are not expected to be influenced by Sandia National Laboratories. For air emissions, the 2005 Sandia National Laboratories dose to the offsite MEI is estimated to be 0.0001 millirem and the 2005 population dose is estimated to be 0.00017 person-rem (SNL 2006). The Sandia National Laboratories MEI dose is 0.0012 percent of the LANL MEI dose, and the Sandia National Laboratories population dose is 0.00047 percent of the LANL population dose. Because the combined impacts would be very small, there would be no significant impact from Sandia National Laboratories and it is not considered in this cumulative impacts section.

The city of Santa Fe; Los Alamos, Mora, Rio Arriba, Sandoval, San Miguel, Santa Fe, and Taos Counties; the Santa Clara and San Ildefonso Pueblos; the New Mexico Department of Transportation; the Bureau of Land Management; and the U.S. Forest Service were contacted for information regarding expected future activities that could contribute to cumulative impacts. The city of Santa Fe and Mora, Sandoval, and San Miguel Counties did not identify any major future actions (Gallegos 2006, Pino 2006, Scales 2006, Tafoya 2006). Rio Arriba County and the Santa Clara and San Ildefonso Pueblos did not provide information for the cumulative impacts analysis. The following activities in the region surrounding LANL were identified.

- Los Alamos County identified residential, commercial, and industrial development on areas transferred from DOE to the county. Residential development will include about 120 homes on 70 acres (28 hectares) in White Rock, with a goal to build approximately 1,000 new homes in Los Alamos County within the next 5 years (Jeppson 2006).

- Taos County identified about 20 subdivisions scheduled for review this year, including 150 to 750 new homes on 300 to 1,500 acres (121 to 607 hectares) (Trujillo 2006). Many of these homes would be located more than 50 miles (80 kilometers) from LANL.

In addition, Los Alamos County is closing the Los Alamos County Landfill and considering use of the San Juan-Chama water allotment. The existing Los Alamos County Landfill will close in 2008. Solid wastes will be shipped out of the county via a new transfer station (LAC 2007). The Bayo Wastewater Treatment Facility in Santa Fe County was replaced in 2007 with an advanced wastewater treatment facility in Pueblo Canyon (Glasco 2008). The San Juan-Chama Project includes examining the feasibility of pumping 1,200 acre-feet of Rio Grande water up the mesa to Los Alamos County (LAC 2004b).

A number of projects were identified that would affect the Santa Fe National Forest, including invasive plant control, road closure, thinning and prescribed fire, fire salvage, mineral extraction; and grazing allotment (USFS 2005b).

The Bureau of Land Management identified smaller projects that would affect the Bureau of Land Management lands such as continued road maintenance, timber harvesting, and grazing permit renewals, as well as larger projects such as the Power Project; New Mexico Products Pipeline; Mid-America Pipeline Western Expansion Project; Santa Domingo Pueblo-Bureau of Land Management land exchange; San Pedro Rock Quarry; treatment of saltcedar and other noxious weeds; and the Buckman Water Diversion Project (BLM 2006a). These larger projects are described below.

- The Power Project involves upgrading and enhancing the electrical power transmission line system in the Santa Fe and Las Vegas, New Mexico, area and widening the existing right-of-way (BLM 2004b).

- The New Mexico Products Pipeline involves adding two additional segments to an existing petroleum products pipeline. Neither of the new segments would be within 50 miles (80 kilometers) of LANL (BLM 2006b).

- The Mid-America Pipeline Western Expansion Project would add 12 separate loop sections to the existing liquefied natural gas pipeline to increase system capacity. A 23-mile (37-kilometer) segment would be placed in Sandoval County, 30 miles (48 kilometers) from the LANL boundary (BLM 2006c). This segment would be constructed parallel to and 25 feet (7.6 meters) away from the existing pipeline right-of-way.

- The Santa Domingo Pueblo-Bureau of Land Management land exchange involves an equal-value exchange of approximately 7,376 acres (2,985 hectares) of the Bureau of Land Management lands for 645 acres (261 hectares) of Santa Domingo Pueblo land in Santa Fe and Taos Counties (BLM 2002). A record of decision has not been issued for this land exchange.

- The San Pedro Mountains Rock Quarry Project has been delayed and will be incorporated into the revised Taos Field Office Resource Management Plan (BLM 2006a).

- The treatment of saltcedar and other noxious weeds is an ongoing adaptive management program for control of exotic weeds. An EA was prepared for this project that resulted in a Finding of No Significant Impact (FONSI) (BLM undated). The project area is approximately 40 miles (64 kilometers) from the LANL boundary.

- The Buckman Water Diversion Project would divert water from the Rio Grande for use by the city of Santa Fe and Santa Fe County (BLM 2006a). The diversion project would withdraw water from the Rio Grande approximately 3 miles downstream from where Route 4 crosses the river. The pipelines for this project would largely follow existing roads and utility corridors. Decreased water withdrawals from the Buckman Well Field would benefit groundwater levels. Potential impacts on fish and aquatic habitats below the proposed project due to effects on water flow would be minimal (BLM and USFS 2007).

Another project would upgrade the existing 46-kilovolt transmission loop system that serves central Santa Fe County with a 115-kilovolt system (PNM 2005). No major new transmission lines are planned for the region around LANL (WAPA 2006).

No new Federal highways are planned within 50 miles (80 kilometers) of LANL (CFLHD 2005). A number of state transportation projects are ongoing or planned. Many of these are relatively minor maintenance, upgrading, widening, and resurfacing projects. Some of the more substantial transportation projects in the region include (NMDOT 2007):

- U.S. Route 84 reconstruction - Pojoaque to Española
- NM 502 reconstruction
- NM 344 four-lane road construction near Interstate 40
- NM 585 Reconstruction Project.

Although maintenance of the transportation infrastructure in the region would continue and a number of upgrade, expansion, and widening projects are scheduled over the next 5 years or so, no new major highway projects are scheduled that could substantially contribute to cumulative impacts at LANL.

The list of EPA National Priorities List sites (also known as Superfund sites) was reviewed to determine whether these sites could contribute to cumulative impacts at LANL. Only one site is within 50 miles (80 kilometers) of LANL. The North Railroad Avenue groundwater contamination plume is located over 12 miles (19 kilometers) from the LANL boundary in Rio Arriba County (EPA 2005b).

Most of these actions at other sites are not expected to affect the cumulative impacts of LANL activities because of their distance from LANL, their routine nature, their relatively small size, and the zoning, permitting, environmental review, and construction requirements they must meet. Available documentation reviewed to assess cumulative impacts include the following sources:

Bureau of Land Management

- *Final Environmental Impact Statement for the Buckman Water Diversion Project* (BLM and USFS 2007).
- Factsheet: "San Juan Public Lands (San Juan Field Center & San Juan National Forest) Draft Environmental Impact Statement (EIS) Northern San Juan Basin Coalbed Methane Project," (BLM 2004a).

- *Farmington Proposed Resource Management Plan and Final Environmental Impact Statement*, BLM-NM-PL-03-014-1610 (BLM 2003b).

- *Farmington Resource Management Plan with Record of Decision* (BLM 2003c).

- Final Air Dispersion Analysis Technical Report, "Revision to the BLM Farmington Resource Management Plan and Amendment of the Rio Puerco Resource Management Plan," (BLM 2003a).

U.S. Forest Service

- "Schedule of Proposed Action 01/01/2006 to 03/31/2006, Santa Fe National Forest," (USFS 2006).

- *Record of Decision for Invasive Plant Control Project Carson and Santa Fe National Forests in Colfax, Los Alamos, Mora, Rio Arriba, San Miguel, Santa Fe, Sandoval, and Taos Counties, New Mexico* (USFS 2005a).

U.S. Bureau of Reclamation

- *Upper Rio Grande Basin Water Operations Review Draft Environmental Impact Statement* (ACE, Reclamation, and ISC 2006).

- *Final Environmental Impact Statement City of Albuquerque Drinking Water Project* (Reclamation 2004).

National Park Service

- "Fire Management Plan for Bandelier National Monument," (NPS 2005b).

State of New Mexico

- *2004-2006 State of New Mexico Integrated Clean Water Act §303(d) §305(b) Report* (NMED 2004a).

- *State of New Mexico Standards for Interstate and Intrastate Surface Waters* (NMAC 20.6.4).

Each resource area in this SWEIS was reviewed to identify potential cumulative impacts and the analyses are summarized in the following paragraphs. The level of detail provided for each resource area depends on the extent of the potential cumulative impacts.

Land Resources

Land resources include impacts to land use and the visual environment. LANL actions proposed under this SWEIS would not likely result in any incompatible land uses. Under the *Land Conveyance and Transfer Environmental Impact Statement (Land Conveyance and Transfer EIS)* (DOE/EIS-0293), land conveyed and transferred by LANL to Los Alamos County and conveyed to the U.S. Department of the Interior in trust for the San Ildefonso Pueblo, could be developed.

Up to 826 acres (334 hectares) of this land could be developed after the transfer and conveyance, representing a potential introduction of incompatible land uses (land in adjacent areas that have land use designations that interfere with or restrict one another) and a loss of recreational opportunities such as hiking or fishing. Under the Expanded Operations Alternative, cumulative impacts would include fewer restrictions on future use of lands remaining part of LANL under the MDA Removal Option than the MDA Capping Option. For the Removal Option, the wastes currently buried in the MDAs would be removed completely and shipped offsite or consolidated in onsite disposal areas, which would allow use of some of these MDAs for other purposes. The Expanded Operations Alternative also would include the Security-Driven Transportation Modification Project, which would not conflict with current land use designations except for an option to construct a bridge over Sandia Canyon. Construction of the Sandia Canyon Bridge would depart from current site development plans. Overall cumulative impacts to land use in the region, however, would be small.

Transfer and conveyance of LANL land could result in visual impacts such as diminished viewsheds and increased ambient light from residential, industrial, and commercial development on previously undeveloped land. For example, Los Alamos County has indicated there are proposals to develop approximately 1,000 new residences on land adjacent to LANL and to develop land for light industry along the Los Alamos Canyon rim across from the airport.

LANL is one of the sites under consideration for a consolidated nuclear production center in the *Complex Transformation SPEIS*. Construction of the consolidated nuclear production center facilities could require up to 545 acres (221 hectares) of land in TA-16 or in TA-16 and TA-55. This proposal is consistent with current land use plans for these TAs. The total land area required for the GNEP advanced fuel cycle facility would be approximately 373 acres (151 hectares) with 144 acres (58 hectares) inside a property protection fence, including approximately 62 acres (25 hectares) within a perimeter intrusion, detection, and assessment system (DOE 2008).

Geology and Soils

Projects proposed under the Expanded Operations Alternative in this SWEIS combined with the *Complex Transformation SPEIS* consolidated nuclear production center facilities and GNEP advanced fuel cycle facility would impact mineral resources at LANL and the surrounding region. Primary impacts would be due to the proposed closures of the MDAs under the Consent Order through either waste containment in place (the MDA Capping Option) or waste removal by excavation and subsequent disposal (the MDA Removal Option).

If the waste at the MDAs remains in place, and some small contaminated areas in TA-49 are capped, the final covers would require 750,000 to 2,000,000 cubic yards (570,000 to 1,500,000 cubic meters) of crushed tuff through fiscal year (FY) 2016. Up to 460,000 cubic yards (350,000 cubic meters) of additional rock, gravel, topsoil, and other bulk materials would be required for the final surface and erosion control. The total quantity of crushed tuff, rock and other bulk materials would range from 1.2 to 2.5 million cubic yards (0.92 to 1.9 million cubic meters). If the waste were removed, approximately 1,300,000 cubic yards (1,000,000 cubic meters) of backfill would be needed to replace the excavated waste and contaminated soil, as well as 61,000 cubic yards (47,000 cubic meters) of rock, gravel, topsoil, and other bulk materials for erosion control and site restoration. In addition, from 220,000 to 600,000 cubic yards (170,000 to 460,000 cubic meters) of crushed tuff and about 160,000 cubic yards (120,000 cubic meters) of topsoil, rock, and other bulk materials would be needed for capping the remaining disposal units at Area G in TA-54, and for capping other landfills and contaminated areas such as those in TA-49. A total of 1.8 to 2.2 million cubic yards (1.4 to 1.7 cubic meters) of crushed tuff, rock, and other bulk materials would be needed.

For economic and feasibility reasons, these materials would need to be excavated from borrow pits and quarries in the LANL area (Stephens and Associates 2005). Obtaining the materials locally would minimize transportation impacts. The only borrow pit now in use at LANL is the East Jemez Road Borrow Pit in TA-61. There would be sufficient tuff available at the pit to provide the needed volumes of crushed tuff. Other sources, however, would be required to provide the other materials (such as soil and coarse material for erosion control) needed to complete the MDA remediation. There are 24 stone and aggregate mines or quarries in the surrounding counties (Rio Arriba, Sandoval, and Santa Fe Counties) producing sand, gravel, base course, caliche, crushed rock, rip-rap, scoria, fill dirt and top soil (Pfeil et al. 2001). Borrow materials also could be collected from onsite areas of opportunity such as facility construction or DD&D areas where excess uncontaminated soils that meet the backfill or capping criteria have been excavated. Use of excavated soils as fill or cap material would minimize the need to import geologic materials from outside the immediate LANL area.

Water Resources

Activities at LANL, in combination with other activities in the vicinity, could affect regional water resources. To assess the cumulative effects on surface water, current and reasonably foreseeable future activities within the watersheds and streams that receive surface water from LANL were considered. The effects of past projects are reflected in the description of the affected environment and current surface water conditions. Most watersheds have headwaters on Santa Fe National Forest or Bandelier National Monument land. The region of consideration for cumulative impacts on groundwater extends from LANL further east toward Santa Fe and focuses on impacts on the regional aquifer due to the activities of landowners and managers other than LANL.

Past effluent discharges from LANL activities, in some cases occurring at least 50 years ago, have contaminated sediments in several canyons and continue to affect the quality of stormwater runoff and stream flows (LANL 2005h). As described in Chapter 4, Section 4.3.1, of this SWEIS, however, current monitoring documents that regional water quality does not exceed state standards downstream from LANL and the existing contamination is expected to diminish over time regardless of the SWEIS alternative selected. The reach of the Rio Grande between San Ildefonso Pueblo and Cochiti Reservoir, which receives surface water flows from LANL, has been identified by the New Mexico Environment Department (NMED 2004a) as impaired because it does not support its designated uses as a cold water or warm water fishery. Turbidity is identified as the probable cause of impairment, but the impairment stems from unknown natural sources. Although turbidity could be exacerbated by earthmoving activities anywhere in the watershed, planned mitigation measures for Federal and state projects would keep soil erosion to a minimum and ensure that additional turbidity is not a reasonably foreseeable cumulative impact.

Fire and Vegetation Management

Fire and fuels management is an annual activity within the Santa Fe National Forest and Bandelier National Monument. Management of the areas within the watersheds upstream from LANL are of primary interest because activities such as prescribed burns, mechanical and manual thinning, native plant revegetation, and establishment of fire breaks could accelerate erosion and sediment delivery to streams, which would affect surface water quality and quantity.

Since 1981, areas within Bandelier National Monument along the southern LANL boundary have been treated with prescribed burns. An area parallel to the southern LANL boundary was thinned from 2002 to 2004 (NPS 2005b). The Fire Management Plan (NPS 2005b), the working document for guiding wildland fire management actions and activities in Bandelier National Monument, identifies two primary fire management areas. Most of the area near LANL falls within the Wildland Fire Use unit where most natural ignitions will be allowed to burn. A small area including the entire Upper Frijoles watershed near the southern LANL boundary and the detached Tsankawi unit located east of State Highway 4 and near San Ildefonso Pueblo fall within the Fire Suppression unit. In the Fire Suppression unit, all natural ignitions are declared unwanted wildland fires and are suppressed, but prescribed burns are utilized as needed.

The Santa Fe National Forest Schedule of Planned Operations does not list specific fire management or other actions in the watersheds that cross LANL over the next year (USFS 2006), but some actions are likely to occur within the next 5 to 10 years. The Santa Fe National Forest and Bandelier National Monument fire management policies and procedures include requirements for mitigation and stabilization measures to ensure that vegetation is re-established and offsite erosion and sedimentation are minimized. For this reason, fire management activities in the region, together with those planned at LANL, are not expected to adversely affect surface water quality or quantity. Instead, these actions may benefit surface water bodies by reducing the potential for the impacts of severe wildfires like the Cerro Grande Fire.

An estimated 300 to 800 acres (121 to 324 hectares) will be treated annually in the Santa Fe National Forest to control invasive weeds (USFS 2005a). Treatments will combine biological, chemical, and mechanical methods. Some of the areas to be treated are likely to be within watersheds that cross LANL, but mitigation measures will be implemented to ensure that there are no adverse effects to water resources. These activities, combined with those planned for LANL, will not affect surface water resources.

Cerro Grande Fire Structures

Structures installed in and around LANL after the Cerro Grande Fire altered surface water flows to retain sediment. The Northern Rio Grande Resource Conservation and Development Council led an effort to rebuild fences, bridges, culverts, and other structures on private land that were destroyed by the Cerro Grande Fire (NRCS 2004). On the Santa Clara and San Ildefonso Pueblos, 15 flood prevention projects were implemented by the U.S. Army Corps of Engineers, including strengthening an existing levee system, installing grade control structures, upgrading water crossings, and installing protection around facilities (ACE 2000). Most private structures are likely to remain in place, but removal of some structures is planned by the U.S. Army Corps of Engineers, in addition to removal of those at LANL; their removal could increase sediment loads temporarily. Where structures are removed, the responsible agencies will likely install temporary sediment traps to minimize downstream sediment transport that would adversely affect surface water quality.

Land Conveyance and Transfer

The *Land Conveyance and Transfer EIS* projected minor increases in the amount of surface water runoff entering the stream system and an approximate 30 percent increase in groundwater withdrawals from the regional aquifer due to new residential development (DOE 1999d).

Rio Grande Flows

Proposed changes in the operations of Abiquiu Dam, Cochiti Dam, and other water structures downstream are currently under consideration by the U.S. Army Corps of Engineers, Bureau of Reclamation, and New Mexico Interstate Stream Commission (ACE, Reclamation, ISC 2006). These changes would slightly affect stream flows in the Rio Chama and Rio Grande, depending on which alternative is selected for implementation, but none would affect the surface water flows of the tributaries that flow through and immediately downstream of LANL. Changes to flows below Abiquiu Dam are not projected to affect hydropower generation used to supplement electricity in Los Alamos County (ACE, Reclamation, ISC 2006).

The city of Albuquerque is currently constructing a dam across the Rio Grande at Albuquerque to divert as much as 94,000 acre-feet per year (11,600 hectare-meters per year) to fully consume their San Juan-Chama Project water. A Final EIS evaluating the impacts of this action was published on March 5, 2004 (Reclamation 2004) and the ROD was issued on June 1, 2004. Direct effects on hydrology from any of the action alternatives were projected to include a constant increase of about 60 to 70 cubic feet per second (1.7 to 2.0 cubic meters per second) from flows of the city's San Juan-Chama Project water between Abiquiu Reservoir and Albuquerque at any time the diversion system is operating (Reclamation 2004). Contamination from canyons flowing through LANL that outlet into the Rio Grande and any potential changes in Rio Grande flows from proposed changes at LANL under any action alternative are not likely to affect Albuquerque's water quality or quantity because any contaminated sediments would be trapped behind the dam and flows would be regulated by water operations at Cochiti Dam.

The city of Santa Fe is proposing to install a diversion dam on the east bank of the Rio Grande across from San Ildefonso Pueblo and upstream from White Rock. The purpose of this project is to seek "sustainable means of accessing surface water supplies that would use the applicants' water rights by diverting San Juan-Chama Project water and native Rio Grande water while reducing their reliance on over-taxed ground water resources" (BLM and USFS 2007). The Buckman Well Field currently consists of thirteen wells that draw from the regional aquifer, but well yields have been reduced and groundwater levels have declined since its inception, depleting nearby streamflows (BLM and USFS 2007). The diversion, which would divert up to 5,230 acre-feet per year from the river (BLM and USFS 2007), would be located in the Rio Grande near the area where Mortandad Canyon outlets on the west side of the river and downstream from the outlets of Pueblo, Sandia, and Los Alamos Canyons.

Santa Fe proposes to continue providing residual offsets from past pumping of the Buckman Well Field (currently about 2,500 acre-feet per year). Under this proposal, pumping from the

Buckman Well Field would be scaled back to a long-term average of approximately 1,000 acre-feet per year. The cone of depression in the regional aquifer from current pumping of the well field has been modeled to extend to the west side of the Rio Grande, encompassing White Rock and the eastern part of LANL (BLM and USFS 2007). The *Final Environmental Impact Statement for the Buckman Well Field Project* predicts that, if the proposed project were implemented, direct diversions with reduced pumping from the Buckman Well Field would result in a 1 percent reduction in Rio Grande flows below the diversion and a significantly smaller cone of depression after the diversion project is established because pumping and aquifer depletions would be greatly reduced (BLM and USFS 2007). The projected reductions of aquifer depletions from reduced pumping of the Buckman Well Field would help offset projected increases in water use by LANL and Los Alamos County.

Under the Radioactive Liquid Waste Treatment Facility action to construct liquid effluent evaporation tanks with the goal of zero discharges from the facility into Mortandad Canyon, reduction of contaminant contributions by eliminating the outfall would positively impact surface water quality and possibly benefit Santa Fe's project. Improved water quality monitoring would also have positive impacts.

Los Alamos County and the San Ildefonso Pueblo are considering diverting Rio Grande water. There also may be other projects similar to the Buckman Project that would divert San Juan-Chama and native waters from the Rio Grande in the vicinity of LANL. The San Ildefonso Pueblo installed a single unit infiltration collector well as a pilot project in 2001. These projects may contribute to cumulative effects on the regional surface water system, but are less well defined, so the effects are impossible to predict at this time (BLM and USFS 2007).

Groundwater Quality

Additional modeling and monitoring wells are being installed to determine the foreseeable future impacts on the regional aquifer from radionuclides and other contaminants that are thought to be migrating through the bedrock. Questions about the rate and direction of contaminant movement must be more thoroughly investigated before the cumulative effects on water resources can be evaluated. LANL will conduct future data collection activities and analyze existing data to better define the interaction between groundwater and the rock matrix. This understanding of the hydrologic and chemical components at the site will aid in developing sound conceptual models of flow and transport through the fractures and matrix of the vadose zone into the saturated zone. The new data, coupled with improvements in numerical flow and transport models and improved calculational techniques, will enable better prediction of flow and transport of groundwater in the LANL region and more accurately define the ultimate impacts on the regional groundwater resources below LANL. Recent news of chromium in the regional aquifer (Snodgrass 2006) also will require additional research to determine the source of the contaminant.

The North Railroad Avenue groundwater contamination plume located over 12 miles (19 kilometers) from the LANL boundary is undergoing remediation. Tetrachloroethylene (perchloroethylene) is the leading concern from this plume because it is the most widespread and is found in the highest concentrations in groundwater. Other contaminants present with possible health effects include trichloroethylene, cis-1,2dichloroethylene, and trans-1,2dichloroethylene (EPA 2006b). For this plume, bioremediation pilot testing began in May 2007 (NMED 2007a).

Because this contamination plume will be remediated to protect drinking water and the Rio Grande from future chlorinated groundwater solvents, it is not expected to migrate into groundwater and surface water impacted by past or present LANL operations.

Air Quality and Noise

Table 5–80 presents the estimated maximum cumulative air quality concentrations offsite or at the site boundary from operations of both the Expanded Operations Alternative and the Complex Transformation consolidated nuclear production center. No data are available at this time related to operation of the GNEP advanced fuel cycle facility. Cumulative concentrations of all of the criteria pollutants except the 24-hour standard for nitrogen dioxide and total suspended particulates are expected to remain in compliance with Federal and state ambient air quality standards. The 24-hour standard for nitrogen dioxide and total suspended particulates could be exceeded on occasion. Based on these potential exceedances, more detailed site-specific analyses would need to be performed if LANL is selected as the site for construction of the consolidated nuclear production center. Cumulative air quality impacts for the No Action Alternative or the Reduced Operations Alternative in combination with the proposed consolidated nuclear production center would be lower than those shown in the table.

Table 5–80 Estimated Maximum Cumulative Air Quality Concentrations at the Site Boundary (micrograms per cubic meter)

Criteria Pollutant	*Averaging Period*	*LANL SWEIS Expanded Operations and Consolidated Nuclear Productions Center* [a]	*Most Stringent Standard or Guideline* [a]
Carbon monoxide	8 Hours 1 Hour	286 1,349	7,900 11,900
Nitrogen dioxide	Annual 24 Hours	26 161	75 150
Sulfur dioxide	Annual 24 Hours 3 Hours	13 93 480	42 209 1,050
Total suspended particulates	Annual 24 Hours	9.7 202	60 150
PM_{10}	Annual 24 Hours	26 143	50 150

PM_{10} = particulate matter less than or equal to 10 microns in diameter, TA = technical area.

[a] Data from Table 5–8 of this *LANL SWEIS* and Table 5.1.4-12 of the Draft *Complex Transformation SPEIS* (DOE 2007b). Criteria pollutants released from LANL operations are emitted primarily from combustion sources such as boilers and emergency generators. Although motor vehicle emissions have an impact on local air quality, no quantitative analysis of vehicle emissions was performed as part of the *LANL SWEIS*. The contribution of vehicle emissions was assumed to be included in the background monitoring concentrations discussed in the current and *1999 SWEIS*. The results of the modeling demonstrate that simultaneous operation of LANL's air emission sources at maximum capacity as described in the Title V permit application would not exceed any state or Federal ambient air quality standards. All of the equipment at the TA-3 Co-Generation Complex, including additional combustion turbine generators that would be constructed in the 2007 to 2013 timeframe, would operate within the emission limits specified in the air quality permit.

Effects on air quality from construction, excavation, and remediation activities could result in temporary increases in air pollutant concentrations at the site boundary and along roads to which the public has access. These impacts would be similar to the impacts that would occur during construction of a housing project or a commercial complex. Emissions of fugitive dust from these activities would be controlled with water sprays and other engineering and management practices as appropriate. The maximum ground-level concentrations offsite and along roads to which the public has regular access would be below the ambient air quality standards, except for possible short-term concentrations of nitrogen oxides and carbon monoxide for certain projects that could occur near the site boundary. Appropriate management controls and scheduling would be used to minimize impacts on the public and to meet regulatory requirements. The impact on the public would likely be minor.

The increase in employee vehicles and the increase in other vehicles resulting from the population increase projected by the state would result in increases in vehicle emissions along the routes used to access the site. As discussed in Section 4.4.2.1 the area around Los Alamos and most of New Mexico is designated as attaining for the National Ambient Air Quality Standards for carbon monoxide, nitrogen oxides, ozone, and the other criteria pollutants (40 CFR 81.332). Even with the continuing growth in population there has been a decreasing or steady trend in concentrations in the region of carbon monoxide, nitrogen oxides, and ozone. Carbon monoxide and nitrogen oxides concentrations are well below the ambient standards (EPA 2006a).

The impacts of toxic air pollutants were assessed based on the analysis in the *1999 SWEIS* and the emission estimates in the LANL Yearbooks. In all but two cases, the estimated toxic pollutant emissions were below the corresponding guideline values established for the screening analysis in the *1999 SWEIS*. Guideline values are the levels established to screen emission rates for further analysis. The two cases where estimated emission rates were above guideline values and were referred to the human health and ecological risk assessment processes were: (1) emissions from High Explosives Firing Facilities operations at TA-14, TA-15, TA-36, TA-39, and TA-40; and (2) additive emissions from all pollutants from all TAs on receptor sites located near the Los Alamos Medical Center. The risk assessment analysis demonstrated that the pollutants released for these two cases would not be expected to cause air quality impacts that would affect human health and the environment.

Cumulative air quality impacts from offsite construction and operation activities were also evaluated. The maximum impacts from construction activities (including fugitive dust) for oil and gas development in the region were shown to occur very close to the source, with concentrations decreasing rapidly with distance (BLM 2003b). Therefore, it is expected that offsite air emissions from disturbance and construction would not contribute substantially to cumulative impacts at LANL.

Impacts of inert pollutants (pollutants other than ozone and its precursors) are generally limited to a few miles downwind from a source (BLM 2003b). For emissions from the well fields analyzed in the *Farmington Proposed Resource Management Plan and Final Environmental Impact Statement* (BLM 2003b), the distance where the nitrogen dioxide concentrations drop below their significance levels would be 15.6 to 24.9 miles (25 to 40 kilometers). Therefore, it is expected that emissions from operation of offsite facilities would not contribute substantially to cumulative impacts at LANL, which is about 100 miles (160 kilometers) away.

In contrast, the maximum effects of volatile organic compounds and nitrogen oxides emissions on ozone levels usually occur several hours after they are emitted and many miles from the sources (BLM 2003b). Although LANL is outside the study areas for the Northern San Juan Basin Coalbed Methane Project, the EIS for this project (BLM 2004a) determined that the cumulative impacts of oil and gas development combined with regional emissions from other sources could exceed visibility thresholds (9 to 25 days annually) in the Class I Areas of the Weminuche Wilderness and Mesa Verde National Park. These impacts could be reduced to 1 to 17 days annually if stricter emissions controls are required for new emission sources of nitrogen oxide (BLM 2004a). LANL is approximately 100 miles (161 kilometers) from the Bloomfield Farmington and San Juan Basin Coalbed Methane Project areas, and it is unclear whether such distant emissions could contribute to cumulative visibility impacts at the Bandelier National Monument.

The air quality analysis in the *Farmington Proposed Resource Management Plan and Final Environmental Impact Statement* (BLM 2003b) included consideration of air emissions from the highly industrialized Bloomfield gas corridor, El Paso Blanco compressor station, Conoco San Juan Gas Plant, and Four Corners and San Juan Power Plants (BLM 2003a). Although LANL is outside the study areas for the *Farmington Proposed Resource Management Plan and Final Environmental Impact Statement* (BLM 2003b), the ROD for this study (BLM 2003c) included a number of mitigation measures designed to reduce cumulative air quality impacts from gas and oil wells and pipelines. One of the more significant mitigation measures requires that new and replacement wellhead compressors limit nitrogen oxide emissions to levels less than 10 grams per horsepower-hour, and that each pipeline compressor station limit its total nitrogen oxide emissions to levels less than 1.5 grams per horsepower-hour. This requirement would apply to all new and replacement compressor engines unless the proponent can demonstrate (using air pollutant dispersion modeling) that a specific higher emission rate would not cause or contribute to exceedance of any ambient air quality standard. This measure is intended to substantially reduce the level and extent of emissions that form ozone throughout the region and to reduce visibility impacts on Class I Areas such as Mesa Verde National Park and Bandelier National Monument (BLM 2003b).

The incremental increase in criteria and toxic pollutant emissions identified in the *Conveyance and Transfer EIS* would not be major and would not cause or contribute to exceedance of any ambient air quality standard.

Ecological Resources

The continuing conveyance and transfer of LANL land would result in the cumulative impacts of the conveyance and transfer of 770 acres (312 hectares) of undeveloped habitat that could be developed. A transfer of resource protection responsibility may also result in a less rigorous environmental protection review process. Electrical power system upgrades would have minimal effects on vegetation and temporary impacts on wildlife. The Wildfire Hazard Reduction Program would have short-term impacts on wildlife, create historic forest conditions, and positively affect the Mexican spotted owl by providing a healthier habitat. Disposition of flood retention structures would have short-term impacts on wildlife and its habitat and potentially on downstream wetlands as well due to possible habitat disturbance and changes in the water flow rate. The Trails Management Program would have short-term impacts on wildlife and increase the diversity of wildlife where trails are closed. Section 5.5 of this SWEIS has a detailed discussion of the effects of each alternative on ecological resources.

Impacts associated with construction of the *Complex Transformation SPEIS* consolidated nuclear production center or the GNEP advanced fuel cycle facility at LANL would include the loss of habitat and of less mobile wildlife, such as reptiles and small mammals. More mobile species, such as birds or large mammals, would be displaced as a result of construction activities; however, these species could relocate to adjacent less developed areas. Successful relocation of more mobile species may not occur due to competition for resources and the carrying capacity limitations of areas outside the proposed development. Best management practices and implementation measures set forth in the LANL *Threatened and Endangered Species Habitat Management Plan* would be used during construction activities to minimize the potential for adverse effects to plant and animal communities and on threatened and endanger or special interest species. Proposed construction sites would be surveyed for the presence of special status species before construction begins, and mitigation actions would be developed. After construction, temporary structures would be removed and the sites reclaimed.

Human Health

Table 5–81 presents the estimated cumulative impacts from radiological emissions and radiation exposure from the LANL SWEIS alternatives and the Complex Transformation consolidated nuclear production center (the GNEP advanced fuel cycle facility is not represented in the table because available preliminary data do not include offsite radiological impacts). Cumulative impacts to the public would likely remain within the maximum level of impacts forecast under the SWEIS Expanded Operations Alternative. The offsite impacts from the addition of the consolidated nuclear production center would be essentially unchanged due to the assumed closure of existing LANL facilities whose functions would be included in the new center. No LCFs would be expected for the MEI or in the general population. The dose to the offsite MEI would be expected to remain within the 10 millirem per year limit required by 40 CFR 61, Subpart H, National Emission Standards for Emissions of Radionuclides Other than Radon from Department of Energy Facilities. There would be no increase in the risk of LCFs among the general public.

Collective worker doses would increase if the Expanded Operations Alternative MDA Removal Option were to be implemented. Collective worker doses would increase from about 280 person-rem per year to an annual average of 540 person-rem per year. The 540 person-rem dose corresponds to an annual risk of an LCF in the worker population of 0.3 (or for each 3 years of operation, 1 chance of an LCF in the worker population). Worker doses would decrease by about 140 person-rem per year after the MDA remediation work was completed. Individual worker dose would be maintained ALARA and within applicable regulatory limits. Worker doses would be expected to increase from operation of the consolidated nuclear production center at LANL. The net increase in collective worker dose would be approximately 105 person-rem per year. The increased annual risk of an LCF in the worker population would be 0.06 (or for each 17 years of operation, 1 additional LCF might be expected in the worker population). The most recent preliminary data for the GNEP advanced fuel cycle facility do not include a worker population dose estimate.

Table 5–81 Estimated Cumulative Radiological Impacts

Activity	*General Public*				*Worker Population*	
	MEI		*Population Within 50 Miles*			
	Dose (millirem per year)	*LCF Risk per Year*	*Collective Dose (person-rem per year)*	*Excess LCFs per Year*	*Collective Dose (person-rem per year)*	*Excess LCFs per Year*
LANL SWEIS Alternatives						
No Action	7.8	4.7×10^{-6}	30	0.018	280	0.17
Reduced Operations	0.78	4.7×10^{-7}	6.1	0.0037	257	0.15
Expanded Operations	8.2	4.9×10^{-6}	36	0.022	543	0.33
Complex Transformation SPEIS [a]						
Consolidated Nuclear Production Center	NC	NC	0.38	2.3×10^{-4}	386	0.23
Minus Plutonium Facilities Complex	NC	NC	-0.20	-1.2×10^{-4}	-220	-0.13
Minus CMR Building	NC	NC	-0.43	-2.6×10^{-4}	-61	-0.04
Total (SPEIS and Expanded Operations)	8.2	4.9×10^{-6}	36	0.022	648	0.39
Dose Limit [b]	10	NA	NA	NA	NA	NA

MEI = maximally exposed individual, LCF = latent cancer fatality, NA = not applicable, NC = no change, CMR = Chemistry and Metallurgy Research.

[a] *Complex Transformation SPEIS*, Tables 5.1.11-2 and 5.1.11-3 (DOE 2007b).

[b] 10 millirem per year limits as required by 40 CFR 61, Subpart H.

Monitoring results for radioisotopes and chemicals in groundwater, surface water, sediments, and soil in and around LANL (see Appendix F, Section F.3) account for any contaminants that have accumulated since the beginning of operations at LANL. Appendix C presents detailed LANL radiological emissions and radiation dose data; all doses are a very small fraction of the normal background dose received by the population in and around LANL. Section 4.6.1 of this SWEIS provides detailed information on cancer mortality and incidence rates in New Mexico and all counties surrounding LANL. These data, along with the final LANL Public Health Assessment, issued on August 31, 2006 by the U.S. Department of Health and Human Services, Agency for Toxic Substances and Disease Registry (ATSDR 2006), show that, "there is no evidence of contamination from LANL that might be expected to result in ill health to the community" and "[o]verall, cancer rates in the Los Alamos area are similar to cancer rates found in other communities." The Centers for Disease Control and Prevention is in the early phase of the dose reconstruction efforts at LANL. As described in their January 2006 publication titled *Interim Report of the Los Alamos Historical Document Retrieval and Assessment Project* (CDC 2006), dose reconstruction is a five phase process involving: (1) retrieval and assessment of data; (2) initial source term development and pathway analysis; (3) screening dose and exposure calculations; (4) development of methods for assessing environmental doses; and (5) calculation of environmental exposures, doses, and risks. The Centers for Disease Control and Prevention project at LANL is still in the initial information gathering phase. Therefore, this information is not available to include in the cumulative impacts analysis.

Cultural Resources

Actions proposed under the *Land Conveyance and Transfer EIS* would result in the cumulative impacts of the conveyance and transfer of cultural resources out of the responsibility and protection of the DOE. A consequence of this conveyance and transfer would be potential damage to cultural resources due to future development and impacts to the protection and accessibility of Native American sacred sites. The environmental justice cumulative impacts section contains additional information regarding cultural resources with respect to environmental justice.

Proposed sites for the *Complex Transformation SPEIS* consolidated nuclear production center facilities in TA-16 or TA-55 and the GNEP advanced fuel cycle facility in TA-36 that involve undisturbed lands are likely to contain archaeological resources due to the high density of these resources in the region. The potential impacts to cultural resources would not be known until a specific footprint on the ground is selected for the proposed facilities. Prior to any ground-disturbing activity, DOE would identify and evaluate any cultural resources that could potentially be impacted by construction activities. Methods for identification could include archival research and consultation with interested Native American tribes. DOE would determine the possibility for impacts to National Register of Historic Places-eligible resources and implement appropriate measures to avoid, reduce, or mitigate the impacts. Identification, evaluation, determination of impact, and implementation of measures would be conducted in consultation with the New Mexico State Historic Preservation Officer and in accordance with *A Plan for the Management of the Cultural Heritage at Los Alamos National Laboratory, New Mexico* (LANL 2006f). If previously unknown cultural or paleontological resources, such as subsurface resources, were discovered during construction, activities in the area of the discovery would stop and the discovery would be evaluated and treated appropriately, as determined by DOE in consultation with the New Mexico State Historic Preservation Officer and other interested parties.

Socioeconomics

Important cumulative socioeconomic impacts occur when the net effect of regional projects or activities would substantially alter the location and distribution of regional populations, substantially raise the unemployment rate, substantially affect the local housing market, or result in the need for new social services. Past and present economic conditions associated with continued operations of LANL are described in Chapter 4, Section 4.8.1, of this SWEIS.

As shown in **Table 5–82**, there are four other major activities that could have significant socioeconomic impacts on the region in the future. These include operation of the Los Alamos Research Park, the conveyance and transfer of land from LANL in accordance with the provisions of Public Law 105-119, the potential siting of a new consolidated nuclear production center, and the potential siting of a GNEP advanced fuel cycle facility at LANL.

By 2011, LANL operations under the No Action Alternative could account for approximately 20 percent of employment in the tri-county area (Los Alamos, Rio Arriba, and Santa Fe Counties) and an even higher percentage of wages due to the large difference in average wages for LANL employees versus the county averages. Under the Expanded Operations Alternative, direct employment at LANL could increase by another 14 percent by 2011 leading to the creation of approximately 1,890 direct and 2,000 indirect jobs. About 1,600 direct jobs and 1,700 indirect jobs would be held by residents of the tri-county area, increasing the estimated percentage of the population employed in the tri-county area as a result of LANL operations activities to 22 percent.

Table 5–82 Estimated Cumulative Socioeconomic Impacts

Activity	*Direct Employment Residing in the Tri-County Area*	*Projected Indirect Jobs*	*LANL-Related Jobs*	*Projected Employment in the Tri-County Area in 2011*
LANL Operations (through 2011)				
– No Action Alternative	11,564	12,236	23,800	120,609
– Reduced Operations Alternative	11,138	11,785	22,923	119,732
– Expanded Operations Alternative	13,182	13,948	27,130	123,939
Research Park [a]	1,600	1,693	3,293	+ 3,293
Conveyance & Transfer of Lands [b]	6,080	6,433	12,513	+ 12,513
Consolidated Nuclear Production Center [c]	1,528	1,617	3,145	+ 3,145
Advanced Fuel Cycle Facility [d]	1,138	1,204	2,342	+ 2,342
Maximum LANL-Related Activity	23,528	24,895	48,423	145,232

[a] DOE 1997b.
[b] DOE 1999d.
[c] DOE 2007b.
[d] DOE 2008.

The Los Alamos Research Park was created on land within LANL that has been leased to Los Alamos County for private sector use as discussed in the *Research Park EA* (DOE 1997b). Under this proposal, one 83,000-square-foot building was completed in 2001, and industry has been leasing space in the building and collaborating with LANL on research activities in the hopes of accelerating economic development in the region. As estimated in the Research Park EA, up to 1,600 direct jobs could eventually be created at the Park (DOE 1997b). If this were to happen, it could lead to the creation of another 1,700 indirect jobs in the region. As of January 2007, there were 19 companies employing approximately 150 individuals working in the Research Park (Holsapple 2007). There is land available within the Research Park for additional buildings and other buildings are expected to be constructed as the demand for available space increases.

In addition, LANL is conveying land to Los Alamos County that may be used for commercial and residential uses as discussed in Section 4.1.1 of this LANL SWEIS. As estimated in the *Land Transfer and Conveyance EIS*, approximately 6,100 direct jobs could be created on these lands (DOE 1999d). This could lead to the creation of another 6,400 indirect jobs in the region. To date, 152 acres of approximately 1,803 acres of land to be conveyed to the County have been conveyed.

If the maximum number of jobs estimated to be created under the *Research Park EA* and the *Land Transfer and Conveyance EIS* were also created by 2011, there could be additional socioeconomic impacts in the region of influence. Cumulatively, the Expanded Operations Alternative and these activities could result in nearly 21,000 direct and 22,000 indirect jobs in the region. This scenario would increase the estimated percentage of the population employed by LANL-related activity to 31 percent of the region of influence. Under this scenario, the rate of population growth in the region would likely exceed current rates placing additional strain on regional infrastructure and social services. For example, additional demand would be placed on regional water and electrical systems, roads would be more heavily traveled, additional housing would need to be constructed, and there may be demands for additional schools and hospitals.

There would also be beneficial gains in terms of average wages and benefits flowing into the local economy since many of these jobs should be relatively higher paying jobs (for example, research jobs), and the unemployment rate would be likely to fall.

At this time, the level of direct employment related to the Research Park and the land conveyances is very low compared to the estimates analyzed in the earlier NEPA documents and it is too early to accurately predict whether these estimates will actually be reached. If they are not reached, the cumulative socioeconomic impacts for the region would be closer to those described in Section 5.8.1 for LANL operations.

It is assumed that approximately 86 percent of the new employees needed to operate the consolidated nuclear production center (1,785) and the advanced fuel cycle facility (1,330) would reside in Los Alamos, Rio Arriba, or Santa Fe County in keeping with current LANL employee preferences. Together with the Research Park and the jobs that could be created as a result of the land transfer and conveyance, these activities could result in the addition of up to 10,300 new direct employees related to LANL and another 10,900 indirect jobs in the tri-county area. Cumulatively these activities could increase the LANL-related jobs in the tri-county area by 78 percent over the levels expected under the Expanded Operations Alternative. Employment in the tri-county area could increase by approximately 17 percent over the levels projected under the Expanded Operations Alternative and the LANL-related jobs would increase to 33 percent of the worker population in the region of influence.

Increases in employment related to the proposed consolidated nuclear production center and the advanced fuel cycle facility would occur further in the future because these facilities would need to be constructed and are not expected to begin operating until at least 2020. In the meantime, regional planning could be undertaken in anticipation of projected increases associated with these facilities to alleviate potential shortfalls such as the need for additional housing, schools, or improved public transportation.

Infrastructure

Table 5–83 presents the estimated cumulative infrastructure requirements within the LANL region of influence for electricity, natural gas, and water. Cumulative infrastructure requirements include usage projections through 2011 for LANL and other Los Alamos County users that rely on the same utility system. Therefore, the projections provided in Section 5.8.2 and adopted here already consider cumulative future usage of these utilities by DOE and non-DOE entities. Projections of future utility use in Los Alamos County are largely related to increased usage due to population growth and associated industrial and commercial development.

As shown in Table 5–83, total combined electric power and water demands under the Expanded Operations Alternative could approach the electric-peak load capacity and total available water rights, respectively. Electrical energy capacity at LANL would not be exceeded under any of the proposed SWEIS alternatives. If the consolidated nuclear production center facilities were sited at LANL, the system capacities for electric-peak load and water could be exceeded and additional resources might need to be identified to satisfy the projected demand. The additional 45 megawatts electric-peak load and 117 million gallons of water usage from the GNEP advanced fuel cycle facility (DOE 2008) would further exacerbate the availability issues. The projection of electric-peak load system capacity does not take into account completion of a new transmission line and other ongoing power grid upgrades that could help offset potential deficits in peak load capacity and ensure electrical energy availability for operations. Also, LANL has provisions to install a second new turbine at the TA-3 Co-Generation Complex that would add an additional 20 megawatts (175,200 megawatt-hours per year) of generating capacity, if needed. A study of the Los Alamos County water system would be required to determine whether the current water supply and distribution systems are adequate to meet additional projected annual water demand due to consolidated nuclear production center operations, the GNEP advanced fuel cycle facility, or both. It is likely that significant modifications would be required and LANL would need to obtain greater water resources, or significantly reduce its potable water use through mitigative measures. Overall LANL work assignments might have to be revamped, reduced, or eliminated so that existing potable water supplies would be adequate to support the assigned LANL work load.

Table 5–83 Estimated Cumulative Infrastructure Requirements for the Los Alamos National Laboratory Region of Influence

Activity	*Electricity*		*Natural Gas (decatherms per year)*	*Water (millions of gallons per year)*
	(megawatt-hours per year)	*Peak load (megawatts)*		
LANL SWEIS Alternatives Projected through 2011 [a]				
No Action	645,000	111	2,215,000	1,621
Reduced Operations	516,000	80.6	2,181,000	1,544
Expanded Operations	827,000	144	2,331,000	1,763
Complex Transformation SPEIS				
Consolidated Nuclear Production Center [b]	264,000	41	Information not available	395
Minus 80 pit manufacturing capability [c] under Expanded Operations	-9,000	- 1	- 28,000	- 8
GNEP PEIS				
Advanced Fuel Cycle Facility [d]	Information not available	45	Information not available	117
Total (Expanded Operations, Consolidated Nuclear Production Center, and Advanced Fuel Cycle Facility)	Information not available	229	Information not available	2,267
System Capacity [e]	1,314,000	150	8,070,000	1,806

[a] Data from Table 5–34, 5–35, and 5–36. Projections through 2011 for electrical energy, peak load, natural gas, and water also include projected usage for other Los Alamos County users that rely upon the same utility system.
[b] Data from Draft *Complex Transformation SPEIS* Tables 5.1.3-2 and 5.1.5-2.
[c] Rounded estimates from Section 5.8.2.3.
[d] Preliminary data for GNEP advanced fuel cycle facility (DOE 2008).
[e] Data from Table 5–33. Electrical energy and peak load capacity reflect the current import capacity of the electric transmission lines that deliver electric power to the Los Alamos Power Pool and completion of upgrades at the TA-3 Co-Generation Complex adding 40 megawatts (350,400 megawatt-hours) of generating capacity. Water system capacity reflects the total water rights from the regional aquifer managed by Los Alamos County.
Note: A decatherm is equivalent to 1,000 cubic feet.

Los Alamos County, as owner and operator of the Los Alamos Water Supply System, is currently pursuing the use of San Juan-Chama Transmountain Diversion Project water to secure additional water rights and supply for its water customers, including LANL. This would supply the Los Alamos area with up to an additional 391 million gallons (1,500 million liters) of water per year. Without the San Juan-Chama water, demand could exceed the available water supply in the future.

In the near term, no infrastructure capacity constraints are anticipated. LANL operational demands on key infrastructure resources, including electricity and water, have been below projected levels and within site capacities. Any potential shortfalls in available capacity would be addressed as increased site requirements are more fully understood.

Waste Management

Table 5–84 presents the estimated amount of radioactive and chemical waste that would be generated by the LANL SWEIS Alternatives (through 2016). Cumulative waste generation rates for all waste types are expected to be substantial, largely due to future remediation and DD&D of facilities. Although this is the case under all of the proposed LANL SWEIS Alternatives, the quantities of wastes projected under the Expanded Operations Alternative are significantly greater than those projected under the other alternatives due to the extensive environmental restoration cleanup projects associated with the MDAs and DD&D activities. Actual waste volumes from environmental remediation may be smaller, depending on regulatory decisions by the New Mexico Environment Department, and on use of waste volume reduction techniques.

Table 5–84 Estimated Cumulative Waste Generation at Los Alamos National Laboratory (2007 to 2016)

Activity	*Transuranic (cubic yards)*	*Low-Level Radioactive (cubic yards)*	*Mixed Low-Level Radioactive (cubic yards)*	*Construction and Demolition Waste (cubic yards)*	*Chemical (pounds)*
LANL SWEIS Alternatives (2007-2016) [a]					
No Action	3,500 to 5,900	72,000 to 167,000	1,800 to 2,800	198,000	19,000,000 to 37,000,000
Reduced Operations	3,500 to 5,900	72,000 to 148,000	1,800 to 2,800	197,000	19,000,000 to 36,000,000
Expanded Operations	5,300 to 33,000	277,000 to 1,414,000	3,900 to 183,000	642,000 to 722,000	64,000,000 to 129,000,000
Total (range) [c]	3,500 to 33,000	72,000 to 1,414,000	1,800 to 183,000	198,000 to 722,000	19,000,000 to 129,000,000

[a] Data rounded from Table 5–37.
[b] The total range includes the minimum and maximum values from the LANL SWEIS Alternatives. The total may not equal the sum of the contributions due to rounding.

The waste estimates under the Expanded Operations Alternative in this SWEIS include waste generated from expanding pit production to up to 80 pits per year from 20 pits per year under the No Action Alternative.

Increases in the cumulative waste generation rate may require construction of additional facilities and assignment of additional staff to manage the wastes. All waste categories are expected to increase generation rates, including solid, chemical, low-level radioactive, transuranic, and mixed wastes. Substantial quantities of low-level radioactive wastes and solid wastes (primarily uncontaminated debris from excavation, construction, and demolition activities) are projected. Efforts will be made to recycle as much of the uncontaminated fill as reasonably possible to reduce the need to bring additional fill from offsite sources to satisfy LANL's ongoing requirement. Most wastes, with the exception of some low-level radioactive wastes, are disposed of offsite at permitted facilities.

Low-level radioactive waste generation rates would increase under all alternatives, but the most significant increase would be under the Expanded Operations Alternative if all waste from MDAs were removed. Depending on the actual volumes generated by remediation, the expansion of TA-54 Area G into Zone 4, and eventually Zone 6, is expected to provide onsite low-level radioactive waste disposal capacity for operations waste through the 2016 timeframe and beyond. In addition, offsite disposal options for low-level radioactive waste include NNSA's Nevada Test Site and commercial facilities. For commercial facilities, some restrictions apply to acceptance of waste based on the origin (state of origin, and DOE or non-DOE generated) and radiological characteristics of the waste. Mixed low-level radioactive waste generation also is expected to increase, but the quantity is projected to be less than two percent of the quantity of low-level radioactive waste. Mixed low-level radioactive wastes may be sent offsite for treatment of the hazardous component and possibly returned to LANL (or disposed of elsewhere) as low-level radioactive waste.[8]

The ROD for the *WIPP SEIS* allows for disposal of 175,600 cubic meters (229,667 cubic yards) of transuranic waste at WIPP (63 FR 3624), of which 21,000 cubic meters (27,466 cubic yards) of contact-handled transuranic waste and 230 cubic meters (301 cubic yards) of remote-handled transuranic waste were anticipated to originate from LANL (DOE 1997a). Transuranic waste generated under the Expanded Operations Alternative and the total cumulative transuranic generation shown in Table 5–84 could exceed the amount assumed to come from LANL. About two-thirds of the projected transuranic waste in Table 5–84, however, is from the assumed removal of transuranic waste, most of which was buried before 1970 in certain MDAs. As noted above, actual transuranic waste volumes will depend on regulatory decisions and on implementation of volume reduction techniques. WIPP disposal capacity is expected to be sufficient for disposal of all retrievably stored waste and all newly generated transuranic waste from the DOE complex over the next few decades, but not sufficient for this waste plus all transuranic waste buried before 1970 across the DOE complex (63 FR 3624). Decisions about disposal of transuranic waste from full removal of LANL MDAs, if generated, will be based on the needs of the entire DOE complex.

Transuranic waste from MDA removal without a disposal pathway would be safely stored onsite until additional disposal capacity at WIPP or elsewhere was identified. The impacts of disposal of transuranic waste at WIPP are evaluated in the *Waste Isolation Pilot Plant Disposal Phase Final Supplemental Environmental Impact Statement* (DOE 1997a).

Although routine generation of chemical wastes is expected to decline under all alternatives compared to current operations at LANL, significant quantities of this waste type are expected due to environmental restoration activities, and to a lesser extent, DD&D activities. This increase would be particularly evident under the Expanded Operations Alternative, if all wastes were removed from MDAs. Offsite treatment options are available at commercial facilities across the country, including treatment and disposal facilities in Nevada, Colorado, Utah, and Texas (ACE 2006).

---

[8] *Mixed waste that is successfully treated for a characteristic would no longer be mixed waste. Listed mixed waste is always mixed. No mixed waste is currently disposed of onsite at LANL.*

Significant quantities of nonradioactive solid wastes, including construction and demolition debris, would be generated under all alternatives. The most significant increase would occur under the Expanded Operations Alternative, if all wastes were removed from MDAs. The planned closure of the Los Alamos County Landfill by the end of 2008 means that, in the future, solid wastes will be disposed of via the Los Alamos County Transfer Station, where wastes would be segregated and then transported to an appropriately permitted solid waste landfill. Construction and demolition wastes would be recycled and reused to the extent practicable. Debris that cannot be recycled would be disposed of at solid waste landfills or construction and demolition debris landfills. Los Alamos County is currently evaluating regional solid waste landfills within 120 miles of LANL for a possible contract for disposal of LANL and Los Alamos County waste, including the Rio Rancho, Sandoval County, and Torrance County/Bernalillo County Landfills. In 2006, the New Mexico Environment Department Solid Waste Bureau estimated that the state had approximately 30 years of landfill capacity remaining (NMED 2006b).

Wastes would be generated during construction of the consolidated nuclear production center if it were sited at LANL. Wastes anticipated from proposed construction would include up to 10,000 cubic yards (7,600 cubic meters) of low-level waste that would be processed and packaged for disposal at TA-54. Other construction wastes that could be generated include hazardous waste and nonhazardous solid and liquid waste. The quantities of hazardous waste that could be generated from construction are small compared to the amount of hazardous waste disposal capacity available in the region. Nonhazardous solid wastes would be recycled to the extent practicable and the remainder would be shipped offsite for disposal at approved commercial landfills located within the state. Nonhazardous liquid waste generated during construction would be processed at the TA-46 Sanitary Wastewater System Plant.

Operation of the consolidated nuclear production center at LANL would result in the generation of additional radioactive waste. Up to 850 cubic yards (650 cubic meters) of transuranic waste and 310 cubic yards (240 cubic meters) of mixed transuranic waste could be generated annually. This waste would be packaged in accordance with the WIPP WAC, placed in TRUPACT-II shipping containers, and shipped to WIPP for disposal. In addition, operations would generate up to 11,640 cubic yards (8,900 cubic meters) of low-level radioactive waste and up to 72 cubic yards (55 cubic meters) of mixed low-level radioactive waste annually. Low-level radioactive waste would be processed and packaged for disposal at TA-54. Mixed low-level radioactive waste could require permitted treatment and disposal in an appropriate facility. Treatment could occur at one of the new facilities that is proposed to have a RCRA-permitted mixed waste treatment capability. Operations could also generate up to 8,925 gallons (33,785 liters) of liquid low-level radioactive waste and up to 3,622 gallons (13,710 liters) of liquid mixed low-level radioactive waste annually. These wastes would be solidified, processed, and packaged for disposal at the waste processing portion of the proposed new consolidated nuclear production center, or at existing facilities in TA-54, and then disposed of in accordance with their regulatory status. Approximately 1,370 cubic yards (1,050 cubic meters) of solid hazardous waste and 8,850 gallons (33,500 liters) of liquid hazardous waste could be generated annually at LANL as a result of consolidated nuclear production center operation. The capacity to collect these wastes, accumulate them at existing storage facilities, solidify the liquid waste, and ship these wastes offsite for treatment and disposal at a commercial facility, presently exists and would be sufficient to handle these volumes. Because operation of the proposed consolidated nuclear production center would not be expected to start until after 2016, these waste quantities have not been included in Table 5–84.

The volumes of low-level (up to 3,450 cubic yards [2,640 cubic meters]) and mixed low-level radioactive waste (up to 4.4 cubic yards [3.4 cubic meters]) projected to be generated annually by the GNEP advanced fuel cycle facility (DOE 2008) would be managed within the current waste management program. The facility could generate up to 928 cubic yards (710 cubic meters) annually of nondefense transuranic waste (DOE 2008), which is not eligible for disposal at WIPP. Transuranic waste without a disposal pathway would be safely stored until a disposal facility became available. The project could also generate up to 34 cubic yards (26 cubic meters) of high-level radioactive waste annually (DOE 2008). Facilities to safely manage high-level radioactive waste until it could be sent to a geologic repository would have to be provided by the project since no high-level radioactive waste is currently managed at LANL.

Transportation

The collective doses, cumulative health effects, and traffic fatalities resulting from approximately 130 years of radioactive material and waste transport across the United States are estimated in **Table 5–85**. The total collective worker doses from all types of shipments (general transportation, historical DOE shipments, reasonably foreseeable actions, and the LANL SWEIS Alternatives) were estimated to be 381,700 to 382,400 person-rem, which would result in about 229 LCFs among the affected transportation workers. The total collective doses to the general public were estimated to be 343,680 to 343,900 person-rem, which would result in about 206 excess LCFs among the affected general population. The total estimated traffic fatalities associated with accidents involving radioactive material and waste transports would be up to 119. The majority of the collective doses for workers and the general population are associated with the general transportation of radioactive material. Examples of these activities are shipments of radiopharmaceuticals to nuclear medicine laboratories and shipments of commercial low-level waste to commercial disposal facilities. The majority of the traffic fatalities are due to the general transportation of radioactive materials (28 fatalities) and reasonably foreseeable actions (85 fatalities).

Table 5–85 presents the transportation impacts over ten years for each of the SWEIS alternatives. The data show that the impacts of each of the alternatives evaluated in this LANL SWEIS are quite small compared with the overall transportation impacts associated with radioactive materials and waste shipments across the United States. LANL SWEIS Alternatives are expected to result in no worker or public cancer deaths (LCFs) and no more than three traffic fatalities (through 2016); therefore, they would not substantially contribute to cumulative impacts. For perspective, in 2004, there were 522 traffic fatalities in New Mexico and 58 in the three neighboring counties (Los Alamos, Rio Arriba, and Santa Fe) (see Chapter 4, Table 4–56). Nationwide, in 2004, there were more than 42,000 traffic fatalities (NCSA 2006).

Table 5–85 Cumulative Impacts of Radioactive Material and Waste Transport (1943 to 2073) [a]

Activity	Worker		General Public		Traffic Fatalities
	Collective Dose (person-rem)	*Latent Cancer Fatality*	*Collective Dose (person-rem)*	*Latent Cancer Fatality*	
LANL SWEIS Alternatives [b]					
No Action	Up to 164	0.098	53 to 58	0.035	0.27
Reduced Operations	Up to 147	0.088	49 to 53	0.032	0.24
Expanded Operations	Up to 910	Up to 0.15	Up to 287	Up to 0.17	Up to 2.7
Other Past, Present, and Reasonably Foreseeable Future Actions					
General Transportation (1943 to 2073) [c]	350,000	210	300,000	180	28
Historical DOE Shipments [c]	330	0.20	230	0.14	No data
Reasonably Foreseeable Actions [c]	25,300	15.2	42,200	25.3	85
High Level Waste and Spent Nuclear Fuel Disposal at Yucca Mountain (up to 2073) [c, d]	5,900	3.5	1,200	0.72	2.8
Total [e]	381,700 to 382,400	229	343,680 to 343,900	206	~119

[a] Collective dose, health effects, and traffic fatalities associated with transporting radioactive materials and waste.
[b] From Table 5–51.
[c] From *Draft Yucca Mountain SEIS* (DOE 2007a) and Table K–10 of this SWEIS.
[d] From *Draft Yucca Mountain SEIS* (DOE 2007a), Proposed Action; mostly rail alternative.
[e] Total is a range that includes the minimum and maximum values from the LANL SWEIS Alternatives. Total may not equal the sum of the contributions due to rounding.
Note: LCFs calculated using a conversion of 0.0006 LCFs per person-rem.

The major radiological transportation actions involving Category I/II special nuclear material related to the Complex Transformation consolidated nuclear production center at LANL would be:

- Pits currently stored at the Pantex Plant would be transported to LANL; and
- Highly enriched uranium currently stored at the Y-12 Complex would be transported to LANL.

After completion of these shipments, there would be no annual shipment of pits and secondaries. The estimated radiological health impacts of the one-time transportation of pits from Pantex, and highly enriched uranium from Y-12, to LANL under this proposal would:

- The general public would receive a collective dose of approximately 118 person-rem from incident-free transportation, resulting in approximately 0.071 LCFs.
- The collective dose to workers handling pits and highly enriched uranium materials for transportation would be about 1,100 and 4,420 person-rem, respectively; this corresponds to an estimated 3.3 LCFs. It should be noted that the annual maximum individual dose is administratively limited to 2 rem (DOE 1999e); this would be a risk of 0.001 of developing an LCF.

Nonradiological impacts associated with this transportation would be expected to result in zero fatalities (0.018) as a result of traffic accidents.

The major transportation actions involving radioactive materials related to the *GNEP PEIS* advanced fuel cycle facility at LANL would be (DOE 2008):

- 39 shipments of light-water reactor spent fuel;
- 50 shipments of transmutation fuel;
- 50 shipments of fast reactor spent fuel; and
- approximately 1,430 waste shipments.

Local Transportation

Potential impacts to traffic at the main access points to LANL are estimated in **Table 5–86**. The No Action Alternative would not be expected to result in an increase in traffic over current levels. If the Reduced Operations Alternative were chosen for this SWEIS, traffic would be expected to decrease by 4 percent compared to the No Action Alternative. The largest estimated daily traffic increase would occur if the SWEIS Expanded Operations Alternative – MDA Removal Option were selected. Under this scenario, daily traffic could increase by up to 18 percent (averaged across all LANL entrances).

Table 5–86 Summary of Changes in Traffic Flow at the Entrances to Los Alamos National Laboratory

Alternative	*Average Daily Vehicle Trips*				
	Diamond Drive Across Los Alamos Canyon	***Pajarito Road at NM 4***	***East Jemez Road at NM 4***	***West Jemez Road at NM 4***	***DP Road at Trinity Drive***
Baseline	24,545	4,984	9,502	2,010	1,255
LANL SWEIS					
Reduced Operations Alternative	-900	-200	-400	-90	-50
Expanded Operations – MDA Removal Option – Increase in Daily Trips	+1,400	+4,200	+1,200	+200	+440
Total Change in Daily Vehicle Trips	-900 to +1,400	-200 to +4,200	-400 to +1,200	-90 to +200	-50 to +440
Percent Change from Baseline	-4 to + 6	- 4 to +84	-4 to +13	-4 to +10	-4 to +35

MDA = material disposal area.
Note: Incremental changes for LANL SWEIS Alternatives may not match earlier tables due to rounding.

Some temporary and intermittent disruption of traffic flow is expected to occur during construction of the Security Driven Transportation Modification Project (DOE 2002k) as well as under the Expanded Operations Alternative of this SWEIS. These traffic disruptions are not expected to affect recreation, habitat management, or timber production in U.S. Forest Service and Bandelier National Monument areas adjacent to LANL.

Development of land conveyed under the *Land Conveyance and Transfer EIS* ROD could, after the land was remediated, increase traffic in the vicinity of the airport and TA-21 based on current Los Alamos County plans for light industry, retail, and residential development on these tracts. This action, combined with increased traffic due to DD&D activities at TA-21, could cause excessive traffic loads on NM 502. Similarly, increases in employment levels at the Los Alamos Research Park could increase traffic, but currently only 150 are employed there.

The addition of proposed facilities and an increased number of workers for the consolidated nuclear production center in TA-16 as analyzed in the *Complex Transformation SPEIS* would likely result in increased traffic along NM 4 from White Rock to West Jemez Road and on West Jemez Road to the center of the LANL. The option to consolidate the facilities in TA-16 would help to alleviate current concerns related to increased traffic along Pajarito Road under the Expanded Operations Alternative somewhat, because there could be a corresponding decrease in traffic along Pajarito Road from NM 4 to TA-55 if the activities at the TA-55 Plutonium Facilities Complex were relocated to TA-16. Conversely, the proposed location of the GNEP advanced fuel cycle facility in TA-36 could lead to increased traffic along Pajarito Road from NM 4.

Environmental Justice

Environmental justice impacts would occur when the net effect of regional projects or activities would result in disproportionately high adverse human and environmental effects to minority or low-income populations. The previous analysis indicates no high and adverse cumulative human health and environmental impacts, including economic impacts and impacts from special pathways. Therefore, no disproportionately high and adverse human and environmental effects to minority or low-income populations are expected as a result of implementing any of the three alternatives under consideration for continued LANL operations in the SWEIS.

Under the Expanded Operations Alternative, as discussed in Section 5.8.1, employment at LANL and in the surrounding region is expected to increase thus creating additional employment opportunities for local individuals. As additional funding flows into the regional economy, increased opportunities for low-income and minority populations should be realized. Also, under the *Land Conveyance and Transfer EIS*, lands currently considered part of LANL would be transferred to the U.S. Department of the Interior to be held in trust for the Pueblo of San Ildefonso, thus benefiting these people.

As discussed in the *Land Conveyance and Transfer EIS*, there is the possibility that transfer activities may impact traditional cultural properties that could be present on the tracts of land being transferred or in adjacent areas (DOE 1999d). This is also true for areas that LANL is cleaning up under its ongoing environmental restoration program. In 2005 and 2006 the Los Alamos Site Office reaffirmed the 1992 accords with the four Pueblos (the Santa Clara, San Ildefonso, Jemez and Cochiti Pueblos) that recognize the Pueblos as sovereign entities that can interact with the Los Alamos Site Office on a government-to-government basis. Los Alamos Site Office has also signed the LANL Pueblo Cooperative Agreements which provide a procedural framework for consultation, as well as committing to provide information and input in long-term planning and decision making. In addition, the LANL management and operating contractor has prepared *A Plan for the Management of the Cultural Heritage at Los Alamos National*

Laboratory, New Mexico (LANL 2006f) in which specific aspects of the consultation process are spelled out. NNSA is committed to continuing to interface with the Pueblos in accordance with these agreements and plan. When a project is planned at LANL, archaeological records are searched to determine if any cultural resource sites are known to exist at the project area. If archaeological records do not exist for the project area, LANL personnel conduct the necessary surveys prior to any work taking place. If it is determined that traditional cultural properties are present on any of the lands to be transferred or those being cleaned-up, the consultations called for under the appropriate accord and the management plan will be undertaken.

Based on the impacts for resource areas, few high and adverse impacts are expected from the construction and operation of a consolidated nuclear production center or the GNEP advanced fuel cycle facility at LANL. To the extent that any impacts may be high and adverse, NNSA expects the impacts to affect all populations in the area equally (DOE 2007b).

5.14 Mitigation Measures

The regulations promulgated by the Council on Environmental Quality to implement the procedural provisions of NEPA (42 U.S.C. §4321) require that an EIS include a discussion of appropriate mitigation measures (40 CFR 1502.14[f]; 40 CFR 1502.16[h]). The term “mitigation” includes the following:

- Avoiding an impact by not taking an action or parts of an action;
- Minimizing impacts by limiting the degree of magnitude of an action and its implementation;
- Rectifying an impact by repairing, rehabilitating, or restoring the affected environment;
- Reducing or eliminating the impact by preservation and maintenance operations during the life of the action; and
- Compensating for the impact by replacing or providing substitute resources or environments (40 CFR 1508.20).

This section describes mitigation measures that are built into the alternatives analyzed as well as additional measures that will be considered by DOE to further mitigate the adverse impacts identified earlier in this chapter. These measures address the range of potential impacts of continuing to operate LANL (including those areas where lack of information regarding resources and mechanisms for assessing impacts to resources result in substantial uncertainty in the impact analyses). The mitigation measures built into the alternatives analyzed (see Section 5.14.1 and 5.14.2) are of two types: (1) existing programs and controls (including regulations, policies, contractual requirements, and administrative procedures); and (2) specific measures built into the alternatives that serve to minimize the effects of activities under the alternatives. The existing programs and controls are too numerous to list here; but a general description is provided, as well as the role of existing programs in operating LANL and pertinent examples of how these programs mitigate adverse impacts. Additional mitigation measures that could further reduce the adverse impacts identified in this chapter are discussed in Section 5.14.3. The description of these measures in this chapter does not constitute a commitment to undertake any of these measures. Any such commitments would be reflected in the ROD following this SWEIS, with a more detailed description and implementation plan provided in a Mitigation Action Plan following the ROD.

5.14.1 Existing Programs and Controls

The activities undertaken at LANL are performed within the constraints of applicable regulations, applicable DOE orders, contractual requirements, and approved policies and procedures. Laws and regulations applicable to Federal facilities are discussed in Chapter 6; many of these requirements are established to protect human health and the environment. It is assumed that these or similar regulatory controls will continue to be in place. When complied with, these regulations mitigate the potentially adverse impacts of operations to the public, the worker, and the environment. For example, the Clean Air Act (42 U.S.C. §7401) regulates air emissions and the Clean Water Act (33 U.S.C. §1251) regulates liquid effluent discharges in a manner designed to protect human health and reduce the adverse environmental effects of routine operations. In addition to the regulations applicable to LANL, Chapter 6 also discusses other requirements (including DOE Orders and external standards and regulations that would not otherwise apply to Federal facilities) that apply to operations at LANL through the contract between DOE and its management and operating contractor. As discussed in Chapter 6, these requirements are established and enforced through contractual mechanisms. As with the regulations that apply to LANL, it is assumed that these or similar controls will continue. These requirements also mitigate the potential for adverse impacts. For example, the application of DOE design standards results in facility designs for modern nuclear facilities that reduce the potential for catastrophic releases from these facilities in the event of earthquakes, high winds, or other natural phenomena. Similarly, the application of occupational safety and health regulations in 29 CFR Part 1900, et seq, and other standards promulgated by the American National Standards Institute, the U.S. Department of Defense, and DOE, as well as the use of other life safety and fire safety codes and manuals, limit worker exposures to workplace hazards, which reduces the potential for adverse worker health effects. DOE and LANL also have instituted policies and procedures applicable to work conducted at LANL to mitigate potentially adverse effects of operations. It is assumed that these or similar policies and procedures will continue. These policies and procedures are numerous and include, but are not limited to:

- Procedures that institute integrated safety management to control work conducted at LANL (to ensure that work conducted is planned and reviewed, funded, within the applicable regulations and requirements, within the range of risks accepted by DOE and its management and operating contractor, and is otherwise authorized);

- Policies regarding the knowledge, skills, and abilities of personnel assigned to perform hazardous work (including required training);

- Policies reflected in agreements with other entities (such as the Accords with the four Pueblos located nearest to LANL) that establish policies and protocols regarding consultations and other discussions regarding LANL activities;

- Policies and procedures regarding stoppage and restart of work where unexpected hazards or resources are identified (for example, policies regarding recovery of information from archaeological sites uncovered by excavation).

Work controls reduce potential impacts by ensuring that work conducted falls within the range of activities that have been studied for potential environmental and human health effects. Policies regarding the knowledge, skills, and abilities of personnel conducting work at LANL reduce potential impacts by ensuring that only personnel having an appropriate understanding of the work and its potential hazards may undertake that work (which minimizes the potential for adverse human health and environmental effects from inadvertent actions due to a lack of such understanding). Policies for consultations and discussions with other entities mitigate effects by providing an opportunity to avoid or change actions that could cause adverse impacts. For example, consultation with the Pueblos could identify a potential for impacts to traditional cultural properties prior to implementing a construction project or operations, as well as identify alternative siting or operational approaches that would avoid the impacts. Policies and procedures regarding the stoppage and restart of work are similar in effect to work controls; when unexpected situations occur that impose unexpected hazards or reveal unexpected resources (for example, cultural resources), work is stopped as soon as stoppage can be accomplished safely until work plans and authorizations can be modified in consideration of the new information. This reduces potential impacts in a manner similar to work controls, as discussed above.

DOE also has established programs and projects at LANL to increase the level of knowledge regarding the environment around LANL, the health of LANL workers, the health of the public around LANL, and the effects of LANL operations on these elements, as well as to avoid or reduce impacts and remediate contamination from previous LANL activities. These programs and projects reduce potentially adverse impacts by providing a heightened understanding of the resources that could be impacted; avoidance of some impacts (where mechanisms for impacts to specific resources are known and avoidable); early identification of impacts (which can enable stoppage or mitigation of the impacts); reduction of ongoing impacts; or beneficial management opportunities for natural, cultural, and sensitive resources, where appropriate. It is assumed that such activities will continue at LANL. Examples of these programs and projects include:

- The Environmental Surveillance and Compliance Program at LANL monitors LANL for permit and environmental management requirements. This program also includes evaluations of samples from various environmental media for radioactive materials and other hazardous materials locally and regionally (see Chapter 4, Section 4.6.1.2). The data generated under this program are collected routinely, publicly reported at least annually, and analyzed to determine regulatory compliance and environmental trends over long periods.

- The Threatened and Endangered Species Habitat Management Plan is intended to provide long-range planning information for future LANL projects and to protect the habitats of endangered species at LANL (see Chapter 4, Section 4.5.4).

- A recently completed *Cultural Heritage Management Plan* for LANL (see Chapter 4, Section 4.7) has undergone public review and is being implemented through a programmatic agreement between DOE, the New Mexico State Historic Preservation Office, and the Advisory Council on Historic Preservation.

- Flue gas recirculation equipment installed in 2002 on the boilers at the TA-3 power plant has reduced nitrogen oxides emissions by 64 percent. Such equipment and administrative controls are applied to the steam plant and other sources to comply with the emission source limitations and the facility-wide emission limitations specified in LANL's air permit (see Chapter 4, Section 4.4.2).

- Studies of public and worker health in and around LANL have been conducted (some by DOE and some by other agencies) to assess both human health in the region and the potential for adverse human health effects due to LANL operations (see Chapter 4, Section 4.6).

- The Health, Safety, and Radiation Protection Program is conducted by LANL to promote the health and safety of its workers. This program addresses the possible impacts that could result from working with ionizing and non-ionizing radiation, hazardous and chemical materials, and biohazard materials. Appropriate controls that protect the health and safety of workers are determined primarily by the type of hazard and the work environment. The level or amount of controls is commensurate with the risk associated with the hazards that would be encountered by the workers for each job activity.

- LANL's NPDES Industrial Stormwater Permit Program regulates stormwater runoff from industrial activities under a Multi-Sector General Permit. Stormwater monitoring and erosion controls are required at these sites. An integrated Stormwater Monitoring Program monitors stormwater runoff on a watershed basis and at individual solid waste management units. LANL recently began to implement these programs in response to the 2004 Federal Facility Compliance Agreement between the EPA and DOE. The NPDES Construction Stormwater Program regulates stormwater from construction activities disturbing 1 acre (0.4 hectares) or more (see Chapter 4, Section 4.3.1.3).

- LANL's Groundwater Protection Management Program assesses current groundwater conditions and monitors and protects groundwater. A Hydrogeologic Work Plan also supplements and verifies existing information on the environmental setting at LANL and collects analytical data on groundwater contamination (see Chapter 4, Section 4.3.2). An Interim Facility-wide Groundwater Monitoring Plan has been submitted to the New Mexico Environment Department as required by the 2005 Consent Order (LANL 2006g).

- The Safeguards and Security Program restricts unauthorized access to areas of LANL that have a high potential for impacts to human health and the environment. Such access restrictions limit the potential for intentional or inadvertent actions that could result in environmental or human health effects.

- LANL's Emergency Management and Response Program effectively combines Federal and local emergency response capabilities and provides planning, preparedness, and response capabilities that can aid in containing and remediating the effects of accidents or adverse operational impacts (see Chapter 4, Section 4.6.4).

- LANL's Fire Protection Program ensures that personnel and property are adequately protected against fire or related incidents, including fire protection and life safety (see Chapter 4, Section 4.6.4).

- An Interagency Wildfire Management Team has been established to coordinate activities related to reducing the fuel loading surrounding the site (see Chapter 4, Section 4.5.1). On the site, LANL is implementing actions around individual facilities that have moderate or higher vulnerability to burning as a result of wildfire.

- Waste minimization and pollution prevention efforts at LANL are coordinated by the Pollution Prevention Program, which works to reduce wastes generated and to some extent effluents and emissions from facilities (see Chapter 4, Section 4.9).

- Water and energy conservation programs at LANL are intended to reduce use of these resources, which should assist in mitigating the effects of water withdrawal and electrical consumption that occasionally exceed supply (see Chapter 4, Section 4.8.2).

- The LANL environmental restoration program (which includes DD&D) assesses and remediates contaminated sites that either were or still are under LANL control (see Chapter 4, Section 4.12). The LANL environmental restoration program serves an important role in reducing the potential for future impacts to human health and the environment due to legacy contaminants in the environment. This analysis assumes that current mitigation practices used in remediation actions will continue.

While this list is not all-inclusive, it reflects the importance of these programs in mitigating the potentially adverse impacts of operating LANL.

5.14.2 Mitigation Measures Incorporated in the SWEIS Alternatives

Several specific mitigation measures are included in the SWEIS alternatives. Unless otherwise noted below, the analyses in this chapter assume that the following measures would be implemented.

- NNSA intends to implement actions necessary to comply with the Consent Order, regardless of decisions it makes on other actions analyzed in the SWEIS; however, specific remediation actions have not been selected. Removal of contamination from MDAs and other PRSs, if necessary, would be conducted in a manner that protects the environment and public and worker health and safety. Removal of waste from some large MDAs may require use of temporary enclosures to limit possible releases of contaminated material to the environment to levels within applicable standards and ALARA. The MDAs where use of enclosures or equivalent measures may be required for safe removal operations include MDAs A, B, T, AB, and G (Expanded Operations Alternative – MDA Removal Option).

- Under all alternatives, nonradioactive air emissions, such as from construction equipment, would be controlled by proper maintenance of equipment.

- Under the Expanded Operations Alternative, noise impacts on sensitive wildlife species during MDA remediation, DD&D, and construction activities would be mitigated by planning activities outside of the breeding season for sensitive species, if any sensitive species' habitat is identified in the area and if the habitat is occupied or the status is uncertain. If appropriate, other protective measures could be employed, such as hand digging.

- Under the No Action and Expanded Operations Alternatives, radiological air emissions would be monitored and tracked to maintain the annual dose to the public from LANSCE emissions under the administrative limit.

- Under the Expanded Operations Alternative, the Science Complex would be constructed on a site in Northwest TA-62, located west of the Research Park area. This site is bounded to the north by an unpaved utility corridor access road with forested land beyond. The utility corridor access road may be paved in the future to provide all-weather access to areas of the Santa Fe National Forest and a local recreational ski facility.

- Under the Expanded Operations Alternative, traffic improvements would be implemented for operation of the new Science Complex on West Jemez Road in TA-62 and the consolidated Warehouse and Truck Inspection Station on East Jemez Road in TA-72 to mitigate the effect of these facilities on traffic flow.

- Under all alternatives, actions would be taken to mitigate the risks of a wildfire on waste storage domes in TA-54. In 2000, the Cerro Grande Fire burned a heavily forested canyon area to within about 0.75 miles (1.2 kilometers) of the waste storage domes in TA-54, but none were burned and there were no radiological releases from domes. Additional fuel reduction has been conducted since the Cerro Grande Fire, both to the vegetation surrounding the TA-54 area and within the domes themselves (for example, wooden pallets have been replaced with metal pallets), to further decrease the potential for a waste storage dome fire occurring as a result of a site wildfire. The LANL management and operating contractor would continue its wildfire management activities (for example, forest thinning) and further reduce risks by shipping legacy transuranic waste, currently stored in the domes, to WIPP.

5.14.3 Other Mitigation Measures Considered

In addition to those mitigation measures described above, other feasible mitigation measures considered in the preparation of this SWEIS are presented below.

- Expanded sealed source program procedures would be instituted under the Expanded Operations Alternative that would ensure adequate controls on the quantities and methods of storing sealed sources containing cobalt-60, iridium-192, or cesium-137 to mitigate the effects of potential accidents. This would reduce the potential direct gamma radiation-streaming dose from a postulated accident that could compromise the shielding around these gamma-emitting radioisotopes.

- Los Alamos County has recently completed a 40-year water plan (Stephens 2006) to address water service needs, balance the uses of water resources, and make recommendations for a water conservation program tailored to meet specific water supply customer needs in the county, including LANL. Only the Expanded Operations Alternative is projected to have water demands that would approach the available water rights from the regional aquifer. Los Alamos County's plans to use up to 391 million gallons (1,500 million liters) of water per year from the San Juan-Chama Transmountain Diversion Project as early as 2010 would alleviate any potential shortfall between future demand and current groundwater rights. LANL's water use would be mitigated somewhat by the use of recycled water from the Sanitary Effluent Recycle Facility for cooling water.

- Ongoing upgrades are being made to the electrical power transmission and distribution system, including construction of a third transmission line to allow import of additional power into the Los Alamos Power Pool and to support a higher electric peak load beyond 2006. In addition, an EA (DOE/EA 1430) was prepared and a FONSI was issued in December 2002 for a project to install two new (20 megawatt) gas-fired combustion turbine generators and to upgrade the existing steam turbines at the TA-3 Co-Generation Complex (DOE 2000f). As discussed in Chapter 4, Section 4.8.2, upgrades and installation of one new combustion turbine generator were completed in September 2007. Although DOE currently has no timeframe for installing a second combustion turbine generator, its installation in the future would add 20 megawatts (equivalent to 175,200 megawatt-hours) of electrical power generating capacity at LANL.

- Under all of the alternatives, particulate matter (fugitive dust) emissions from exposed soil and roadways during construction activities would be controlled using routine watering as appropriate. As necessary, air pollutant emissions from construction activities and MDA remediation activities would be controlled using standard construction emissions controls. Application of chemical stabilizers to exposed areas and administrative controls such as planning, scheduling, and use of special equipment could further reduce emissions under all of the alternatives.

- Use of containment vessels for high explosives testing under all of the alternatives could further reduce air pollutant emissions, such as beryllium and depleted uranium, from this activity. The use of vessels for certain tests could reduce emissions from these tests by close to 100 percent.

- The possibility exists that traffic into and out of LANL could increase over the next several years. Additional traffic studies should be undertaken to determine if activities under consideration in the SWEIS would increase traffic to unacceptable levels and to identify possible solutions in the event such problems are identified.

- Traffic and noise impacts on residents of the Royal Crest Mobile Home Park and Los Alamos Town Center due to increased truck traffic under the Expanded Operations Alternative could be mitigated by scheduling activity for off-peak hours, rerouting truck traffic, using multiple shifts, using alternative entries and exits, and, in the case of TA-21 remediation and DD&D, possible construction of a bridge or another road off of DP Mesa to allow alternate routing of traffic. Stockpiling fill and cover materials on the sites during off-peak hours also could be considered to avoid frequent trips during peak hours.

- To alleviate concerns associated with additional employees commuting to LANL from areas such as Rio Arriba and Santa Fe Counties, it may be necessary to expand the park-and-ride bus services that are currently offered from Española and Santa Fe.

5.15 Resource Commitments

This section describes the unavoidable adverse environmental impacts that could result from changes in ongoing activities at LANL; the relationship between short-term uses of the environment and maintenance and enhancement of long-term productivity; and irreversible and irretrievable commitments of resources. Unavoidable adverse environmental impacts are impacts that would occur after implementation of all feasible mitigation measures. The relationship between short-term uses of the environment and maintaining and enhancing long-term productivity addresses issues associated with the condition and maintenance of existing environmental resources used to support the Proposed Action and the utility of these resources after their use. Resources that would be irreversibly and irretrievably committed are those that cannot be recovered or recycled and those that are consumed or reduced to unrecoverable forms.

5.15.1 Unavoidable Adverse Environmental Impacts

Ongoing activities at LANL under any of the three alternatives analyzed in this SWEIS could result in unavoidable adverse impacts on the human environment. In general, these impacts would be minimal and would come from incremental impacts attributed to ongoing LANL operations.

Ongoing activities at LANL will continue to result in unavoidable radiation and chemical exposure to workers and the public. Generation of radioactive isotopes under any of the three alternatives is unavoidable. Radioactive waste generated during operations would be collected, treated, stored, and eventually removed for suitable recycling or disposal in accordance with applicable DOE and EPA regulations.

Operations at LANL under any of the three alternatives would have minimal unavoidable adverse impacts from air emissions. Air emissions include various chemical or radiological constituents in the routine emissions typical of nuclear facility operations. Decontamination and decommissioning of buildings could result in the one-time generation of radioactive and nonradioactive waste material that could affect storage requirements. This could produce unavoidable impacts on the amount of available and anticipated storage space and the requirements of disposal facilities at LANL.

Temporary construction impacts associated with the construction of new facilities at LANL also would be unavoidable. These impacts would include generation of fugitive dust, and noise, as well as increased construction vehicle traffic.

5.15.2 Relationship Between Local Short-Term Uses of the Environment and Maintenance and Enhancement of Long-Term Productivity

Ongoing operations at LANL under any of the three alternatives would require short-term commitments of resources and permanent commitments of certain resources (such as energy). Environmental resources have already been committed to continuing operations at LANL.

Additional commitments would serve to maintain existing environmental conditions with little or no impact on the long-term productivity of the environment.

Short-term commitments of resources would include space and materials required to construct new buildings; new operations support facilities; transportation; and disposal resources and materials for continued LANL operations. Workers, the public, and the environment could be exposed to increased amounts of hazardous and radioactive materials over the period of this SWEIS analysis due to relocation of materials, including process emissions, and handling of radioactive waste.

Regardless of changes in the location and levels of activities at LANL Key Facilities, additional air emissions could introduce small amounts of radiological and nonradiological constituents to the air in the region around LANL. These emissions would result in additional loading and exposure, but would not be expected to impact compliance with air quality or radiation exposure standards at LANL. There would be no significant residual environmental effects on long-term environmental viability.

Management and disposal of additional sanitary solid waste and nonrecyclable radiological waste would require the use of energy and space at LANL treatment, storage, or disposal facilities or at replacement offsite disposal facilities. Regardless of location, the land required to meet solid waste needs at LANL would require a long-term commitment of terrestrial resources. Activities being considered at LANL, such as consolidation of new facilities, could result in further disturbance, use, and commitment of previously undisturbed land. Ultimately, after closure of facilities at LANL, NNSA plans to decontaminate and decommission the buildings and equipment and restore them to brownfield sites that could be made available for future reuse.

5.15.3 Irreversible and Irretrievable Commitments of Resources

Irreversible and irretrievable commitments of resources unanticipated in the *1999 SWEIS* would include mineral resources consumed during the life of certain projects and energy and water used to operate buildings and facilities at LANL. Commitments of capital, energy, labor, and materials are generally irreversible.

Energy expended would be in the form of fuel for equipment and vehicles, electricity for facility operations, and human labor. Changes in LANL operations could generate nonrecyclable waste streams such as radiological and nonradiological solid waste and some wastewater. Certain materials and equipment used during operations, however, could be recycled when buildings are decontaminated and decommissioned.

Operations at LANL require water, electricity, and diesel fuel. These resources are discussed in Section 5.8.2.

Disposal of hazardous and radioactive wastes also would cause irreversible and irretrievable commitments of land, mineral, and energy resources.

CHAPTER 6
APPLICABLE LAWS, REGULATIONS, AND OTHER REQUIREMENTS

6.0 APPLICABLE LAWS, REGULATIONS, AND OTHER REQUIREMENTS

Chapter 6 provides an update to the laws, regulations, agreements, and consultations that relate to environmental protection at the Los Alamos National Laboratory (LANL).

As part of the National Environmental Policy Act (NEPA) process, an agency must consider whether an action could threaten a violation of any Federal, state, or local law or requirement (40 *Code of Federal Regulations* [CFR] 1508.27) or require a permit, license, or other entitlement (40 CFR 1502.25). This chapter identifies and summarizes the major environmental requirements, agreements, and permits that could be required to support the *Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico* (SWEIS).

A number of Federal environmental laws affect environmental protection, health, safety, compliance, and consultation at every U.S. Department of Energy (DOE) location. In addition, certain environmental requirements have been delegated to state authorities for enforcement and implementation and state legislatures have passed laws to protect human health and safety and the environment. It is DOE policy to conduct its operations in a manner that ensures the protection of public health, safety, and the environment through compliance with all applicable Federal and state laws, regulations, DOE Orders, and other requirements.

The alternatives analyzed in this SWEIS involve either the operation of existing DOE facilities or the construction and operation of new DOE facilities. Actions required to comply with laws, regulations, and other Federal and State of New Mexico requirements may depend on whether a facility is newly built (preoperational), operational, undergoing decontamination and decommissioning, or incorporated in whole or in part into an existing facility.

Requirements governing the continuation of LANL operations arise primarily from six sources: the Congress, Federal agencies, Executive Orders, legislatures of the affected states, state agencies, and local governments. In general, Federal statutes establish national policies, create broad legal requirements, and authorize Federal agencies to create regulations that conform to the statutes. Detailed implementation of these statutes is delegated to various Federal agencies such as DOE, the U.S. Department of Transportation (DOT), and the U.S. Environmental Protection Agency (EPA). For many environmental laws under EPA jurisdiction, state agencies may be delegated responsibility for the majority of program implementation activities, such as permitting and enforcement, but EPA usually retains oversight of the delegated program.

Some applicable laws such as NEPA, the Endangered Species Act, and the Emergency Planning and Community Right-To-Know Act require specific reports and consultations rather than ongoing permits or activities. These are satisfied through the legal and regulatory process, including the preparation of this SWEIS.

Other applicable laws establish general requirements that must be satisfied, but do not include processes (such as the issuance of permits or licenses) that consider compliance prior to specific violations or other events that trigger their provisions. These include the Toxic Substances Control Act (TSCA) (affecting polychlorinated biphenyl transformers and other designated substances); the Federal Insecticide, Fungicide, and Rodenticide Act (affecting pesticide and herbicide applications); the Hazardous Materials Transportation Act; and (in the event of a spill of a hazardous substance) the Comprehensive Environmental Response, Compensation, and Liability Act (Superfund).

Executive Orders establish policies and requirements for Federal agencies. Executive Orders are applicable to Executive branch agencies, but do not have the force of law or regulation.

In addition to implementing some Federal programs, state legislatures develop their own laws to supplement as well as implement Federal laws for protection of air and water quality and groundwater. State legislation in New Mexico addresses solid and hazardous waste management programs, locally rare or endangered species, and local resource, historic, and cultural values. The laws of local governments add a further level of protection of the public, often focusing on zoning, utilities, and public health and safety concerns.

Regulatory agreements and compliance orders also may be initiated to establish responsibilities and timeframes for Federal facilities to comply with provisions of applicable Federal and state laws. Other agreements, memoranda of understanding, and formalized arrangements also establish cooperative relationships and requirements.

The actions being considered in this SWEIS would be all located on LANL property controlled by the National Nuclear Security Administration (NNSA). NNSA has authority to regulate some environmental activities, as well as the health and safety aspects of nuclear facilities operations. The Atomic Energy Act of 1954, as amended, is the principal authority for DOE regulatory activities not externally regulated by other Federal or state agencies. Regulation of DOE activities is primarily established through the use of DOE Orders and regulations.

External environmental laws, regulations, and Executive Orders can be categorized as applicable to either broad environmental planning and consultation requirements or regulatory environmental protection and compliance activities, although some requirements are applicable to both planning activities and ongoing operations.

Section 6.1 of this chapter discusses major applicable Federal laws, regulations, and permits that impose nuclear safety and environmental protection requirements on the activities conducted at LANL. Each of the applicable regulations and statutes establishes how activities are to be conducted or how potential releases of pollutants are to be controlled or monitored. They include requirements for issuing permits or licenses for new operations or new emission sources and for amending existing permits or licenses to allow new types of operations at existing sources.

Section 6.2 discusses new or revised Executive Orders that may be applicable to LANL activities. Section 6.3 identifies DOE Orders for compliance with the Atomic Energy Act, the Occupational Safety and Health Act, and other environmental, safety, and health requirements that may be applicable to LANL activities. Section 6.4 identifies state and local laws, regulations, permits and ordinances, as well as local agreements that potentially impact LANL. Consultations with applicable agencies and federally recognized Native American Nations are discussed in Section 6.5.

6.1 Applicable Federal Laws, Regulations, and Permits

This section describes the Federal environmental, safety, and health laws and regulations and permits that could apply to LANL. These regulations address such areas as energy conservation, administrative requirements and procedures, nuclear safety, and classified information. Activities under all alternatives would need to be conducted in compliance with applicable Federal laws, regulations, and permits. Chapter 4 describes the resources at LANL that are potentially addressed by these laws, regulations, and permits. Chapter 5 discusses the potential impacts to those resources under each alternative. Consultations with applicable agencies and federally recognized Native American Nations as required by Federal laws and regulations are discussed in Section 6.5.

The major Federal laws and regulations, Executive Orders, and other requirements that currently apply or could apply in the future to the various alternatives analyzed in this SWEIS are identified in **Table 6–1**. For ease of identification, laws are identified in the table with a *United States Code* (U.S.C.) or Public Law citation; regulations are identified with a CFR citation; and Executive Orders are listed in italics. This table does not include DOE Orders, which are provided in Section 6.3, nor does it include state requirements, which are provided in Section 6.4.

American Indian Religious Freedom Act of 1978 (42 U.S.C. 1996)—This Act reaffirms American Indian religious freedom under the First Amendment and sets U.S. policy to protect and preserve the inherent and constitutional right of American Indians to believe, express, and exercise their traditional religions. The Act requires that Federal actions avoid interfering with access to sacred locations and traditional resources that are integral to the practice of religions.

Antiquities Act of 1906, as amended (16 U.S.C. 431 *et seq*.)—This Act protects historic and prehistoric ruins, monuments, and antiquities, including paleontological resources, on federally controlled lands from appropriation, excavation, injury, and destruction without permission.

Archaeological and Historic Preservation Act of 1960, as amended (16 U.S.C. 469 *et seq.* 469c-1)—The purpose of this Act is to preserve historical and archaeological data (including relics and specimens) that might otherwise be irreparably lost or destroyed as the result of Federal actions.

Toxic Substances Control Act of 1976	15 U.S.C. 2601 *et seq.*

U.S.C. = *United States Code*, CFR = *Code of Federal Regulations*.

Archaeological Resources Protection Act of 1979, as amended (16 U.S.C. 470aa *et seq*.)— This Act requires a permit for any excavation or removal of archaeological resources from Federal or American Indian lands. Excavation must be undertaken to further archaeological knowledge in the public interest, and resources removed are to remain the property of the United States. The law requires that whenever any Federal agency finds that its activities may cause irreparable loss or destruction of significant scientific, prehistoric, or archaeological data, the agency must notify the U.S. Department of the Interior and may request that the Department of Interior undertake the recovery, protection, and preservation of such data. Consent must be obtained from the American Indian Tribe or Federal agency that has authority over the land on which a resource is located before issuance of a permit, and the permit must contain the terms and conditions requested by the Tribe or Federal agency.

Atomic Energy Act of 1954 (42 U.S.C. 2011 *et seq*.) as amended by the Price-Anderson Act and the Bob Stump National Defense Authorization Act—The Act provides fundamental jurisdictional authority to DOE and the U.S. Nuclear Regulatory Commission (NRC) over governmental and commercial use of nuclear materials. The Atomic Energy Act authorizes DOE to establish standards to protect health or minimize dangers to life or property for activities under DOE jurisdiction. DOE has issued a series of Departmental Orders to establish an extensive system of standards and requirements to ensure safe operation of DOE facilities (see Section 6.3).

DOE regulations are found in Title 10 of the CFR. The DOE regulations that are most relevant to radioactive materials, waste management, and worker health and safety include:

- "Nuclear Safety Management" (10 CFR Part 830),
- "Occupational Radiation Protection" (10 CFR Part 835),
- "Chronic Beryllium Disease Prevention Program" (10 CFR Part 850),
- "Worker Health and Safety Program" (10 CFR Part 851), and
- "Byproduct Material" (10 CFR Part 962).

The Atomic Energy Act also gives EPA the authority to develop generally applicable standards for protection of the general environment from radioactive materials. EPA has promulgated several regulations under this authority. The EPA regulation that is relevant to the radioactive waste and materials management activities addressed by this SWEIS is the "Environmental Radiation Protection Standards for Management and Disposal of Spent Nuclear Fuel, High-Level and Transuranic Radioactive Wastes" (40 CFR Part 191). This regulation establishes radiation standards for the management and storage of spent nuclear fuel, high-level radioactive waste, and transuranic waste at facilities regulated by NRC or Agreement States, as well as radiation standards for management and storage of spent nuclear fuel, high-level radioactive waste, and transuranic waste at disposal facilities operated by DOE that are not regulated by NRC or Agreement States. The regulation also establishes limitations on radiation doses that might occur after closure of the disposal system. These standards include both individual protection requirements and groundwater protection standards.

The Price-Anderson Act – signed into law in 1957 as an amendment to the Atomic Energy Act of 1954—provides for payment of public liability claims in the event of a nuclear incident. The following are key features of this Act:

- Assures the availability of billions of dollars to compensate members of the public who suffer a loss as the result of a nuclear incident;
- Establishes a simplified claim process for the public to expedite recovery for losses;
- Provides for immediate emergency reimbursement for costs associated with any evacuation that may be ordered;
- Establishes liability limits for each nuclear incident involving commercial nuclear energy and government use of nuclear materials; and
- Guarantees that the Federal Government will review the need for compensation beyond that provided (NEI 2005).

The Bob Stump National Defense Authorization Act, enacted by the Congress in 2002, amended the Atomic Energy Act to add Section 234C requiring DOE to promulgate worker health and safety regulations to cover contractors with Price-Anderson indemnification agreements in their contracts. DOE promulgated regulations under this Act in February 2006 (71 FR 6857) as 10 CFR Part 851, "Worker Safety and Health Program." The regulations codified and enhanced the DOE worker protection program.

Bald and Golden Eagle Protection Act of 1973, as amended (16 U.S.C. 668 *et seq.*)—The Bald and Golden Eagle Protection Act, as amended, makes it unlawful to take, pursue, molest, or disturb bald (American) and golden eagles, their nests, or their eggs anywhere in the United States. A permit must be obtained from the U.S. Department of the Interior to relocate a nest that interferes with resource development or recovery operations.

Clean Air Act of 1970, as amended (42 U.S.C. 7401 *et seq*.)—The Clean Air Act is intended to "protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population." Section 118 of the Clean Air Act (42 U.S.C. 7418) requires that each Federal agency with jurisdiction over any property or facility engaged in any activity that might result in the discharge of air pollutants comply with "all Federal, state, interstate, and local requirements" regarding the control and abatement of air pollution.

Section 109 of the Clean Air Act (42 U.S.C. 7409 *et seq*.) directs EPA to set national ambient air quality standards for criteria pollutants. EPA has identified and set national ambient air quality standards under 40 CFR Part 50 for the following criteria pollutants: particulate matter, sulfur dioxide, carbon monoxide, ozone, nitrogen dioxide, and lead. Section 111 of the Clean Air Act (42 U.S.C. 7411) requires establishment of national standards of performance for new or modified stationary sources of atmospheric pollutants. Section 160 of the Clean Air Act (42 U.S.C. 7470 *et seq*.) requires that specific emission increases be evaluated prior to permit approval to prevent significant deterioration of air quality. Section 112 of the Clean Air Act (42 U.S.C. 7412) requires specific standards for releases of hazardous air pollutants (including radionuclides).

Emissions of air pollutants are regulated by EPA under 40 CFR Parts 50 through 99. Emissions of radionuclides and hazardous air pollutants from DOE facilities are regulated under the

National Emissions Standards for Hazardous Air Pollutants Program (40 CFR Part 61 and 40 CFR Part 63**,** respectively).

Clean Water Act of 1972, as amended (33 U.S.C. 1251 *et seq*.)—The Clean Water Act, which amended the Federal Water Pollution Control Act, was enacted to "restore and maintain the chemical, physical, and biological integrity of the Nation's water." The Clean Water Act prohibits the "discharge of toxic pollutants in toxic amounts" to navigable waters of the United States. Section 313 of the Clean Water Act requires all branches of the Federal Government engaged in any activity that might result in a discharge of runoff of pollutants to surface waters to comply with Federal, state, interstate, and local requirements.

Section 404 of the Clean Water Act gives the U.S. Army Corps of Engineers permitting authority over activities that discharge dredge or fill materials into waters of the United States, including wetlands.

The Clean Water Act also provides guidelines and limitations for effluent discharges from point-source discharges and establishes the National Pollutant Discharge Elimination System (NPDES) permit program. The NPDES program is administered by EPA, pursuant to regulations in 40 CFR Part 122 *et seq.*, and authority may be delegated to states. Sections 401 through 405 of the Water Quality Act of 1987 added Section 402(p) to the Clean Water Act, which requires EPA to establish regulations for permits for stormwater discharges associated with industrial activities, including construction activities disturbing 5 or more acres (2 hectares) (64 *Federal Register* [FR] 68721). After March 2003, the threshold for obtaining a permit was lowered to 1 acre (0.4 hectare). Stormwater provisions of the NPDES program are set forth at 40 CFR 122.26. Permit modifications are required if discharge effluent is altered. The State of New Mexico is now seeking authorization for the NPDES program so that it will have authority to administer the program instead of EPA. Currently, New Mexico is not authorized, and EPA Region 6 administers all LANL NPDES issues and permits. The State is expecting to be authorized by the end of 2006.

Many water-related permits for LANL have been issued or are awaiting approval (see **Table 6–2**). The EPA and DOE entered into a Federal Facility Compliance Agreement (Agreement) pursuant to the Clean Water Act (EPA 2005a). The purpose of the Agreement is to establish a compliance program for the regulation of stormwater discharges from Solid Waste Management Units and Areas of Concern at LANL until those sources are regulated by an individual stormwater permit issued by EPA pursuant to the NPDES. The purpose of the compliance program is to provide a schedule to ensure compliance with the NPDES stormwater-permitting program. The scope of this Agreement is limited to providing a compliance program for the regulation of stormwater discharges from solid waste management units (SWMUs) and Areas of Concern at LANL in lieu of LANL's Stormwater Multi-Sector General Permit (EPA 2005a).

The discharge of stormwater at LANL is regulated by NPDES Stormwater Multi-Sector General Permit Numbers NMR05A734 (University of California) and NMR05A735 (DOE) (the "General Permit"), which became effective on December 23, 2000, pursuant to 65 FR 64746 (October 30, 2000). The point source discharges of stormwater regulated by the General Permit include LANL's SWMUs (EPA 2005a).

Table 6–2 Federal Permits

Category	*Approved Activity*	*Issue Date*	*Expiration Date*
Clean Water Act/NPDES - Permit Number NM0028355	Discharge of industrial and sanitary liquid effluents. (This is a single permit covering many of LANL's industrial and sanitary discharges. The permit covers 17 total outfalls.)	August 1, 2007	July 31, 2012
Clean Water Act/NPDES Multi-Sector General Permit Number NMR05A734 (University of California) and NMR05A735 (DOE)	Multi-Sector General Permit-Stormwater discharges from industrial activities.	October 30, 2000	October 30, 2005 (Permit has been administratively continued pending issuance of a new permit, expected in 2007.)
Clean Water Act/NPDES	General Permit for Stormwater discharges from construction activities	Varies. A new General Construction Permit will be needed after 2008.	July 1, 2008
Clean Water Act Sections 404/401	Individual Dredge and Fill permits for work within perennial, intermittent, or ephemeral watercourses.	Varies	Varies
Toxic Substances Control Act Disposal Authorization	Disposal of polychlorinated biphenyls at Technical Area 54, Area G	June 25, 1996	June 25, 2001 (Permit has been administratively continued.)

NPDES = National Pollutant Discharge Elimination System.
Sources: EPA 2005a, LANL 2006h.

Since 2003, the General Permit has been in transition. Stormwater discharges from LANL SWMUs ultimately will be regulated under an individual NPDES permit specific to the SWMUs. LANL submitted the first part of the individual permit application in late 2004. When granted, this individual permit will replace existing SWMU coverage under the General Permit (see Table 6–2).

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 (42 U.S.C. 9601 *et seq*.) (also known as Superfund)—CERCLA provides among other things: (1) a program for emergency response to and reporting of a release or threat of a release of a hazardous substance to the environment; and (2) a statutory framework for remediation of hazardous substance releases from private, state, and Federal sites. Using the Hazard Ranking System, contaminated sites are ranked and may be included on the National Priorities List. Section 120 of CERCLA specifies requirements for investigations, remediation, and natural resource restoration, as necessary, at Federal facilities, and also provides reporting requirements for hazardous substance contamination on properties to be transferred. LANL is not on the National Priorities List. Potential release sites at LANL are investigated and remediated under state authorities (see Section 6.4 for further discussion).

Department of Commerce, Justice, and State, the Judiciary, and Related Agencies Appropriations Act, 1998 (Public Law 105-119)—Section 632 of the Act directed the Secretary of Energy to identify and convey to the Incorporated County of Los Alamos, New Mexico, or to the designee of Los Alamos County, and to transfer to the Secretary of the Interior in trust for the Pueblo of San Ildefonso, parcels of land under the jurisdictional administrative control of the Secretary at or in the vicinity of LANL that meet certain identified criteria. DOE prepared the *Final Environmental Impact Statement for the Conveyance and*

Transfer of Certain Land Tracts Administered by the U.S. Department of Energy and Located at Los Alamos National Laboratory, Los Alamos and Santa Fe Counties, New Mexico (DOE 1999d) to examine potential environmental impacts associated with conveyance and transfer of identified land parcels. A Record of Decision for this action was issued in December 1999. Remedial actions (required in some parcels) and conveyances and transfers are ongoing.

Emergency Planning and Community Right-to-Know Act (42 U.S.C. 11001 *et seq*.)—This amendment to CERCLA requires that facilities provide notice to and coordinate emergency planning with communities and government agencies concerning inventories and any unplanned releases of specific hazardous chemicals. EPA implements this Act under regulations found in 40 CFR Parts 355, 370, and 372. Under Subtitle A of this Act, Federal facilities are required to provide information to and coordinate with local and state emergency response planning authorities, to ensure that emergency plans are sufficient to respond to unplanned releases of hazardous substances. Implementation of the provisions of this Act at LANL began voluntarily in 1987, and chemical inventories and emissions have been reported annually since 1988.

Endangered Species Act of 1973 (16 U.S.C. 1531 *et seq.*)—This Act is intended to prevent the further decline of endangered and threatened species and to restore these species and their habitats. Section 7 of the Act requires Federal agencies that have reason to believe that a prospective action may affect an endangered or threatened species or its habitat to consult with the U.S. Fish and Wildlife Service of the U.S. Department of the Interior or the National Marine Fisheries Service of the U.S. Department of Commerce to ensure the action does not jeopardize the species or destroy its habitat. If, despite reasonable and prudent measures to avoid or minimize such impacts, the species or its habitat would be jeopardized by the action, a review process is specified to determine whether the action may proceed as an incidental taking (50 CFR Part 17).

Federal Facility Compliance Act of 1992 (42 U.S.C. 6961 *et seq*.)—The Federal Facility Compliance Act, enacted on October 6, 1992, amended the Resource Conservation and Recovery Act (RCRA). The Act made Federal facilities subject to potential fines and penalties for violations of RCRA, the law that sets requirements for management of hazardous waste. Prior to its passage, mixed waste stored at DOE sites generally did not comply with RCRA mixed waste land-disposal restrictions because of a lack of treatment options. The Act required DOE to: (1) prepare and submit a national inventory report identifying its mixed waste volume, characteristics, treatment capacity, and available technologies; and (2) prepare and submit (to the appropriate state or EPA regulators) Site Treatment Plans for developing or using the needed treatment capacity along with schedules for treating the mixed waste at each DOE site.

LANL's approved Site Treatment Plan is enforced by a Compliance Order issued by the New Mexico Environment Department in October 1995. It is available for review at the DOE Headquarters reading room, the DOE Center for Environmental Management Information, and the LANL reading room (see Section 6.4 for further discussion).

Fish and Wildlife Coordination Act (16 U.S.C. 661 *et seq*.)—The Fish and Wildlife Coordination Act promotes effective planning and cooperation between Federal, state, public, and private agencies for the conservation and rehabilitation of the Nation's fish and wildlife and authorizes the U.S. Department of the Interior to provide assistance. This Act requires consultation with the U.S. Fish and Wildlife Service on the possible effects to wildlife from construction, projects, or activities affecting bodies of water in excess of 10 acres (approximately 4 hectares) in surface area. This Act also requires consultation with the head of the state agency that administers wildlife resources in the affected state.

Hazardous Materials Transportation Act of 1975, as amended (49 U.S.C. 5101 *et seq*.)—The Hazardous Materials Transportation Act of 1975, as amended, requires the U.S. Department of Transportation to prescribe uniform national regulations for transportation of hazardous materials (including radioactive materials). Most state and local regulations regarding such transportation that are not substantively the same as the U.S. Department of Transportation regulations are preempted (49 U.S.C. 5125). This, in effect, allows state and local governments to enforce only the Federal regulations, not to change or expand upon them.

This program is administered by the Research and Special Programs Administration of the U.S. Department of Transportation, which, when covering the same activities, coordinates its regulations with NRC (under the Atomic Energy Act) and EPA (under RCRA). The U.S. Department of Transportation regulations, which may be found under 49 CFR Parts 171 through 178 and 49 CFR Parts 383 through 397, contain requirements for identifying a material as hazardous or radioactive. These regulations interface with the NRC regulations for identifying material, but U.S. Department of Transportation hazardous material regulations govern the hazard communication (such as marking, labeling, vehicle placarding, and emergency response information) and shipping requirements. Requirements for transport by rail, air, and public highway are included. In addition, EPA regulations at 40 CFR Part 262 apply to offsite transportation of hazardous wastes from LANL.

Public access to many portions of the LANL facility is controlled at all times through the use of gates and guards. Onsite transportation of hazardous materials, wastes, and contaminated equipment that is conducted entirely on DOE property is subject to applicable DOE directives and safety requirements set forth in 10 CFR Part 830 Subpart B. Offsite transportation of hazardous materials, wastes, and contaminated equipment from LANL over public highways is subject to applicable U.S. Department of Transportation and EPA regulations, as well as to applicable DOE directives.

The NRC Packaging and Transportation of Radioactive Material (10 CFR Part 71) regulations include detailed packaging design requirements and package certification testing requirements. Complete documentation of design and safety analysis and the results of required certification tests are submitted to NRC to certify the package for use. This certification testing involves the following components: heat, physical drop onto an unyielding surface, water submersion, puncture by dropping the package onto a steel bar, and gas tightness.

Low-Level Radioactive Waste Policy Act of 1980, as amended (42 U.S.C. 2021 *et seq.*)—This Act amended the Atomic Energy Act to specify that the Federal Government is responsible for disposal of low-level radioactive waste generated by certain activities, and that each state is responsible for disposal of other low-level radioactive waste generated within its borders. It provides for and encourages interstate compacts to carry out state responsibilities. As a result of this Act, low-level radioactive waste owned or generated by DOE remains the responsibility of the Federal Government.

Manhattan Project National Historical Park Study Act (Public Law 108-340)—This Act was written to direct the Secretary of the Interior to conduct a study on the preservation and interpretation of the historic sites of the Manhattan Project for potential inclusion in the National Park System (October 18, 1998).

Migratory Bird Treaty Act of 1918, as amended (16 U.S.C. 703 *et seq*.)—The Migratory Bird Treaty Act, as amended, is intended to protect birds that follow common migration patterns across the United States, Canada, Mexico, Japan, and Russia. It regulates the harvest of migratory birds by specifying conditions such as mode of harvest, hunting seasons, and bag limits. The Act stipulates that it is unlawful, unless permitted by regulations, to "pursue, hunt, take, capture, kill, attempt to take, capture or kill, possess, …any migratory bird…or any part, nest, or egg of any such bird." Although no permit for this project is required under the Act, DOE is required to consult with the U.S. Fish and Wildlife Service regarding impacts on migratory birds and to avoid or minimize these effects in accordance with the U.S. Fish and Wildlife Service Mitigation Policy. A split of authority currently exists between Federal courts regarding whether this Act applies to Federal agencies.

National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 *et seq*.)—The purposes of NEPA of 1969, as amended, are to: (1) declare a national policy that will encourage productive and enjoyable harmony between man and his environment, (2) promote efforts that will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man, (3) enrich the understanding of the ecological systems and natural resources important to the Nation, and (4) establish a Council on Environmental Quality (CEQ). NEPA establishes a national policy requiring that Federal agencies consider the environmental impacts of major Federal actions significantly affecting the quality of the human environment before making decisions and taking actions to implement those decisions. Implementation of NEPA requirements in accordance with CEQ regulations (40 CFR Parts 1500 to 1508) can result in a categorical exclusion, an environmental assessment and Finding of No Significant Impact, or an environmental impact statement. This SWEIS was prepared in accordance with NEPA requirements, CEQ regulations (40 CFR Part 1500 *et seq.*), and DOE provisions for implementing the procedural requirements of NEPA (10 CFR Part 1021; DOE Order 451.1B, Change 1). It discusses reasonable alternatives and their potential environmental consequences.

National Historic Preservation Act of 1966, as amended (16 U.S.C. 470 *et seq*.)—The Act provides that sites with significant national historic value be placed on the National Register of Historic Places, which is maintained by the Secretary of the Interior. The major provisions of the Act for DOE consideration are Sections 106 and 110. Both sections aim to ensure that historic properties are appropriately considered in planning Federal initiatives and actions. Section 106 is a specific, issue-related mandate to which Federal agencies must adhere. It is a reactive mechanism driven by a Federal action. Section 110, in contrast, sets out broad Federal agency responsibilities with respect to historic properties. It is a proactive mechanism that emphasizes ongoing management of historic preservation sites and activities at Federal facilities. No permits or certifications are required under the Act.

Section 106 requires the head of any Federal agency with direct or indirect jurisdiction over a proposed Federal or federally assisted undertaking to ensure compliance with the provisions of the Act. It compels Federal agencies to "take into account" the effect of their projects on historical and archaeological resources and to give the Advisory Council on Historic Preservation the opportunity to comment on such effects. Section 106 mandates consultation during Federal actions if the undertaking has the potential to affect a historic property. This consultation normally involves State or Tribal Historic Preservation Officers, or both, and may include other organizations and individuals such as local governments and American Indian Tribes. If an adverse effect is found, the consultation often ends with the execution of a memorandum of agreement that states how the adverse effect will be resolved.

The regulations implementing Section 106, found in 36 CFR Part 800, were revised on December 12, 2000, to modify the process by which Federal agencies consider the effects of their undertakings on historic properties and provide the Advisory Council on Historic Preservation with a reasonable opportunity to comment on such undertakings, as required by Section 106 of the Act. In promulgating the new regulations, the Council sought to better balance the interests and concerns of various users of the Section 106 process, including Federal agencies, State Historic Preservation Officers, Tribal Historic Preservation Officers, American Indians and Native Hawaiians, industry, and the public.

Native American Graves Protection and Repatriation Act of 1990 (25 U.S.C. 3001 *et seq*.)— This Act establishes a means for Native Americans to request the return or repatriation of human remains and other cultural items presently held by Federal agencies or federally assisted museums or institutions. The Act also contains provisions regarding the intentional excavation and removal of, inadvertent discovery of, and illegal trafficking in Native American human remains and cultural items. Major actions under this law include: (1) establishing a review committee with monitoring and policymaking responsibilities; (2) developing regulations for repatriation, including procedures for identifying lineal descent or cultural affiliation needed for claims; (3) providing oversight of museum programs designed to meet the inventory requirements and deadlines of this law; and (4) developing procedures to handle unexpected discoveries of graves or grave goods during activities on Federal or Tribal lands. All Federal agencies that manage land or are responsible for archaeological collections obtained from their lands or generated by their activities must comply with the Act. DOE managers of ground-disturbing activities on Federal and Tribal lands are to be aware of the statutory provisions treating inadvertent discoveries of Native American remains and cultural objects. Regulations implementing the Act are found at 43 CFR Part 10.

Noise Control Act of 1972, as amended (42 U.S.C. 4901 *et seq*.)—Section 4 of the Noise Control Act of 1972, as amended, directs all Federal agencies to carry out "to the fullest extent within their authority" programs within their jurisdictions that further the national policy of promoting an environment free from noise that jeopardizes health and welfare. Federal, state, and local agencies enforce the standards and requirements of this Act to regulate noise at facilities such as LANL. DOE must comply with the Act for any of the activities being considered under this SWEIS.

Occupational Safety and Health Act of 1970 (29 U.S.C. 651 *et seq*.)—Section 4(b)(1) of the Occupational Safety and Health Act exempts DOE and its contractors from the occupational safety requirements of the Occupational Safety and Health Administration. However, 29 U.S.C. 668 requires Federal agencies to establish their own occupational safety and health programs for their places of employment, consistent with Occupational Safety and Health Administration standards. DOE Order 440.1A, "Worker Protection Management for DOE Federal and Contractor Employees," states that DOE will implement a written worker protection program that: (1) provides a place of employment free from recognized hazards that are causing or are likely to cause death or serious physical harm to their employees, and (2) integrates all requirements contained in paragraphs 4a to 4l of DOE Order 440.1A; 29 CFR Part 1960, "Basic Program Elements for Federal Employee Occupational Safety and Health Programs and Related Matters;" and other related site-specific worker protection activities.

Pollution Prevention Act of 1990 (42 U.S.C. 13101 *et seq*.)—The Pollution Prevention Act establishes a national policy for waste management and pollution control. Source reduction is given first preference, followed by environmentally safe recycling, with disposal or releases to the environment as a last resort. In response to the policies established by the Pollution Prevention Act, DOE committed to participation in the Superfund Amendments and Reauthorization Act, Section 313, EPA 33/50 Pollution Prevention Program. The goal for facilities involved in compliance with Section 313 was to achieve a 33-percent reduction (from a 1993 baseline) in the release of 17 priority chemicals by 1997. On November 12, 1999, then-U.S. Secretary of Energy Bill Richardson established 14 pollution prevention and energy efficiency goals for DOE to build environmental accountability and stewardship into DOE's decisionmaking process. Under these goals, DOE will strive to minimize waste and maximize energy efficiency as measured by continuous cost-effective improvements in the use of materials and energy, using the years 2005 and 2010 as interim measurement points.

Safe Drinking Water Act of 1974, as amended (42 U.S.C. 300(f) *et seq*.)—The primary objective of the Safe Drinking Water Act is to protect the quality of public drinking water supplies and sources. The implementing regulations, administered by EPA unless delegated to the states, establish standards applicable to public water systems. These regulations include maximum contaminant levels (including those for radioactivity) in public water systems, which are defined as water systems with at least 15 service connections that are used by year-round residents or regularly serve at least 25 year-round residents. EPA regulations implementing the Safe Drinking Water Act are found in 40 CFR Parts 141 through 149. For radioactive material, the regulations specify that the average annual concentration of beta particles and photon energy from manmade radionuclides in drinking water, as delivered to the user by such a system, shall not produce a dose equivalent to the total body or an internal organ greater than 4 millirem per year. They further specify a concentration limit for gross alpha particle activity (excluding radon and uranium) of 15 picocuries per liter and for uranium of 0.03 milligrams per liter (40 CFR 141.66). Other programs established by the Safe Drinking Water Act include the Sole Source Aquifer Program, the Wellhead Protection Program, and the Underground Injection Control Program.

Solid Waste Disposal Act of 1965, as amended by the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments of 1984 (42 U.S.C. 6901 *et seq.*)—The Solid Waste Disposal Act of 1965, as amended, governs the transportation, treatment, storage, and disposal of hazardous waste and nonhazardous waste (that is, municipal solid waste). Under the RCRA of 1976, which amended the Solid Waste Disposal Act of 1965, EPA defines and identifies hazardous waste; establishes standards for its transportation, treatment, storage, and disposal; and requires permits for persons engaged in hazardous waste activities. Section 3006 of RCRA (42 U.S.C. 6926) allows states to establish and administer these permit programs with EPA approval.

The EPA regulations implementing RCRA are found in 40 CFR Parts 260 through 283. The New Mexico Environment Department is authorized to administer the RCRA program in New Mexico and issued LANL's RCRA operating permit (see Section 6.4). Regulations imposed on a generator or on a treatment, storage, or disposal facility vary according to the type and quantity of hazardous waste generated, treated, stored, or disposed of and the methods of treatment, storage, and disposal.

Toxic Substances Control Act of 1976 (15 U.S.C. 2601 *et seq*.)—TSCA provides EPA with the authority to require testing of chemical substances entering the environment and to regulate them as necessary. The law complements and expands existing toxic substance laws, such as Section 112 of the Clean Air Act and Section 307 of the Clean Water Act. The Act requires compliance with the inventory reporting and chemical control provisions of the legislation to protect the public from risks of exposure to chemicals.

The Act also imposes strict limitations on the use and disposal of polychlorinated biphenyls, chlorofluorocarbons, asbestos, dioxins, certain metal-working fluids, and hexavalent chromium. EPA issued the disposal authorization documents to LANL for management of its polychlorinated biphenyls waste disposal facility at Technical Area 54.

Waste Isolation Pilot Plant Land Withdrawal Act (Public Law 102-579) and the Waste Isolation Pilot Plant Land Withdrawal Act Amendments (Public Law 104-201)—The Waste Isolation Pilot Plant Land Withdrawal Act withdrew land from the public domain for the purpose of creating and operating the Waste Isolation Pilot Plant (WIPP), the geologic repository in New Mexico designated as the national disposal site for defense transuranic waste. The Act also defined the characteristics and amount of waste that will be disposed of at the facility. Amendments to the Act exempt waste to be disposed of at WIPP from the RCRA land disposal restrictions. Prior to sending any transuranic waste from LANL to WIPP, DOE would have to determine whether the waste meets all statutory and regulatory requirements for disposal at WIPP.

6.2 Executive Orders

This section identifies environment-, health-, and safety-related Executive Orders applicable to LANL operations. Activities under all alternatives would need to be conducted in compliance with applicable Executive Orders. Chapter 4 describes the resources at LANL that are addressed by Executive Orders, and Chapter 5 discusses the potential impacts to those resources under each alternative. Consultations with applicable agencies and federally recognized Native American Nations as required by these Executive Orders are discussed in Section 6.5.

Executive Order 11514, *Protection and Enhancement of Environmental Quality* (March 5, 1970)—This Executive Order requires Federal agencies to continually monitor and control their activities to: (1) protect and enhance the quality of the environment, and (2) develop procedures to ensure the fullest practicable provision of timely public information and understanding of the Federal plans and programs that may have potential environmental impact so that views of interested parties can be obtained. DOE has issued regulations (10 CFR Part 1021) and DOE Order 451.1B to comply with this Executive Order.

Executive Order 11593, *National Historic Preservation* (May 13, 1971)—This Order directs Federal agencies to locate, inventory, and nominate properties under their jurisdiction or control to the National Register of Historic Places if they qualify. This process requires DOE to provide the Advisory Council on Historic Preservation an opportunity to comment on the possible impacts of proposed activities on any potentially eligible or listed resources.

Executive Order 11990, *Protection of Wetlands* (May 24, 1977)—This Order (implemented by DOE in 10 CFR Part 1022) requires Federal agencies to avoid any short- or long-term adverse impacts on wetlands wherever there is a practicable alternative. Each agency must also provide opportunities for early public review of any plans or proposals for new construction in wetlands.

Executive Order 11988, *Floodplain Management* (May 24, 1977)—This Order (implemented by DOE in 10 CFR Part 1022) requires Federal agencies to establish procedures to ensure that the potential effects of flood hazards and floodplain management are considered for any action undertaken in a floodplain, and that floodplain impacts are avoided to the extent practicable.

Executive Order 12088, *Federal Compliance with Pollution Control Standards*, (October 13, 1978) as amended by Executive Order 12580, *Superfund Implementation* (January 23, 1987)—This Order directs Federal agencies to comply with applicable administrative and procedural pollution control standards established by, but not limited to, the Clean Air Act, the Noise Control Act, the Clean Water Act, the Safe Drinking Water Act, TSCA, and RCRA.

Executive Order 12148, *Federal Emergency Management* (July 20, 1979), as amended by the Homeland Security Act of 2002 (Public Law 107-296) and Section 301 of Title 3 U.S.C.—This Order transfers functions and responsibilities associated with Federal emergency management to the Director of the Federal Emergency Management Agency. The Order assigns the Director the responsibility to establish Federal policies for, and to coordinate all civil defense and civil emergency planning, management, mitigation, and assistance functions of, Executive branch agencies. The amendment replaces the name, Federal Emergency Management Agency, wherever it appears with the name, Department of Homeland Security.

Executive Order 12656, *Assignment of Emergency Preparedness Responsibilities* (November 18, 1988)—This Order assigns emergency preparedness responsibilities to Federal departments and agencies.

Executive Order 12699, *Seismic Safety of Federal and Federally Assisted or Regulated New Building Construction* (January 5, 1990)—This Order requires Federal agencies to reduce risks to occupants of buildings owned, leased, or purchased by the Federal Government, or buildings constructed with Federal assistance, and to persons who would be affected by failures of Federal buildings in earthquakes; to improve the capability of existing Federal buildings to function during or after an earthquake; and to reduce earthquake losses of public buildings, all in a cost-effective manner. Each Federal agency responsible for the design and construction of a Federal building shall ensure that the building is designed and constructed in accordance with appropriate seismic design and construction standards.

Executive Order 12856, *Right-to-Know Laws and Pollution Prevention Requirements* (August 3, 1993)—Executive Order 12856 directs Federal agencies to reduce and report toxic chemicals entering any waste stream; improve emergency planning, response, and accident notification; and meet the requirements of the Emergency Planning and Community Right-to-Know Act.

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations* (February 11, 1994)—This Order requires each Federal agency to identify and address the disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations.

The CEQ, which oversees the Federal Government's compliance with Executive Order 12898 and NEPA, has developed guidelines to assist Federal agencies in incorporating the goals of Executive Order 12898 into the NEPA process. This guidance, published in 1997, is intended to "…assist Federal agencies with their NEPA procedures so that environmental justice concerns are effectively identified and addressed." As part of this process, DOE conducted an analysis to determine whether implementing any of the proposed alternatives would result in disproportionately high or adverse impacts on minority and low-income populations. The results of this analysis are discussed in the environmental justice sections of Chapter 4 of this SWEIS for each of the alternatives under consideration.

Executive Order 12902, *Energy Efficiency and Water Conservation at Federal Facilities* (March 8, 1994)—This Order requires Federal agencies to develop and implement a program to conserve energy and water resources. As part of this program, agencies are required to conduct comprehensive facility audits of their energy and water use.

Executive Order 12938, *Proliferation of Weapons of Mass Destruction* (November 14, 1994)—This Order states that the proliferation of nuclear, biological, and chemical weapons ("weapons of mass destruction") and the means of delivering such weapons constitute an unusual and extraordinary threat to the national security, foreign policy, and economy of the United States, and that a national emergency would be declared to deal with that threat.

Executive Order 13007, *Indian Sacred Sites* (May 24, 1996)—This Order directs Federal agencies, to the extent practicable, as permitted by law, and not clearly inconsistent with essential agency functions, to: (1) accommodate access to and ceremonial use of American Indian sacred sites by their religious practitioners, and (2) avoid adversely affecting the physical integrity of such sacred sites. Where appropriate, agencies are to maintain the confidentiality of sacred sites.

Executive Order 13045, *Protection of Children from Environmental Health Risks and Safety Risks* (April 21, 1997), as amended by Executive Order 13229 (October 9, 2001)—This Order requires each Federal agency to give high priority to identifying and assessing environmental health risks and safety risks that may disproportionately affect children and to ensure that its policies, programs, activities, and standards address disproportionate risks to children that result from environmental health risks or safety risks.

Executive Order 13101, *Greening the Government through Waste Prevention, Recycling, and Federal Acquisition* (September 14, 1998)—This Order requires each Federal agency to incorporate waste prevention and recycling in its daily operations and to work to increase and expand markets for recovered materials. This Order states that it is national policy to prefer pollution prevention, whenever feasible. Pollution that cannot be prevented should be recycled; pollution that cannot be prevented or recycled should be treated in an environmentally safe manner. Disposal should be employed only as a last resort.

Executive Order 13112, *Invasive Species* (February 3, 1999)—This Order requires Federal agencies to prevent the introduction of invasive species, to provide for their control, and to minimize their economic, ecological, and human health impacts.

Executive Order 13123, *Greening the Government through Efficient Energy Management* (June 8, 1999)—This Order sets goals for agencies to expand their use of renewable energy sources and to reduce greenhouse gas emissions from facility energy use, energy consumption per gross square foot of facilities, energy consumption per gross square foot or unit of production, use of petroleum within facilities, overall energy use, and water consumption and associated energy requirements.

Executive Order 13148, *Greening the Government through Leadership in Environmental Management* (April 21, 2000)—This Order requires agencies to integrate environmental accountability into day-to-day decisionmaking and long-term planning processes. The Order sets goals for implementing environmental management systems and audits, reporting pollution releases to the public, preventing pollution or reducing it at the source, and reducing toxic releases and transfers of toxic chemicals, use of toxic chemicals and hazardous substances, and generation of hazardous and radioactive waste types. It also sets goals for phasing out the use of Class I ozone-depleting substances and promoting environmentally sound landscaping practices.

Executive Order 13175, *Consultation and Coordination with Indian Tribal Governments* (November 6, 2000)—This Order supplements the Executive Memorandum (dated April 29, 1994) entitled, "Government-to-Government Relations with Tribal Governments," and states that each Executive branch department and agency shall consult, to the greatest extent practicable and to the extent permitted by law, with Tribal Governments prior to taking actions that affect federally recognized Tribal Governments. This Order also states that each Executive branch department and agency shall assess the impact of Federal Government plans, projects, programs, and activities on Tribal trust resources and assure that Tribal Government rights and concerns are considered during the development of such plans, projects, programs, and activities.

Executive Order 13287, *Preserve America* (March 3, 2003)—The goals of the initiative addressed by this Order include a greater shared knowledge about the Nation's past, strengthened regional identities and local pride, increased local participation in preserving cultural and natural heritage assets, and support for the economic vitality of our communities. The Order establishes Federal policy to provide leadership in preserving America's heritage by actively advancing the protection, enhancement, and contemporary use of the historic properties owned by the Federal Government and by promoting intergovernmental cooperation and partnerships for the preservation and use of historic properties.

6.3 Applicable DOE Orders

The Atomic Energy Act authorizes DOE to establish standards to protect health and minimize the dangers to life or property from activities under DOE's jurisdiction. Through a series of DOE Orders and regulations, an extensive system of standards and requirements has been established to ensure safe operation of DOE facilities. A number of DOE Orders have been issued in support of environmental, safety, and health programs. Many of these were revised and reorganized to reduce duplication and eliminate obsolete provisions. The new DOE Directives System is organized by series, with each Order identified by three digits, and is intended to include all DOE Orders, policies, manuals, requirement documents, notices, and guides. Existing DOE Orders (identified by four digits) are expected to be revised and converted to the new DOE numbering system. The major DOE Orders pertaining to the alternatives in this SWEIS are listed in **Table 6–3**.

DOE Order 151.1C, *Comprehensive Emergency Management System* (November 2, 2005)— This Order establishes policy to assign and describe roles and responsibilities for the DOE Emergency Management System. The Emergency Management System provides the framework for development, coordination, control, and direction of all emergency planning, preparedness, readiness assurance, response, and recovery actions. The Emergency Management System applies to DOE and to NNSA.

DOE Order 231.1A, *Environment, Safety, and Health Reporting* (August 19, 2003; Change 1, June 3, 2004)—This Order establishes responsibilities and requirements to ensure timely collection, reporting, analysis, and dissemination of information on environment, safety, and health issues as required by law or regulations or as needed to ensure that DOE and NNSA are kept fully informed on a timely basis about events that could adversely affect the health and safety of the public, the workers, or the environment; the intended purpose of DOE facilities; or the credibility of DOE.

Table 6–3 Applicable DOE Orders and Directives (as of December 8, 2006)

DOE Order/Number	Subject (date)
Leadership/Management/Planning	
O 151.1C	Comprehensive Emergency Management System (11/02/05)
Information and Analysis	
O 231.1A	Environment, Safety, and Health Reporting (08/19/03; Change 1, 06/03/04)
Work Process	
O 413.3A	Program and Project Management for the Acquisition of Capital Assets (07/28/06)
O 414.1C	Quality Assurance (06/17/05)
O 420.1B	Facility Safety (12/22/05)
O 425.1C	Startup and Restart of Nuclear Facilities (03/13/03)
O 430.1B	Real Property Assessment Management (09/24/03)
O 433.1	Maintenance Management Program for DOE Nuclear Facilities (06/01/01)
O 435.1	Radioactive Waste Management (07/09/99; Change 1, 08/28/01)
O 440.1B	Worker Protection Management for DOE Federal and Contractor Employees (05/17/07)
O 450.1	Environmental Protection Program (01/15/03; Change 2, 12/07/05; Admin. Change 1, 01/03/07)
O 451.1B	National Environmental Policy Act Compliance Program, (10/26/00; Change 1, 09/28/01)
O 460.1B	Packaging and Transportation Safety (04/04/03)
O 460.2A	Departmental Materials Transportation and Packaging Management (12/22/04)
O 461.1A	Packaging and Transfer or Transportation of Materials of National Security Interest (04/26/04)
O 470.2B	Independent Oversight and Performance Assurance Program (10/31/02)
O 470.4	Safeguards and Security Program (08/26/05)
External Relationships	
O 1230.2	American Indian Tribal Government Policy (04/08/92) – as revised by DOE Notice 144.1 (10/20/06)
Environmental Quality and Impact	
O 5400.5	Radiation Protection of the Public and the Environment (02/08/90; Change 2, 01/07/93)
O 5480.19	Conduct of Operations Requirements for DOE Facilities (07/09/90; Change 1, 05/18/92; Change 2, 10/23/01)
O 5480.20A	Personnel Selection, Qualification, and Training Requirements for DOE Nuclear Facilities (11/15/94; Change 1, 07/12/01)
Emergency Preparedness	
O 5530.3	Radiological Assistance Program (01/14/92; Change 1, 04/10/92)
O 5530.5	Federal Radiological Monitoring and Assessment Center (07/10/92; Change 1, 12/02/92)
Office of National Nuclear Security Administration	
O 5660.1B	Management of Nuclear Materials (05/26/94)

DOE Order 413.3A, *Program and Project Management for the Acquisition of Capital Assets* (July 28, 2006)—This Order provides DOE, including NNSA, project management direction for the acquisition of capital assets that are delivered on schedule, within budget, and fully capable of meeting mission performance and environmental, safety, and health standards.

DOE Order 414.1C, *Quality Assurance* (June 17, 2005)—The objectives of this Order are to ensure that DOE, including NNSA, products and services meet or exceed customers' expectations and to achieve quality assurance for all work based upon the following principles:

- That quality is assured and maintained through a single, integrated, effective quality assurance program (management system);
- That management support for planning, organization, resources, direction, and control is essential to quality assurance;
- That performance and quality improvement require thorough, rigorous assessment and corrective action;
- That workers are responsible for achieving and maintaining quality; and
- That environmental, safety, and health risks and impacts associated with work processes can be minimized while maximizing reliability and performance of work products.

DOE Order 420.1B *Facility Safety* (December 22, 2005)—This Order establishes facility safety requirements related to nuclear safety design, criticality safety, fire protection, and mitigation of hazards related to natural phenomena.

DOE Order 425.1C, *Startup and Restart of Nuclear Facilities* (March 13, 2003)—This Order establishes DOE requirements for startup of new nuclear facilities and restart of existing nuclear facilities that have been shut down. The requirements specify a readiness review process that must demonstrate that it is safe to start (or restart) the subject facility. The facility must be started (or restarted) only after documented independent reviews of readiness have been conducted and the approvals specified in the Order have been received.

DOE Order 430.1B, *Real Property Asset Management* (September 24, 2003)—This Order establishes a corporate, holistic, and performance-based approach to real property life-cycle asset management that links real property asset planning, programming, budgeting, and evaluation to program mission projections and performance outcomes. This Order also identifies requirements and establishes reporting mechanisms and responsibilities for real property asset management. Planning for disposition must be initiated when real property assets are identified as no longer required for current or future programs. Disposition includes stabilizing, preparing for reuse, deactivating, decommissioning, decontaminating, dismantling, demolishing, and disposing of real property assets.

DOE Order 433.1, *Maintenance Management Program for DOE Nuclear Facilities* (June 1, 2001)—This Order defines the program for the management of cost-effective maintenance of DOE nuclear facilities. Guidance for compliance with this Order is contained in

DOE Guide 433.1-1, "Nuclear Facility Maintenance Management Program Guide for Use with DOE Order 433.1," which references Federal regulations, DOE directives, and industry best practices using a graded approach to clarify requirements and guidance for maintaining DOE-owned government property.

DOE Order 435.1, *Radioactive Waste Management* (July 9, 1999)—This Order and its associated manual and guidance establish responsibilities and requirements for the management of DOE high-level radioactive waste, transuranic waste, low-level radioactive waste, and the radioactive component of mixed waste. These documents provide detailed radioactive waste management requirements, including waste incidental to reprocessing determinations; waste characterization, certification, and treatment, storage, and disposal; and radioactive waste facility design and closure.

DOE Order 440.1B, *Worker Protection Management for DOE Federal and Contractor Employees* (May 17, 2007)—This Order establishes the framework for an effective worker protection program that reduces or prevents injuries, illnesses, and accidental losses by providing safe and healthful DOE Federal and contractor workplaces.

DOE Order 450.1, *Environmental Protection Program* (January 15, 2003; Change 2, December 7, 2005; Admin. Change 1, January 3, 2007)—Under DOE Order 450.1, it is DOE policy to conduct its operations in a manner that ensures the protection of public health, safety, and the environment through compliance with applicable Federal and state laws, regulations, Orders, and other requirements. The objective of this Order is to implement sound stewardship practices that protect the air, water, land, and other natural and cultural resources impacted by DOE operations. This objective is to be accomplished by implementing environmental management systems at DOE sites. An environmental management system is a continuing cycle of planning, implementing, evaluating, and improving processes and actions undertaken to achieve environmental goals.

DOE Order 451.1B, *National Environmental Policy Act Compliance Program* (October 26, 2000; Change 1, September 28, 2001; DOE Notice 451.1, October 10, 2006)— The purpose of this Order is to establish DOE internal requirements and responsibilities for implementing NEPA, the CEQ Regulations Implementing the Procedural Provisions of NEPA (40 CFR Parts 1500 to 1508), and the DOE NEPA Implementing Procedures (10 CFR Part 1021). The goal is to ensure efficient and effective implementation of DOE NEPA responsibilities through teamwork. A key responsibility for all participants is to control the cost and time for the NEPA process while maintaining its quality.

DOE Order 460.1B, *Packaging and Transportation Safety* (April 14, 2003)—This Order sets forth DOE policy and assigns responsibilities for proper packaging and transporting of DOE offsite shipments and onsite transfers of hazardous materials and for modal transport.

DOE Order 460.2A, *Departmental Materials Transportation and Packaging Management* (December 22, 2004)—This Order requires DOE operations to comply with all applicable international, Federal, state, local, and Tribal laws, rules, and regulations governing materials transportation that are consistent with Federal regulations, unless exemptions or alternatives are approved. This Order also states that it is DOE policy that shipments will comply with the

U.S. Department of Transportation 49 CFR 100 through 185 requirements, except those that infringe on maintenance of classified information.

DOE Order 461.1A, *Packaging and Transfer or Transportation of Materials of National Security Interest* (April 26, 2004)—This Order establishes requirements and responsibilities for offsite shipments of naval nuclear fuel elements, Security Category I and II special nuclear material, nuclear explosives, nuclear components, special assemblies, and other materials of national security interest; onsite transfers of naval nuclear fuel elements, Security Category I and II special nuclear material, nuclear components, special assemblies and other materials of national security interest; and certification of packages for Security Category I and II special nuclear material, nuclear components, and other materials of national security interest.

DOE Order 470.2B, *Independent Oversight and Performance Assurance Program* (October 31, 2002)—This Order establishes the Independent Oversight Program to enhance DOE safeguards and security; cyber security; emergency management; and environment, safety, and health programs by providing DOE, contractor managers, the Congress, and other stakeholders with an independent evaluation of the adequacy of DOE policy and the effectiveness of line management performance in these and other critical functions as directed by the Secretary.

DOE Order 470.4, *Safeguards and Security Program* (August 26, 2005)—This Order establishes the roles and responsibilities for the DOE Safeguards and Security Program, which consists of six key elements: (1) program planning and management, (2) physical protection, (3) protective force, (4) information security, (5) personnel security, and (6) nuclear material control and accountability. Specific requirements for each of the key elements are contained in their respective programmatic manuals. The requirements identified in these manuals are based on national policy promulgated in laws, regulations, and Executive Orders to prevent unacceptable adverse impacts on national security, the health and safety of DOE and contractor employees, the public, and the environment.

DOE Order 1230.2, *American Indian Tribal Government Policy* (April 8, 1992) as revised by DOE Notice 144.1 (October 20, 2006)—This Order establishes responsibilities and transmits the DOE American Indian and Alaska Native Policy. The policy outlines the principles to be followed by DOE in its interactions with federally recognized American Indian Tribes. It is based on Federal policy treaties, Federal law, and DOE's responsibilities as a Federal agency to ensure that Tribal rights and interests are identified and considered pertinent during decisionmaking.

DOE Order 5400.5, *Radiation Protection of the Public and the Environment* (February 8, 1990; Change 2, January 7, 1993)—This Order establishes standards and requirements for DOE operations to protect members of the public and the environment against undue risk from radiation. It is DOE policy to implement legally applicable radiation protection standards and to consider and adopt, as appropriate, recommendations by authoritative organizations; for example, the National Council on Radiation Protection and Measurements and the International Commission on Radiological Protection. It is also DOE policy to adopt and implement standards generally consistent with those of NRC for DOE facilities and activities that are not subject to NRC licensing authority.

DOE Order 5480.19, ***Conduct of Operations Requirements for DOE Facilities*** **(July 9, 1990; Change 1, May 18, 1992; Change 2, October 23, 2001)—**This Order provides requirements and guidelines for Departmental Elements including NNSA, to use in developing directives, plans, or procedures relating to the conduct of operations at DOE facilities.

DOE Order 5480.20A, ***Personnel Selection, Qualification, and Training Requirements for DOE Nuclear Facilities*** **(November 15, 1994; Change 1, July 12, 2001)**—This Order establishes the selection, qualification, and training requirements for DOE contractor personnel involved in the operation, maintenance, and technical support of DOE nuclear reactors and nonreactor nuclear facilities. DOE objectives under this Order are to ensure the development and implementation of contractor-administered training programs that provide consistent and effective training for personnel at DOE nuclear facilities. The Order contains minimum requirements that must be included in training and qualification programs.

DOE Order 5530.3, ***Radiological Assistance Program*** **(January 14, 1992; Change 1, April 10, 1992)—**This Order establishes DOE policy, procedures, authorities, and responsibilities for its Radiological Assistance Program. Through this program, DOE provides assistance to state, local, and Tribal jurisdictions in preparing for a radiological emergency. The Order requires DOE to establish response plans, maintain resources, and assist Federal, state, local, and Tribal governments in the event of a real or potential emergency.

DOE Order 5530.5, ***Federal Radiological Monitoring and Assessment Center*** **(July 10, 1992; Change 1, December 2, 1992)—**This Order establishes DOE policy, procedures, authorities, and requirements for the establishment of a Federal Radiological Monitoring and Assessment Center, as set forth in the Federal Radiological Emergency Response Plan (50 FR 46542).

DOE Order 5660.1B, ***Management of Nuclear Materials*** **(May 26, 1994)—**This Order establishes requirements and procedures for the management of nuclear materials within the DOE.

6.4 Applicable State of New Mexico and Local Statutes, Regulations, and Agreements

Certain environmental requirements have been delegated to state authorities for implementation and enforcement. It is DOE policy to conduct its operations in an environmentally safe manner that complies with all applicable statutes, regulations, and standards, including state laws and regulations. A list of applicable State of New Mexico and local statutes, regulations, agreements, and Orders are provided in **Table 6–4**.

Since the last SWEIS was published, the State of New Mexico has entered into a Compliance Order on Consent (Consent Order) with DOE and the University of California pursuant to Section 74-4-10 of the Hazardous Waste Act and 74-9-36(D) of the Solid Waste Act. The Consent Order requires DOE and the University of California (or its successor) to conduct a site-wide investigation and cleanup of contamination at LANL in accordance with the procedures and schedules set forth in the Consent Order. The Consent Order sets forth requirements to investigate and remediate a large number of potential release sites and areas of concern, including, but not limited to, several former material disposal areas.

Table 6–4 State and Local Requirements

Activity	*Citation*	*Requirements*
Endangered Plant Species	New Mexico Administrative Code (NMAC), Title 19, Chapter 21, Endangered Plants (revised November 30, 2006).	Establishes plant species list and rules for collection.
Environmental Oversight and Monitoring Agreement	Agreement in Principle Between DOE and the State of New Mexico, November 2000.	Provides DOE support for state activities in environmental oversight, monitoring, access, and emergency response.
Federal Facility Compliance Order	October 1995 (issued to both DOE and LANL).	Order used by the New Mexico Environment Department to enforce the Federal Facility Compliance Act. It requires compliance with the approved LANL Site Treatment Plan, which documents the development and use of treatment capacities and technologies, as well as use of offsite facilities for treating mixed radioactive waste stored at LANL.
Los Alamos County Noise Restrictions	Los Alamos County Code, Chapter 8.28.	Imposes noise restrictions and makes provisions for exceedances.
Environmental Improvement Act	New Mexico Statutes Annotated (NMSA) 1978, Sections 74-1-1 through 74-1-15; NMAC, 20.5.1 through 20.5.17, August 15, 2003. The New Mexico Environment Department recently changed their regulations for storage tanks, combining the regulations for aboveground and underground storage tanks into the Petroleum Storage Tank regulations. Petroleum Storage Tank regulations found in 20.5.1 NMAC through 20.5.17 NMAC; filed for publication in the *New Mexico Register* on July 16, 2003; effective August 15, 2003.	Aboveground tank regulations were modified to include requirements for the registration, installation, modification, repair, and closure or removal of aboveground storage tanks, as well as release detection, record-keeping, and financial responsibility in the State of New Mexico.
New Mexico Air Quality Control Act	NMSA, Chapter 74, "Environmental Improvement," Article 2, "Air Pollution" (revised 10/31/02), and implementing regulations at NMAC Title 20, "Environmental Protection," Chapter 2, "Air Quality" (revised October 31, 2002).	Establishes air quality standards and requires a permit prior to construction or modification of an air contaminant source. Also requires an operating permit for major producers of air pollutants and imposes emission standards for hazardous air pollutants.
New Mexico Cultural Properties Act	NMSA, Chapter 18, "Libraries and Museums," Article 6, "Cultural Properties."	Establishes the State Historic Preservation Office and requirements to prepare an archaeological and historic survey and consult with the State Historic Preservation Office.
New Mexico Groundwater Protection Act	NMSA, Chapter 74, Article 6B, "Groundwater Protection."	Establishes state standards for protection of groundwater from leaking underground storage tanks.
New Mexico Hazardous Chemicals Information Act	NMSA, Chapter 74, Article 4E-1, "Hazardous Chemicals Information."	Implements the hazardous chemical information and toxic release reporting requirements of the Emergency Planning and Community Right-to-Know Act of 1986 (SARA Title III) for covered facilities.

Activity	*Citation*	*Requirements*
New Mexico Hazardous Waste Act	NMSA, Chapter 74, Article 4, "Hazardous Waste," and implementing regulations found in NMAC Title 20, "Environmental Protection," Chapter 4, "Hazardous Waste" (revised June 14, 2000).	Establishes permit requirements for construction, operation, modification, and closure of a hazardous waste management facility and establishes state standards for cleanup of releases from leaking underground storage tanks.
New Mexico Endangered Plant Species Act	NMSA, Chapter 75, Miscellaneous Natural Resource Matters, Article 6, "Endangered Plants."	Requires coordination with the State.
New Mexico Night Sky Protection Act	NMSA, Chapter 74, Article 12 "Night Sky Protection:" 74-12-1 to 74-12-10) (House Bill 39/A, March 1, 1999).	Regulates outdoor night lighting fixtures to preserve and enhance the State's dark sky while promoting safety, conserving energy, and preserving the environment for astronomy.
New Mexico Radiation Protection Act	NMSA, Chapter 74, Article 3, "Radiation Control" and implementing regulations found in NMAC Title 20 Chapter 3, "Radiation Protection" (revised April 15, 2004) "Environmental Protection."	Establishes state requirements for worker protection.
New Mexico Raptor Protection Act	NMSA, Chapter 17, Article 2-14.	Makes it unlawful to take, attempt to take, possess, trap, ensnare, injure, maim, or destroy any of the species of hawks, owls, and vultures.
New Mexico Solid Waste Act	NMSA, Chapter 74, Article 9, Solid Waste Act, and implementing regulations found in NMAC Title 20, "Environmental Protection," Chapter 9, Solid Waste (revised November 27, 2001).	Requires permit prior to construction or modification of a solid waste disposal facility.
New Mexico Water Quality Act	NMSA, Chapter 74, Article 6, "Water Quality," and implementing regulations found in NMAC, Title 20, "Environmental Protection," Chapter 6, "Water Quality" (revised February 16, 2006).	Establishes water quality standards and requires a permit prior to the construction or modification of a water discharge source.
New Mexico Wildlife Conservation Act	NMSA, Chapter 17, Game and Fish, Article 2, Hunting and Fishing Regulations, Part 3, Wildlife Conservation Act.	Requires a permit and coordination if a project may disturb habitat or otherwise affect threatened or endangered species.
Compliance Order on Consent	March 1, 2005 (entered into by the State of New Mexico, DOE, and the University of California) (NMED 2005).	Requires site investigations of known or potentially contaminated sites at LANL and cleanup in accordance with a specified process and schedule.
Pueblo Accords	DOE 2006 Restatement of Accords with each of four Pueblos (Pueblos of Cochiti, Jemez, Santa Clara, and San Ildefonso).	Set forth the specifications for maintaining a government-to-government relationship between DOE and each of the four Pueblos closest to LANL.
Threatened and Endangered Species of New Mexico	NMAC Title 19, "Natural Resources and Wildlife," Chapter 33, "Threatened and Endangered Species," 19.33.6.8 (revised December 29, 2006).	Establishes the list of threatened and endangered species.

Table 6–5 lists the state permits that have been issued to LANL. Certain open burning permits that were previously included on this table were withdrawn from the regulatory authority (LANL 2006c).

Table 6–5 State Environmental Permits

Category/Approved Activity	***Permit***	***Date Issued***	***Expiration Date***
Air Permits			
Facilities with emissions greater than 100 tons per year of nitrogen oxide, volatile organic compound, and carbon monoxides (NMAC Operating Permit)	Operating Permit Number P100 M1	June 15, 2006	April 30, 2009

6.5 Consultations

6.5.1 Consultation Requirements

Certain laws, such as the Endangered Species Act, the U.S. Fish and Wildlife Coordination Act, and the National Historic Preservation Act, require DOE to consult and coordinate with other governmental entities including other Federal agencies, state and local agencies, and federally recognized Native American Governments. In addition, the DOE American Indian and Alaska Native Tribal Government Policy requires DOE to consult with any Native American or Alaska Native Tribal Government regarding any property to which the Tribe attaches religious or cultural importance that might be affected by a DOE action. The following sections describe consultations and other interactions that took place during the preparation of this SWEIS.

6.5.1.1 Ecological Resources

Biotic resource consultations generally pertain to the potential for activities to disturb sensitive species or habitats. Under the terms of the LANL *Threatened and Endangered Species Habitat Management Plan* (LANL 2000b), NNSA submitted a *Biological Assessment of the Continued Operation of Los Alamos National Laboratory on Federally Listed Threatened and Endangered Species* (LANL 2006b) to the U.S. Fish and Wildlife Service on February 22, 2006. The U.S. Fish and Wildlife Service response to NNSA's consultation request is presented in Section 6.5.2.

6.5.1.2 Cultural Resources

Cultural resource consultations relate to the potential for disruption of important cultural resources and archaeological sites. As required by NEPA and Section 106 of the National Historic Preservation Act, DOE consults with the Advisory Council on Historic Preservation, the appropriate State Historic Preservation Officers, and Tribal Historic Preservation Officers. Under the terms of the *Programmatic Agreement for Management of Historic Properties at Los Alamos National Laboratory* (DOE 2006b), a copy of the Draft SWEIS was submitted to the State Historic Preservation Officer. The response to NNSA's request for consultation with the New Mexico State Historic Preservation Officer is presented in Section 6.5.2.

6.5.1.3 Tribal Consultations

Native American consultations are concerned with the potential for impacts on any rights and interests, including disturbance of Native American ancestral sites, sacred sites, and traditional and religious practices, or natural resources of importance to Native Americans. DOE is committed to meeting its responsibilities in maintaining its government-to-government relationships with federally recognized Native American Tribes. **Table 6–6** lists Executive Memoranda and DOE direction regarding government-to-government relations with Native American Tribal Governments.

Table 6–6 Government-to-Government Relationships with Tribal Governments

Date	*Title*
January 20, 2006	Memorandum for the Head of Departmental Elements from Secretary Samuel W. Bodman. DOE reaffirms government-to-government relationships with Tribal Governments (references American Indian and Alaska Natives Tribal Government Policy).
September 23, 2004	Memorandum for the Heads of Executive Departments and Agencies Government-to-Government Relationship with Tribal Governments (references Executive Order 13175, Consultation and Coordination with Indian Tribal Governments, and Executive Order 13336, entitled "American Indian and Alaska Native Education"). This complements and partially supersedes the similar executive memorandum of April 29, 1994.
August 21, 2001	Secretary Abraham reaffirms DOE's Government-to-Government Relations with Native American Tribal Governments (references American Indian and Alaska Natives Tribal Government Policy).
April 29, 1994	Memorandum for the Heads of Executive Departments and Agencies, Government-to-Government Relations with Native American Tribal Governments.

DOE undertook an extensive effort to consult with Native American Tribal Governments during preparation of the 1999 *Site-Wide Environmental Impact Statement for the Continued Operation of the Los Alamos National Laboratory, Los Alamos, New Mexico (1999 SWEIS)* (DOE/EIS-0238). DOE has initiated consultations with the appropriate Native American Tribal Governments, as required by Executive Memoranda and DOE Order 1230.2, "American Indian Tribal Government Policy," as revised by DOE Notice 144.1. NNSA continued its consultations with the pueblos during the preparation of this SWEIS.

As part of its Government-to-Government interactions, restatements of four Pueblo Accords were signed by the Governor of each pueblo (Cochiti, San Ildefonso, Jemez, and Santa Clara) and the Secretary of Energy in 2005 and 2006. Twice yearly, executive meetings are held among the Los Alamos Site Office Manager, the LANL Director, and the respective Accord Pueblo Governors. In addition, the Los Alamos Site Office Manager meets monthly with each governor of the two pueblos closest to LANL (San Ildefonso and Santa Clara) and with the other Accord Pueblo Governors on a less frequent basis. In both the executive meetings and the private meetings, the Los Alamos Site Office Manager discussed the SWEIS and the importance of the pueblos participating in the SWEIS preparation process.

The NNSA NEPA Document Manager requested the involvement of pueblo representatives during the SWEIS preparation period. In the spring of 2004 the Document Manager notified the Four Accord Pueblos of NNSA's intention to prepare a Supplement Analysis of the *1999 SWEIS* to determine whether a new or supplemental SWEIS should be prepared, and attended meetings at the four Accord Pueblos to brief Pueblo representatives on how the Supplement Analysis would be prepared.

When NNSA made the decision in late 2004, to prepare a supplement to the *1999 SWEIS*, the NNSA NEPA Document Manager sent notification letters inviting each of the Four Accord Pueblos to become Cooperating Agencies. Two pueblos (San Ildefonso and Santa Clara) responded that they wished to be involved. While neither signed formal agreements, over the next year both pueblos continued to participate in internal working meetings during preparation of the Draft SWEIS including review of sections and chapters of the document.

On January 5, 2005, NNSA issued a *Federal Register* Notice of Intent to prepare a *Supplemental Environmental Impact Statement to the Final Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory (Supplemental SWEIS)* (70 FR 807). In the Notice of Intent, NNSA invited public comment on the *Supplemental SWEIS* proposal and listed the issues initially identified by NNSA for evaluation in the *Supplemental SWEIS*. The four Accord Pueblos were also invited to comment on the scope of the proposed action. A public scoping meeting was held in Pojoaque, New Mexico, on January 19, 2005. The public scoping period ended February 17, 2005.

A post-scoping internal working meeting was held on March 8, 2005, to discuss the scoping comments and proposed project reviews. The Four Accord Pueblos were invited to send representatives and two of the Accord Pueblos participated in the meeting.

The Draft SWEIS was issued to the public and LANL stakeholders, including approximately 23 American Indian Tribes who had expressed interest in LANL, on July 7, 2006, followed by a public comment period extending through September 20, 2006. During the review period, the Santa Clara Pueblo hosted a meeting to which the Eight Northern Pueblos and the two Accord Pueblos that are not members of the Eight Northern Pueblos (the Pueblo of Cochiti and the Pueblo of Jemez) were invited. The purpose of this meeting was for the Los Alamos Site Office Manager, the NNSA Document Manager, and LANL staff to discuss the Draft SWEIS. Several pueblos submitted comments on the Draft LANL SWEIS that were considered in completing the final document.

6.5.2 Consultation Letters

Consultation letters associated with this SWEIS are attached at the end of this section and include correspondence from the New Mexico Department of Cultural Affairs and the U.S. Fish and Wildlife Service. Letters from the latter organization are in response to the request for Section 7 consultation under the Endangered Species Act made by NNSA upon its transmittal of a biological assessment for continued operation of LANL (LANL 2006b).

Re: Draft SWEIS for Continued Operation of LANL, Los Alamos; HPD Log 78716.

Dear Dr. Isaacson:

Thank you for sending our office a copy of the June 2006 *Draft Site-Wide Environmental Impact Statement* [SWEIS] *for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico.* We look forward to receiving the Final document.

Currently, our Section 106 reviews follow the terms of the Programmatic Agreement (LA-UR-06-1975) between the U.S. Department of Energy, the National Nuclear Security Administration, the Los Alamos Site Office, the New Mexico State Historic Preservation Officer and the Advisory Council on Historic Preservation. This agreement and the management plan for cultural heritage at Los Alamos National Laboratory dated February 2006 guide the management for the historic properties of Los Alamos National Laboratory and our consultation process.

Thank you again, and we look forward to receiving the Final SWEIS.

Sincerely,

Katherine A. Slick

Cons. # 22420-2006-I-0066

Ms. Elizabeth R. Withers
ESA Program Manager
National Nuclear Security Administration
Los Alamos Site Office
Los Alamos, New Mexico 87544

Dear Ms. Withers:

Thank you for your February 22, 2006, Biological Assessment (BA) of the Continued Operation of Los Alamos National Laboratory (LANL) on Federally Listed Threatened and Endangered Species. LANL reviewed eighteen projects that had not received U.S. Fish and Wildlife Service (Service) consultation or concurrence, as well as the two aspects of ongoing operations, ecological risk from legacy contaminants and the Outfall Reduction Project were determined to have the potential to affect Federally Listed species. Your letter requesting consultation for the proposed projects and their effects on the threatened Mexican spotted owl (owl) (*Strix occidentalis lucida*) and the threatened bald eagle (*Haliaeetus leucocephalus*) and the endangered southwestern willow flycatcher (flycatcher) (*Empidonax trailii extimus*) was received by the Service on February 22, 2006. You determined that proposed projects listed on Tables 1 and 2 "may affect, is not likely to adversely affect" the bald eagle, the flycatcher, and the owl, and requested concurrence.

LANL produced a Threatened and Endangered Species Habitat Management Plan (HMP) (LANL 1999). The HMP is a comprehensive plan that balances current LANL operations and future development with habitat of listed species. The HMP facilitates Department of Energy compliance with the Endangered Species Act of 1973, as amended (Act). The HMP defines site plans and monitoring plans for species that may occur on LANL. The owl, bald eagle, and flycatcher habitat is labeled areas of environmental interest (AEIs). As such, the HMP provides a list of activities named reasonable and prudent alternatives (RPAs), which, if they are conducted, will not adversely affect these species. The projects listed below adhere to the activities identified in the HMP. Our concurrences are listed for the owl, bald eagle, and flycatcher (Tables 1 and 2).

Ms. Elizabeth R. Withers 2

Table 1. LANL project determinations and concurrences for the bald eagle and flycatcher.

Project	Bald Eagle determination	Concurrence rationale:	Flycatcher determination	Concurrence rationale:
Ecological risk from legacy contaminants	May affect, not likely to adversely affect	1) RPAs will be applied. 2) LANL may consider a new bald eagle risk assessment.	May affect, not likely to adversely affect	1) LANL will continue to monitor/survey potential breeding sites, and evaluate areas that could develop into suitable habitat. 2) Available evidence indicates LANL does not contribute excess adverse risk to the flycatcher from environmental contaminants. 3) RPAs will be applied.
Science complex	May affect, not likely to adversely affect	1) The proposed project site is not near the bald eagle AEI. 2) Bald eagle foraging habitat RPAs will be applied.		
TA-3 Replacement Office Buildings	May affect, not likely to adversely affect	1) The proposed project site is more than 4.6 miles from the bald eagle AEI. 2) Bald eagle foraging

Project	Bald Eagle determination	Concurrence rationale:	Flycatcher determination	Concurrence rationale:
				needed. 4) RPAs will be followed.
DynEX Assembly Chamber	May affect, not likely to adversely affect	1) The proposed project site is not near the bald eagle AEI. 2) Bald eagle foraging habitat RPAs will be applied.		
Remediation of MDA D at TA-33	May affect, not likely to adversely affect	1) The proposed project site is in core and buffer habitat but it is already developed. 2) No roost trees will be disturbed. 3) Back-up indicators on trucks will be muted within safety standards. 3) Reseeding and erosion protection will follow where needed. 4) Bald eagle foraging habitat RPAs will be applied		

Table 2. LANL project determinations and concurrences for the owl.

Project	Owl determination	Concurrence rationale:

Ms. Elizabeth R. Withers 7

Project	**Owl determination**	**Concurrence rationale:**
Ecological risk from legacy contaminants	May affect, not likely to adversely affect	RPAs will be applied.
Science complex	May affect, not likely to adversely affect	1) No suitable nesting habitat would be removed. 2) Owls have not been detected in Los Alamos Canyon. 3) Consultation will be reinitiated if owls are found.
TA-3 Replacement Office Buildings	May affect, not likely to adversely affect	1) RPAs will be applied. 2) The project would remove approximately 11 acres of buffer habitat. 3) Owls have not been detected in Los Alamos Canyon
Nuclear Materials Safeguards and Security Upgrade	May affect, not likely to adversely affect	1) RPAs plus additions and qualifications identified in the BA for this project would be implemented. 2) The project would remove approximately7 acres of buffer habitat. 3) Owls were detected in Mortandad Canyon (2004 and 2005). 4) No core habitat would be developed.
TA-48 Radiological Science Institute	May affect, not likely to adversely affect	1) RPAs will be applied. 2) Most of the new construction would not be in owl habitat.
Characterization and Remediation of MDA C	May affect, not likely to adversely affect	1) Proposed project would not remove suitable roosting or nesting habitat.
Radioactive Liquid Waste Treatment Facility Replacement	May affect, not likely to adversely affect	1) Approximately 75 percent of the project area has been disturbed

Ms. Elizabeth R. Withers 8

Project	Owl determination	Concurrence rationale:
		by other construction. 2) RPAs will be applied. 3) Noise levels should attenuate below limits set in the HMP. 4) Project activities would take place within or adjacent to developed areas.
Disposition of the Flood Retention Structure and Steel Diversion Wall in Pajarito Canyon	May affect, not likely to adversely affect	RPAs will be applied. 2) Owls have not been detected within the proposed project area. 3) No trees greater than 8 inches diameter at breast height would be removed. 4) Owl core habitat is protected from disturbance by the mesa that separates Pajarito and Three-Mile canyons.
Decontamination, Decommissioning, and Demolition of TA-18	May affect, not likely to adversely affect	1) Noise disturbance would be temporary and short duration. 2) All disturbed soils would be reseeded with native seeds. 3) No trees greater than 8 inches diameter at breast height would be removed. 4) Back-up indicators on all trucks and heavy equipment would be muted consistent with the safety of human workers.
Remediation of MDAs A, T, and U at TA-21	May affect, not likely to adversely affect	1) RPAs from the BA (Appendix B) would be implemented. 2) No suitable foraging or

Ms. Elizabeth R. Withers 9

Project	Owl determination	Concurrence rationale:
		nesting habitat will be lost; 3) The proposed project area is already highly disturbed. 4) Owls have not been detected in Los Alamos Canyon. 5) If owls are detected the Service would be contacted and reinitiation would be needed.
Decontamination, Decommissioning, and Demolition of TA-21	May affect, not likely to adversely affect	1) RPAs from the BA (Appendix B) would be implemented. 2) No suitable foraging or nesting habitat will be lost. 3) The proposed project area is already highly disturbed. 4) Owls have not been detected in Los Alamos Canyon. 5) If owls are detected the Service would be contacted and reinitiation would be needed.
DynEX Assembly Chamber	May affect, not likely to adversely affect	1) No suitable roosting or nesting habitat will be lost. 2) Owl surveys in Canon de Valle would continue. 3) Approximately 2 acres would be developed. 4) RPAs from the BA (Appendix B) would be implemented. 5) If owls are detected within 0.25 mile of the construction site, activities would be suspended until September 1.

Ms. Elizabeth R. Withers 10

Project	Owl determination	Concurrence rationale:
Remediation of MDAs N and Z at TA-15	May affect, not likely to adversely affect	1) The proposed project would not remove nesting or roosting habitat. 2) Owl surveys would continue. 3) Approximately 2 acres of owl habitat would be disturbed. 4) RPAs from the BA (Appendix B) would be implemented. 5) If owls are detected within 0.25 mile of the construction site, activities would be suspended until September 1.

Cumulative effects were not analyzed by the Service for this letter of concurrence because under section 7 of the Act, those effects are future State and private activities, not involving Federal activities that are reasonably certain to occur within the action area of the Federal action subject to consultation. This definition applies only to section 7 analyses and should not be confused with the broader use of this term in the National Environmental Policy Act or other environmental laws. Cumulative effects under section 7 will be analyzed in a subsequent biological opinion for the Outfall Reduction Project, the Security-Driven Transportation Modifications Project, and the Security-Driven Transportation Modifications Options Project.

Section 7(a)(1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. In the appendix, we enclose conservation recommendations for the bald eagle, the flycatcher, and other migratory birds.

This concludes the informal consultation for the Continued Operation of Los Alamos National Laboratory on Federally Listed Threatened and Endangered Species. Please contact the Service if: (1) new information reveals effects of the agency action that may affect the species to an extent not considered in this consultation; (2) the agency action is subsequently modified in a manner that causes an effect to the species that was not considered by the proposed action, (3) owls or bald eagles or flycatchers are detected within any project area, and (4) a new species is listed or critical habitat designated that may be affected by the proposed project.

Ms. Elizabeth R. Withers 11

We appreciate the thorough analyses provided in the letter and the EA and your efforts to protect endangered and threatened species. In future communications regarding this consultation please refer to consultation #22420-2006-I-0066. If we can be of further assistance, please contact Santiago R. Gonzales or Nancy Baczek of my staff at (505) 761-4755 or (505) 761-4711, respectively.

Sincerely,

Brian Hanson

Ms. Elizabeth R. Withers 12

Appendix A.

Species Specific Conservation Recommendations for BA of Continued Operation of Los Alamos National Laboratories

Flycatcher

- Cease project activity during May, the time period in which flycatchers most frequently migrate through LANL.
- Develop a habitat management plan to eradicate and control non-native invasive riparian/wetland vegetation. (Tamarisk sp., Russian Olive, and Siberian Elm)
- Enhance native riparian/wetland vegetation following drought and project impacts.
- A new state-wide assessment is recommended for the flycatcher and contaminants, considering that contaminant data, safe limits, and other modeling parameters have changed considerably. (RE: p.170 of BA)

Bald Eagle

- Develop an avian protection plan for power lines and towers. (RE: p. 171of BA)
- Because contaminant data reflective of the terrestrial portion (mostly carrion) of resident bald eagles diets have changed considerably since the last modeling assessment, and safe limits and other modeling parameters have changed considerably, consideration should be made for a new risk assessment on the bald eagle.

Migratory Birds

- Use "bird-glass" in new buildings and replacement of old glass.
- Use window blinds to shut out lab/office-light from night environment.
- Habitat disruption/removal should only take place during migratory bird non-nesting season, or following negative surveys.

Ms. Elizabeth R. Withers
ESA Program Manager
National Nuclear Security Administration
Los Alamos Site Office
Los Alamos, New Mexico 87544

Dear Ms. Withers:

Thank you for your February 22, 2006, biological assessment (BA) of the Continued Operation of Los Alamos National Laboratory on Federally Listed Threatened and Endangered Species – Outfall Reduction Project. The Los Alamos National Laboratory (LANL) proposes to eliminate seven industrial effluent outfalls. Your letter requesting consultation for the proposed project and its effects for the threatened Mexican spotted owl (owl) (*Strix occidentalis lucida*) was received by the U.S. Fish and Wildlife Service (Service) on February 22, 2006. The LANL has determined that proposed project "may affect, is likely to adversely affect" the owl.

You concluded that the Outfall Reduction Project may adversely affect the abundance and diversity of prey species along approximately 400 feet of perennial and intermittent stream by eliminating outfall discharges. It is our understanding that your determination is centered upon potential indirect impacts (eliminating outfalls may impact prey species habitat). We appreciate that you are taking a conservative approach for this project in your determination of "may affect likely to adversely affect" the owl. Nevertheless, we respectfully disagree with your conclusion for the following reasons: 1) the proposed elimination of an outfall is located within restricted habitat and will not directly affect owl; 2) nesting has not been documented in Mortandad-Sandia Canyon; 3) a perennial stream is present in the action area; 4) the closure of outfall 03A027 is not likely to have a substantial negative impact on the Sandia wetland; 5) outfall 03A130 contributes to a wetland that has no perennial streams or other outfalls; 6) reasonable and prudent alternatives would be implemented to reduce or avoid potential impacts; 7) effects from the proposed project are not expected to be adverse in the Canon de Valle Area of Environmental Interest (AEI); and 8) although 1.36 acres of wetland and 400 feet of perennial stream would be impacted in Mortandad-Sandia Canyon, we do not anticipate the owl or its prey will be adversely affected. For these reasons we conclude that, as described, the effects to the owl from the elimination of outfalls in Mortandad-Sandia Canyon will be insignificant and discountable, and will not result in adverse effects to the owl.

This concludes the informal consultation for the Outfall Reduction Project. Please contact the Service if: (1) new information reveals effects of the agency action that may affect the species to

Ms. Elizabeth R. Withers 2

an extent not considered in this consultation; (2) the agency action is subsequently modified in a manner that causes an effect to the species that was not considered by the proposed action, and (3) a new species is listed or critical habitat designated that may be affected by the proposed project.

We appreciate the thorough analyses provided in the letter and the BA and your efforts to protect endangered and threatened species. In future communications regarding this consultation please refer to consultation #22420-2006-I-0091. If we can be of further assistance, please contact Santiago R. Gonzales of my staff at (505) 761-4755.

Sincerely,

for Wally Murphy

Ms. Elizabeth R. Withers
ESA Program Manager
National Nuclear Security Administration
Los Alamos Site Office
Los Alamos, New Mexico 87544

Dear Ms. Withers:

Thank you for your February 22, 2006, biological assessment (BA) of the Continued Operation of Los Alamos National Laboratory on Federally Listed Threatened and Endangered Species – Security-Driven Transportation Modifications Project. The Los Alamos National Laboratory (LANL) proposes to upgrade and enhance security in the Pajarito Corridor West area. Construction of parking lots, pedestrian walkways, roads, and bridges associated with the proposed project would result in some temporary noise levels near new roads from construction equipment and activities and permanent increases in noise levels from vehicular and pedestrian traffic. There would be permanent light sources associated with the parking lots, walkways and roads. Your letter requesting consultation for the proposed project and its effects for the threatened Mexican spotted owl (owl) (*Strix occidentalis lucida*) was received by the U.S. Fish and Wildlife Service (Service) on February 22, 2006.

You concluded that the Security-Driven Transportation Modifications Project may adversely affect the owl foraging and nesting habitat. It is our understanding that your determination is centered upon potential indirect impacts (removal of approximately 20 acres of undeveloped habitat). We appreciate that you are taking a conservative approach for this project in your determination of "may affect likely to adversely affect" the owl. Nevertheless, we respectfully disagree with your conclusion for the following reasons: 1) the parking lot in TA-48 would be approximately 11 acres and would not be located in listed species habitat; 2) the parking lot at TA-63 would total approximately 20 acres and currently consists on open field and junipers and ponderosa pine woodland; and 3) reasonable and prudent alternatives would be implemented to reduce or avoid potential impacts. For these reasons we conclude that, as described, the effects to the owl from the construction activities associated with the proposed project will be insignificant and discountable, and will not result in adverse effects to the owl.

This concludes the informal consultation for the Security-Driven Transportation Modifications Project. Please contact the Service if: (1) new information reveals effects of the agency action that may affect the species to an extent not considered in this consultation; (2) the agency action is subsequently modified in a manner that causes an effect to the species that was not considered

Ms. Elizabeth R. Withers 2

by the proposed action, and (3) a new species is listed or critical habitat designated that may be affected by the proposed project.

We appreciate the thorough analyses provided in the letter and the BA and your efforts to protect endangered and threatened species. In future communications regarding this consultation please refer to consultation #22420-2006-I-0092. If we can be of further assistance, please contact Santiago R. Gonzales of my staff at (505) 761-4755.

Cons. # 22420-2006-I-0093

Ms. Elizabeth R. Withers
Document Site-wide EIS Manager
National Nuclear Security Administration
Los Alamos Site Office
Los Alamos, New Mexico 87544

Dear Ms. Withers:

Thank you for your February 22, 2006, biological assessment (BA) of the Continued Operation of Los Alamos National Laboratory on Federally Listed Threatened and Endangered Species – Security Transportation Modifications (Optional Actions) Project. The Los Alamos National Laboratory (LANL) proposes Option A: Paving Sigma Mesa Road with a bridge over Mortandad Canyon and Option B: Bridge Over Sandia Canyon. Your letter requesting formal consultation for the proposed options and their effects on the threatened Mexican spotted owl (owl) (*Strix occidentalis lucida*) was received by the U.S. Fish and Wildlife Service (Service) on February 22, 2006.

The BA describes two options: 1) Paving Sigma Mesa Road with a bridge over Mortandad Canyon and 2) a bridge over Sandia Canyon. However, the BA does not identify which alternative LANL has selected. The BA also does not identify a specific location of the bridge crossing, nor does it describe the design of the bridge over Mortandad Canyon or Sandia Canyon. The Service cannot analyze the affects of these two options because LANL has not selected the preferred alternative. When LANL determines, through a biological assessment or other review, which action will be proposed, LANL should submit to the Service a request for consultation. The BA should only analyze the effects of your preferred alternative, not both alternatives.

The Service recommends bridge placement over Sandia Canyon and not over Mortandad Canyon. We believe that a bridge placement over Sandia Canyon would avoid adverse affects to the owl, whereas a bridge over Motandad Canyon would be place directly over the area where resident owls have been located and could cause adverse affects to the owl. Please contact the Service when you decide on the bridge placement and timetable for implementation of the proposed bridge project.

We appreciate the analyses provided in the BA and your efforts to protect endangered and threatened species. In future communications regarding this consultation please refer to

Ms. Elizabeth R. Withers 2

consultation #22420-2006-I-0093. If we can be of further assistance, please contact Santiago R. Gonzales of my staff at (505) 761-4755.

CHAPTER 8
GLOSSARY

8.0 GLOSSARY

absorbed dose—For ionizing radiation, the energy imparted to matter by ionizing radiation per unit mass of the irradiated material (such as biological tissue). The units of absorbed dose are the rad and the gray. (See rad and gray.)

accident sequence—With regard to nuclear facilities, an initiating event followed by system failures or operator errors, which can result in significant core damage, confinement system failure, and/or radionuclide releases.

actinide—Any member of the group of elements with atomic numbers from 89 (actinium) to 103 (lawrencium) including uranium and plutonium. All members of this group are radioactive.

activation products—Nuclei, usually radioactive, formed by the bombardment and absorption in material with neutrons, protons, or other nuclear particles.

administrative control level—A dose level that is established well below the regulatory limit to administratively control and help reduce individual and collective radiation doses. Facility management should establish an annual facility administrative control level that should, to the extent feasible, be more restrictive than the more general administrative control level.

air pollutant—Generally, an airborne substance that could, in high enough concentrations, harm living things or cause damage to materials. From a regulatory perspective, an air pollutant is a substance for which emissions or atmospheric concentrations are regulated, or for which maximum guideline levels have been established because of potential harmful effects on human health and welfare.

air quality control region—Geographic subdivisions of the United States, designed to deal with pollution on a regional or local level. Some regions span more than one state.

alluvium—Sediment deposited by flowing water, as in a riverbed, flood plain, or delta.

alpha activity—The emission of alpha particles by radioactive materials.

alpha particle—A positively charged particle ejected spontaneously from the nuclei of some radioactive elements. It is identical to a helium nucleus and has a mass number of 4 and an electrostatic charge of +2. It has low penetrating power and a short range (a few centimeters in air). (See alpha radiation.)

alpha radiation—A strongly ionizing, but weakly penetrating, form of radiation consisting of positively charged alpha particles emitted spontaneously from the nuclei of certain elements during radioactive decay. Alpha radiation is the least penetrating of the three common types of ionizing radiation (alpha, beta, and gamma). Even the most energetic alpha particle generally fails to penetrate the dead layers of cells covering the skin and can be easily stopped by a sheet of paper. Alpha radiation is most hazardous when an alpha-emitting source resides inside an organism. (See alpha particle.)

ambient—Surrounding.

ambient air—The surrounding atmosphere as it exists around people, plants, and structures.

ambient air quality standards—The level of pollutants in the air prescribed by regulations that may not be exceeded during a specified time in a defined area. Air quality standards are used to provide a measure of the health-related and visual characteristics of the air.

analytical chemistry—The branch of chemistry that deals with the separation, identification, and determination of the components of a sample.

aquatic—Living or growing in, on, or near water.

aquifer—An underground geological formation, group of formations, or part of a formation that is capable of yielding a significant amount of water to wells or springs.

archaeological sites (resources)—Any location where humans have altered the terrain or discarded artifacts during either prehistoric or historic times.

Area of Concern (AOC)—Any area that may have had a release of a hazardous waste or hazardous constituent, which is not a Solid Waste Management Unit.

artifact—An object produced or shaped by human workmanship of archaeological or historical interest.

as low as is reasonably achievable (ALARA)—An approach to radiation protection to manage and control worker and public exposures (both individual and collective) and releases of radioactive material to the environment to as far below applicable limits as social, technical, economic, practical, and public policy considerations permit. ALARA is not a dose limit but a process for minimizing doses to as far below limits as is practicable.

atmospheric dispersion—The process of air pollutants being dispersed in the atmosphere. This occurs by the wind that carries the pollutants away from their source, by turbulent air motion that results from solar heating of the Earth's surface, and air movement over rough terrain and surfaces.

Atomic Energy Act—A law originally enacted in 1946 and replaced in 1954 that placed nuclear production and control of nuclear materials within a civilian agency, originally the Atomic Energy Commission. The functions of the Atomic Energy Commission were replaced by the U.S. Nuclear Regulatory Commission and the U.S. Department of Energy.

Atomic Energy Commission—A five-member commission, established by the Atomic Energy Act of 1946, to supervise nuclear weapons design, development, manufacturing, maintenance, modification, and dismantlement. In 1974, the Atomic Energy Commission was abolished, and all functions were transferred to the Nuclear Regulatory Commission and the Administrator of the Energy Research and Development Administration. The Energy Research and Development Administration was later terminated, and functions vested by law in the Administrator were transferred to the Secretary of Energy.

atomic number—The number of positively charged protons in the nucleus of an atom or the number of electrons on an electrically neutral atom.

attainment area—An area that the U.S. Environmental Protection Agency has designated as being in compliance with one or more of the National Ambient Air Quality Standards for sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and particulate matter. An area may be in attainment for some pollutants but not for others. (See National Ambient Air Quality Standards, nonattainment area, and particulate matter.)

attractiveness level—A categorization of nuclear material types and compositions that reflects the relative ease of processing and handling required to convert that material to a nuclear explosive device.

backfill—The replacement of excavated earth or other material into an open trench, cavity, or other opening in the earth.

background radiation—Radiation from (1) cosmic sources, (2) naturally occurring radioactive materials, including radon (except as a decay product of source or special nuclear material), and (3) global fallout as it exists in the environment (such as from the testing of nuclear explosive devices).

barrier—Any material or structure that prevents or substantially delays movement of pollutants or materials containing radionuclides toward the accessible environment.

basalt—The most common volcanic rock, dark gray to black in color, high in iron and magnesium and low in silica. It is typically found in lava flows.

baseline—The existing environmental conditions against which impacts of the Proposed Action and its alternatives can be compared. The environmental baseline is the site environmental conditions as they exist or are estimated to exist in the absence of the Proposed Action.

basin—Geologically, a circular or elliptical downwarp or depression in the Earth's surface that collects sediment. Younger sedimentary beds occur in the center of basins. Topographically, a depression into which water from the surrounding area drains.

becquerel—A unit of radioactivity equal to one disintegration per second. Thirty-seven billion becquerels is equal to 1 curie.

bedrock—The solid rock that lies beneath soil and other loose surface materials.

BEIR VII—Biological Effects of Ionizing Radiation; referring to the seventh in a series of committee reports from the National Research Council.

benthic—Plants and animals dwelling at the bottom of oceans, lakes, rivers, and other surface waters.

beryllium—An extremely light-weight element with the atomic number 4. It is metallic and is used in reactors as a neutron reflector.

best management practices—Structural, nonstructural, and managerial techniques, other than effluent limitations, to prevent or reduce pollution of surface water. They are the most effective and practical means to control pollutants that are compatible with the productive use of the resource to which they are applied. Best Management Practices are used in both urban and agricultural areas. Best Management Practices can include schedules of activities; prohibitions of practices; maintenance procedures; treatment requirements; operating procedures; and practices to control plant site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

beta particle—A particle emitted in the radioactive decay of many radionuclides. A beta particle is identical to an electron. It has a short range in air and a small ability to penetrate other materials.

biomimetic—Imitating, copying, or learning from nature.

biota (biotic)—The plant and animal life of a region (pertaining to biota).

block—U.S. Bureau of the Census term describing small areas bounded on all sides by visible features or political boundaries; used in tabulation of census data.

boron-10—An isotope of the element boron that has a high capture cross section for neutrons. It is used in reactor absorber rods for reactor control.

borrow—Excavated material that has been taken from one area to be used as raw material or fill at another location.

bound—To use simplifying assumptions and analytical methods in analyzing potential impacts or risks such that the result provides an overestimate or upper limit that "bounds" the potential impacts or risks.

bounded—Producing the greatest consequences of any assessment of impacts associated with normal or abnormal operations.

Breccia—Rock composed of sharp-angled fragments embedded in a fine-grained matrix.

burial ground—In regard to radioactive waste, a place for burying unwanted radioactive materials in which the earth acts as a receptacle to prevent the escape of radiation and the dispersion of waste into the environment.

cancer—The name given to a group of diseases characterized by uncontrolled cellular growth, with cells having invasive characteristics such that the disease can transfer from one organ to another.

canister—A general term for a container, usually cylindrical, used in handling, storage, transportation, or disposal of waste.

capable fault—A fault that has exhibited one or more of the following characteristics: (1) movement at or near the ground surface at least once within the past 35,000 years, or movement of a recurring nature within the past 500,000 years; (2) macro-seismicity instrumentally determined with records of sufficient precision to demonstrate a direct relationship with the fault; (3) a structural relationship to a capable fault according to characteristic (1) or (2) above, such that movement on one could be reasonably expected to be accompanied by movement on the other.

carbon dioxide—A colorless, odorless gas that is a normal component of ambient air; it results from fossil fuel combustion, and is an expiration product.

carbon monoxide—A colorless, odorless, poisonous gas produced by incomplete fossil fuel combustion.

carcinogen—An agent that may cause cancer. Ionizing radiation is a physical carcinogen; there are also chemical and biological carcinogens, and biological carcinogens may be external (such as viruses) or internal (such as genetic defects).

cask—A heavily shielded container used to store or ship radioactive materials.

categories of special nuclear material (Categories I, II, III, and IV)—A designation determined by the quantity and type of special nuclear material or a designation of a special nuclear material location based on the type and form of the material and the amount of nuclear material present. A designation of the significance of special nuclear material based upon the material type, form of the material, and amount of material present in an item, grouping of items, or in a location

cation—A positively charged ion.

cavate—Consists of a room carved into a cliff face within the Bandelier Tuff geological formation. The category includes isolated cavates, multi-roomed contiguous cavates, and groups of adjacent cavates that together form a cluster or complex.

cell—See hot cell.

chain reaction—A reaction that initiates its own repetition. In nuclear fission, a chain reaction occurs when a neutron induces a nucleus to fission and the fissioning nucleus releases one or more neutrons which induce other nuclei to fission.

chemical wastes—Defined as hazardous waste (designated under the Resource Conservation and Recovery Act regulations); toxic waste (asbestos and polychlorinated biphenyls, designated under the Toxic Substances Control Act); and special waste (designated under the New Mexico Solid Waste Regulations and including industrial waste, infectious waste, and petroleum contaminated soils). In the past, LANL tracking efforts for chemical waste included construction and demolition debris and all other non-radioactive waste that managed through the Solid Chemical and Radioactive Waste Facilities. For waste projections in this SWEIS, construction and demolition debris are presented as a separate categories.

classified information—(1) Information that has been determined pursuant to Executive Order 12958, any successor order, or the Atomic Energy Act of 1954 (42 U.S.C. 2011) to require protection against unauthorized disclosure; (2) certain information requiring protection against unauthorized disclosure in the interest of national defense and security or foreign relations of the United States pursuant to Federal statute or Executive Order.

clay—The name for a family of finely crystalline sheet silicate minerals that commonly form as a product of rock weathering. Also, any particle smaller than or equal to about 0.002 millimeters (0.00008 inches) in diameter.

Clean Air Act—This Act mandates and provides for enforcement of regulations to control air pollution from various sources.

Clean Water Act of 1972, 1987—This Act regulates the discharge of pollutants from a point source into navigable waters of the United States in compliance with a National Pollutant Discharge Elimination System permit, and regulates discharges to or dredging of wetlands.

***Code of Federal Regulations* (CFR)—**All Federal regulations in effect are published in codified form in the CFR. References to the CFR usually take the form of XX CFR Part YY, where XX refers to Title (major division) and YY refers to Part (section).

collective dose—The sum of the individual doses received in a given period of time by a specified population from exposure to a specified source of radiation. Collective dose is expressed in units of person-rem or person-sievert.

colluvium (colluvial)—A loose deposit of rock debris accumulated at the base of a cliff or slope.

committed dose equivalent—The dose equivalent to organs or tissues that will be received by an individual during the 50-year period following the intake of radioactive material. It does not include contributions from radiation sources external to the body. Committed dose equivalent is expressed in units of rems or sieverts.

committed effective dose equivalent—The dose value obtained by—(1) multiplying the committed dose equivalents for the organs or tissues that are irradiated and the weighting factors applicable to those organs or tissues, and (2) summing all the resulting products. Committed effective dose equivalent is expressed in units of rem or sievert. (See committed dose equivalent and weighting factor.)

community (biotic)—All plants and animals occupying a specific area under relatively similar conditions.

community (environmental justice definition)—A group of people or a site within a spatial scope exposed to risks that potentially threaten health, ecology, or land values; or are exposed to industry that stimulates unwanted noise, smell, industrial traffic, particulate matter, or other nonaesthetic impacts.

Compliance Order on Consent (Consent Order)—An enforcement document signed by the New Mexico Environment Department, the U.S. Department of Energy, and the Regents of the University of California on March 1, 2005, which prescribes the requirements for corrective action at Los Alamos National Laboratory. The purposes of the Consent Order are (1) to define the nature and extent of releases of contaminants at, or from, the facility; (2) to identify and evaluate, where needed, alternatives for corrective measures to clean up contaminants in the environment and prevent or mitigate the migration of contaminants at, or from, the facility; and (3) to implement such corrective measures. The Consent Order supersedes the corrective action requirements previously specified in Module VIII of the LANL Hazardous Waste Facility Permit.

conformity—Conformity is defined in the Clean Air Act as the action's compliance with an implementation plan's purpose of eliminating or reducing the severity and number of violations of the National Ambient Air Quality Standards, and achieving expeditious attainment of such standards; and that such activities will not: (1) cause or contribute to any new violation of any standard in any area; (2) increase the frequency or severity of any existing violation of any standard in any area; or (3) delay timely attainment of any standard or any required interim emission reduction, or other milestones in any area.

contact-handled waste—Radioactive waste or waste packages whose external dose rate is low enough to permit contact handling by humans during normal waste management activities, (such as waste with a surface dose rate not greater than 200 millirem per hour). (See remote-handled waste.)

container—With regard to radioactive wastes, the metal envelope in the waste package that provides the primary containment function of the waste package.

contamination—The deposition of undesirable radioactive material on the surfaces of structures, areas, objects, or personnel.

control rod—A rod containing material such as boron that is used to control the power of a nuclear reactor. By absorbing excess neutrons, a control rod prevents the neutrons from causing further fissions that would increase power generation.

coolant—A substance, either gas or liquid, circulated through a nuclear reactor or processing plant to remove heat.

criteria pollutants—An air pollutant that is regulated by National Ambient Air Quality Standards. The U.S. Environmental Protection Agency must describe the characteristics and potential health and welfare effects that form the basis for setting, or revising, the standard for each regulated pollutant. Criteria pollutants include sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter, less than or equal to 10 micrometers (0.0004 inch) in diameter, and less than or equal to 2.5 micrometers (0.0001 inch) in diameter. New pollutants may be added to, or removed from, the list of criteria pollutants as more information becomes available. (See National Ambient Air Quality Standards.)

critical assembly—A critical assembly is a system of fissile material (uranium-233, uranium-235, plutonium-239, or plutonium-241) with or without a moderator in a specific proportion and shape. The critical assembly can be gradually built up by adding additional fissile material and/or moderator until this system achieves the dimensions necessary for a criticality condition. A continuous neutron source is placed at the center of this assembly to measure the fission rate of the critical assembly as it approaches and reaches criticality.

critical habitat—Habitat essential to the conservation of an endangered or threatened species that has been designated as critical by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures outlined in the Endangered Species Act and its implementing regulations (50 CFR Part 424). The lists of Critical Habitats can be found in 50 CFR 17.95 (fish and wildlife), 50 CFR 17.96 (plants), and 50 CFR Part 226 (marine species). (See endangered species and threatened species.)

critical mass—The smallest mass of fissionable material that will support a self-sustaining nuclear chain reaction.

criticality—The condition in which a system is capable of sustaining a nuclear chain reaction.

cultural resources—Archaeological materials (artifacts) and sites that date to the prehistoric, historic, and ethnohistoric periods and that are currently located on the ground surface or buried beneath it; standing structures and/or their component parts that are over 50 years of age and are important because they represent a major historical theme or era, including the Manhattan Project and the Cold War era and structures that have an important technological, architectural, or local significance; cultural and natural places, select natural resources, and sacred objects that have importance for American Indians; American folklife traditions and arts; "historic properties" as defined in the National Historic Preservation Act; "archaeological resource" as defined in the Archaeological Resources Protection Act; and "cultural items" as defined in the Native American Graves Protection and Repatriation Act.

cumulative impacts—The impacts on the environment that result from the incremental impacts of the action when added to other past, present, and reasonably foreseeable future actions, regardless of the agency or person who undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7).

curie—A unit of radioactivity equal to 37 billion disintegrations per second (37 billion becquerels); also a quantity of any radionuclide or mixture of radionuclides having 1 curie of radioactivity.

deactivation—The placement of a facility in a radiologically and industrially safe shutdown condition that is suitable for a long-term surveillance and maintenance phase prior to final decontamination and decommissioning.

decay (radioactive)—The decrease in the amount of any radioactive material with the passage of time due to spontaneous nuclear disintegration (the emission from atomic nuclei of charged particles, photons, or both).

decibel (dB)—A unit for expressing the relative intensity of sounds on a logarithmic scale where 0 is below human perception and 130 is above the threshold of pain to humans. For traffic and industrial noise measurements, the A-weighted decibel, a frequency-weighted noise unit, is widely used. The A-weighted decibel scale corresponds approximately to the frequency response of the human ear and thus correlates well with loudness.

decibel, A-weighted (dBA)—A unit of frequency-weighted sound pressure level, measured by the use of a metering characteristic and the “A” weighting specified by the American National Standards Institution (ANSI S1.4-1983 [R1594]) that accounts for the frequency response of the human ear.

decommissioning—Retirement of a facility, including any necessary decontamination and dismantlement.

decontamination—The actions taken to reduce or remove substances that pose a substantial present or potential hazard to human health or the environment, such as radioactive or chemical contamination, from facilities, equipment, or soils by washing, heating, chemical or electrochemical action, mechanical cleaning, or other techniques.

decontamination, decommissioning, and demolition (DD&D) – actions taken at the end of the useful life of a building or structure to reduce or remove substances that pose a substantial hazard to human health or the environment, retire it from service, and ultimately eliminate all or a portion of the structure.

degrees C (degrees Celsius)—A unit for measuring temperature using the centigrade scale in which the freezing point of water is 0 degrees and the boiling point is 100 degrees.

degrees F (degrees Fahrenheit)—A unit for measuring temperature using the Fahrenheit scale in which the freezing point of water is 32 degrees and the boiling point is 212 degrees.

depleted uranium—Uranium whose content of the fissile isotope uranium-235 is less than the 0.7 percent (by weight) found in natural uranium, so that it contains more uranium-238 than natural uranium. (See enriched uranium, highly enriched uranium, natural uranium, low-enriched uranium, and uranium.)

deposition—In geology, the laying down of potential rock-forming materials; sedimentation. In atmospheric transport, the settling on ground and building surfaces of atmospheric aerosols and particles ("dry deposition") or their removal from the air to the ground by precipitation ("wet deposition" or "rainout").

design basis—For nuclear facilities, information that identifies the specific functions to be performed by a structure, system, or component, and the specific values (or ranges of values) chosen for controlling parameters for reference bounds for design. These values may be: (1) restraints derived from generally accepted state-of-the-art practices for achieving functional goals; (2) requirements derived from analysis (based on calculation and/or experiments) of the effects of a postulated accident for which a structure, system, or component must meet its functional goals; or (3) requirements derived from Federal safety objectives, principles, goals, or requirements.

dewatering—The removal of water. Saturated soils are "dewatered" to make construction of building foundations easier.

discharge—In surface water hydrology, the amount of water issuing from a spring or in a stream that passes a specific point in a given period of time.

disposition—The ultimate "fate" or end use of a surplus U.S. Department of Energy facility following the transfer of the facility to the Office of the Assistant Secretary for Environmental Management.

diversion—The unauthorized removal of nuclear material from its approved use or authorized location.

DOE Orders—Requirements internal to the U.S. Department of Energy (DOE) that establish DOE policy and procedures, including those for compliance with applicable laws.

dose (radiological)—A generic term meaning absorbed dose, dose equivalent, effective dose equivalent, committed dose equivalent, committed effective dose equivalent, or committed equivalent dose, as defined elsewhere in this glossary. It is a measure of the energy imparted to matter by ionizing radiation. The unit of dose is the rem or rad.

dose equivalent—A measure of radiological dose that correlates with biological effect on a common scale for all types of ionizing radiation. Defined as a quantity equal to the absorbed dose in tissue multiplied by a quality factor (the biological effectiveness of a given type of radiation) and all other necessary modifying factors at the location of interest. The units of dose equivalent are the rem and sievert.

dose rate—The radiation dose delivered per unit of time (such as rem per year).

dosimeter—A small device (instrument) carried by a radiation worker that measures cumulative radiation dose (such as a film badge or ionization chamber).

drinking water standards—The level of constituents or characteristics in a drinking water supply specified in regulations under the Safe Drinking Water Act as the maximum permissible.

ecology—A branch of science dealing with the interrelationships of living organisms with one another and with their nonliving environment.

ecosystem—A community of organisms and their physical environment interacting as an ecological unit.

effective dose equivalent—The dose value obtained by multiplying the dose equivalents received by specified tissues or organs of the body by the appropriate weighting factors applicable to the tissues or organs irradiated, and then summing all of the resulting products. It includes the dose from radiation sources internal and external to the body. The effective dose equivalent is expressed in units of rems or sieverts. (See committed dose equivalent and committed effective dose equivalent.)

effluent—A waste stream flowing into the atmosphere, surface water, groundwater, or soil. Most frequently the term applies to wastes discharged to surface waters.

electron—An elementary particle with a mass of 9.107×10^{-28} gram (or 1/1,837 of a proton) and a negative charge. Electrons surround the positively charged nucleus and determine the chemical properties of the atom.

emission—A material discharged into the atmosphere from a source operation or activity.

emission standards—Legally enforceable limits on the quantities and/or kinds of air contaminants that can be emitted into the atmosphere.

endangered species—Plants or animals that are in danger of extinction through all or a significant portion of their ranges and that have been listed as endangered by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures outlined in the Endangered Species Act and its implementing regulations (50 CFR Part 424). The lists of endangered species can be found in 50 CFR 17.11 for wildlife, 50 CFR 17.12 for plants, and 50 CFR 222.23(a) for marine organisms. (See threatened species.)

enriched uranium—Uranium whose content of the fissile isotope uranium-235 is greater than the 0.7 percent (by weight) found in natural uranium. (See depleted uranium, uranium, natural uranium, low-enriched uranium, and highly enriched uranium.)

Environment, Safety, and Health Program—In the context of the U.S. Department of Energy (DOE), encompasses those requirements, activities, and functions in the conduct of all DOE and DOE-controlled operations that are concerned with impacts to the biosphere; compliance with environmental laws, regulations, and standards controlling air, water, and soil pollution; limiting the risks to the well-being of both operating personnel and the general public; and protecting property against accidental loss and damage. Typical activities and functions related to this program include, but are not limited to, environmental protection, occupational safety, fire protection, industrial hygiene, health physics, occupational medicine, process and facility safety, nuclear safety, emergency preparedness, quality assurance, and radioactive and hazardous waste management.

environmental impact statement (EIS)—The detailed written statement required by the National Environmental Policy Act (NEPA) section 102(2)(C) for a proposed major Federal action significantly affecting the quality of the human environment. A U.S. Department of Energy (DOE) EIS is prepared in accordance with applicable requirements of the Council on Environmental Quality National Environmental Policy Act regulations in 40 CFR Parts 1500 to 1508 and DOE NEPA regulations in 10 CFR Part 1021. The statement includes, among other information, discussions of the environmental impacts of the Proposed Action and all reasonable alternatives, adverse environmental effects that cannot be avoided should the proposal be implemented, the relationship between short-term uses of the human environment and enhancement of long-term productivity, and any irreversible and irretrievable commitments of resources.

environmental justice—The fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including racial, ethnic, or socioeconomic groups, should bear a disproportionate share of the negative environmental consequences resulting from industrial, municipal, and commercial operations or the execution of Federal, state, local, and tribal programs and policies. Executive Order 12898 directs Federal agencies to make achieving environmental justice part of their missions by identifying and addressing disproportionately high and adverse effects of agency programs, policies, and activities on minority and low-income populations. (See minority population and low-income population.)

ephemeral stream—A stream that flows only after a period of heavy precipitation.

epidemiology—Study of the occurrence, causes, and distribution of disease or other health-related states and events in human populations, often as related to age, sex, occupation, ethnicity, and economic status, to identify and alleviate health problems and promote better health.

excavation—A cavity in the Earth's surface formed by cutting, digging, or scooping by excavating, such as with the use of heavy construction equipment.

exposure limit—The level of exposure to a hazardous chemical (set by law or a standard) at which or below which adverse human health effects are not expected to occur.

fault—A fracture or a zone of fractures within a rock formation along which vertical, horizontal, or transverse slippage has occurred. A normal fault occurs when the hanging wall has been depressed in relation to the footwall. A reverse fault occurs when the hanging wall has been raised in relation to the footwall.

fissile materials—An isotope that readily fissions after absorbing a neutron of any energy, either fast or slow. Fissile materials are uranium-235, uranium-233, plutonium-239, and plutonium-241. Uranium-235 is the only naturally occurring fissile isotope. Although sometimes used as a synonym for fissionable material, this term has acquired a more restricted meaning, namely, any material fissionable by thermal (slow) neutrons. The three primary fissile materials are uranium-233, uranium-235, and plutonium-239.

fission—The splitting of the nucleus of a heavy atom into two lighter nuclei. It is accompanied by the release of neutrons, gamma rays, and kinetic energy of fission products.

fission products—Nuclei (fission fragments) formed by the fission of heavy elements, plus the nuclides formed by the fission fragments' radioactive decay.

floodplain—The lowlands and relatively flat areas adjoining inland and coastal waters and the flood prone areas of offshore islands. Floodplains include, at a minimum, that area with at least a 1.0 percent chance of being inundated by a flood in any given year.

> The *base floodplain* is defined as the area that has a 1.0 percent or greater chance of being flooded in any given year. Such a flood is known as a 100-year flood.
>
> The *critical action floodplain* is defined as the area that has at least a 0.2 percent chance of being flooded in any given year. Such a flood is known as a 500-year flood. Any activity for which even a slight chance of flooding would be too great (such as storage of highly volatile, toxic, or water-reactive materials) should not occur in the critical action floodplain.
>
> The *probable maximum flood* is the hypothetical flood considered to be the most severe reasonably possible flood, based on the comprehensive hydrometeorological application of maximum precipitation and other hydrological factors favorable for maximum flood runoff (such as sequential storms and snowmelts). It is usually several times larger than the maximum recorded flood.

flux—Rate of flow through a unit area; in reactor operation, the apparent flow of neutrons in a defined energy range. (See neutron flux.)

formation—In geology, the primary unit of formal stratigraphic mapping or description. Most formations possess certain distinctive features.

fugitive emissions—(1) Emissions that do not pass through a stack, vent, chimney, or similar opening where they could be captured by a control device, or (2) any air pollutant emitted to the atmosphere other than from a stack. Sources of fugitive emissions include pumps; valves; flanges; seals; area sources such as ponds, lagoons, landfills, piles of stored material (such as coal); and road construction areas or other areas where earthwork is occurring.

gabions—Wire mesh boxes filled with rock used as a nonvegetative stabilization measure.

gamma radiation—High-energy, short wavelength, electromagnetic radiation emitted from the nucleus of an atom during radioactive decay. Gamma radiation frequently accompanies alpha and beta emissions and always accompanies fission. Gamma rays are very penetrating and are best stopped or shielded by dense materials, such as lead or depleted uranium. Gamma rays are similar to, but are usually more energetic than, x-rays.

genetic effects—Inheritable changes (chiefly mutations) produced by exposure to ionizing radiation or other chemical or physical agents of the parts of cells that control biological reproduction and inheritance.

genomics—The study of genes and their function.

geology—The science that deals with the Earth—the materials, processes, environments, and history of the planet, including rocks and their formation and structure.

glovebox—Large enclosure that separates workers from equipment used to process hazardous material, while allowing the workers to be in physical contact with the equipment; normally constructed of stainless steel, with large acrylic/lead glass windows. Workers have access to equipment through the use of heavy-duty, lead-impregnated rubber gloves, the cuffs of which are sealed in portholes in the glovebox windows.

graben—A usually elongated depression between geologic faults.

grading—Any stripping, cutting, filling, stockpiling, or combination thereof that modifies the land surface.

ground shine—The radiation dose received from an area on the ground where radioactivity has been deposited by a radioactive plume or cloud.

groundwater—Water below the ground surface in a zone of saturation.

habitat—The environment occupied by individuals of a particular species, population, or community.

half-life—The time in which one-half of the atoms of a particular radioactive isotope disintegrate to another nuclear form. Half-lives vary from millionths of a second to billions of years.

Hazard Index—The ratio of the potential exposure to a substance and the highest exposure level at which no adverse effects are expected. If the Hazard Index is calculated to be less than 1, then no adverse health effects are expected as a result of exposure. If the Hazard Index is greater than 1, then adverse health effects are possible.

hazardous air pollutants—Air pollutants not covered by ambient air quality standards but which may present a threat of adverse human health effects or adverse environmental effects. Those specifically listed in 40 CFR 61.01 are asbestos, benzene, beryllium, coke oven emissions, inorganic arsenic, mercury, radionuclides, and vinyl chloride. More broadly, hazardous air pollutants are any of the 189 pollutants listed in or pursuant to the Clean Air Act, Section 112(b). Very generally, hazardous air pollutants are any air pollutants that may realistically be expected to pose a threat to human health or welfare.

hazardous chemical—Under 29 CFR Part 1910 Subpart Z, hazardous chemicals are defined as “any chemical which is a physical hazard or a health hazard.” Physical hazards include combustible liquids, compressed gases, explosives, flammables, organic peroxides, oxidizers, pyrophorics, and reactives. A health hazard is any chemical for which there is good evidence that acute or chronic health effects occur in exposed employees. Hazardous chemicals include carcinogens, toxic or highly toxic agents, reproductive toxins, irritants, corrosives, sensitizers, hepatotoxins, nephrotoxins, agents that act on the hematopoietic system, and agents that damage the lungs, skin, eyes, or mucous membranes.

hazardous material—A material, including a hazardous substance, as defined by 49 CFR 171.8, that poses a risk to health, safety, and property when transported or handled.

hazardous waste—A category of waste regulated under the Resource Conservation and Recovery Act (RCRA). To be considered hazardous, a waste must be a solid waste under RCRA and must exhibit at least one of four characteristics described in 40 CFR 261.20-24 (ignitability, corrosivity, reactivity, or toxicity) or be specifically listed by the U.S. Environmental Protection Agency in 40 CFR 261.31-33.

hazards classification—The process of identifying the potential threat to human health of a chemical substance.

high-efficiency particulate air (HEPA) filter—An air filter capable of removing at least 99.97 percent of particles 0.3 micrometers (about 0.00001 inches) in diameter. High-efficiency particulate air filters include a pleated fibrous medium (typically fiberglass) capable of capturing very small particles.

high-level radioactive waste—High level waste is the highly radioactive waste material resulting from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing and any solid material derived from such liquid waste that contains fission products in sufficient concentrations; and other highly radioactive material that is determined, consistent with existing law, to require permanent isolation.

highly enriched uranium—Uranium whose content of the fissile isotope uranium-235 has been increased through enrichment to 20 percent or more (by weight). (See uranium, natural uranium, enriched uranium, highly enriched uranium, and depleted uranium.)

historic artifact scatter/trash scatter—A concentration of items produced and deposited after AD 1593 (but most typically in the Los Alamos area deposited after about AD 1900).

historic resources—Archaeological sites, architectural structures, and objects produced after the advent of written history, dating to the time of the first European-American contact in an area.

historic structure—A building or other structure constructed after AD 1593 (but most typically in the Los Alamos area constructed after about AD 1900).

Holocene—An epoch of the Quaternary period that began at the end of the Pleistocene, or the "Ice Age," about 10,000 years ago and continuing to the present. It is named from the Greek words "holos" (entire) and "ceno" (new).

hot cell—A shielded facility that requires the use of remote manipulators for handling radioactive materials.

hydrology—The science dealing with the properties, distribution, and circulation of natural water systems.

hydrophobic soils—Non-permeable soil areas created as a result of very high temperatures often associated with wild fires).

Idaho National Laboratory (INL)—Formerly the Idaho National Engineering and Environmental Laboratory and the Argonne National Laboratory-West, INL is a U.S. Department of Energy (DOE) laboratory complex located in southeast Idaho about 25 miles west of Idaho Falls, that is managed and operated by a private consortium under contract to DOE.

incident-free risk—The radiological or chemical impacts resulting from emissions during normal operations and packages aboard vehicles in normal transport. This includes the radiation or hazardous chemical exposure of specific population groups and workers.

injection wells—A well that takes water from the surface into the ground, either through gravity or by mechanical means.

ion—An atom that has too many or too few electrons, causing it to be electrically charged.

ion exchange—A unit physiochemical process that removes anions and cations, including radionuclides, from liquid streams (usually water) for the purpose of purification or decontamination.

ion exchange resin—An organic polymer that functions as an acid or base. These resins are used to remove ionic material from a solution. Cation exchange resins are used to remove positively charged particles (cations), and anion exchange resins are used to remove negatively charged particles (anions).

ionizing radiation—Alpha particles, beta particles, gamma rays, high-speed electrons, high-speed protons, and other particles or electromagnetic radiation that can displace electrons from atoms or molecules, thereby producing ions.

irradiated—Exposure to ionizing radiation. The condition of reactor fuel elements and other materials in which atoms bombarded with nuclear particles have undergone nuclear changes.

isolates—A population of bacteria or other cells that has been isolated.

isotope—Any of two or more variations of an element in which the nuclei have the same number of protons (and thus the same atomic number), but different numbers of neutrons so that their atomic masses differ. Isotopes of a single element possess almost identical chemical properties, but often different physical properties (for example, carbon-12 and -13 are stable; carbon-14 is radioactive).

joule—A metric unit of energy, work, or heat, equivalent to one watt-second, 0.737 foot-pound, or 0.239 calories.

landscape character—The arrangement of a particular landscape as formed by the variety and intensity of the landscape features (land, water, vegetation, and structures) and the four basic elements (form, line, color, and texture). These factors give an area a distinctive quality that distinguishes it from its immediate surroundings.

latent cancer fatalities (LCFs)—Deaths from cancer occurring some time after, and postulated to be due to, exposure to ionizing radiation or other carcinogens.

lithic scatter—The description of rocks on the basis of such characteristics as color, mineralogic composition, and grain size.

loam—Soil material that is composed of 7 percent to 27 percent clay particles, 28 percent to 50 percent silt particles, and less than 52 percent sand particles.

long-lived radionuclides—Radioactive isotopes with half-lives greater than 30 years.

long-term impact—In general, an impact that endures beyond the timeframe of the action or activity that causes the impact.

low-income population—Low-income populations, defined in terms of Bureau of the Census annual statistical poverty levels (Current Population Reports, Series P-60 on Income and Poverty), may consist of groups or individuals who live in geographic proximity to one another or who are geographically dispersed or transient (such as migrant workers or American Indians), where either group experiences common conditions of environmental exposure or effect. (See environmental justice and minority population.)

low-level radioactive waste—Waste that contains radioactivity but is not classified as high-level waste, transuranic waste, spent nuclear fuel, or byproduct material as defined by Section 11e (2) of the Atomic Energy Act of 1954, as amended. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level radioactive waste, provided the concentration of transuranic waste is less than 100 nanocuries per gram.

material access area—A type of security area that is authorized to contain a security Category I quantity of special nuclear material and which has specifically defined physical barriers, is located within a Protected Area, and is subject to specific access controls.

material characterization—The measurement of basic material properties, and the change in those properties as a function of temperature, pressure, or other factors.

material control and accountability—The part of safeguards that detects or deters theft or diversion of nuclear materials and provides assurance that all nuclear materials are accounted for appropriately.

material disposal area (MDA)—An area used any time between the beginning of Los Alamos National Laboratory operations in the early 1940s and the present for disposing of chemically, radioactively, or chemically and radioactively contaminated materials.

maximally exposed individual (MEI)—A hypothetical individual whose location and habits result in the highest total radiological or chemical exposure (and thus dose) from a particular source for all exposure routes (inhalation, ingestion, direct exposure).

maximally exposed individual (transportation analysis)—A hypothetical individual receiving radiation doses from transporting radioactive materials on the road. For the incident-free transport operation, the maximally exposed individual would be an individual stuck in traffic next to the shipment for 30 minutes. For accident conditions, the maximally exposed individual is assumed to be an individual located approximately 33 meters (100 feet) directly downwind from the accident.

maximum contaminant level—The designation for U.S. Environmental Protection Agency standards for drinking water quality under the Safe Drinking Water Act. The maximum contaminant level for a given substance is the maximum permissible concentration of that substance in water delivered by a public water system. The primary maximum contaminant levels (40 CFR Part 141) are intended to protect public health and are federally enforceable. They are based on health factors, but are also required by law to reflect the technological and economic feasibility of removing the contaminant from the water supply. Secondary maximum contaminant levels (40 CFR Part 143) are set by the U.S. Environmental Protection Agency to protect the public welfare. The secondary drinking water regulations control substances in drinking water that primarily affect aesthetic qualities (such as taste, odor, and color) relating to the public acceptance of water. These regulations are not federally enforceable, but are intended as guidelines for the states.

megawatt—A unit of power equal to 1 million watts. Megawatt thermal is commonly used to define heat produced, while megawatt-electric defines electricity produced.

metabolomics—The study of the small molecules, or metabolites, contained in a human cell, tissue or organ (including fluids) and involved in primary and intermediary metabolism.

MeV (million electron volts)—A unit used to quantify energy. In this SWEIS, it describes a particle's kinetic energy, which is an indicator of particle speed.

micron—One-millionth of 1 meter.

migration—The natural movement of a material through the air, soil, or groundwater; also, seasonal movement of animals from one area to another.

Migratory Bird Treaty Act—This Act states that it is unlawful to pursue, take, attempt to take, capture, possess, or kill any migratory bird, or any part, nest, or egg of any such bird other than permitted activities.

millirem—One-thousandth of 1 rem.

minority population—Minority populations exist where either: (a) the minority population of the affected area exceeds 50 percent, or (b) the minority population percentage of the affected area is meaningfully greater than in the general population or other appropriate unit of geographic analysis (such as a governing body's jurisdiction, a neighborhood, census tract, or other similar unit). "Minority" refers to individuals who are members of the following population groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic. "Minority populations" include either a single minority group or the total of all minority persons in the affected area. They may consist of groups of individuals living in geographic proximity to one another or a geographically dispersed/transient set of individuals (such as migrant workers or American Indians), where either group experiences common conditions of environmental exposure or effect. (See environmental justice and low-income population.)

mitigate—Mitigation includes: (1) avoiding an impact altogether by not taking a certain action or parts of an action; (2) minimizing impacts by limiting the degree or magnitude of an action and its implementation; (3) rectifying an impact by repairing, rehabilitating, or restoring the affected environment; (4) reducing or eliminating the impact over time by preservation and maintenance operations during the life of an action; or (5) compensating for an impact by replacing or providing substitute resources or environments.

mixed waste—Waste that contains both nonradioactive hazardous waste and radioactive waste, as defined in this glossary.

National Ambient Air Quality Standards—Standards defining the highest allowable levels of certain pollutants in the ambient air (the outdoor air to which the public has access). Because the U.S. Environmental Protection Agency must establish the criteria for setting these standards, the regulated pollutants are called *criteria* pollutants. Criteria pollutants include sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter (less than or equal to 10 micrometers [0.0004 inches] in diameter and less than or equal to 2.5 micrometers [0.0001 inches] in diameter). Primary standards are established to protect public health; secondary standards are established to protect public welfare (such as visibility, crops, animals, buildings). (See criteria pollutant.)

National Emission Standards for Hazardous Air Pollutants—Emissions standards set by the U.S. Environmental Protection Agency for air pollutants which are not covered by National Ambient Air Quality Standards and which may, at sufficiently high levels, cause increased fatalities, irreversible health effects, or incapacitating illness. These standards are given in 40 CFR Parts 61 and 63. National Emission Standards for Hazardous Air Pollutants are given for many specific categories of sources (such as equipment leaks, industrial process cooling towers, dry cleaning facilities, petroleum refineries). (See hazardous air pollutants.)

National Environmental Policy Act (NEPA) of 1969—This Act is the basic national charter for protection of the environment. It establishes policy, sets goals (Section 101), and provides means (Section 102) for carrying out policy. Section 102(2) contains "action-forcing" provisions to ensure that Federal agencies follow the letter and spirit of the act. For major Federal actions significantly affecting the quality of the human environment, Section 102(2)(C) of the National Environmental Policy Act requires Federal agencies to prepare a detailed statement that includes the environmental impacts of the Proposed Action and other specified information.

National Historic Preservation Act—This Act provides that property resources with significant national historic value be placed on the National Register of Historic Places. It does not require any permits, but pursuant to Federal code, if a Proposed Action might impact a historic property resource, it mandates consultation with the proper agencies.

National Pollutant Discharge Elimination System—A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by the U.S. Environmental Protection Agency, a state, or, where delegated, a tribal government on an Indian reservation. The National Pollutant Discharge Elimination System permit lists either permissible discharges, the level of cleanup technology required for wastewater, or both.

National Register of Historic Places—The official list of the Nation's cultural resources that are worthy of preservation. The National Park Service maintains the list under direction of the Secretary of the Interior. Buildings, structures, objects, sites, and districts are included in the National Register for their importance in American history, architecture, archaeology, culture, or engineering. Properties included on the National Register range from large-scale, monumentally proportioned buildings to smaller-scale, regionally distinctive buildings. The listed properties are not just of nationwide importance; most are significant primarily at the state or local level. Procedures for listing properties on the National Register are found in 36 CFR Part 60.

natural phenomena accidents—Accidents that are initiated by phenomena such as earthquakes, tornadoes, floods, etc.

natural uranium—Uranium with the naturally occurring distribution of uranium isotopes (approximately 0.7-weight percent uranium-235, and the remainder essentially uranium-238). (See uranium, depleted uranium, enriched uranium, highly enriched uranium, and low-enriched uranium.)

neptunium-237—A manmade element, with the atomic number 93. Pure neptunium is a silvery metal. The neptunium-237 isotope has a half-life of 2.14 million years. When neptunium-237 is bombarded by neutrons, it is transformed to neptunium-238, which in turn undergoes radioactive decay to become plutonium-238. When neptunium-237 undergoes radioactive decay, it emits alpha particles and gamma rays.

neutron—An uncharged elementary particle with a mass slightly greater than that of the proton. Neutrons are found in the nucleus of every atom heavier than hydrogen-1.

neutron flux—The product of neutron number density and velocity (energy), giving an apparent number of neutrons flowing through a unit area per unit time.

nitrogen—A natural element with the atomic number 7. It is diatomic in nature and is a colorless and odorless gas that constitutes about four-fifths of the volume of the atmosphere.

nitrogen oxides—Refers to the oxides of nitrogen, primarily nitrogen oxide and nitrogen dioxide. These are produced in the combustion of fossil fuels and can constitute an air pollution problem. Nitrogen dioxide emissions contribute to acid deposition and formation of atmospheric ozone.

noise—Undesirable sound that interferes or interacts negatively with the human or natural environment. Noise may disrupt normal activities (hearing, sleep), damage hearing, or diminish the quality of the environment.

noise pollution—Any sound that is undesirable because it interferes with speech and hearing, or is intense enough to damage hearing, or is otherwise annoying or undesirable.

nonattainment area—An area that the U.S. Environmental Protection Agency has designated as not meeting (not being in attainment of) one or more of the National Ambient Air Quality Standards for sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and particulate matter. An area may be in attainment for some pollutants, but not for others. (See attainment area, National Ambient Air Quality Standards, and particulate matter.)

non-nuclear aboveground experimentation—Aboveground experimentation or testing in support of nuclear weapons programs that does not involve detonation of a nuclear explosive.

nonproliferation—Preventing the spread of nuclear weapons, nuclear weapon materials, and nuclear weapon technology.

normal operations—All normal (incident-free) conditions and those abnormal conditions that frequency estimation techniques indicate occur with a frequency greater than 0.1 events per year.

Notice of Intent (NOI)—Public announcement that an environmental impact statement will be prepared and considered. It describes the Proposed Action, possible alternatives, and scoping process, including whether, when, and where any scoping meetings will be held. The NOI is usually published in the *Federal Register* and local media. The scoping process includes holding at least one public meeting and requesting written comments on issues and environmental concerns that an environmental impact statement should address.

nuclear criticality—See criticality.

nuclear explosive—Any assembly containing fissionable and/or fusionable materials and main-charge high-explosive parts or propellants capable of producing a nuclear detonation.

nuclear facility—A facility that is subject to requirements intended to control potential nuclear hazards. Defined in U.S. Department of Energy directives as any nuclear reactor or any other facility whose operations involve radioactive materials in such form and quantity that a significant nuclear hazard potentially exists to the employees or the general public.

nuclear material—Composite term applied to—(1) special nuclear material; (2) source material such as uranium or thorium or ores containing uranium or thorium; and (3) byproduct material, which is any radioactive material that is made radioactive by exposure to the radiation incident to the process of producing or using special nuclear material.

nuclear reactor—A device that sustains a controlled nuclear fission chain reaction that releases energy in the form of heat.

Nuclear Regulatory Commission (NRC)—The Federal agency that regulates the civilian nuclear power industry in the United States.

nuclear weapon—The general name given to any weapon in which the explosion results from the energy released by reactions involving atomic nuclei, either fission, fusion, or both.

nuclear weapons complex—The sites supporting the research, development, design, manufacture, testing, assessment, certification, and maintenance of the Nation's nuclear weapons and the subsequent dismantlement of retired weapons.

nuclide—A species of atom characterized by the constitution of its nucleus and hence by the number of protons, the number of neutrons, and the energy content.

Oak Ridge National Laboratory (ORNL)—A U.S. Department of Energy (DOE) laboratory complex located in eastern Tennessee about 25 miles west of Knoxville, that is managed and operated by a private consortium under contract to DOE.

Occupational Safety and Health Administration—The U.S. Federal Government agency that oversees and regulates workplace health and safety; created by the Occupational Safety and Health Act of 1970.

offsite—The term denotes a location, facility, or activity occurring outside the site boundary.

One- to three-room structure/fieldhouse—The remains of a small surface structure constructed of adobe, jacal, or masonry. This site typically consists of square to rectangular-shaped rock alignments, with individual units being no more than 3 m in length. The majority of these sites are identical to what many researchers term fieldhouses. Also included in the one- to three-room structure category is one example of a single unusually large rectangular structure, along with several smallish structures that are unusual due to the presence of upright stones or because of their location. Some of these "unusual" structures may represent shrines or other purposes not directly related to agriculture.

onsite—The term denotes a location or activity occurring within the boundary of a DOE complex site.

oralloy—Introduced in early Los Alamos documents to mean enriched uranium (Oak Ridge alloy); now uncommon except to signify highly enriched uranium.

outfall—The discharge point of a drain, sewer, or pipe as it empties into the environment.

ozone—The triatomic form of oxygen; in the stratosphere, ozone protects the Earth from the sun's ultraviolet rays, but in lower levels of the atmosphere, ozone is considered an air pollutant.

package—For radioactive materials, the packaging, together with its radioactive contents, as presented for transport (the packaging plus the radioactive contents equals the package).

packaging—With regard to hazardous or radionuclide materials, the assembly of components necessary to ensure compliance with Federal regulations. It may consist of one or more receptacles, absorbent materials, spacing structures, thermal insulation, radiation shielding, and devices for cooling or absorbing mechanical shocks. The vehicle tie-down system and auxiliary equipment may be designated as part of the packaging.

paleontological resources—The physical remains, impressions, or traces of plants or animals from a former geologic age; may be sources of information on ancient environments and the evolutionary development of plants and animals.

particulate matter (PM)—Any finely divided solid or liquid material, other than uncombined (pure) water. A subscript denotes the upper limit of the diameter of particles included. Thus, PM_{10} includes only those particles equal to or less than 10 micrometers (0.0004 inches) in diameter; $PM_{2.5}$ includes only those particles equal to or less than 2.5 micrometers (0.0001 inches) in diameter.

perennial stream—A stream that flows throughout the year.

permeability—In geology, the ability of rock or soil to transmit a fluid.

person-rem—A unit of collective radiation dose applied to populations or groups of individuals; that is, a unit for expressing the dose when summed across all persons in a specified population or group. One person-rem equals 0.01 person-sieverts. (See collective dose.)

Perimeter Intrusion Detection and Assessment System (PIDAS)—A mutually supporting combination of barriers, clear zones, lighting, and electronic intrusion detection, assessment, and access control systems constituting the perimeter of the Protected Area and designed to detect, impede, control, or deny access to the Protected Area.

pit—The central core of a primary assembly in a nuclear weapon typically composed of plutonium-239 and/or highly-enriched uranium and other materials.

Plaza Pueblo—Contains one or more pueblo roomblocks that partially or completely enclose a plaza. Plaza pueblos typically are much larger (in both room numbers and site size) than single pueblo roomblock sites.

Pleistocene—The geologic time period of the earliest epoch of the Quaternary period, spanning between about 1.6 million years ago and the beginning of the Holocene epoch at 10,000 years ago. It is characterized by the succession of northern glaciations and also called the "Ice Age."

plume—The elongated volume of contaminated water or air originating at a pollutant source such as an outlet pipe or a smokestack. A plume eventually diffuses into a larger volume of less contaminated material as it is transported away from the source.

plutonium—A heavy, radioactive, metallic element with the atomic number 94. It is produced artificially by neutron bombardment of uranium. Plutonium has 15 isotopes with atomic masses ranging from 232 to 246 and half-lives from 20 minutes to 76 million years.

plutonium-238—An isotope with a half-life of 87.74 years used as the heat source for radioisotope power systems. When plutonium-238 undergoes radioactive decay, it emits alpha particles and gamma rays. Plutonium-238 may fission if exposed to neutrons. The likelihood of plutonium-238 undergoing fission is dependent upon many factors including the number and energy of neutrons, temperature, plutonium-238 purity and shape, and the presence and proximity of other elements.

plutonium-239—An isotope with a half-life of 24,110 years that is the primary radionuclide in weapons-grade plutonium. When plutonium-239 decays, it emits alpha particles. Plutonium-239 may fission if exposed to neutrons. The likelihood of plutonium-239 undergoing fission is dependent upon many factors including the number and energy of neutrons, temperature, plutonium-239 purity and shape, and the presence and proximity of other elements.

population dose—See collective dose.

potential release site (PRS)—A site suspected of releasing or having the potential to release contaminants (radioactive, chemical, or both) into the environment. PRS is a generic term that includes solid waste management units and areas of concern that are cited and defined in the Compliance Order on Consent (Consent Order).

pounds per square inch—A measure of pressure; atmospheric pressure is about 14.7 pounds per square inch.

prehistoric resources—The physical remains of human activities that predate written records; they generally consist of artifacts that may alone or collectively yield otherwise inaccessible information about the past.

Prevention of Significant Deterioration—Regulations established to prevent significant deterioration of air quality in areas that already meet National Ambient Air Quality Standards. Specific details of Prevention of Significant Deterioration are found in 40 CFR 51.166. Among other provisions, cumulative increases in sulfur dioxide, nitrogen dioxide, and PM_{10} levels after specified baseline dates must not exceed specified maximum allowable amounts. These allowable increases, also known as increments, are especially stringent in areas designated as Class I areas (such as national parks, wilderness areas) where the preservation of clean air is particularly important. All areas not designated as Class I are currently designated as Class II. Maximum increments in pollutant levels are also given in 40 CFR 51.166 for Class III areas, if any such areas should be so designated by EPA. Class III increments are less stringent than those for Class I or Class II areas. (See National Ambient Air Quality Standards.)

prime farmland—Land that has the best combination of physical and chemical characteristics for producing food, feed, fiber, forage, oil-seed, and other agricultural crops with minimum inputs of fuel, fertilizer, pesticides, and labor, without intolerable soil erosion, as determined by the Secretary of Agriculture (Farmland Protection Act of 1981, 7 CFR Part 7, paragraph 658).

probabilistic risk assessment—A comprehensive, logical, and structured methodology that accounts for population dynamics and human activity patterns at various levels of sophistication, considering time-space distributions and sensitive subpopulations. The probabilistic method results in a more complete characterization of the exposure information available, which is defined by probability distribution functions. This approach offers the possibility of an associated quantitative measure of the uncertainty around the value of interest.

process—Any method or technique designed to change the physical or chemical character of the product.

protactinium—An element that is produced by the radioactive decay of neptunium-237. The pure metal has a bright metallic luster. The protactinium-233 isotope has a half-life of 27 days and emits beta particles and gamma rays during radioactive decay.

Protected Area—A type of security area defined by physical barriers (walls or fences), to which access is controlled, used for protection of security Category II special nuclear materials and classified matter and/or to provide a concentric security zone surrounding a Material Access Area (security Category I nuclear materials) or a Vital Area.

Proteomics—The analysis of the expression, localizations, functions, and interactions of the proteins expressed by the genetic material of an organism.

proton—An elementary nuclear particle with a positive charge equal in magnitude to the negative charge of the electron; it is a constituent of all atomic nuclei, and the atomic number of an element indicates the number of protons in the nucleus of each atom of that element.

Pueblo roomblock—The remains of a contiguous, multi-room habitation structure (four or more rooms with no enclosed plaza) constructed of adobe, jacal, or masonry. In several cases, somewhat amorphous mounds containing evidence of stone rubble but no distinct alignments were included in this category.

Quaternary—The second geologic time period of the Cenozoic era, dating from about 1.6 million years ago to the present. It contains two epochs: the Pleistocene and the Holocene. It is characterized by the first appearance of human beings on Earth.

rad—See radiation absorbed dose.

radiation (ionizing)—See ionizing radiation.

radiation absorbed dose (rad)—The basic unit of absorbed dose equal to the absorption of 0.01 joules per kilogram (100 ergs per gram) of absorbing material.

radioactive waste—In general, waste that is managed for its radioactive content. Waste material that contains source, special nuclear, or byproduct material is subject to regulation as radioactive waste under the Atomic Energy Act. Also, waste material that contains accelerator-produced radioactive material or a high concentration of naturally occurring radioactive material may be considered radioactive waste.

radioactivity—

Defined as a *process*: The spontaneous transformation of unstable atomic nuclei, usually accompanied by the emission of ionizing radiation.

Defined as a *property*: The property of unstable nuclei in certain atoms to spontaneously emit ionizing radiation during nuclear transformations.

radioisotope or radionuclide—An unstable isotope that undergoes spontaneous transformation, emitting radiation. (See isotope.)

radioisotope power system—Any one of a number of technologies used in spacecraft and in national security technologies that produces heat or electricity from the radioactive decay of suitable radioactive substances such as plutonium-238. They are typically used in applications such as to enable the operation of instruments and sensors where energy sources such as solar power are undesirable or impractical due to the remoteness or extreme conditions of the operating environment.

radioisotope thermoelectric generator (RTG)—An electrical generator that derives its electric power from heat produced by the decay of radioactive strontium-90, plutonium-238, or other suitable isotopes. The heat generated is directly converted into electricity, in a passive process, by an array of thermocouples.

radon—A gaseous, radioactive element with the atomic number 86, resulting from the radioactive decay of radium. Radon occurs naturally in the environment and can collect in unventilated enclosed areas, such as basements. Large concentrations of radon can cause lung cancer in humans.

RADTRAN—A computer code combining user-determined meteorological, demographic, transportation, packaging, and material factors with health physics data to calculate the expected radiological consequences and accident risk of transporting radioactive material.

reactor facility—Unless it is modified by words such as containment, vessel, or core, the term "reactor facility" includes the housing, equipment, and associated areas devoted to the operation and maintenance of one or more reactor cores. Any apparatus that is designed or used to sustain nuclear chain reactions in a controlled manner, including critical and pulsed assemblies and research, test, and power reactors, is defined as a reactor. All assemblies designed to perform subcritical experiments that could potentially reach criticality are also considered reactors.

Record of Decision (ROD)—A document prepared in accordance with the requirements of 40 CFR 1505.2 and 10 CFR 1021.315 that provides a concise public record of the U.S. Department of Energy's (DOE) decision on a Proposed Action for which an environmental impact statement was prepared. A ROD identifies the alternatives considered in reaching the decision; the environmentally preferable alternative; factors balanced by DOE in making the decision; and whether all practicable means to avoid or minimize environmental harm have been adopted, and, if not, the reason why they were not.

reference dose—The chronic-exposure dose (milligram or kilogram per day) for a given hazardous chemical at which or below which adverse human noncancer health effects are not expected to occur.

region of influence (ROI)—A site-specific geographic area in which the principal direct and indirect effects of actions are likely to occur.

rem (roentgen equivalent man)—A unit of dose equivalent. The dose equivalent in rem equals the absorbed dose in rad in tissue multiplied by the appropriate quality factor and possibly other modifying factors. Derived from "roentgen equivalent man," referring to the dosage of ionizing radiation that will cause the same biological effect as one roentgen of x-ray or gamma-ray exposure. One rem equals 0.01 sieverts. (See absorbed dose and dose equivalent.)

remediation—The process, or a phase in the process, of rendering radioactive, hazardous, or mixed waste environmentally safe, whether through processing, entombment, or other methods.

remote-handled waste—In general, refers to radioactive waste that must be handled at a distance to protect workers from unnecessary exposure (waste with a dose rate of 200 millirem per hour or more at the surface of the waste package). (See contact-handled waste.)

resin—See ion exchange resin.

Resource Conservation and Recovery Act (RCRA), as amended—A law that gives the U.S. Environmental Protection Agency the authority to control hazardous waste from "cradle to grave" (from the point of generation to the point of ultimate disposal), including its minimization, generation, transportation, treatment, storage, and disposal. The Resource Conservation and Recovery Act also sets forth a framework for the management of nonhazardous solid wastes. (See hazardous waste.)

riparian—Of, on, or relating to the banks of a natural course of water.

risk—The probability of a detrimental effect of exposure to a hazard. Risk is often expressed quantitatively as the probability of an adverse event occurring multiplied by the consequence of that event (in other words, the product of these two factors). However, separate presentation of probability and consequence is often more informative.

risk assessment (chemical or radiological)—The qualitative and quantitative evaluation performed in an effort to define the risk posed to human health and/or the environment by the presence or potential presence and/or use of specific chemical or radiological materials.

rock shelter—An overhang, indentation, or alcove formed naturally in a rock face or large boulder, or alternatively, a partly enclosed area created by rock falls leaning against a rock face or large boulder, and which exhibits evidence of human use. Rock shelters generally are not of great depth, in contrast to caves.

roentgen—A unit of exposure to ionizing x- or gamma radiation equal to or producing one electrostatic unit of charge per cubic centimeter of air.

runoff—The portion of rainfall, melted snow, or irrigation water that flows across the ground surface, and eventually enters streams.

Safe Drinking Water Act—This Act protects the quality of public water supplies, water supply and distribution systems, and all sources of drinking water.

safeguards—An integrated system of physical protection, material accounting, and material control measures designed to deter, prevent, detect, and respond to unauthorized access, possession, use, or sabotage of nuclear materials.

Safety Analysis Report—A report that systematically identifies potential hazards within a nuclear facility, describes and analyzes the adequacy of measures to eliminate or control identified hazards, and analyzes potential accidents and their associated risks. Safety analysis reports are used to ensure that a nuclear facility can be constructed, operated, maintained, shut down, and decommissioned safely and in compliance with applicable laws and regulations. Safety analysis reports are required for U.S. Department of Energy nuclear facilities and as a part of applications for U.S. Nuclear Regulatory Commission licenses. The U.S. Nuclear Regulatory Commission regulations or DOE Orders and technical standards that apply to the facility type provide specific requirements for the content of safety analysis reports. (See nuclear facility.)

sand—Loose grains of rock or mineral sediment formed by weathering that range in size from 0.0625 to 2.0 millimeters (0.0025 to 0.08 inches) in diameter, and often consists of quartz particles.

sandstone—A sedimentary rock composed mostly of sand-size particles cemented usually by calcite, silica, or iron oxide.

sanitary waste—Wastes generated by normal housekeeping activities, liquid or solid (includes sludge), that are not hazardous or radioactive.

Savannah River Site (SRS)—A U.S. Department of Energy (DOE) industrial complex located in southwestern South Carolina about 20 miles southeast of Augusta, Georgia, that is managed and operated by a private consortium under contract to DOE.

scope—In a document prepared pursuant to the National Environmental Policy Act of 1969, the range of actions, alternatives, and impacts to be considered.

scoping—An early and open process, including public notice and involvement, for determining the scope of issues to be addressed in an environmental impact statement (EIS) and for identifying the significant issues related to a Proposed Action. The scoping period begins after publication in the *Federal Register* of a Notice of Intent to prepare an EIS. The public scoping process is that portion of the process where the public is invited to participate. The U.S. Department of Energy’s scoping procedures are found in 10 CFR 1021.311.

security—An integrated system of activities, systems, programs, facilities, and policies for the protection of Restricted Data and other classified information or matter, nuclear materials, nuclear weapons and nuclear weapons components, and/or U.S. Department of Energy or contractor facilities, property, and equipment.

sediment—Soil, sand, and minerals washed from land into water that deposit on the bottom of a water body.

seismic—Pertaining to any Earth vibration, especially an earthquake.

seismicity—The frequency and distribution of earthquakes.

select agent—A select agent is defined as an agent, virus, bacteria, fungi, rickettsiae or toxin listed in Appendix A of *Federal Register* 29327 (42 CFR Part 72) titled, *Additional Requirements for Facilities Transferring or Receiving Select Agents*. Select Agents also includes (a) genetically modified micro-organisms or (b) genetic elements that contain nucleic acid sequences associated with pathogenicity from organisms listed in Appendix A, (c) genetically modified micro-organisms listed in Appendix A, and (d) genetically modified micro-organisms or genetic elements that contain nucleic acid sequences coding for any of the toxins in Appendix A, or their toxic subunits.

severe accident—An accident with a frequency rate of less than 10^{-6} per year that would have more severe consequences than a design-basis accident, in terms of damage to the facility, offsite consequences, or both. Also called a beyond-design-basis accident.

sewage—The total organic waste and wastewater generated by an industrial establishment or a community.

shielding—With regard to radiation, any material of obstruction (bulkheads, walls, or other construction) that absorbs radiation to protect personnel or equipment.

short-lived nuclides—Radioactive isotopes with half-lives no greater than about 30 years (such as cesium-137 and strontium-90).

short-term impact—In general, an impact that occurs during or for a short time after the action or activity that causes the impact.

silt—A sedimentary material consisting of fine mineral particles, intermediate in size between sand and clay. In general, soils categorized as silt show greater rates of erosion than soils categorized as sand.

soils—All unconsolidated materials above bedrock. Natural earthy materials on the Earth's surface, in places modified or even made by human activity, containing living matter, and supporting or capable of supporting plants out of doors.

solid waste management unit (SWMU)—Any discernible unit at which solid waste has been placed at any time, and from which the New Mexico Environment Department determines there may be a risk of a release of hazardous waste or hazardous waste constituents, irrespective of whether the unit was intended for the management of solid or hazardous waste. Such units include any area at the Facility (LANL) at which solid wastes have been routinely and systematically released; they do not include one-time spills. See 61 FR 19431 (May 1, 1996).

somatic effect—Any effect that may manifest in the body of the exposed individual over his or her lifetime.

source material—Depleted uranium, normal uranium, thorium, or any other nuclear material determined, pursuant to Section 61 of the Atomic Energy Act of 1954, as amended, to be source material, or ores containing one or more of the foregoing materials in such concentration as may be determined by regulation.

source term—The amount of a specific pollutant (chemicals, radionuclides) emitted or discharged to a particular environmental medium (air, water, earth) from a source or group of sources. It is usually expressed as a rate (amount per unit time).

spallation—A nuclear reaction in which the energy of the incident particle is so high that more than two or three particles are ejected from the target nucleus, and both its mass number and atomic number are changed.

special nuclear material(s)—A category of material subject to regulation under the Atomic Energy Act, consisting primarily of fissile materials. It is defined to mean plutonium, uranium-233, uranium enriched in the isotopes of uranium-233 or -235, and any other material that the Nuclear Regulatory Commission determines to be special nuclear material, but it does not include source material.

spectral characteristics—The natural property of a structure as it relates to the multidimensional temporal accelerations.

staging—The process of using several layers to achieve a combined effect greater than that of one layer.

stockpile—The inventory of active nuclear weapons for the strategic defense of the United States.

stockpile stewardship program—A program that ensures the operational readiness (safety and reliability) of the U.S. nuclear weapons stockpile by the appropriate balance of surveillance, experiments, and simulations.

straw wattles—Tubes of rice straw used for erosion control, sediment control and stormwater runoff control.

sulfur oxides—Common air pollutants (primarily sulfur dioxide), a heavy, pungent, colorless gas (formed in the combustion of fossil fuels, considered a major air pollutant) and sulfur trioxide. Sulfur dioxide is involved in the formation of acid rain. It can also irritate the upper respiratory tract and cause lung damage.

supernatant—The liquid that stands over a precipitated material.

surface water—All bodies of water on the surface of the Earth and open to the atmosphere, such as rivers, lakes, reservoirs, ponds, seas, and estuaries.

target—A tube, rod, or other form containing material that, on being irradiated in a nuclear reactor or an accelerator, would produce a desired end product.

technical area (TA)—Geographically distinct administrative units established for the control of LANL operations. There are currently 49 active TAs; 47 in the 41 square miles of the LANL site, one at Fenton Hill, west of the main site, and one comprising leased properties in town.

tectonic—Of or relating to motion in the Earth's crust and occurring on geologic faults.

Tertiary—The first geologic time period of the Cenozoic era (after the Mesozoic era and before the Quaternary period), spanning between about 66 million and 1.6 million years ago. During this period, mammals became the dominant life form on Earth.

threatened species—Any plants or animals that are likely to become endangered species within the foreseeable future throughout all or a significant portion of their ranges and which have been listed as threatened by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures set out in the Endangered Species Act and its implementing regulations (50 CFR Part 424). (See endangered species.)

threshold limit values—The recommended highest concentrations of contaminants to which workers may be exposed according to the American Conference of Governmental Industrial Hygienists.

total effective dose equivalent—The sum of the effective dose equivalent from external exposures and the committed effective dose equivalent from internal exposures.

Toxic Substances Control Act of 1976—This Act authorizes the U.S. Environmental Protection Agency (EPA) to secure information on all new and existing chemical substances and to control any substances determined to cause an unreasonable risk to public health or the environment. This law requires that the health and environmental effects of all new chemicals be reviewed by the EPA before they are manufactured for commercial purposes.

transmutation—The transformation of one isotope into another isotope by changing its nuclear structure. It can occur naturally through radioactive decay, or the fission and neutron capture processes can be hastened by using nuclear reactors or particle accelerators. By converting long-lived hazards into materials that are, or soon will be, sable and harmless, the nuclear cycle is effectively complete.

transuranic—Refers to any element whose atomic number is higher than that of uranium (atomic number 92), including neptunium, plutonium, americium, and curium. All transuranic elements are produced artificially and are radioactive.

transuranic waste—Radioactive waste containing more than 100 nanocuries (3,700 becquerels) of alpha-emitting transuranic isotopes per gram of waste, with half-lives greater than 20 years, except for: (1) high-level radioactive waste; (2) waste that the Secretary of Energy has determined, with the concurrence of the Administrator of the Environmental Protection Agency, does not need the degree of isolation required by the 40 CFR Part 191 disposal regulations; of (3) waste that the U.S. Nuclear Regulatory Commission has approved for disposal on a case-by-case basis in accordance with 10 CFR Part 61 (DOE 435.1).

tuff—A fine-grained rock composed of ash or other material formed by volcanic explosion or aerial expulsion from a volcanic vent.

Type B packaging—A regulatory category of packaging for transportation of radioactive material. The U.S. Department of Transportation and U.S. Nuclear Regulatory Commission require Type B packaging for shipping highly radioactive material. Type B packages must be designed and demonstrated to retain their containment and shielding integrity under severe accident conditions, as well as under the normal conditions of transport. The current U.S. Nuclear Regulatory Commission testing criteria for Type B package designs (10 CFR Part 71) are intended to simulate severe accident conditions, including impact, puncture, fire, and immersion in water. The most widely recognized Type B packages are the massive casks used for transporting spent nuclear fuel. Large-capacity cranes and mechanical lifting equipment are usually needed to handle Type B packages.

Type B shipping cask—A U.S. Nuclear Regulatory Commission-certified cask with a protective covering that contains and shields radioactive materials, dissipates heat, prevents damage to the contents, and prevents criticality during normal shipment and accident conditions. It is used for transport of highly radioactive materials and is tested under severe, hypothetical accident conditions that demonstrate resistance to impact, puncture, fire, and submersion in water.

unconfomably—Refers to a break or gap in the geological time of deposited materials.

uranium—A radioactive, metallic element with the atomic number 92; one of the heaviest naturally occurring elements. Uranium has 14 known isotopes, of which uranium-238 is the most abundant in nature. Uranium-235 is commonly used as a fuel for nuclear fission. (See natural uranium, enriched uranium, highly enriched uranium, and depleted uranium.)

Vadose zone—The portion of Earth between the land surface and the water table.

vault (special nuclear material)—A penetration-resistant, windowless enclosure having an intrusion alarm system activated by opening the door and which also has—walls, floor, and ceiling substantially constructed of materials that afford forced-penetration resistance at least equivalent to that of 20-centimeter- (8-inch-) thick reinforced concrete; and a built-in combination-locked steel door, which for existing structures is at least 2.54-centimeters (1-inch) thick exclusive of bolt work and locking devices, and which for new structures meets standards set forth in Federal specifications and standards.

viewshed—The extent of an area that may be viewed from a particular location. Viewsheds are generally bounded by topographic features such as hills or mountains.

volatile organic compounds—A broad range of organic compounds, often halogenated, that vaporize at ambient or relatively low temperatures, such as benzene, chloroform, and methyl alcohol. With regard to air pollution, any organic compound that participates in atmospheric photochemical reaction, except for those designated by the U.S. Environmental Protection Agency Administrator as having negligible photochemical reactivity.

waste acceptance criteria—The requirements specifying the characteristics of waste and waste packaging acceptable to a disposal facility, and the documents and processes the generator needs to certify that the waste meets applicable requirements.

waste classification—Wastes are classified according to DOE Order 435.1, Radioactive Waste Management, and include high-level, transuranic, and low-level wastes.

Waste Isolation Pilot Plant (WIPP)—A U.S. Department of Energy facility designed and authorized to permanently dispose of defense-related transuranic waste in a mined underground facility in deep geologic salt beds. It is located in southeastern New Mexico, 42 kilometers (26 miles) east of the city of Carlsbad.

waste management—The planning, coordination, and direction of those functions related to generation, handling, treatment, storage, transportation, and disposal of waste, as well as associated surveillance and maintenance activities.

waste minimization and pollution prevention—An action that economically avoids or reduces the generation of waste and pollution by source reduction, reducing the toxicity of hazardous waste and pollution, improving energy use, or recycling. These actions will be consistent with the general goal of minimizing present and future threats to human health, safety, and the environment.

water table—The boundary between the unsaturated zone and the deeper, saturated zone. The upper surface of an unconfined aquifer.

watt—A unit of power equal to 1 joule per second. (See joule.)

wetland—Wetlands are "... those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas" (33 CFR 328.3).

whole-body dose—In regard to radiation, dose resulting from the uniform exposure of all organs and tissues in a human body. (See effective dose equivalent.)

wind rose—A circular diagram showing, for a specific location, the percentage of the time the wind is from each compass direction. A wind rose for use in assessing consequences of airborne releases also shows the frequency of different wind speeds for each compass direction.

yield—The force in tons of TNT of a nuclear or thermonuclear explosion.

CHAPTER 10
LIST OF PREPARERS

10.0 LIST OF PREPARERS

ELIZABETH WITHERS, U.S. DEPARTMENT OF ENERGY, NATIONAL NUCLEAR SECURITY ADMINISTRATION (NEPA COMPLIANCE OFFICER, NNSA SERVICE CENTER)
EIS RESPONSIBILITIES: EIS DOCUMENT MANAGER, CHAPTER 1

Education: M.S., Life Sciences, Louisiana Tech University
B.S., Botany, Louisiana Tech University

Experience/Technical Specialty:
Twenty-four years. Environmental investigations and NEPA compliance.

KIRK OWENS, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: PROJECT MANAGER

Education: B.S., Environmental Resource Management, The Pennsylvania State University

Experience/Technical Specialty:
Twenty-six years. Radioactive waste management, regulatory, and environmental compliance and assessment, radiological assessment.

STEPHEN R. ALCORN, TIME SOLUTIONS CORP.
EIS RESPONSIBILITIES: GROUNDWATER, GEOCHEMISTRY, EVAPOTRANSPIRATIVE COVERS

Education: Ph.D., Geology, University of Georgia
M.S., Geology, University of South Carolina
A.B., Geology, Lafayette College

Experience/Technical Specialty:
Twenty-seven years. Geology and geochemistry, transport behavior of radionuclides, geochemical and hydrological modeling and analysis, performance assessment, environmental compliance.

KAREN ANTIZZO, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: PROJECT-SPECIFIC ANALYSES

Education: M.S., Technology/Environmental Management, University of Maryland
B.S., Education, Towson University

Experience/Technical Specialty:
Sixteen years. Infrastructure, radioactive waste management, regulatory review, public participation.

TERRI L. BINDER, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: APPENDIX C, RADIOLOGICAL AIR EMISSIONS AND HUMAN HEALTH

Education: M.A., Organizational Learning and Instructional Technology
B.A., Mathematics

Experience/Technical Specialty:
Fifteen years. Radiological facility site-specific training, DOE compliance, computer programming.

KENNETH F. BRINSTER, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: GROUNDWATER

Education: M.S., Geology, University of North Dakota
B.S., Biology and Education, Dickinson State University

Experience/Technical Specialty:
Twenty-eight years. Professional Geologist, Minnesota. Geology, hydrology, groundwater modeling, air permitting, solid and hazardous waste management, stormwater permitting, pollution prevention.

STEVEN P. CONNER, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: GEOLOGY AND SOILS

Education: Ph.D., Geology, Texas A&M University
M.S., Geology, Texas A&M University
B.S. Geology, University of Delaware

Experience/Technical Specialty:
Seventeen years. Professional Geologist, South Carolina and Alabama. Environmental studies, risk assessment, earth resources and geologic characterization, contaminant fate and transport.

RICHARD D. CUNNINGHAM, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: APPENDIX J LEAD, PROJECT-SPECIFIC ANALYSES

Education: M.U.R.P., Urban and Regional Planning, University of Pittsburgh
Graduate Diploma in Social Science, Political Science, University of Stockholm
B.A., Political Science and History, Fairfield University

Experience/Technical Specialty:
Thirty-four years. NEPA, ES&H, environmental policy and regulations, facilities planning, land use, cultural resources, transportation.

M. J. DAVIS, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: WASTE MANAGEMENT

Education: J.D., Law, Georgetown University
B.S., Nuclear Engineering, University of Cincinnati

Experience/Technical Specialty:
Twenty-one years. Regulatory compliance and legal analysis, specializing in environmental protection.

ELLEN R. DIETRICH, SCIENCE APPLICATIONS INTERNATIONAL CORP.
EIS RESPONSIBILITIES: SUMMARY, WATER RESOURCES

Education: B.A., Anthropology, University of Illinois
Graduate school programs in Archaeology and Soil Science, The Pennsylvania State University

Experience/Technical Specialty:
Thirty years. Soil science, NEPA, soil and water resource planning and management.

JOHN DIMARZIO, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: CUMULATIVE IMPACTS

Education: M.S., Geology, George Washington University
B.S., Geology, University of Maryland

Experience/Technical Specialty:
Twenty-three years. NEPA compliance, geology, water resources, waste management, and cumulative impacts.

JOHN EICHNER, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: CHAPTER 5 MANAGER, SOCIOECONOMICS

Education: B.S., Accounting, Syracuse University
B.S., Finance, Syracuse University

Experience/Technical Specialty:
Twenty-six years. Project management, impact analysis, socioeconomics, cost-benefit analyses.

SUSAN ENGELKE, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: APPENDIX G, PROJECT-SPECIFIC ANALYSES

Education: B.S., Environmental Science/Geology, University of California at Sacramento

Experience/Technical Specialty:
Four years. Environmental analyst on NEPA/CEQA documents.

SANDRA B. ENYEART, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: APPENDIX G LEAD, CUMULATIVE IMPACTS, PROJECT-SPECIFIC ANALYSES

Education: B.S., Civil Engineering, Georgia Institute of Technology
B.F.A., Art, Idaho State University

Experience/Technical Specialty:
Thirty-one years. Professional Engineer (Civil Engineer), Idaho. NEPA analysis, cumulative impacts, safety analyses, environmental monitoring, water resources management and impact analysis.

BETH FARRELL HALE, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: PUBLIC AFFAIRS LEAD, EMERGENCY MANAGEMENT

Education: B.A., Liberal Arts, University of New Mexico

Experience/Technical Specialty:
Seventeen years. Public affairs, public involvement, and risk communication.
Fifteen years. Emergency management.

DEBBIE J. FINFROCK, TIME SOLUTIONS CORP.
EIS RESPONSIBILITIES: WATER RESOURCES

Education: M.S., Civil Engineering (Environmental Emphasis), University of New Mexico
B.S., Mechanical Engineering, University of Kentucky

Experience/Technical Specialty:
Twenty-four years. Professional Engineer, New Mexico. Waste management and pollution prevention, water resources management, landfill closure design and modeling.

KEVIN T. FOLK, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: INFRASTRUCTURE, PROJECT-SPECIFIC ANALYSES

Education: M.S., Environmental Biology, Hood College
B.A., Geoenvironmental Studies, Shippensburg University

Experience/Technical Specialty:
Seventeen years. Water resources management, utility infrastructure analysis, NPDES permitting and regulatory analysis, earth resources and geologic hazards assessment.

STEVE GEIGER, URS CORPORATION

EIS RESPONSIBILITIES: SCIENCE COMPLEX AND WAREHOUSE FACILITY PROJECT-SPECIFIC ANALYSES (WASTE AND WATER RESOURCES)

Education: Ph.D., Environmental/Agricultural Engineering, The Colorado State University
B.S., M.S. Civil Engineering, The University of New Mexico

Experience/Technical Specialty:

Sixteen years. Professional Engineer, New Mexico. Civil engineering, hydrology, and environmental engineering design, risk management, remediation, compliance, project management.

MILTON E. GORDEN, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION

EIS RESPONSIBILITIES: APPENDIX H CO-LEAD, PROJECT-SPECIFIC ANALYSES

Education: B.S., Nuclear Engineering, North Carolina State University

Experience/Technical Specialty:

Sixteen years. Engineer-in-training (Georgia). Waste management, transportation, human health impacts, socioeconomics, environmental remediation technologies.

TENA A. GRABEN, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION

EIS RESPONSIBILITIES: MATERIAL DISPOSAL AREAS CHARACTERIZATION AND HAZARD ASSESSMENT

Education: B.S., Professional Biology, University of North Alabama

Experience/Technical Specialty:

Twenty years. Applied health physics, occupational and environmental radiological hazards assessment and dose modeling, regulatory compliance, emergency management.

KATIE A. GRASTY, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION

EIS RESPONSIBILITIES: GENERAL SUPPORT

Education: M.E.M., Conservation Science and Policy, Duke University
B.S., Geography, Radford University

Experience/Technical Specialty:

Two years. Environmental law and compliance, ecosystem and natural resource science.

CHADI D. GROOME, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: DEPUTY PROJECT MANAGER, CHAPTER 3 MANAGER

Education: M.S., Environmental Engineering Sciences, University of Florida
B.S., Zoology, Clemson University

Experience/Technical Specialty:
Twenty-six years. Environmental and nuclear regulatory compliance, permitting, and licensing, NPDES permitting, radioactive and hazardous waste management.

CATHY G. HAUPT, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: CHAPTER 6 MANAGER

Education: M.S., Science Education (Biology), Clarion University
B.S., Secondary Education (Geography/Environmental Science), Clarion State College

Experience/Technical Specialty:
Twenty-five years. Regulatory compliance, technical research, quality control.

ROBERT G. HOFFMAN, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: APPENDIX H CO-LEAD, PROJECT-SPECIFIC ANALYSES

Education: B.S., Environmental Resource Management, The Pennsylvania State University

Experience/Technical Specialty:
Twenty years. NEPA compliance, regulatory review, land use planning.

ROBERT W. HULL, LOS ALAMOS TECHNICAL ASSOCIATES, INCORPORATED
EIS RESPONSIBILITIES: ENVIRONMENTAL REMIDIATION DATA AND ACCIDENT ANALYSIS

Education: M.S., Civil Engineering (focus Environmental Engineering), Stanford University
M.S., Geochemistry and Environmental Geology, Florida State University
B.S., Geology, Florida State University

Experience/Technical Specialty:
Thirty-five years. Environmental impacts assessments, environmental baseline surveys, human health risk assessment, environmental remediation.

JAMES D. JAMISON, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: HUMAN HEALTH IMPACTS, SPECIAL PATHWAYS ASSESSMENTS

Education: B.A., Physics, Doane College

Experience/Technical Specialty:
Thirty-six years. Certified Health Physicist. Occupational and environmental radiation safety, accident analysis, assessment of impacts from release of radioactive materials and toxic chemicals.

CHARLES M. JOHNSON, JR., SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: MATERIAL DISPOSAL AREAS CHARACTERIZATION AND HAZARD ASSESSMENT

Education: M.S., Chemistry, Western Carolina University
B.S., Geology, Western Carolina University

Experience/Technical Specialty:
Twenty-two years. Radiochemistry, radiochemical data analysis, validation, and interpretation, site characterization.

CANDI L. JONES, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: BIOLOGICAL SCIENCES

Education: B.S., Cell and Molecular Biology, Minor, Chemistry, University of Montana

Experience/Technical Specialty:
Nine years. Biochemistry, biological warfare and biological warfare agents, risk assessments, biological containment, threat analysis.

ROY KARIMI, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: PROJECT ENGINEER, TRANSPORTATION AND RISK ASSESSMENT

Education: Sc.D., Nuclear Engineering, Massachusetts Institute of Technology
N.E., Nuclear Engineering, Massachusetts Institute of Technology
M.S., Nuclear Engineering, Massachusetts Institute of Technology
B.Sc., Chemical Engineering, Abadan Institute of Technology

Experience/Technical Specialty:
Twenty-nine years. Nuclear power plant safety, risk and reliability analysis, design analysis, criticality analysis, accident analysis, consequence analysis, spent fuel dry storage safety analysis, probabilistic risk assessments.

JULIE KUTZ, URS CORPORATION
EIS RESPONSIBILITIES: SCIENCE COMPLEX AND WAREHOUSE FACILITY PROJECT-SPECIFIC ANALYSES (BIOLOGICAL RESOURCES, FLOODPLAINS AND WETLANDS, VISUAL RESOURCES, AND SOCIOECONOMICS)

Education: B.S., Biology, University of New Mexico

Experience/Technical Specialty:
Six years. Environmental and natural resources.

DALE LYONS, URS CORPORATION

EIS RESPONSIBILITIES: SCIENCE COMPLEX AND WAREHOUSE FACILITY PROJECT-SPECIFIC ANALYSES (SOILS, HUMAN HEALTH, TRANSPORTATION, AND GENERAL ENVIRONMENTAL RESOURCE CONSIDERATIONS)

Education: M.S., Soil Chemistry and Land Rehabilitation, The Montana State University
B.S., Soils and Environmental Science, The Montana State University

Experience/Technical Specialty:
Fourteen years. Environmental consulting, scientific research, and project management.

JASPER G. MALTESE, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION

EIS RESPONSIBILITIES: ACCIDENT ANALYSIS, RADIOLOGICAL AND CHEMICAL IMPACTS

Education: M.S., Operations Research, George Washington University
B.S., Mathematics, Fairleigh Dickinson University

Experience/Technical Specialty:
Forty-two years. NEPA assessments, accident analyses, safety analysis report reviews, facility safety audits, system reliability analyses.

GREGORY F. MARTIN, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION

EIS RESPONSIBILITIES: HUMAN HEALTH IMPACTS, SPECIAL PATHWAYS ASSESSMENTS

Education: M.S., Radiological Physics, San Diego State University
B.S., Physics, San Diego State University

Experience/Technical Specialty:
Twenty-four years. Hazards assessment, accident analysis, environmental transport of hazardous materials, and assessment of human impacts.

PAUL MINK, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION

EIS RESPONSIBILITIES: MATERIAL DISPOSAL AREAS CHARACTERIZATION AND HAZARD ASSESSMENT

Education: M.S., Nuclear (Radiological) Engineering (coursework completed, thesis in progress), University of Tennessee
B.S., Industrial Engineering, University of Tennessee

Experience/Technical Specialty:
Thirteen years. Health physics, evaluation of survey data and radiological engineering analysis.

STEVEN M. MIRSKY, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: HUMAN HEALTH LEAD, APPENDIX D LEAD, ACCIDENT ANALYSIS

Education: M.S., Nuclear Engineering, The Pennsylvania State University
B.S., Mechanical Engineering, Cooper Union

Experience/Technical Special:
Thirty years. Professional Engineer (Mechanical) Maryland. Safety analysis, nuclear powerplant design, operations, foreign nuclear powerplant system analysis, accident analysis, thermal hydraulics, shielding and dose assessment, spent nuclear fuel dry storage safety analysis.

STEVEN E. MIXON, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: TECHNICAL EDITOR

Education: B.S., Communications, University of Tennessee

Experience/Technical Specialty:
Eighteen years. Program analyst, technical writer and editor, speechwriter, publications specialist.

SHEA NELSON, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: GENERAL SUPPORT, QUALITY ASSURANCE

Education: M.E., Environmental Engineering, University of Maryland
B.A., Environmental Science, University of Virginia

Experience/Technical Specialty:
Six years. Regulatory compliance, environmental remediation, technical writing, quality assurance/quality control.

ARIS PAPADOPOULOS, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: WORKER AND PUBLIC HEALTH AND SAFETY

Education: M.S., Nuclear Engineering, University of Utah
B.S., Physics, Hamline University

Experience/Technical Specialty:
Thirty-seven years. NEPA compliance, nuclear facilities regulatory compliance, radiological risk analysis, health physics, radioactive waste management.

WILDA E. PORTNER, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: PUBLIC INVOLVEMENT, TECHNICAL EDITOR

Education: A.A., Business Administration, Frederick Community College

Experience/Technical Specialty:
Sixteen years. Public information, Tribal relations, technical writing and editing.

JEFFREY J. RIKHOFF, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: DEPUTY PROJECT MANAGER, CHAPTER 2, ENVIRONMENTAL JUSTICE

Education: M.R.P., Regional/Environmental Planning, University of Pennsylvania
M.S., International Economic Development and Appropriate Technology, University of Pennsylvania
B.A., English, DePauw University

Experience/Technical Specialty:
Nineteen years. NEPA compliance, regulatory compliance and permitting, socioeconomics, environmental justice, comprehensive land-use and development planning, cultural resources.

JOSEPH F. ROBBINS, U.S. DEPARTMENT OF ENERGY, NATIONAL NUCLEAR SECURITY ADMINISTRATION (NEPA COMPLIANCE OFFICER, ALBUQUERQUE SERVICE CENTER)
EIS RESPONSIBILITIES: DOCUMENT REVIEW

Education: B.S., Biology, University of Maine
Graduate Studies, University of Massachusetts and Utah State University

Experience/Technical Specialty:
Thirty-one years. Environmental investigations, NEPA compliance.

NESETARI A. ROBINSON, SCIENCE APPLICATION INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: ENVIRONMENTAL DATA ANALYSES

Education: B.S., Chemical Engineer, University of Maryland Baltimore County

Experience/Technical Specialty:
Nine months. Engineer-in-training (Maryland). Technical writer and compiling data into graphs and charts.

GARY W. ROLES, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: MATERIAL DISPOSAL AREA REMEDIATION, CANYON CLEANUPS, AND OTHER COMPLIANCE ORDER ACTIONS LEAD

Education: M.S., Nuclear Engineering, University of Arizona
B.S., Mechanical Engineering, Arizona State University

Experience/Technical Speciality:
Twenty-eight years. Radioactive waste management; regulatory and compliance analysis.

THOMAS L. RUCKER, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: MATERIAL DISPOSAL AREAS CHARACTERIZATION AND HAZARD ASSESSMENT

Education: Ph.D., Analytical Chemistry, Health Physics Minor, University of Tennessee
M.S., Environmental Chemistry, University of Tennessee
B.S., Chemistry, David Lipscomb University

Experience/Technical Specialty:
Thirty-three years. Analytical chemistry, radiochemistry, radiological monitoring, dose and risk assessment, and environmental and waste characterization.

PETER C. SANFORD, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: PROJECT-SPECIFIC ANALYSES, DD&D AND CONSTRUCTION PARAMETER ESTIMATES

Education: M.S., Metallurgical Engineering, Colorado School of Mines
B.S.E., Chemical Engineering/Material Science, University of Connecticut

Experience/Technical Specialty:
Twenty-six years. Project management, actinide recovery and processing, health physics, decontamination and decommissioning, waste management, and environmental compliance.

JAMES R. SCHINNER, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: CHAPTER 4 MANAGER, LAND, VISUAL, ECOLOGICAL, AND CULTURAL RESOURCES

Education: Ph.D., Wildlife Management, Michigan State University
M.S., Zoology, University of Cincinnati
B.S., Zoology, University of Cincinnati

Experience/Technical Specialty:
Thirty-three years. Ecological field assessments, NEPA documentation, regulatory reviews.

JENNIFER C. SMITH, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: PAST PERFORMANCE AND DESCRIPTION OF ALTERNATIVES

Education: M.S., Natural Resources and Environment, University of Michigan
B.A., Environmental Studies, University of Vermont

Experience/Technical Specialty:
Two years. Environmental education and public awareness, risk communication.

MARY ALICE SPIVEY, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: LAWS AND REGULATIONS

Education: B.S., Environmental Science, Florida Institute of Technology

Experience/Technical Specialty:
Twenty-three years. Regulatory analysis and compliance, waste management, NEPA compliance.

ELLEN TAYLOR, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: CHAPTER 5, PROJECT-SPECIFIC ANALYSES

Education: Ph.D., Biology, University of Pennsylvania
B.A., Zoology, University of Vermont

Experience/Technical Specialty:
Twenty-four years. Environmental compliance and NEPA assessments.

ALAN L. TOBLIN, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: ACCIDENT ANALYSIS, RADIOLOGICAL AND CHEMICAL IMPACTS

Education: M.S., Chemical Engineering, University of Maryland
B.E., Chemical Engineering, Cooper Union

Experience/Technical Specialty:
Thirty-five years. Contaminant transport through air, groundwater, and surface water, accident risk analysis.

TOBY WALTERS, URS CORPORATION
EIS RESPONSIBILITIES: SCIENCE COMPLEX AND WAREHOUSE FACILITY PROJECT-SPECIFIC ANALYSES (GEOLOGIC AND ENVIRONMENTAL RESOURCES)

Education: M.S., Water Resources Management, The University of New Mexico
B.S., Geology, The University of New Mexico

Experience/Technical Specialty:
Twenty-six years. Environmental consulting and project management.

ROBERT H. WERTH, SCIENCE APPLICATIONS INTERNATIONAL CORPORATION
EIS RESPONSIBILITIES: NOISE ANALYSIS, AIR QUALITY MODELING

Education: B.A., Physics, Gordon College

Experience/Technical Specialty:
Thirty years. Acoustics and air quality analysis, regulatory reviews, and NEPA documentation.

JACK YOUNG, URS CORPORATION

EIS RESPONSIBILITIES: SCIENCE COMPLEX AND WAREHOUSE FACILITY PROJECT-SPECIFIC ANALYSES (ARCHAEOLOGICAL DATA ANALYSIS)

Education: M.A., Archaeological Survey and Cultural Resource Planning, Durham
B.A., History, The University of New Mexico

Experience/Technical Specialty:

Nine years. Cultural resource management and planning throughout the greater Southwestern USA and Britain; New Mexico State Land Use Permit for Archaeology 2005 NM-05-187; 2005 Laboratory of Anthropology curation agreement and ARMS user agreement.

CHAPTER 11
DISTRIBUTION LIST

11. DISTRIBUTION LIST

The U.S. Department of Energy (DOE) provided copies of the *Final Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico* (SWEIS) to Federal, state, and local elected and appointed officials; Native American representatives; public interest groups; and other organizations and individuals listed in this chapter. Approximately 400 copies of the Final SWEIS and 400 copies of the Final SWEIS Summary were distributed. Copies will be provided to others on request.

United States Congress

U.S. House of Representatives

Steve Pearce, R-New Mexico
Tom Udall, D-New Mexico
Heather A. Wilson, R-New Mexico

U.S. Department of Energy

National Nuclear Security Administration

Los Alamos Site Office

Availability of the Final Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico

To submit general questions regarding this EIS, or to request a copy, please contact:

Elizabeth Withers, EIS Document Manager
NNSA Service Center - Albuquerque
National Nuclear Security Administration
U.S. Department of Energy
P. O. Box 5400
KAFB East, SC-1
Albuquerque, NM 87185-5400
Telephone: 505-845-4984

Printed with soy ink on recycled paper

COVER SHEET

Responsible Agency: U.S. Department of Energy (DOE)
National Nuclear Security Administration (NNSA)

Title: *Final Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico* (SWEIS) (DOE/EIS-0380)

Location: Los Alamos, New Mexico

For additional information or for copies of the SWEIS, contact:

Elizabeth Withers, EIS Document Manager
NNSA Service Center - Albuquerque
National Nuclear Security Administration
U.S. Department of Energy
P. O. Box 5400
KAFB East, SC-1
Albuquerque, NM 87185-5400
Telephone: 505-845-4984

For general information on the DOE National Environmental Policy Act (NEPA) process, contact:

Carol M. Borgstrom, Director
Office of NEPA Policy and Compliance
U.S. Department of Energy
1000 Independence Avenue, SW
Washington, DC 20585
Telephone: 202-586-4600, or leave a message at 1-800-472-2756

This document is available on the DOE NEPA website (www.eh.doe.gov/nepa) and the NNSA Los Alamos Site Office website (www.doeal.gov/laso/NEPASWEIS.aspx) for viewing and downloading.

***Abstract*:** NNSA proposes to continue operating Los Alamos National Laboratory (LANL), which is located in Los Alamos County in north-central New Mexico. NNSA has identified and assessed three alternatives for continued operation of LANL: (1) No Action, (2) Reduced Operations, and (3) Expanded Operations. Under the No Action Alternative, NNSA would continue the historical mission support activities conducted at LANL at currently approved operational levels. Under the Reduced Operations Alternative, NNSA would eliminate some activities and limit the operations of other activities. Under the Expanded Operations Alternative, NNSA would operate LANL at the highest levels of activity currently foreseeable, including full implementation of mission assignments. Expanded Operations is NNSA's Preferred Alternative. NNSA intends to implement actions necessary to comply with the March 2005 Compliance Order on Consent (Consent Order) to address the investigation and remediation of environmental contamination at LANL, regardless of decisions it makes on other actions analyzed in the SWEIS. Under all of the alternatives, the affected environment is primarily within 50 miles (80 kilometers) of LANL. Analyses indicate little difference in the environmental impacts of the alternatives on many resource areas. The primary discriminators are public risk due to radiation exposure, collective worker risk due to radiation exposure, socioeconomic effects due to LANL employment changes, electrical power and water demand, waste management, and transportation. A classified appendix assesses the potential impacts of terrorist acts.

Public Comments: In preparing the Final SWEIS, NNSA considered comments received during the scoping period (January 19 to February 17, 2005) and during the public comment period on the Draft SWEIS (July 7 to September 20, 2006). Public hearings on the Draft SWEIS were held in Los Alamos, Española, and Santa Fe, New Mexico. Comments on the Draft SWEIS were requested during a period of 75 days following publication of the U.S. Environmental Protection Agency's (EPA's) Notice of Availability in the *Federal Register*. All comments, including any late comments, were considered during preparation of the Final SWEIS.

The Final SWEIS contains revisions and new information based in part on comments received on the Draft SWEIS. Vertical change bars in the margins indicate the locations of these revisions and new information. Volume 3 contains the comments received during the public comment period on the Draft SWEIS and NNSA's responses to the comments. NNSA will use the analysis presented in this Final SWEIS, as well as other information, in preparing the Record(s) of Decision (RODs) regarding the level of continued operations at LANL. NNSA will issue ROD(s) no sooner than 30 days after the EPA publishes a Notice of Availability of this Final SWEIS in the *Federal Register*.

APPENDIX A
FEDERAL REGISTER NOTICES

DEPARTMENT OF ENERGY

Record of Decision: Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory in the State of New Mexico

AGENCY: Department of Energy.

ACTION: Record of decision.

SUMMARY: The Department of Energy (DOE) is issuing this Record of Decision on the continued operation of the Los Alamos National Laboratory (LANL) in the State of New Mexico. This Record of Decision is based on the information and analysis contained in the Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory, DOE/EIS–0238 (including the classified supplement), and other factors, including the mission responsibilities of the Department, and comments received on the final Site-Wide Environmental Impact Statement. DOE has decided to implement the Preferred Alternative, which, with certain limitations, is the Expanded Operations Alternative. This alternative would expand operations at LANL, as the need arises, to increase the level of existing operations to the highest reasonably foreseeable levels, and to fully implement the mission elements assigned to LANL.

FOR FURTHER INFORMATION CONTACT: For further information on the Site-Wide Environmental Impact Statement or to receive a copy of the Site-Wide Environmental Impact Statement or other information related to this Record of Decision, contact: Corey Cruz, Document Manager, U.S. Department of Energy, Albuquerque Operations Office, P.O. Box 5400, Albuquerque, NM 87185, (505) 845–4282.

For information on the DOE National Environmental Policy Act (NEPA) process, contact: Carol M. Borgstrom, Director, Office of NEPA Policy and Assistance (EH–42), U.S. Department of Energy, 1000 Independence Avenue, SW, Washington, DC 20585, (202) 586–4600, or leave a message at (800) 472–2756.

SUPPLEMENTARY INFORMATION:

Background

DOE prepared this Record of Decision pursuant to the regulations of the Council on Environmental Quality for implementing NEPA (40 CFR Parts 1500–1508) and DOE's NEPA Implementing Procedures (10 CFR Part 1021). This Record of Decision is based, in part, on DOE's Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory, (DOE/EIS–0238). LANL is located in north-central New Mexico, 60 miles (96 kilometers) north-northeast of Albuquerque, 25 miles (40 kilometers) northwest of Santa Fe, and 20 miles (32 kilometers) southwest of Española. LANL occupies an area of approximately 27,832 acres (11,272 hectares), or approximately 43 square miles (111 square kilometers), of which 86 percent lies within Los Alamos County and 14 percent within Santa Fe County. The Fenton Hill site (Technical Area [TA]–57), a remote site 20 miles (32 kilometers) west of LANL, occupies 15 acres (6 hectares) in Sandoval County on land leased from the U.S. Forest Service. LANL is divided into 49 separate Technical Areas. LANL is a multi-disciplinary, multipurpose national laboratory engaged in theoretical and experimental research and development. DOE has assigned elements of each of its four principal missions (National Security, Energy Resources, Environmental Quality, and Science) to LANL, and has established and maintains several capabilities in support of these mission elements, including applications of science and technology to the nuclear weapons program. These capabilities also support applications for other Federal agencies and other organizations in accordance with national priorities and policies.

DOE is currently engaged in other NEPA reviews that include LANL as an alternate location for the action under consideration. These other NEPA reviews include programmatic and project Environmental Impact Statements for Waste Management and Surplus Plutonium Disposition. Since these other Environmental Impact Statements identify potential new or expanded activities for LANL, the impacts of these activities are described under the Preferred Alternative in the Site-Wide Environmental Impact Statement. The nature of the decisions in this Record of Decision with regard to the Waste Management programmatic and project proposals is simply to reserve infrastructure at LANL pending completion of these programmatic and project reviews and the corresponding decision document. With regard to the Surplus Plutonium Disposition program, the nature of the decision in this Record of Decision is to maintain the competency and capability to fabricate the Lead Assemblies as evaluated in the Surplus Plutonium Disposition Environmental Impact Statement (SPD EIS). However, the availability and capacity of facilities to perform such work may be limited because of competing priorities from the weapons program. DOE's resolution of any such competing priorities will be reflected in the Record of Decision for the SPD EIS.

DOE was directed by Congress (Pub. L. 105–119) to convey or transfer parcels of DOE land in the vicinity of LANL to the Incorporated County of Los Alamos, New Mexico, and the Secretary of the Interior, in trust for the San Ildefonso Pueblo. Such parcels, or tracts of land, must not be required to meet the national security mission of LANL and must also meet other criteria established by the Act. DOE has issued a Draft Environmental Impact Statement to examine the potential environmental impacts associated with the conveyance or transfer of 10 specific parcels. EPA published a Notice of Availability for the Draft Environmental Impact Statement for the Conveyance and Transfer of Certain Land Tracts Administered by the Department of Energy and Located at Los Alamos National Laboratory, Los Alamos and Santa Fe Counties, New Mexico, in the Federal Register on February 26, 1999.

The Site-Wide Environmental Impact Statement considers the environmental impacts of ongoing and proposed activities at LANL. DOE expects that it will continue to suggest new programs, projects, and facilities for LANL (or consider LANL as an alternative site for such facilities or activities). These new proposals will be analyzed in programmatic or project-specific NEPA reviews, as they become ripe for decision. Subsequent NEPA reviews will make reference to, and be tiered from, the Site-wide Environmental Impact Statement; and subsequent DOE decisions on these proposals may amend this Record of Decision.

Alternatives Considered

DOE analyzed four broad alternative levels of operation at the Los Alamos National Laboratory. The four alternatives are as follows:

Alternative 1—No Action

The No Action Alternative reflects the levels of operation at LANL that are currently planned. This includes operations that provide for continued support of DOE's four primary missions, but would not include an increase in the existing pit manufacturing capacity (beyond the current capacity of 14 pits per year) nor expansion of the low-level waste disposal facility at Technical Area–54 (the remaining space in the existing Area G footprint would be used, but some low-level waste would be shipped off-site for disposal). This alternative includes the maintenance of existing capabilities, continued support/infrastructure activities, and implementation of several facility construction or modification projects throughout LANL that have previous NEPA reviews.

Alternative 2—Expanded Operations (DOE's Preferred Alternative Except for Pit Manufacturing)

The Expanded Operations Alternative would expand operations at LANL, as the need arises, to increase the level of existing operations to the highest reasonably foreseeable levels, and to fully implement the mission elements assigned to LANL. This includes the impacts of the full implementation of pit manufacturing up to a capacity of 50 pits per year under single-shift operations (80 pits per year using multiple shifts). This alternative includes the expansion of the low-level waste disposal site at Technical Area–54, including receipt of off-site wastes. In addition, this alternative includes the continued maintenance of existing and expanded capabilities, continued support/infrastructure activities, and implementation of several facility construction or modification projects at Technical Area–53 (i.e., the Long-Pulse Spallation Source, the 5-Megawatt Target/Blanket Experimental Area, the Dynamic Experiment Laboratory, and the Isotope Production Facility).

Alternative 3—Reduced Operations

The Reduced Operations Alternative reflects the minimum levels of operation at LANL considered necessary to maintain the capabilities to support DOE missions over the near-term (through the year 2007). While the capabilities are maintained under this alternative, this may not constitute full support of the mission elements currently assigned to LANL. This alternative reflects pit manufacturing at a level below the existing capacity (at 6 to 12 pits per year) and reflects shipment of much of the low-level waste generated at LANL for off-site disposal (on-site disposal would be limited to those waste types for which LANL has a unique capability at Area G). This alternative includes the maintenance of existing capabilities, continued support/infrastructure activities, and implementation of several facility construction or modification projects throughout LANL that have previous NEPA reviews; some of the projects previously reviewed under NEPA would be reduced in scope or eliminated (e.g., the Low-Energy Demonstration Accelerator would only be operated at the lower end of its energy range).

Alternative 4—''Greener''

The ''Greener'' Alternative reflects increased levels of operation at LANL in support of nonproliferation, basic science, and materials recovery/stabilization mission elements, and reduced levels of operation in support of defense and nuclear weapons mission elements. All LANL capabilities are maintained for the short term under this alternative; however, this may not constitute full support of the nuclear weapons mission elements currently assigned to LANL. This alternative reflects pit manufacturing at a level below the existing capacity (at 6 to 12 pits per year) and reflects shipment of much of the low-level waste generated at LANL for off-site disposal (on-site disposal would be limited to those waste types for which LANL has a unique capability at Area G). This alternative includes the maintenance of existing capabilities, continued support/infrastructure activities, and implementation of several facility construction or modification projects at Technical Area–53 (i.e., the Long-Pulse Spallation Source, the 5-Megawatt Target/Blanket Experimental Area, the Dynamic Experiment Laboratory, and the Isotope Production Facility.) The name and general description for this alternative were provided by interested public stakeholders as a result of the scoping process.

Preferred Alternative

In the draft Site-Wide Environmental Impact Statement, the Preferred Alternative was the Expanded Operations Alternative. In the final Site-Wide Environmental Impact Statement, the Expanded Operations Alternative is the Preferred Alternative with one modification, which involves the level at which pit manufacturing would be implemented at LANL. Under the Expanded Operations Alternative, DOE would expand operations at LANL, as the need arises, to increase the level of existing operations to the highest reasonably foreseeable levels. This expansion of operations would apply broadly to the essential science and technology activities across LANL, and would apply to the level of activity for those operations (e.g., increased throughput or increased numbers of experiments). The Expanded Operations alternative includes expansion to fully implement pit manufacturing up to the capacity of 50 pits per year under single-shift operations (80 pits per year using multiple shifts) assigned to LANL in the Record of Decision for the Stockpile Stewardship and Management Programmatic Environmental Impact Statement.

However, as a result of delays in the implementation of the Capability Maintenance and Improvement Project and recent additional controls and operational constraints applied to work conducted in the Chemistry and Metallurgy Research (CMR) Building, DOE has determined, as a matter of policy, to postpone any decision to expand pit manufacturing beyond a level of a nominal 20 pits per year in the near future (through the year 2007), and to study further methods for implementing the 50 pits per year production capacity. The revised Preferred Alternative reflects implementing pit manufacturing at the 20-pit-per-year level. This postponement does not modify the long-term goal announced in the Record of Decision for the Stockpile Stewardship and Management Programmatic Environmental Impact Statement of 50 pits per year (up to 80 pits per year using multiple shifts).

The Preferred Alternative includes the expansion of the low-level waste disposal site at Technical Area–54. The Preferred Alternative also includes the continued maintenance of existing and expanded capabilities, continued support/infrastructure activities, and implementation of several facility construction or modification projects at Technical Area–53 (i.e., the Long-Pulse Spallation Source, the 5-Megawatt Target/Blanket Experimental Area, the Dynamic Experiment Laboratory, and the Isotope Production Facility).

Environmentally Preferable Alternative

The Council on Environmental Quality, in its ''Forty Most Asked Questions Concerning CEQ's NEPA Regulations'' (46 FR 18026, 2/23/81), with regard to 40 CFR 1505.2, defined the ''environmentally preferable alternative'' as the alternative ''that will promote the national environmental policy as expressed in NEPA's Section 101. Ordinarily, this means the alternative that causes the least damage to the biological and physical environment; it also means the alternative which best protects, preserves, and enhances historic, cultural, and natural resources.''

After considering impacts to each resource area by alternative, DOE has identified Alternative 3, Reduced Operations, as the environmentally preferable alternative. Alternative 3 was identified as having the fewest direct impacts to the physical environment and to worker and public health and safety because all operations would be at the lowest levels. However, the analyses indicate that there would be very little difference in the environmental impacts among the alternatives analyzed. The major discriminators among alternatives are collective worker risks due to radiation exposure, socioeconomic effects due to LANL employment changes, and electrical power demand. Therefore, Reduced Operations would have the fewest impacts and Expanded Operations would have the most.

Environmental Impacts of Alternatives

DOE weighed environmental impacts as one factor in its decision making. DOE analyzed the potential impacts that might occur to land resources; geology, geological conditions, and soils; water resources, air quality; ecological and biological resources, human health, environmental justice, cultural resources; and socioeconomic, infrastructure, and waste management for the four alternatives. DOE considered the impacts that might occur from use of special nuclear materials, facility accidents, and the transportation of radioactive and other materials associated with LANL operations. DOE considered the impacts of projects and activities associated with each alternative, the irreversible or irretrievable commitments of resources, and the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity.

The highest resource impacts under any of the alternatives will be to the electrical power infrastructure. Peak electrical demand under the Reduced Operations Alternative exceeds supply during the winter months and may result in periodic brownouts. Peak electrical demand under the No Action, Expanded Operations, and Greener Alternatives exceeds the power supply in both winter and summer, when this may result in periodic brownouts. (Power supply to the Los Alamos area has been a concern for a number of years, and DOE continues to work with other users in the area and power suppliers to increase supply and reduce use.)

Nonradioactive hazardous air pollutants would not be expected to degrade air quality or affect human health under any of the alternatives. The differences in activities among the alternatives do not result in large differences in chemical usage. The activities at LANL are such that large amounts of chemicals are not typically used in any industrial process at LANL (compared to what may be used in commercial manufacturing facilities); but research and development activities involving many users dispersed throughout the site are the norm. Air emissions are, therefore, not expected to change by a magnitude that would, for example, trigger more stringent regulatory requirements or warrant continuous monitoring. Radioactive air emissions change slightly, but are within a narrow range due to the controls placed on these types of emissions and the need to assure compliance with regulatory standards. The collective population radiation doses from these emissions range from about 11 person-rem per year to 33 person-rem per year across the alternatives, and the radiation dose to the maximally exposed individual ranges from 1.9 millirem per year to 5.4 millirem per year across the alternatives. These doses were considered in the human health impact analysis.

The total radiological doses from normal operations over the next 10 years to the public under any of the alternatives are relatively small and are not expected to result in any excess latent cancer fatalities (LCFs) to members of the public. Additionally, exposure to chemicals due to LANL operations under any of the alternatives is not expected to result in significant effects to either workers or the public. Exposure pathways associated with the traditional practices of communities in LANL area (special pathways) would not be expected to result in human health effects under any of the alternatives. The annual collective radiation dose to workers at LANL ranges from 170 person-rem per year to 833 person-rem per year across the alternatives. These dose levels would be expected to result in from 0.07 to 0.33 excess LCFs per year of operation, respectively, among the exposed workforce. These impacts, in terms of excess LCFs per year of operation, reflect the numbers of excess fatal cancers estimated to occur among the exposed members of the work force over their lifetimes per year of LANL operations. These impacts form an upper bound, and the actual consequences could be less, but probably would not be worse.

Worker exposures to physical safety hazards are expected to result in a range of 417 (Reduced Operations) to 507 (Expanded Operations) reportable cases each year; typically, such cases would result in minor or short-term effects to workers, but some of these incidents could result in long-term health effects or even death.

LANL employment (including the University of California employees and those of the two subcontractors with the largest employment among LANL subcontractors) ranges from 9,347 (Reduced Operations) to 11,351 (Expanded Operations) full-time equivalents across the alternatives, as compared to 9,375 LANL full-time equivalents in 1996. These changes in employment would result in changes in regional population, employment, personal income, and other socioeconomic measures. Under any of the alternatives, these secondary effects would change existing conditions in the region by less than 5 percent.

Water demand for LANL ranges from 602 million gallons (2,279 million liters) per year to 759 million gallons (2,873 million liters) per year across the alternatives; the total water demand (including LANL and the residences and other businesses and agencies in the area) is within the existing DOE Rights to Water, and would result in average drops of 10 to 15 feet (3.1 to 4.6 meters) in the water levels in DOE well fields over the next 10 years. Usage, therefore, will remain within a fairly tight range among the alternatives. The related aspect of wastewater discharges is also within a narrow range for that reason. Outfall flows range from 218 to 278 million gallons (825 to 1,052 million liters) per year across the alternatives, and these flows are not expected to result in substantial changes to existing surface or groundwater quantities. Outfall flows are not expected to result in substantial surface contaminant transport under any of the alternatives. However, since mechanisms for recharge to groundwater are highly uncertain, it is possible that discharges under any of the alternatives could result in contaminant transport in groundwater and off the site, particularly beneath Los Alamos Canyon and Sandia Canyon, which have increased outfall flows. The outfall flows associated with the Expanded Operations and Greener Alternatives reflect the largest potential for such contaminant transport, and the flows associated with the Reduced Operations Alternative have the least potential for such transport.

There is little difference in the impacts to geology, geological conditions, and soils across the alternatives. Wastewater discharge volumes with associated contaminants do change across the alternatives, but not to a degree noticeable in terms of impacts (such as causing soil erosion, for example). Under all of the alternatives, small quantities (as compared to existing conditions) of contaminants would be deposited in soils due to continued LANL operations, and the Environmental Restoration Project would continue to remove existing contaminants at sites to be remediated. Geological mapping and fault trenching studies at LANL are currently under way or recently completed to better define the rates of fault movements, specifically of the Pajarito Fault, and the location and possible southern termination of the Rendija Canyon Fault. Ongoing and recently completed seismic hazard studies indicate that slip rates (recurrence intervals for earthquakes) are within the parameters assumed in the 1995 seismic hazards study at LANL.

There is little difference in the impacts to land resources between the No Action, Reduced Operations, and the Greener Alternatives. Differences among the alternatives are primarily associated with operations in existing facilities, and very little new development is planned. Therefore, these impacts are essentially the same as currently experienced. The Expanded Operations Alternative has very similar land resources impacts to those of the other three alternatives, with the principal differences being attributable to the visual impacts of lighting along the proposed transportation corridor between the Plutonium Facility and the Chemistry and Metallurgy Research Building (this corridor will not be built under the Preferred Alternative) and the noise and vibration associated with increased frequency of high explosives testing (as compared to the other three alternatives).

No significant adverse impact to ecological and biological resources is projected under any of the alternatives. The separate analyses of impacts to air and water resources constitute some of the source information for analysis of impacts in this area; as can be seen from the above discussion, the variation across the alternatives is not of a sufficient magnitude to cause large differences in effects. The impacts of the Expanded Operations Alternative differ from those of the other alternatives in that there is some projected loss of habitat; however, this habitat loss is small (due to limited new construction) compared to available similar habitat in the immediate vicinity.

DOE expects no environmental justice impacts from the operation of LANL under any of the alternatives, i.e., projected impacts are not disproportionately high for minority or low-income populations in the area. DOE also analyzed human health impacts from exposure through special pathways, including ingestion of game animals, fish, native vegetation, surface waters, sediments, and local produce; absorption of contaminants in sediments through the skin; and inhalation of plant materials. The special pathways have the potential to be important to the environmental justice analysis because some of these pathways may be more important or viable for the traditional or cultural practices of minority populations in the area. However, human health impacts associated with these special pathways also will not present disproportionately high and adverse impacts to minority or low-income populations.

Under all of the Site-Wide Environmental Impact Statement alternatives, there is a negligible to low potential for impacts to archaeological and historic resources due to shrapnel and vibration caused by explosives testing and contamination from emissions. Potential impacts will vary in intensity in accordance with the frequency of explosives tests and the operational levels that generate emissions (e.g., Reduced Operations would reflect the lowest potential, and Expanded Operations would reflect the highest potential). Recent assessments of prehistoric resources indicate a low potential compared to the effects of natural conditions (wind, rain, etc.). In addition to these potential impacts, the Expanded Operations Alternative includes the expansion of the low-level waste disposal site at Technical Area-54, which contains several National Register of Historic Places sites; if any significant cultural resources will be adversely effected by the undertaking, DOE will consult with the New Mexico State Historic Preservation Office and other consulting parties to resolve the adverse effect.

The potential impacts to specific traditional cultural properties would depend on their number, characteristics, and location. Such resources could be adversely affected by changes in water quality and quantity, erosion, shrapnel from explosives testing, noise and vibration from explosives testing, and contamination from ongoing operations. Such impacts would vary in intensity in accordance with the frequency of explosive tests and the operational levels that generate emissions. The current practice of consultation would continue to be used to provide opportunities to avoid or minimize adverse impacts to any traditional cultural properties located at LANL.

LANL chemical waste generation ranges from 3,173 to 3,582 tons (2,878,000 to 3,249,300 kilograms) per year across the alternatives. LANL low-level waste generation, including low-level mixed waste, ranges from 338,210 to 456,530 cubic feet (9,581 to 12,837 cubic meters) per year across the alternatives. LANL transuranic (TRU) waste generation, including mixed TRU waste, ranges from 6,710 to 19,270 cubic feet (190 to 547 cubic meters) across the alternatives. Disposal of these wastes at on-site or off-site locations is projected to constitute a relatively small portion of the existing capacity for disposal sites; disposal of all LANL low-level waste on the site would require expansion of the low-level waste disposal capacity beyond the existing footprint of Technical Area-54 Area G under all alternatives (although this is only included in the analysis of the Expanded Operations Alternative).

Radioactively contaminated space in LANL facilities would increase by about 63,000 square feet (5,853 square meters) under the No Action, Reduced Operations, and Greener Alternatives (due primarily to actions previously reviewed under NEPA but not fully implemented at the time the existing contaminated space estimate was established [May 1996]). The Expanded Operations Alternative would increase contaminated space in LANL facilities by about 73,000 square feet (6,782 square meters). The creation of new contaminated space causes a clean-up burden in the future, including the generation of radioactive waste for treatment and disposal; the actual impacts of such clean-up actions are highly uncertain because they are dependent on the actual characteristics of the facilities, the technologies available, and the applicable requirements at the time of the cleanup.

Incident-free transportation associated with LANL activities over the next 10 years would be conservatively expected to cause radiation doses that would result in about one excess latent cancer fatality to a member of the public and two excess latent cancer fatalities to members of LANL workforce over their lifetimes under each of the Site-Wide Environmental Impact Statement alternatives. There is little variation in impacts because effects are small, and the increased transport of radioactive materials is not enough to make a significant change in those small effects.

Transportation accidents without an associated cargo release over the next 10 years of LANL operations are conservatively projected to result in from 33 to 76 injuries and 3 to 8 fatalities (including workers and the public) across the alternatives. The bounding off-site and on-site transportation accidents over the next 10 years involving a release of cargo would not be expected to result in any injuries or fatalities to members of the public for any of the alternatives. Accidents were analyzed by type of material, and the maximum quantities were selected for analysis. These parameters do not change across the alternatives. Total risk also does not change appreciably across the alternatives because the frequency of shipments does not vary enough to substantially influence the result.

The accident analyses (other than transportation and worker physical safety incidents/accidents) considered a variety of initiators (including natural and manmade phenomena), the range of activities at LANL, and the range of radioactive and other hazardous materials at LANL. Transportation accidents and the relatively frequent worker physical safety incidents/accidents were considered separately. The accidents discussed below are those that bound the accident risks at LANL (other than transportation and physical safety incidents/accidents).

The operational accident analysis included four scenarios that would result in multiple source releases of hazardous materials: three due to a site-wide earthquake and one due to a wildfire, resulting in three different degrees of consequences and one wildfire scenario. These four scenarios dominate the radiological risk due to accidents at LANL because they involve radiological releases at multiple facilities and are considered credible (that is, they would be expected to occur more often than once in a million years), with the wildfire considered likely.

Another earthquake-initiated accident, labeled RAD–12, is facility-specific (to Building Technical Area–16–411) and is dominated by the site-wide earthquake accidents due to its very low frequency (about 1.5×10^{-6} per year). It is noteworthy that the consequences of such earthquakes are dependent on the frequency of the earthquake event, the facility design, and the amount of material that could be released due to the earthquake; such features do not change across the alternatives, so the impacts of these accidents are the same for all four alternatives. The risks were estimated conservatively in terms of both the frequency of the events and the consequences of such events. (In particular, it is noteworthy that the analysis assumes that any building that would sustain structural or systems damage in an earthquake scenario does so in a manner that creates a path for release of material outside of the building.) The total risk of an accident is the product of the accident frequency and the consequences to the total population within 50 miles (80 kilometers). This risk ranges from 0.046 (SITE–01, i.e., seismic event) and 0.034 (SITE–04, i.e., wildfire event) excess latent cancer fatalities per year of operation, to extremely small numbers for most of the radiological accidents. The risk for release of chemicals, such as chlorine, is calculated similarly as the product of the frequency and numbers of people exposed to greater than the selected guideline concentration, Emergency Response Planning Guideline (ERPG)–2. (ERPG–2 is the maximum airborne concentration below which it is believed that nearly all individuals could be exposed for up to 1 hour without irreversible or serious health effects or symptoms that could impair their abilities to take protective action). Under all alternatives, the risks for chemical releases range from 6.4 (SITE–01) people exposed per year of operation to extremely small numbers for some chemical releases. In general, such earthquakes would be expected to cause fatalities due to falling structures or equipment; this also would be true for LANL facilities. Thus, worker fatalities due to the direct effects of the earthquakes would be expected. Worker injuries or fatalities due to the release of radioactive or other hazardous materials would be expected to be small or modest increments to the injuries and fatalities due to the direct effects of the earthquakes.

Comments on the Final Site-Wide Environmental Impact Statement

DOE distributed approximately 500 copies of the final Site-Wide Environmental Impact Statement to Congressional members and committees, the State of New Mexico, various American Indian Tribal governments and organizations, local governments, other Federal agencies, and the general public. Comments were received from the U.S. Department of the Interior (DOI) and Chestnut Law Offices, representing San Ildefonso Pueblo. The U.S. Environmental Protection Agency (EPA) did not provide comments on the final Site-Wide Environmental Impact Statement stating in the **Federal Register** (64 FR 18901) that ''Review of the FEIS was not deemed necessary. No formal comment letter was sent to the preparing agency.''

DOI identified two areas of concern with the final Site-Wide Environmental Impact Statement. The first concern is that the Site-Wide Environmental Impact Statement does not adequately assess the direct, indirect, and cumulative effects of programs and activities associated with the continued operation of LANL either on or off the site. DOI maintains that the existing impacts from the environmental baseline should be quantified and not restricted to the evaluation of only two site-specific projects. DOI further states that while programs and activities that are proposed or under way may help to reduce adverse impacts, these programs and activities were not adequately evaluated in the Site-Wide Environmental Impact Statement.

Chapter 4 (Volume I) of the Site-Wide Environmental Impact Statement presents the environmental setting and existing conditions associated with LANL operations. The information presented in Chapter 4 forms a baseline for use in evaluating the environmental impacts of the four Site-Wide alternatives. For all alternatives, assessment of significance was accomplished both quantitatively where data and analysis were available, and qualitatively. The assessment of the potential effects, both positive and adverse, of the Expanded Operations, Reduced Operations, Greener, and No Action Alternatives was based on the degree of change from baseline conditions and was presented in Chapter 5 (Volume I) of the Site-Wide Environmental Impact Statement. DOE integrated many programs and activities, including the Natural Resources Management Plan (see Mitigation Measures), that would reduce adverse impacts in its analysis of environmental impacts.

DOI's second concern is threatened and endangered species protection at LANL. DOI does not concur with DOE's determination that implementation of the Expanded Operation Alternative may affect but would not likely adversely affect four listed species at LANL. The DOI believes that measures necessary to reduce impacts to threatened and endangered species that are identified through the consultation process should be incorporated into the Site-Wide Environmental Impact Statement as required measures.

On April 29, 1999, subsequent to DOI's submittal of comments on the final Site-Wide Environmental Impact Statement, DOE initiated formal section 7 consultation between the DOI and DOE for DOE's proposal to expand existing operations at LANL. DOE sees this consultation process as an opportunity to further the stewardship of listed species provided by the recently implemented Threatened and Endangered Species Management Plan for LANL. Based on communications with the U.S. Fish and Wildlife Service, DOE anticipates that the Service will issue a Biological Opinion in the near future. Upon its receipt DOE will continue to coordinate with the Service the integration into the operation of LANL of any needed measures recommended in the Biological Opinion that will contribute to the welfare of listed species. DOE believes that this process should proceed on a separate, parallel track from that of the Site-Wide Environmental Impact Statement process.

The Chestnut Law Offices, representing San Ildefonso Pueblo, identified three issues of concern with the final Site-Wide Environmental Impact Statement. First, Chestnut Law Offices states that the environmental justice analysis is flawed because it divides San Ildefonso Pueblo into several different segments thereby not indicating any adverse impacts to the Pueblo. Chestnut Law Offices states that most environmental risk is at the perimeter of the laboratory directly affecting San Ildefonso Pueblo, and that the Site-Wide Environmental Impact Statement determines there is no greater impact on the Pueblo than on other disadvantaged communities. Chestnut Law Offices states that this approach in environmental justice analysis does not comply with Federal law and is inadequate.

DOE prepared the environmental justice analysis in accordance with guidance from the Council on Environmental Quality and Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations. The segments referred to in the comments were used to identify and highlight the locations of low-income and/or minority populations for the impact analyses. Using this tool, the San Ildefonso Pueblo was identified as housing minority and/or low-income populations for consideration in the Environmental Justice analysis. DOE has not identified any disproportionately high and adverse human health or environmental impacts on minority or low-income populations under any of the alternatives analyzed in the Site-Wide Environmental Impact Statement. To the extent that there is a potential for adverse impacts, DOE analysis has shown that most of the impact would affect all populations equally. In the cases of air emissions and on-site transportation, the residential populations nearest to LANL, which have a relatively low percentage of minority and low-income populations, would be affected to a greater extent than other populations within the 50-mile radius.

The impacts addressed in the environmental justice analysis in the Site-Wide Environmental Impact Statement include land resources, geology, soils, water resources, ecological resources, air quality, human health, waste management, socioeconomic, and transportation. This analysis includes the projected impacts due to contamination in the area from past LANL activities. As part of its human health impact analysis, DOE looked at potential exposure through special pathways, including ingestion of game animals, fish, native vegetation, surface waters, sediments, and local produce; absorption of contaminants in sediments through the skin; and inhalation of plant materials. For LANL, the special pathways influence the environmental justice analysis because some of these pathways are more important or viable to the traditional or cultural practices of minority populations in the area. Even considering these special pathways, DOE did not find disproportionately high and adverse health impacts to minority or low-income populations.

The Chestnut Law Offices' second concern is groundwater contamination due to LANL activities. The Chestnut Law Offices states that the final Site-Wide Environmental Impact Statement does not address the recent groundwater contamination but downplays it, and that this section of the Site-Wide Environmental Impact Statement should be re-evaluated.

DOE believes that drinking water quality in the Los Alamos area continues to meet all Federal and New Mexico chemical and radiological standards. In February 1999 DOE discovered, as part of implementing the Hydrogeologic Workplan (the multi-year effort to characterize the flow and extent of contamination of the main aquifer), high explosives contamination while drilling a well (R–25) in the western part of the Laboratory. Based on current knowledge, DOE believes it will take at least 50 years for these contaminants to reach the drinking water production wells approximately three and a half miles to the East of R–25. DOE has and will continue to sample the drinking water to ensure it is safe. Groundwater monitoring data from implementation of the Hydrogeologic Workplan is still under review and evaluation. As new information becomes available, the LANL Environmental Surveillance and Compliance Program will be revised to incorporate the additional data.

Chestnut Law Offices' third concern is that the Site-Wide Environmental Impact Statement does not consider the shutdown of the low-level waste disposal area, Area G, a reasonable alternative. The commentor states the alternatives in the Site-Wide Environmental Impact Statement are based on the assumption that LANL will be a regional low-level waste disposal site. The commentor believes the Site-Wide Environmental Impact Statement does not analyze the possibility that another site may be chosen as the regional low-level waste disposal site, thereby providing the opportunity for the waste to be removed from Area G. The commentor states this is a serious flaw since it does not anticipate a clearly reasonable alternative in light of existing planning documents.

The shutdown of the low-level waste disposal area, Area G, was not considered a reasonable alternative for analysis in the Site-Wide Environmental Impact Statement because Area G has a unique capability for the disposal of certain wastes generated by LANL. Such wastes include classified wastes and other wastes that would be difficult to transport to other sites. The Expanded Operations Alternative was the only alternative that analyzed the impacts of LANL being chosen as a regional low-level waste disposal site.

Under the Waste Management Programmatic Environmental Impact Statement, which evaluated locations for treatment and disposal of low-level radioactive waste and mixed low-level radioactive waste, these wastes would be treated on the site at LANL and disposed of at a regional site to be determined after consultation with stakeholders. One of the potential regional disposal sites for low-level waste is LANL. Therefore, in the Expanded Operations Alternative, the Site-Wide Environmental Impact

Statement addressed treatment and disposal of LANL-generated low-level waste, as well as disposal of off-site generated low-level waste. The Expanded Operations Alternative analyzes the environmental impacts and the footprint needed at Area G to allow for the implementation of this alternative.

If LANL is not selected as a regional disposal site, some low-level waste could be sent off-site for disposal, as reflected in the No Action, Reduced, and Greener Alternatives. The current low-level waste capacity available at Area G is limited. If LANL were selected as a regional disposal site, the expansion of Area G would occur at the fastest rate. If LANL continues to dispose of its own wastes, the expansion would still occur, but at a slower rate. Currently LANL generates some low-level waste that, primarily because of its size and shape, does not meet the acceptance criteria for disposal at other DOE sites, such as the Nevada Test Site. However, the decision as to the ultimate treatment and disposal of low-level waste and mixed low-level waste will be made in a Record of Decision for the Waste Management Programmatic Environmental Impact Statement.

It should also be noted that the EPA, State of New Mexico, and representatives of the Pueblos (four Accord Pueblos) near LANL were invited to review and comment on the Classified Supplement for the Draft Site-Wide Environmental Impact Statement (EPA declined the invitation). Comments from that review were received shortly after the final Site-Wide Environmental Impact Statement was issued. This final Classified Supplement and all comments provided were considered in reaching the decisions in this Record of Decision.

Other Decision Factors

As noted in the final Site-Wide Environmental Impact Statement, LANL houses unique facilities and expertise that have been developed over the past 50 years. These have served several National Security and other national needs in the past. It is expected that, for the foreseeable future, the U.S. will maintain a nuclear weapons stockpile and require ''cutting edge'' science and manufacturing capabilities to address issues of national importance for the maintenance of that stockpile and for other purposes, including assuring the safety and reliability of that stockpile. The unique facilities and expertise at LANL are needed to assist in finding solutions to these issues. As noted in the final Site-Wide Environmental Impact Statement, LANL's role in supporting DOE's missions has expanded as the DOE nuclear weapons complex has been downsized over the last decade. Additionally, it is expected that there will be continued emphasis on applying the unique capabilities at LANL to support DOE's basic science mission and to apply technologies developed in DOE laboratories to improve the U.S. technological position and competitiveness. These factors were also considered (in addition to the human health and environmental impact information discussed above) in reaching this Record of Decision.

Decisions

DOE has decided to continue to operate LANL for the foreseeable future and to expand the scope and level of its operations at LANL. DOE is implementing the Preferred Alternative, that is Alternative 2, Expanded Operations, but with pit production limited to a capacity that can be accommodated within the limited space currently set aside for this activity in the plutonium facility (estimated at nominally 20 pits per year). This alternative reflects a broad expansion of science and technology research, and applications of this research to a variety of issues of national importance; this alternative also includes the continued maintenance of existing and expanded capabilities, and continued support/infrastructure activities. The following discussion describes the major actions to be taken, with an emphasis on those areas that have had the most extensive programmatic or public interest.

It should be noted that the decisions in this Record of Decision will be reflected in DOE budget requests and management practices. However, the actual implementation of these decisions is dependent on DOE funding levels and allocations of DOE budget across competing priorities.

Pit Production and Other Plutonium Operations

DOE remains committed to meeting pit production requirements to support the enduring nuclear weapons stockpile. As part of its implementation of the Preferred Alternative, DOE will establish, over time, a pit production capability at LANL with a capacity of nominally 20 pits per year; this decision reflects an intent to establish a pit production capability at LANL within the existing floor space set aside for this operation (about 11,400 ft^2 [1060 m^2]). This will eliminate the need to transfer several Technical Area-55 plutonium operations (to ''make room'' for pit production activities in Technical Area-55) either to the CMR Building, or to newly constructed nuclear space, as contemplated in the Site-Wide Environmental Impact Statement. Thus, the Preferred Alternative for Pit Production can be implemented without an expansion of the plutonium operations floor space at LANL. The exact production capacity of this floor space is not known with certainty (pending process optimization studies), but has been characterized as nominally 20 pits per year. This level provides adequate capacity to meet the near-term pit production requirements to maintain the enduring stockpile (about 20 pits per year), as expressed in the Record of Decision for the Stockpile Stewardship and Management Programmatic Environmental Impact Statement. While this does not change the 50-pit-per-year mission assignment made in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement Record of Decision, it does suspend full implementation of that decision until an undetermined time in the future.

Implementation of the pit production mission at LANL will be phased. The first pit for delivery to the U.S. nuclear weapons stockpile will be made in 2001. It is expected that, through equipment installation in existing facilities, the limited production capacity of nominally 20 pits per year will be achieved in 2007. At these levels of production, there is no need to move plutonium operations from the Plutonium Facility, Technical Area-55, to the CMR Building, and there is no need to construct a corridor between Technical Area-55 and Technical Area-3. Thus, DOE has decided not to move these operations or construct the road at this time.

Chemistry and Metallurgy Research Building—As the Site-Wide Environmental Impact Statement was being prepared, DOE was working on two sets of information associated with CMR operations: (1) Establishment of a modern authorization basis for these operations (referred to as the CMR Basis for Interim Operations, or BIO); and, (2) studies of the seismicity of the Technical Area-55 and Technical Area-3 areas. Both sets of information are included in the impact analyses in the Site-Wide Environmental Impact Statement (where details were not known, the analyses in the Site-Wide Environmental Impact Statement were, in fact, bounding of the details determined through these efforts). Through this effort, it became apparent that the subprojects included in the CMR Upgrades Construction Project should be reprioritized and oriented to provide for the continued safe operation of the CMR Building through about 2010. The single most substantive change in this project was to replace the proposed seismic upgrades with a combination of material containerization, a reduction in the amount of Material at Risk (or MAR, which is the amount of in-process material that would be subject to release if there were a catastrophic accident), and a substantial reduction in the amount of combustible material allowed in the CMR Building. With these controls in place, the worst-case plausible accidents involving the CMR Building would have minimal effects on public health (effects would be within applicable guidelines intended to protect human health).

The 1996 Stockpile Stewardship and Management Programmatic Environmental Impact Statement analyzed the environmental impacts of locating a pit manufacturing capability at either LANL or the Savannah River Site. In December 1996, DOE issued a Record of Decision reestablishing the pit manufacturing mission at LANL. In August 1998, the U.S. District Court for the District of Columbia, while ruling in DOE's favor in litigation challenging the adequacy of the Stockpile Stewardship and Management Programmatic Environmental Impact Statement, directed DOE to take another look at certain new studies regarding seismic hazards at LANL, and to provide a factual report and technical analysis of the plausibility of a building-wide fire at LANL's plutonium facility (PF–4 at Technical Area-55). The Court directed that DOE prepare a Supplement Analysis, pursuant to DOE's NEPA regulations (10 CFR 1021.314(c)), to help determine whether a supplemental Stockpile Stewardship and Management Programmatic Environmental Impact Statement should be issued to address these studies. These seismic studies have been released to the public and are examined in more detail in the draft Supplement Analysis released for public review and comment on July 1, 1999. On September 2, 1999, DOE issued a final Supplement Analysis and determined that none of the issues analyzed in the Supplement Analysis represents substantial changes to the actions considered in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement, nor do those issues provide significant new information relevant to the environmental concerns discussed in that Programmatic Environmental Impact Statement. Therefore no supplement to that Programmatic Environmental Statement is required.

Secondaries

While LANL was considered as a production site for secondaries (components of a nuclear weapon that contains elements needed to initiate the fusion reaction in a thermonuclear reaction) in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement, this mission was assigned to the Y–12 plant at Oak Ridge, Tennessee. However, DOE expects LANL to maintain an understanding of secondary production technologies, as well as the characteristics of War Reserve secondaries in the stockpile.

Tritium

LANL will continue to support both research and development and production activities involving tritium (neutron tube target loading for nuclear weapons stockpile components). These will include development of new reservoirs and reservoir fill operations, surveillance and performance testing on tritium components, tritium recovery and purification technologies, and production operations associated with neutron generator production for the stockpile. The expansion of these activities results in: (1) tritium throughputs on an annual basis increase by a factor of up to 2.5; and (2) the on-site inventory of tritium increases by a factor of 10.

High Explosives Processing and Testing

Operations in this area will increase such that annual explosives throughput will increase to about 82,700 pounds, and the annual mock explosives throughput will increase to about 2,910. These quantities include continued research, development, and fabrication of high-power detonators, including support of up to 40 major product lines per year in support of the Stockpile Stewardship and Management program. In addition, the number of hydrodynamic tests will increase to about 100 per year; the annual amount of depleted uranium will increase to about 6,900 pounds.

Accelerator Operations

DOE will implement several facility construction or modification projects at Technical Area–53: the Long-Pulse Spallation Source, the 5-Megawatt Target/Blanket Experimental Area, the Dynamic Experiment Laboratory, and the Isotope Production Facility.

Expansion of Technical Area–54/Area G Low-Level Waste Disposal Area

As part of the implementation of the Preferred Alternative, DOE will continue the on-site disposal of LANL generated low-level waste using the existing footprint at Area G low-level waste disposal area and will expand disposal capacity into Zones 4 and 6 at Area G (this expansion would cover up to 72 acres [29 hectares]). DOE will develop both Zones 4 and 6 in a step-wise fashion, expanding these areas as demand requires.

Mitigation Measures

The Site-Wide Environmental Impact Statement included a discussion of existing programs and plans and controls built into the operations at LANL, including operating within applicable regulations, DOE Orders, contractual requirements and approved policies and procedures. The following discussion outlines the mitigation measures that DOE will undertake to reduce the impacts of continuing to operate LANL at the levels outlined in this Record of Decision.

Electrical Power

The Site-Wide Environmental Impact Statement recognizes the need for an increase in electrical power supply and reliability under the Preferred Alternative as well as other alternatives analyzed. The impact analyses emphasize the severity of these issues and consequences if they are not resolved, e.g., brownouts. Solutions to power supply issues are essential to mitigate the effects of power demand under all alternatives. An operating plan for improved load monitoring, equipment upgrades, and optimization of some available power sources was discussed. Additional measures under consideration by DOE include: (1) Limiting operation of large users of electricity to periods of low demand, and contractual mechanisms to bring additional electric power to the region and some form of on-site cogeneration as an incremental resource. DOE and other users of electrical power in the area have been working with suppliers to resolve these foreseeable power and reliability issues. One solution under consideration for improved reliability is the provision of a third power line from the existing Public Service Company of New Mexico Norton substation to the existing LANL substations. This solution could include a new LANL substation. In any case, DOE is committed to manage electric power demands to prevent periods of brownouts by adjusting to the limitations of available power until a solution for a long-term increase in power is in place. DOE is also committed to approve and begin implementing a Utility Procurement Plan by November 1999.

Water Supply and Demand

Prior to September 8, 1998, DOE supplied all potable water for LANL, Bandelier National Monument, and Los Alamos County, including the towns of Los Alamos and White Rock. This water was derived from DOE's groundwater right to withdraw 5,541.3 acre-feet or about 1,806 million gallons of water per year from the main aquifer. On this date, DOE leased these rights to the County of Los Alamos. This lease also included DOE's contracted annual right obtained in 1976 to 1,200 acre-feet of San Juan-Chama Transmountain Diversion Project water. This lease agreement is effective for three years, at which point DOE expects to convey 70 percent of the water right to the County of Los Alamos and lease the remaining 30 percent to them. The San Juan-Chama rights will be transferred in their entirety to the County. On several occasions since 1986 through 1998, LANL operations have exceeded 30 percent of the total DOE annual water right. The agreement between DOE and the County does not preclude provision of additional waters in excess of the 30 percent agreement, if available. However, the agreement also states that should the County be unable to provide water to its customers, the County shall be entitled to reduce water services to DOE in an amount equal to the water rights deficit.

DOE is committed to managing water demand to prevent exceedances of DOE water rights. LANL will develop and implement by June 2000 procedures to assure that all new projects will implement water conservation design and techniques. LANL will also develop water conservation goals and begin implementing them by October 2001.

Waste Management

DOE is committed to the proper management and minimization of all wastes. LANL will integrate waste minimization into Integrated Safety Management by October 2000. By June 2000 LANL will develop and implement procedures to assure that all new projects will implement waste minimization for TRU and mixed TRU waste streams. In addition LANL will reduce by December 2005 waste from routine operations by 80% using 1993 as a baseline for hazardous, low-level radioactive, and mixed low-level radioactive wastes. Also, LANL will recycle 40% of sanitary waste from routine operations by December 2005.

LANL will also purchase EPA-designated items with recycled content according to the conditions of Executive Order 12873. A LANL Implementing Requirement for waste minimization activities is currently in draft.

Wildfire

The final Site-Wide Environmental Impact Statement included an accident scenario from a wildfire that was initiated on land adjacent to LANL and spread to the LANL site. The analysis concluded that a major fire is not only credible but also likely. The current and future risks of wildfires at LANL can only be mitigated through purposeful environmental intervention and active land management. LANL will develop by December 1999 a preliminary program plan for comprehensive wildfire mitigation, including construction and maintenance of strategic fire roads and fire breaks, creation of defensible space surrounding key facilities, and active forest management to reduce fuel loadings. LANL will prepare and begin implementation of a long-term strategy for wildfire mitigation actions before the start of the 2000 fire season.

Cultural Resources

DOE is committed through ongoing consultation processes with affected Native American tribes to ensure protection of cultural resources and sites of cultural, historic, or religious importance to the tribes. With input from the tribes participating in the Los Alamos Pueblos Project (LAPP), DOE will develop a strategy to increase the understanding of traditional cultural properties at LANL, to determine strategies for the long-term management of identified traditional cultural properties and sacred sites and to determine appropriate mitigation measures for specific traditional cultural properties. The strategies could include the development of access agreements to traditional cultural properties and sacred sites. In the past, attempts to identify specific traditional cultural properties at LANL have encountered concerns from traditional groups because of the potential for increased risk to these resources if they are individually identified; thus, DOE will explore the potential benefits and risks of such a study, and options to such a study, with the LAPP tribes. This approach is intended to ensure appropriate respect and consideration regarding cultural concerns, while attempting to provide the information and ability to mitigate or avoid potential impacts to traditional cultural properties (which are currently not specifically known, to a large extent). The goal of the consultation and coordination would be an agreement with the relevant Native American tribes for the management of these resources.

DOE will complete an Integrated Cultural Resource Management Plan (ICRMP) by April 2002. The ICRMP will detail how LANL will manage, preserve, and protect cultural resources within the scope of Federal and State laws, regulations, Executive Orders, standards, as well as to the extent practicable, follow Tribal criteria and guidelines. The ICRMP will provide a basis for a unified approach to address the multiplicity of cultural resources located on LANL lands. The plan will serve to streamline many of the administrative steps required by Federal and State laws and regulations. The scope of activities for the ICRMP would include development of the plan, completion of surveys of archeological resources and historic buildings, and implementation of long-term monitoring.

Natural Resources

DOE will develop and begin implementation of an integrated Natural Resources Management Plan (NRMP) by October 2002, which will integrate the principles of ecosystem management into the critical missions of LANL to conserve ecosystem processes and biodiversity. The NRMP will support DOE's policy to manage all of its land and facilities as valuable national resources. This stewardship will integrate LANL's mission and operations with its biological, water, soil, and air resources in a comprehensive plan that will guide land and facility use decisions. The plan will consider the site's larger regional context and be developed in consultation with regional land managing agencies and owners (particularly Bandelier National Monument, Santa Fe National Forest, and Native American Pueblos), State agencies, and the U.S. Fish and Wildlife Service. This cooperative effort will ensure a consistent, integrated, and structured approach to regional natural resource management.

The NRMP is viewed as a sequenced planning document that will include specific tasks and studies as part of the process of development. It will include new initiatives as well as integrating ongoing programs, plans, and activities at LANL, some of which may be reassessed to ensure their contribution to the goals and objectives of integrated ecosystem management.

Mitigation Action Plan

In accordance with 10 CFR 1021.331, DOE is preparing a Mitigation Action Plan that will identify specific actions needed to implement these mitigation measures and provide schedules for completion. These mitigation measures represent all practicable means to avoid or minimize harm from the alternative selected.

Conclusion

DOE has considered environmental impacts, stakeholder concerns, and National policy in its decisions regarding the management and use of LANL. The analysis contained in the Site-Wide Environmental Impact Statement is both programmatic and site specific in detail. It is programmatic from the broad multi-use facility management perspective and site specific in the detailed project and program activity analysis. The impacts identified in the Site-Wide Environmental Impact Statement were based on conservative estimates and assumptions. In this regard, the analyses bound the impacts of the alternatives evaluated in the Site-Wide Environmental Impact Statement. The Expanded Operations Alternative was defined to include activities to implement the programmatic decisions made or that may be made as a result of other DOE Environmental Impact Statements (some of which are currently in progress). This Site-Wide Environmental Impact Statement and the analyses it contains can be used to support these future programmatic or project decisions.

In accordance with the provisions of NEPA, its implementing procedures and regulations, and DOE's NEPA regulations, I have considered the information contained within the Site-Wide Environmental Impact Statement, including the classified supplement and public comments received in response to the final Site-Wide Environmental Impact Statement. Being fully apprised of the environmental consequences of the alternatives and other decision factors described above, I have decided to continue and expand the use of LANL and its resources as described. This will enhance DOE's ability to meet its primary National security mission responsibility and create an environment that fosters technological innovation in both the public and private sectors.

Issued at Washington, DC, September 13, 1999.

Thomas F. Gioconda,

Brigadier General, USAF, Acting Assistant Secretary for Defense Programs.

[FR Doc. 99–24456 Filed 9–17–99; 8:45 am]

BILLING CODE 6450–01–P

DEPARTMENT OF ENERGY

National Nuclear Security Administration

Notice of Intent to Prepare a Supplemental Environmental Impact Statement to the Final Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory

AGENCY: U.S. Department of Energy, National Nuclear Security Administration.

ACTION: Notice of Intent.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended (42 U.S.C. 4321 *et seq.*), the Council on Environmental Quality's (CEQ) and the U.S. Department of Energy's (DOE) regulations implementing NEPA (40 CFR parts 1500–1508 and 10 CFR part 1021, respectively), the National Nuclear Security Administration (NNSA), an agency within the DOE, announces its intent to prepare a supplemental site-wide environmental statement (S–SWEIS) to update the analyses presented in the Final Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory (SWEIS) (DOE/EIS–0238; January 1999). The purpose of this notice is to invite individuals, organizations, and government agencies and entities to participate in developing the scope of the S–SWEIS.

In its September 1999 Record of Decision (ROD) based on the SWEIS, DOE announced its decision to implement the Expanded Operations Alternative analyzed in the SWEIS, with modifications to weapons related production work (the Preferred Alternative), at Los Alamos National Laboratory (LANL). That decision is being implemented at LANL. Pursuant to 40 CFR 1502.20, the S–SWEIS will rely on and expand on the analysis in the original SWEIS. The No Action Alternative for the S–SWEIS is the continued implementation of the SWEIS ROD, together with other actions described and analyzed in subsequent NEPA reviews. The Proposed Action in the S–SWEIS will include changes since the SWEIS 1999 ROD.

DATES: NNSA invites comments on the scope of this S-SWEIS through February 27, 2005. NNSA will hold a public scoping meeting in Pojoaque, New Mexico, at the Pablo Roybal Elementary School on January 19, 2005, from 6 to 8 pm. Scoping comments received after February 27, 2005, will be considered to the extent practicable.

ADDRESSES: To submit comments on the scope of the S-SWEIS, questions about the document or scoping meeting, or requests to be placed on the document distribution list, please write or call: Ms. Elizabeth Withers (e-mail address: *lanl_sweis@doeal.gov;* mailing address: NNSA Los Alamos Site Office, NEPA Compliance Officer, 528 35th Street, Los Alamos, New Mexico, 87544; (toll free) telephone 1–877–491–4957; or Facsimile 505–667–9998).

FOR FURTHER INFORMATION CONTACT: For general information about the DOE NEPA process, please contact: Ms. Carol Borgstrom, Director, Office of NEPA Policy and Compliance (EH–42), U.S. Department of Energy, 1000 Independence Avenue, SW, Washington, DC 20585, 202–586–4600, or leave a message at 1–800–472–2756.

SUPPLEMENTARY INFORMATION: LANL is located in north-central New Mexico, 60 miles north-northeast of Albuquerque, 25 miles northwest of Santa Fe, and 20 miles southwest of Española in Los Alamos and Santa Fe Counties. It is located between the Jemez Mountains to the west and the Sangre de Cristo Mountains and Rio Grande to the east. LANL occupies about 40 square miles (104 square kilometers) and is operated for NNSA under contract, by the University of California. (The contract for LANL's management and operation is undergoing a competitive bid process; however, the selection of the LANL management and operations contractor in the future will not affect the nature of the NNSA and DOE work performed at LANL.)

LANL is a multidisciplinary, multipurpose institution primarily engaged in theoretical and experimental research and development. LANL has been assigned science, research and development, and production mission support activities that are critical to the accomplishment of the national security objectives (as reflected in the ROD for the September 1996 Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management (DOE/EIS–0236)). Specific LANL assignments will continue for the foreseeable future include production of War-Reserve products, assessment and certification of the stockpile, surveillance of the War-Reserve components and weapon systems, ensuring safe and secure storage of strategic materials, and management of excess plutonium inventories. LANL's main role in the fulfillment of DOE mission objectives includes a wide range of scientific and technological capabilities that support nuclear materials handling, processing and fabrication; stockpile management; materials and manufacturing technologies; nonproliferation programs; and waste management activities.

The Final LANL SWEIS, issued in January 1999, considered the operation of LANL at various levels for about a 10-year period of time. Alternatives considered in that document were: No Action Alternative, the Expanded Operations Alternative, the Reduced Operations Alternative, and the Greener Alternative. In addition to providing an overview of the LANL site and its activities and operations, the SWEIS identified 15 LANL "Key Facilities" for the purposes of NEPA analysis. "Key

[1] Protection from public disclosure involving this kind of specific information is based upon 18 CFR 4.32(b)(3)(ii) of the Commission's regulations implementing the Federal Power Act.

Facilities'' are those facilities that house operations with the potential to cause significant environmental impacts; are of most interest or concern to the public based on scoping comments; or are facilities that would be the most subject to change due to potential programmatic decisions. The operations of these ''Key Facilities'' were described in the SWEIS and, together with other non-key facility functions, formed the basis of the description of LANL facilities and operations analyzed for their potential impacts. The Preferred Alternative was the Expanded Operations Alternative with certain reductions in weapons-related manufacturing capabilities. This alternative was chosen for implementation in the ROD issued in September 1999.

In mid-2004, NNSA undertook the preparation of a Supplement Analysis for the SWEIS pursuant to DOE's regulatory requirement to evaluate site-wide NEPA documents at least every 5 years (10 CFR 1021.330) and determine whether the existing EIS remains adequate, to prepare a new site-wide EIS, or prepare a supplement to the existing EIS. During the development of this Supplement Analysis, NNSA decided to proceed immediately with a supplement to the existing SWIES in order to expedite the NEPA process and to save time and money. DOE NEPA regulations (10 CFR 1021.314) require the preparation of a Supplemental EIS if there are substantial changes to a proposal or significant new circumstances or information relevant to environmental concerns. Substantial changes to the level of LANL operations may result from proposed, modified or enhanced activities and operations within LANL facilities (discussed later in subsequent paragraphs of this Notice), and new circumstances and information with regard to effects from the Cerro Grande Fire (which burned a part of LANL), a reduction in the size of the LANL reservation due to recent land conveyance and transfers, and contaminant migration have come to light over the past five years that could be deemed significant under 10 CFR 1021.314.

Since the issuance of the Final SWEIS in 1999, DOE and NNSA have finalized several environmental impact statements, environmental assessments (EA), and a special environmental analysis dealing with LANL operations and actions taken immediately after the 2000 Cerro Grande Fire. The activities analyzed in these NEPA documents and developing changes to the LANL environmental setting led NNSA to conclude it would be prudent and efficient to begin updating the SWEIS now by preparing a supplemental SWEIS. NNSA will use the S–SWEIS to consider the potential impacts of proposed modifications to LANL activities, as well as the cumulative impacts associated with on-going activities at LANL, on the changed LANL environment.

The S–SWEIS will provide a review of the impacts resulting from implementing the SWEIS ROD over the past 5 years at LANL and compare these impacts to the impacts projected in the SWEIS analyses for that alternative to provide an understanding of the SWEIS's ability to identify potential impacts. The S–SWEIS analyses will focus primarily on aspects of the existing environment that could be impacted by newly proposed changes to LANL operations at certain facilities and by environmental cleanup actions that could occur over the next 5 to 6 years in response to a consent order from the State of New Mexico. The S–SWEIS Proposed Action will analyze projected impacts anticipated from operating LANL at the 1999 ROD level for at least the next 5 years, with some modified work now being proposed at certain facilities. NNSA is considering proposed operational changes within at least two new ''Key Facilities'' at LANL:

• The Nicholas C. Metropolis Center for Modeling and Simulation (formerly called the Strategic Computing Complex), and
• The Nonproliferation and International Security Center (NISC).

The construction and operation of the Nicholas C. Metropolis Center for Modeling and Simulation were analyzed in a December 1998 EA and a finding of no significant impact (FONSI) for that proposed action was issued based on the impact analyses for operating the computational facility up to a 50–TeraOp platform (a TeraOp is a trillion floating point operations per second). The Center has been constructed and is currently operating below the operations level analyzed in the 1998 EA; however, NNSA proposes to increase the facility's operational capacity up to 100 TeraOps before 2009 with corresponding increases to the facility's consumption of water and electrical power resources. This proposed increase in the operating platform from 50 TeraOps up to 100 TeraOps will be analyzed in the S–SWEIS.

The NISC's construction and operation were analyzed in a July 1999 EA and a FONSI was issued for that proposed action based on the impact analyses for consolidating activities and operating the facility as it was envisioned at that time. The facility is currently operating as evaluated in the 1999 EA; however, NNSA is now proposing to move certain operations from the Technical Area 18 (TA–18) Pajarito Site (another of LANL's ''Key Facilities,'' which is also discussed in the following paragraph) into the NISC. This would change the amount of nuclear material stored in the facility, with corresponding potential increases to worker exposures in the case of a site accident. The proposed changes to operations and material stored in NISC will be analyzed in the S–SWEIS.

NNSA will also eliminate one former LANL ''Key Facility'' identified in the 1999 SWEIS—the TA–18 Pajarito Site. In its 2002 EIS (the TA–18 Relocation Final EIS (DOE/EIS–319)) and ROD, the NNSA decided to relocate TA–18 security category I and II operations and associated nuclear material to the Nevada Test Site. Implementation of the relocation decision began in 2004 and will continue over the next 5 years. After relocation of operations and materials, this facility will no longer be a LANL ''Key Facility'' within the meaning of the SWEIS, and therefore will not be listed as such a facility. There are certain proposals related to the relocation of the TA–18 security category III and IV operations and the disposition of the TA–18 facilities that were not analyzed in the 2002 EIS; these proposed actions and their projected impacts will be evaluated in the S–SWEIS impact analyses.

Certain aspects of operational changes, construction and activities that have occurred or are being proposed for LANL over the next 5 years that were not analyzed in the 1999 SWEIS will also be considered and analyzed in the S–SWEIS. Changes that have been made to existing LANL operations that will also be considered further in the S–SWEIS include some permanent modifications to on-going operations that have recently been made as a result of decreases in specific work and projects performed at some LANL facilities, and changes to the locations of various types of materials at risk (MAR) at LANL facilities or off-site locations. Examples of newly proposed actions at LANL include the remediation of 10 major material disposal areas (MDAs) at LANL; the operation of a Biosafety Level-3 (BSL–3) Facility (this facility will become part of an existing ''Key Facility'' at LANL, the former Health Research Laboratory (HRL) now known as the Bioscience Facilities); the construction and operation of a new solid waste transfer station, an office and light laboratory complex, a consolidated warehouse and truck inspection station, and a new radiography facility; and recently proposed increases in the types and quantities of sealed sources accepted for waste management at LANL. Some of these newly proposed actions may be analyzed explicitly in the S–SWEIS in project specific analyses, while others may be analyzed in separate EAs to be prepared over the next several months, such as the new BSL–3 Facility EA. The potential impacts of the BSL–3 Facility will be included in the S–SWEIS evaluation of cumulative impacts, as will the impacts of all of the newly proposed actions. A comparison of the newly projected operational impacts will also be made to the projected impacts identified in the SWEIS.

The NEPA compliance process for the BSL–3 Facility at LANL has spanned several years. In early 2002, the NNSA issued an EA and FONSI for the construction and operation of the facility at LANL. Due to the need to consider new circumstances and information relevant to the actual construction of the BSL–3 Facility and its future operation, the NNSA withdrew the 2002 FONSI for operating this facility and determined that a new EA should be prepared that re-evaluates the proposed operations of the facility as it has been constructed. The new EA is currently being prepared and a draft EA will be issued for public review and comment in early 2005. The EA will be used by NNSA in making a decision about whether to issue a FONSI for operation of the BSL–3 Facility. If a FONSI cannot be issued, the analyses for the operation of the BSL–3 Facility will be included in the S–SWEIS Proposed Action.

In accordance with applicable DOE and CEQ NEPA regulations, the No Action Alternative will also be analyzed in the S–SWEIS. In this case, the No Action Alternative will be the continued implementation of the 1999 ROD at LANL over the next 5 years as this alternative was originally analyzed in the SWEIS, and will also include the implementation of other actions selected in DOE and NNSA RODs supported by separate NEPA reviews (specifically, actions analyzed since the issuance of the final SWEIS in the Final Environmental Impact Statement for the Conveyance and Transfer of Certain Land Tracts Administered by the U.S. Department of Energy and Located at Los Alamos National Laboratory, Los Alamos and Santa Fe Counties, New Mexico (DOE/EIS–293), the Final Environmental Impact Statement for the Proposed Relocation of Technical Area 18 Capabilities and Materials at Los Alamos National Laboratory (DOE/EIS–319), the Final Environmental Impact Statement for the Chemistry and Metallurgy Research Building Replacement Project at Los Alamos National Laboratory, Los Alamos, New Mexico (DOE/EIS–0350), and in about 20 various EAs and their associated FONSIs, as well as actions categorically excluded from the need for preparation of either an EA or an EIS). The Los Alamos Site Office has posted a list of EAs and their associated FONSIs that pertain to LANL operations dating from the completion of the 1999 SWEIS on their Web site at: *http://www.doeal.gov/LASO/nepa.* The full text of most of these EAs is also available through links provided at that Web site; copies of all of the documents may be obtained by contacting Ms. Withers at any of the addresses provided previously in this Notice.

Changes or new information have also surfaced regarding the environmental setting at LANL over the past 5 years that may affect future LANL operations, such as changes to LANL watersheds as the result of the Cerro Grande Fire, new information and changes resulting from thinning the forests around LANL, and the long-term effects from the regional drought. Additionally, there have been changes to both the number of LANL workers and to the surrounding population that have occurred or are being projected that are different from those on which the SWEIS socioeconomic and other impact analyses were based. To the extent that changes to or new information about the existing LANL environment may significantly affect natural and cultural resource areas originally considered in the 1999 SWEIS, projected impacts associated with implementing the Proposed Action over the next 5 years at LANL will be analyzed in the S–SWEIS.

Direct, indirect, and unavoidable impacts to the various natural and cultural resources present at LANL, together with irreversible and irretrievable commitments and mitigations, will also be analyzed in the S–SWEIS. Further, operational and site differences require a re-evaluation of LANL operational accident analyses and a new assessment and understanding of cumulative impacts of LANL operations will also be addressed.

Public Scoping Process: The scoping process is an opportunity for the public to assist the NNSA in determining the issues for impact analysis, and at least one public scoping meeting is held. The purpose of the scoping meeting is to provide attendees an opportunity to present oral and written comments, ask questions, and discuss concerns regarding the S–SWEIS with NNSA officials. Comments and recommendations can also be mailed to Elizabeth Withers at any of the identified addresses noted in the previous paragraphs of this Notice. The S–SWEIS meeting will use a format to facilitate dialogue between NNSA and the public and will be an opportunity for individuals to provide written or oral statements. NNSA welcomes specific comments or suggestions on the content of the document that could be considered. The potential scope of the S–SWEIS discussed in the previous portions of this Notice is tentative and is intended to facilitate public comment on the scope of this S–SWEIS. It is not intended to be all-inclusive, nor does it imply any predetermination of potential impacts. The S–SWEIS will describe the potential environmental impacts of the alternatives by using available data where possible and obtaining additional data where necessary. Copies of written comments and transcripts of oral comments provided to NNSA during the scoping period will be available at the following locations: Los Alamos Outreach Center, 1350 Central Avenue, Suite 101, Los Alamos, New Mexico, 87544; and the Zimmerman Library, University of New Mexico, Albuquerque, New Mexico 87131.

S–SWEIS Preparation Process: The S–SWEIS preparation process begins with the publication of this Notice of Intent in the **Federal Register**. After the close of the public scoping period, NNSA will begin developing the draft S–SWEIS. NNSA expects to issue the Draft S–SWEIS for public review in the fall of 2005. Public comments on the Draft S–SWEIS will be received during a comment period of at least 45 days following publication of the Notice of Availability. The Notice of Availability, also published in the **Federal Register**, along with notices placed in local newspapers, will provide dates and locations for public hearings on the Draft S–SWEIS and the deadline for comments on the draft document. Issuance of the Final S–SWEIS is scheduled for early 2006.

Issued in Washington, DC, this 29th day of December, 2004.

Everet H. Beckner,

Deputy Administrator for Defense Programs, National Nuclear Security Administration.

BILLING CODE 6450–01–P

DEPARTMENT OF ENERGY

National Nuclear Security Administration

Notice of Availability of the Draft Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, NM

AGENCY: U.S. Department of Energy (DOE), National Nuclear Security Administration (NNSA).

ACTION: Notice of availability and public hearings.

SUMMARY: NNSA announces the availability of the Draft Site-wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico (LANL Draft SWEIS) (DOE/EIS – 0380), and the dates and locations for the public hearings to receive comments on the Draft LANL SWEIS. The Draft LANL SWEIS was prepared in accordance with the Council on Environmental Quality's National Environmental Policy Act (NEPA) Implementing Regulations (40 CFR parts 1500–1508) and the DOE NEPA Implementing Procedures (10 CFR part 1021). The Draft LANL SWEIS analyzes the potential environmental impacts associated with continuing ongoing Los Alamos National Laboratory (LANL) operations and foreseeable new and modified operations and facilities. The Draft LANL SWEIS analyzes the No Action Alternative and two action alternatives: a Reduced Operations Alternative and an Expanded Operations Alternative. The No Action Alternative would continue currently assigned operations at LANL in support of DOE and NNSA missions. The Reduced Operation Alternative also includes most operations discussed under the No Action Alternative with reductions to certain LANL activities below the No Action Alternative level. The Expanded Operations Alternative includes operations discussed under the No Action Alternative plus new and expanded levels of operations in support of reasonably foreseeable future mission requirements.

DATES: The NNSA invites members of Congress, American Indian Tribal Governments, state and local governments, other Federal agencies, and the general public to provide comments on the Draft LANL SWEIS. The comment period extends from the publication of this Notice of Availability through September 5, 2006. Written comments must be received or postmarked by September 5, 2006. Comments postmarked after this date will be considered to the extent practicable. The NNSA will consider the comments in the preparation of the Final LANL SWEIS. Public hearings to present information and receive comments on the Draft LANL SWEIS will be held at three locations. This information will also be published in local New Mexico newspapers in advance of the hearings. Any necessary changes will be announced in the local media and on the web site noted in the **ADDRESSES** section of this notice. Oral and written comments will be accepted at the public hearings. The locations, dates, and times for these public hearings are as follows:

Tuesday, August 8, 2006, at 6:30 p.m. to 9:30 p.m., Fuller Lodge, Pajarito Room, 2132 Central Avenue, Los Alamos, NM.

Wednesday, August 9, 2006, at 6:30 p.m. to 9:30 p.m., Northern New Mexico Community College, Eagle Memorial Sportsplex, 921 Paseo de Onate, Española, NM.

Thursday, August 10, 2006, at 6:30 p.m. to 9:30 p.m., Santa Fe Community College, Main Building, Jemez Rooms, 6401 Richards Avenue, Santa Fe, NM.

The following Web site may be accessed for additional information: *http://www.doeal.gov/laso/nepa/sweis.htm* . For information or to record comments call 1–877–491–4957

ADDRESSES: Copies of the Draft LANL SWEIS are available for review at: The Los Alamos Outreach Center, 1619 Central Avenue, Los Alamos, New Mexico, 87544; the Office of the Northern New Mexico Citizens Advisory Board, 1660 Old Pecos Trail, Suite B, Santa Fe, New Mexico; and the Zimmerman Library, University of New Mexico, Albuquerque, New Mexico 87131. The Draft SWEIS will also be available on the Department of Energy Los Alamos Site Office's LASO NEPA website at: *http://www.doeal.gov/laso/nepa/sweis.htm.* Additionally, a copy of the Draft LANL SWEIS or its Summary may be obtained upon request by writing to: U.S. Department of Energy, National Nuclear Security Administration, Los Alamos Site Office, Attn: Ms. Elizabeth Withers, Office of Environmental Stewardship, 528 35th Street, Los Alamos, New Mexico, 87544; or by facsimile ((505) 667–5948); or by e-mail at: *LANL_SWEIS@doeal.gov.*

Specific information regarding the public hearings can also be obtained by the means described above. Comments concerning the Draft LANL SWEIS can be submitted to the NNSA Los Alamos Site Office by the means described above or by leaving a message on the LASO EIS Hotline at (toll free) 1 –877–491–4957. The Hotline will have instructions on how to record comments. Please mark all envelopes, faxes and e-mail: "Draft LANL SWEIS Comments".

FOR FURTHER INFORMATION CONTACT: For general information on NNSA NEPA process, please contact: Ms. Alice Williams, NA–56, NEPA Compliance Officer for Defense Programs, U.S. Department of Energy, National Nuclear Security Administration, 1000 Independence Avenue, SW., Washington, DC 20585, or telephone 202–586–6847, or Ms. Elizabeth Withers, NEPA Compliance Officer, U.S. Department of Energy, Los Alamos Site Office, 528 35th Street, Los Alamos, New Mexico, 87004, or telephone 505 – 845–4984. For general information about the DOE NEPA process, please contact: Ms. Carol Borgstrom, Director, Office of NEPA Policy and Compliance (EH–42), U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585, (202) 586–4600, or leave a message at 1–800–472–2756.

SUPPLEMENTARY INFORMATION: The primary purpose and need for continued operation of LANL is to provide support for DOE and NNSA core missions as directed by Congress and the President. NNSA's need to continue operating LANL is focused on their obligation to ensure a safe and reliable nuclear weapons stockpile. LANL is also needed to support other Federal agencies, including the Department of Homeland Security. The Draft LANL SWEIS analyzes the environmental impacts of operations at LANL.

LANL is located in north-central New Mexico and covers an area of about 40 square miles (104 square kilometers). LANL was established in 1943 as "Project Y" of the Manhattan Project with a single-focused national defense mission—to build the world's first nuclear weapon. After World War II ended, Project Y was designated a permanent research and development laboratory and its mission support work was expended from defense and related research and development to incorporate a wide variety of new work assignments in support of other Federal Government and civilian programs. LANL is now a multi-disciplinary, multipurpose institution engaged in theoretical and experimental research and development.

DOE issued a Final SWEIS and Record of Decision in 1999 for the continued operation of LANL. DOE regulations implementing NEPA require the evaluation of site-wide NEPA analyses every five years to determine their continued applicability; such a five-year evaluation was initiated for the 1999 SWEIS in 2004, and NNSA subsequently made a determination to prepare a new SWEIS for LANL operations. Decisions regarding LANL operations that will be based upon impact information contained within this SWEIS will replace previous decisions announced through the 1999 ROD for LANL operations.

The alternatives evaluated in the Draft LANL SWEIS represent a range of operational levels ranging from the minimal reasonable activity levels (Reduced Operations Alternative), to the highest reasonable activity levels that could be supported by current facilities, plus the potential expansion and construction of new facilities for existing capabilities and for specifically identified future actions (Expanded Operations Alternative). The No Action Alternative would continue current mission support work at LANL and includes approved interim actions and facility construction, expansions or modifications, and decontamination and decommissioning for which NEPA impact analysis has already been completed. All alternatives assume LANL will continue to operate as a NNSA national security laboratory for the foreseeable future.

Following the end of the public comment period described above, the NNSA will consider and respond to the comments received, and issue the Final LANL SWEIS. The NNSA will consider the environmental impact analysis presented in the Final LANL SWEIS, along with other information, in determining the Record of Decision for the continued operation of LANL.

Signed in Washington, DC, this 26th day of May 2006.

Thomas P. D'Agostino,

Acting Administrator, National Nuclear Security Administration.

BILLING CODE 6450–01–P

DEPARTMENT OF ENERGY

National Nuclear Security Administration

Extension of Comment Period on the Draft Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, NM

AGENCY: U.S. Department of Energy (DOE), National Nuclear Security Administration (NNSA).

ACTION: Notice of comment period extension.

SUMMARY: On July 7, 2006, NNSA published a Notice of Availability for the Draft Site-wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico (LANL Draft SWEIS) (DOE/EIS –0380) (71 FR 38638) and announced a 60-day public comment period ending September 5, 2006. Subsequently, in response to requests for additional time to review and comment on the document, NNSA is extending the public comment period until September 20, 2006.

DATES: Comments should be submitted to NNSA no later than September 20, 2006. NNSA will consider comments submitted after this date to the extent practicable.

ADDRESSES: Comments, or requests for copies of the LANL Draft SWEIS should be sent to: U.S. Department of Energy, National Nuclear Security Administration, Los Alamos Site Office, Attn: Ms. Elizabeth Withers, SWEIS Document Manager, 528 35th Street, Los Alamos, New Mexico, 87544; or by facsimile (1–505-667–5948); or by e-mail at: *LANL_SWEIS@doeal.gov*.

Requests for copies of the LANL Draft SWEIS or recorded comments may also be made by calling 1–877–491–4957. Please mark all envelopes, faxes and e-mail: "LANL Draft SWEIS Comments". The LANL Draft SWEIS and its reference documents are available for review at: the Robert J. Oppenheimer Study Center Research Library, Technical Area 3, Los Alamos National Laboratory, Los Alamos, New Mexico; the Office of the Northern New Mexico Citizens Advisory Board, 1660 Old Pecos Trail, Suite B, Santa Fe, New Mexico; and the Zimmerman Library, University of New Mexico, Albuquerque, New Mexico. The Draft SWEIS is available on the DOE Los Alamos Site Office's NEPA Web site at: *http://www.doeal.gov/laso/nepa/sweis.htm*.

FOR FURTHER INFORMATION CONTACT: U.S. Department of Energy, Los Alamos Site Office, Attn: Ms. Elizabeth Withers, SWEIS Document Manager, 528 35th Street, Los Alamos, New Mexico 87544; or telephone 1–505–845–4984.

Issued in Los Alamos, NM, this 24th day of August, 2006.

Edwin L. Wilmot,

Manager.

BILLING CODE 6450–01–P

DEPARTMENT OF ENERGY

Notice of Intent To Prepare a Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030

AGENCY: National Nuclear Security Administration, Department of Energy.

ACTION: Notice of intent.

SUMMARY: The National Nuclear Security Administration (NNSA), an agency within the U.S. Department of Energy (DOE or Department), announces its intent to prepare a *Supplement to the Stockpile Stewardship and Management Programmatic Environmental Impact Statement—Complex 2030* (Complex 2030 SEIS or SEIS, DOE/EIS–0236–S4), pursuant to the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 *et seq.*), the Council on Environmental Quality's (CEQ's) and DOE's regulations implementing NEPA (40 CFR parts 1500–1508 and 10 CFR part 1021, respectively). The SEIS will analyze the environmental impacts from the continued transformation of the United States' nuclear weapons complex by implementing NNSA's vision of the complex as it would exist in 2030, which the Department refers to as Complex 2030, as well as alternatives. Since the end of the Cold War, there continue to be significant changes in the requirements for the nation's nuclear arsenal, including reductions in the number of nuclear weapons. To fulfill its responsibilities for certifying the safety and reliability of nuclear weapons without underground testing, DOE proposed and implemented the Stockpile Stewardship and Management (SSM) Program in the 1990s. Stockpile Stewardship includes activities required to maintain a high level of confidence in the safety and reliability of nuclear weapons in the absence of underground testing, and in the capability of the United States to resume nuclear testing if directed by the President. Stockpile Management activities include dismantlement, maintenance, evaluation, repair, and replacement of weapons and their components in the existing stockpile.

NNSA's proposed action is to continue currently planned modernization activities and select a site for a consolidated plutonium center for long-term research and development, surveillance, and pit [1] manufacturing; consolidate special nuclear materials throughout the complex; consolidate, relocate, or eliminate duplicative facilities and programs and improve operating efficiencies; identify one or more sites for conducting NNSA flight test operations; and accelerate nuclear weapons dismantlement activities. This Notice of Intent (NOI), the initial step in the NEPA process, informs the public of NNSA's intention to prepare the Complex 2030 SEIS, announces the schedule for public scoping meetings, and solicits public input. Following the scoping period, NNSA will prepare and issue a draft of the Complex 2030 SEIS that will describe the Complex 2030 proposal, the alternatives analyzed, and potential impacts of the proposal and the alternatives.

This NOI also announces that NNSA has cancelled the previously planned *Supplemental Programmatic Environmental Impact Statement on Stockpile Stewardship and Management for a Modern Pit Facility* (DOE/EIS–0236–S2).

DATES: NNSA invites comments on the scope of the Complex 2030 SEIS. The public scoping period starts with the publication of this NOI in the **Federal Register** and will continue through January 17, 2006. Scoping comments received after this date will be considered to the extent practicable. NNSA will hold public scoping meetings to discuss issues and receive oral and written comments on the scope of the Complex 2030 SEIS. The locations, dates, and times for these public scoping meetings are listed below and will be announced by additional appropriate means. NNSA requests federal agencies that desire to be designated as cooperating agencies on the SEIS to contact NNSA's Office of Transformation at the address listed under **ADDRESSES** by the end of the scoping period.

- North Augusta, South Carolina, North Augusta Community Center, 495 Brookside Avenue. November 9, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.
- Oak Ridge, Tennessee, Oak Ridge City Center Club Room, 333 Main Street. November 13, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.
- Amarillo, Texas, Amarillo Globe-News Center, Education Room, 401 S. Buchanan. November 15, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.
- Las Vegas, Nevada, Cashman Center, 850 Las Vegas Boulevard North (at Washington). November 28, 2006. 11 a.m.—3 p.m., 6 p.m.—10 p.m.
- Tonopah, Nevada, Tonopah Convention Center, 301 Brougher Avenue. November 29, 2006, 6 p.m.—10 p.m.
- Socorro, New Mexico, Macey Center (at New Mexico Tech), 801 Leroy Place. December 4, 2006, 6 p.m.—10 p.m.
- Albuquerque, New Mexico, Albuquerque Convention Center, 401 2nd St. NW. December 5, 2006, 11 a.m.—3 p.m., 6 p.m.—10 p.m.
- Los Alamos, New Mexico, Mesa Public Library, 2400 Central Avenue. December 6, 2006, 10:30 a.m.—2:30 p.m.
- Santa Fe, New Mexico, Genoveva Chavez Community Center, 3221 Rodeo Road. December 6, 2006, 6 p.m.—10 p.m.
- Livermore, California, Robert Livermore Community Center, 4444 East Avenue. December 12, 2006, 11 a.m.—3 p.m.
- Tracy, California, Tracy Community Center, 950 East Street. December 12, 2006, 6 p.m.—10 p.m.
- U.S. Department of Energy, 1000 Independence Avenue, SW., Room 1E–245, Washington, DC. December 14, 2006, 1 p.m.—5 p.m.

NNSA officials will be available to informally discuss the Complex 2030 proposal during the first hour. Following this, NNSA intends to hold a plenary session at each scoping meeting in which officials will explain the Complex 2030 proposal and the SEIS, including preliminary alternatives. The meetings will provide the public with an opportunity to provide oral and written comments to NNSA on the scope of the SEIS. Input from the scoping meetings will assist NNSA in preparing the draft SEIS.

ADDRESSES: General questions concerning the NOI can be asked by calling toll-free 1–800–832–0885 (ext. 63519), e-mailing to *Complex2030@nnsa.doe.gov*, or writing to Theodore A. Wyka, Complex 2030 SEIS Document Manager, Office of Transformation, U.S. Department of Energy, NA–10.1, 1000 Independence Avenue, SW., Washington, DC 20585. Written comments on the scope of the SEIS or requests to be placed on the document distribution list can be sent to the Complex 2030 SEIS Document Manager. Additional information regarding Complex 2030 is available on Complex2030PEIS.com.

For general information on the DOE NEPA process, please contact Carol M. Borgstrom, Director, Office of NEPA Policy and Compliance, U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585, (202) 586–4600 or 1–800–472–2756. Additional information regarding DOE NEPA activities and access to many DOE NEPA documents are available on the Internet through the DOE NEPA Web site at *http://www.eh.doe.gov/nepa.*

SUPPLEMENTARY INFORMATION:

[1] A pit is the central core of a nuclear weapon typically containing plutonium-239 that undergoes fission when compressed by high explosives.

Background: The early days of the nuclear weapons complex after World War II saw a rapid build-up of capability and capacity to support the growth of the stockpile to fight the Cold War. By the 1960s, the United States had built a large stockpile of nuclear weapons, and the nation began to focus on improving, rather than expanding, the stockpile. NNSA's predecessor agencies began to consolidate operations and close some production facilities. In the 1980s, facilities were shut down across the nuclear weapons complex, including certain facilities at the Savannah River Site in South Carolina; the Oak Ridge Reservation in Tennessee; the Rocky Flats Plant in Colorado; the Fernald Site in Ohio; the Hanford Reservation in Washington; and elsewhere.

Prior DOE NEPA Reviews: DOE completed a Nuclear Weapons Complex Reconfiguration (''Complex-21'') Study in January 1991, which identified significant cost savings that could be achieved by further downsizing of the nuclear weapons complex.

DOE then initiated a programmatic EIS (Reconfiguration PEIS) examining alternatives for reconfiguring the nuclear weapons complex. However, in December 1991, the Department decided to separate proposals for transforming non-nuclear production from the Reconfiguration PEIS because (1) proposals to consolidate non-nuclear facilities might not require preparation of an EIS, and (2) proposals and decisions regarding transformation of non-nuclear production would neither significantly affect nor be affected by proposals and decisions regarding transformation of nuclear production. On January 27, 1992, the Department issued an NOI (57 FR 3046) to prepare an environmental assessment (DOE/EA–0792) for the consolidation of non-nuclear production activities within the nuclear weapons complex. Following the collapse of the Soviet Union, the United States reduced the budget for the nuclear weapons program. President George H. W. Bush imposed a moratorium in 1992 on underground nuclear testing.

On September 14, 1993, DOE published a Finding of No Significant Impact (FONSI) regarding its proposal to consolidate non-nuclear component production (58 FR 48043). This proposal included termination of non-nuclear production missions at the Mound Plant in Ohio, the Pinellas Plant in Florida, and the Rocky Flats Plant in Colorado. The electrical and mechanical manufacturing functions were consolidated at the Kansas City Plant. Detonators and beryllium capabilities for technology and pit support were consolidated at Los Alamos National Laboratory (LANL) in New Mexico, and neutron generator production was relocated to Sandia National Laboratories in New Mexico.

In October 1993, President William J. Clinton issued Presidential Decision Directive 15 (PDD–15), which directed DOE to establish the Stockpile Stewardship Program. PDD–15 significantly redirected the nuclear weapons program. Throughout the Cold War, the Department of Defense (DOD) and DOE's nuclear weapons laboratories had based a portion of their confidence in the reliability of nuclear weapons on performance data from atmospheric and underground tests. To ensure weapons reliability during the moratorium on testing, DOE proposed to invest in new scientific tools to assess the complex phenomena involved in the detonation of nuclear weapons. DOE also began to develop sophisticated tools and computer-based simulation techniques to assess various aging phenomena as nuclear weapons continued to serve well beyond their originally anticipated lifetimes. These actions enhanced research and development (R&D) and deferred spending on the production complex.

DOE concluded in October 1994 that the alternatives described in the Reconfiguration PEIS no longer contained realistic proposals for reconfiguration of the nuclear weapons complex. That conclusion was based on several factors, including: comments offered at the September-October 1993 Reconfiguration PEIS scoping meetings; the anticipation that no production of new nuclear weapons types would be required for the foreseeable future; budget constraints; and the Department's decision to prepare a separate PEIS on Storage and Disposition of Weapons-Usable Fissile Materials (DOE/EIS–0229; NOI published June 21, 1994, 59 FR 17344).

Consequently, the Department separated the Reconfiguration PEIS into two new PEISs: (1) A Tritium Supply and Recycling PEIS (DOE/EIS–0161); and (2) the SSM PEIS (DOE/EIS–0236). The Final PEIS for Tritium Supply and Recycling was issued on October 27, 1995 (60 FR 55021). In its Record of Decision (ROD) on May 14, 1999 (64 FR 26369 [2]), DOE decided it would produce the tritium needed to maintain the nuclear arsenal at commercial light water reactors owned and operated by the Tennessee Valley Authority and extract tritium at a new DOE-owned Tritium Extraction Facility at the Savannah River Site. With regard to the SSM PEIS, DOE issued an NOI on June 6, 1995 (60 FR 31291), a final SSM PEIS on November 19, 1996 (61 FR 58871), and a ROD on December 26, 1996 (61 FR 68014) announcing its decision to transform the weapons production complex by (1) reducing the weapon assembly capacity located at the Pantex Plant in Texas; (2) reducing the high-explosives fabrication capacity at Pantex; (3) reducing the uranium, secondary, and case fabrication capacity in the Y–12 National Security Complex in Tennessee; (4) reducing nonnuclear component fabrication capacity at the Kansas City Plant; and (5) reestablishing a modest interim pit fabrication capability at Los Alamos National Laboratory in New Mexico while evaluating the need for greater pit manufacturing capacity in the future.

In accordance with the decisions in the SSM PEIS, the *Non-nuclear Consolidation Environmental Assessment* (EA), and the Tritium Supply and Recycling PEIS, DOE began transforming the nuclear weapons complex to its present configuration. DOE has also prepared other EISs that facilitated the transformation of the complex. The relevant RODs for these site-wide and project-specific EISs are listed below:

- 1996 ROD for the *EIS for the Nevada Test Site and Off-Site Locations in the State of Nevada* (61 FR 65551, December 13, 1996).
- 1997 ROD for the *EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (62 FR 3880, January 27, 1997).
- 1999 ROD for the Site-wide EIS for Continued Operation of the Los Alamos National Laboratory (64 FR 50797, September 20, 1999).
- 1999 ROD for the *EIS for Site-wide Operation of Sandia National Laboratories* (64 FR 69996, December 15, 1999).
- 2000 *Amended ROD for the Nevada Test Site EIS* (65 FR 10061, February 25, 2000).
- 2002 ROD for the *Site-wide EIS for the Oak Ridge Y–12 National Security Complex* (67 FR 11296, March 13, 2002).
- 2002 ROD for the *EIS for the Relocation of Technical Area 18 Capabilities and Materials at the Los Alamos National Laboratory* (67 FR 79906, December 31, 2002).
- 2004 ROD for the *EIS for the Chemistry and Metallurgy Research Building Replacement Project, Los*

[2] This ROD also contains decisions for the EIS for Construction and Operation of a Tritium Extraction Facility at the Savannah River Site (DOE/EIS–0271) and EIS for the Production of Tritium in a Commercial Light Water Reactor (DOE/EIS–0288).

Alamos National Laboratory (69 FR 6967, February 12, 2004).

• 2005 ROD for the *Site-wide EIS for Continued Operation of Lawrence Livermore National Laboratory and Supplemental Stockpile Stewardship and Management Programmatic EIS* (70 FR 71491, November 29, 2005).

Nuclear Weapons Complex: The current nuclear weapons complex consists of eight major facilities located in seven states. NNSA maintains a limited capability to design and manufacture nuclear weapons; provides surveillance of and maintains nuclear weapons currently in the stockpile; and dismantles retired nuclear weapons. Major facilities and their primary responsibilities within the nuclear weapons complex are listed below:

Savannah River Site (SRS) (Aiken, South Carolina)—Extracts tritium (when the Tritium Extraction Facility becomes operational in 2007); provides loading, unloading and surveillance of tritium reservoirs. SRS does not maintain Category I/II [3] quantities of special nuclear material (SNM) [4] associated with weapons activities, but does maintain Category I/II quantities of SNM associated with other Department activities (*e.g.*, environmental management).

Pantex Plant (PX) (Amarillo, Texas)—Dismantles retired weapons; fabricates high-explosives components; assembles high explosive, nuclear, and non-nuclear components into nuclear weapons; repairs and modifies weapons; and evaluates and performs non-nuclear testing of weapons. Maintains Category I/II quantities of SNM for the weapons program and material no longer needed by the weapons program.

Y–12 National Security Complex (Y–12) (Oak Ridge, Tennessee)—Manufactures nuclear weapons secondaries, cases, and other weapons components; evaluates and performs testing of weapon components; maintains Category I/II quantities of SNM; conducts dismantlement, storage, and disposition of nuclear weapons materials; and supplies SNM for use in naval reactors.

Kansas City Plant (KCP) (Kansas City, Missouri)—Manufactures and acquires non-nuclear weapons components; and evaluates and performs testing of weapon components. No Category I/II quantities of SNM are maintained at the KCP.

Lawrence Livermore National Laboratory (LLNL) (Livermore, California)—Conducts research and development of nuclear weapons; designs and tests advanced technology concepts; designs weapons; maintains a limited capability to fabricate plutonium components; and provides safety and reliability assessments of the stockpile. Maintains Category I/II quantities of SNM associated with the weapons program and material no longer needed by the weapons program.

Los Alamos National Laboratory (LANL) (Los Alamos, New Mexico)—Conducts research and development of nuclear weapons; designs and tests advanced technology concepts; designs weapons; provides safety and reliability assessments of the stockpile; maintains interim production capabilities for limited quantities of plutonium components (e.g., pits); and manufactures nuclear weapon detonators for the stockpile. Maintains Category I/II quantities of SNM associated with the nuclear weapons program and material no longer needed by the weapons program.

Sandia National Laboratories (SNL) (Albuquerque, New Mexico; Livermore, California)—Conducts system engineering of nuclear weapons; designs and develops non-nuclear components; conducts field and laboratory non-nuclear testing; conducts research and development in support of the nuclear weapon non-nuclear design; manufactures non-nuclear weapon components; provides safety and reliability assessments of the stockpile; and manufactures neutron generators for the stockpile. Maintains Category I/II quantities of SNM associated with the nuclear weapons program.

Nevada Test Site (NTS) (Las Vegas, Nevada)—Maintains capability to conduct underground nuclear testing; conducts experiments involving nuclear material and high explosives; provides capability to disposition a damaged nuclear weapon or improvised nuclear device; conducts non-nuclear experiments; and conducts research and training on nuclear safeguards, criticality safety and emergency response. Maintains Category I/II quantities of SNM associated with the nuclear weapons program.

Purpose and Need for the Stockpile Stewardship and Management Program: Under the Atomic Energy Act of 1954 (42 U.S.C. 2011 et seq.), DOE is responsible for providing nuclear weapons to support the United States' national security strategy. The National Nuclear Security Administration Act (Pub. L. 106–65, Title XXXII) assigned this responsibility to NNSA within DOE. One of the primary missions of NNSA is to provide the nation with safe and reliable nuclear weapons, components and capabilities, and to accomplish this in a way that protects the environment and the health and safety of workers and the public.

Changes in national security needs and budgets have necessitated changes in the way NNSA meets its responsibilities regarding the nation's nuclear stockpile. As a result of a changed security environment, unilateral decisions by the United States and international arms control agreements, the nation's stockpile is significantly smaller today and by 2012, it will be the smallest since the Eisenhower administration (1953–1961). The Treaty of Moscow will eventually lead to a level of 1,700–2,200 operationally-deployed strategic nuclear weapons.

However, nuclear deterrence will continue to be a cornerstone of United States national security policy, and NNSA must continue to meet its responsibilities for ensuring the safety and reliability of the nation's nuclear weapons stockpile. The current policy is contained in the Nuclear Posture Review, submitted to Congress in early 2002, which states that the United States will:

• Change the size, composition and character of the nuclear weapons stockpile in a way that reflects that the Cold War is over;

• Achieve a credible deterrent with the lowest possible number of nuclear warheads consistent with national security needs, including obligations to allies; and

• Transform the NNSA nuclear weapons complex into a responsive infrastructure that supports the specific stockpile requirements established by the President and maintains the essential United States nuclear capabilities needed for an uncertain global future.

Complex 2030 SEIS: NNSA has been evaluating how to establish a more responsive nuclear weapons complex infrastructure since the Nuclear Posture Review was transmitted to Congress in early 2002. The Stockpile Stewardship Conference in 2003, the Department of Defense Strategic Capabilities Assessment in 2004, the recommendations of the Secretary of Energy Advisory Board (SEAB) Task Force on the Nuclear Weapons Complex Infrastructure in 2005, and the Defense

[3] Category I/II quantities of special nuclear material are determined by grouping materials by type, attractiveness level, and quantity. These grouping parameters are defined in DOE Manual 470.4–6, Nuclear Material Control and Accountability [see *https://www.directives.doe.gov*].

[4] As defined in section 11 of the Atomic Energy Act of 1954, special nuclear material are: (1) Plutonium, uranium enriched in the isotope 233 or in the isotope 235, and any other material which the U.S. Nuclear Regulatory Commission determines to be special nuclear material; or (2) any material artificially enriched by plutonium or uranium 233 or 235.

Science Board Task Force on Nuclear Capabilities in 2006 have provided information for NNSA's evaluations.

In early 2006, NNSA developed a planning scenario for what the nuclear weapons complex would look like in 2030. See *http://www.nnsa.doe.gov* for more information regarding Complex 2030 planning. The Complex 2030 planning scenario incorporates many of the decisions NNSA has already made based on the evaluations in the SSM PEIS, Tritium Supply and Recycling PEIS, and other NEPA documents. See discussion in background above. The following table identifies which components of Complex 2030 are based on the existing SSM PEIS and Tritium PEIS RODs, including RODs for subsequent tiered EISs:

Components of Complex 2030 that reflect earlier decisions	SSM PEIS ROD	Tritium PEIS ROD
Maintain but reduce the existing weapon assembly capacity located at Pantex	X	....
Maintain but reduce the high-explosives fabrication capacity at Pantex	X	....
Maintain but reduce the existing uranium, secondary, and case fabrication capacity at the Y–12 Plant at Oak Ridge	X	....
Reduce the non-nuclear component fabrication capacity at the Kansas City Plant	X	....
Reestablish limited pit fabrication capability at Los Alamos National Laboratory while evaluating the need for a larger capability	X	....
Irradiate tritium producing rods in commercial light water reactors; construct and operate a new Tritium Extraction Facility at DOE's Savannah River Site	....	X

Types of Decisions that Would Be Based on the Complex 2030 SEIS: The decisions set forth in the Complex 2030 ROD would:

- Identify the future missions of the SSM Program and the nuclear weapons complex; and
- Determine the configuration of the future weapons complex needed to accomplish the SSM Program.

For specific programs or facilities, NNSA may need to prepare additional NEPA documents to implement the decisions announced in the ROD. The baseline that will be used for the analyses of program and facility needs in the SEIS is 1,700–2,200 operationally-deployed strategic nuclear weapons, in addition to augmentation weapons, reliability-reserve weapons and weapons required to meet NATO commitments. The numbers are consistent with international arms-control agreements. Consistent with national security policy directives, replacement warhead design concepts may be pursued under the alternatives as a means of, for example, enhancing safety and security, improving manufacturing practices, reducing surveillance needs, and reducing need for underground tests.

The SEIS will evaluate reasonable alternatives for future transformation of the nuclear weapons complex. The Proposed Action and alternatives to the Proposed Action will assume continued implementation of the following prior siting decisions that DOE made in the SSM PEIS and Tritium PEIS RODs, including RODs for subsequent tiered EISs:

- Location of the weapon assembly/disassembly operations at the Pantex Plant in Texas.
- Location of uranium, secondary, and case fabrication at the Y–12 National Security Complex in Tennessee.
- Location of tritium extraction, loading and unloading, and support operations at the Savannah River Site in South Carolina.

NNSA does not believe it is necessary to identify additional alternatives beyond those present in the SSM PEIS. Regarding the uranium, secondary, and case fabrication at Y–12, NNSA is currently preparing a Y–12 Site-wide EIS to evaluate reasonable alternatives for the continued modernization of the Y–12 capabilities. The Complex 2030 SEIS will incorporate any decisions made pursuant to the Y–12 Site-wide EIS.

While the Complex 2030 planning scenario proposes to consolidate further non-nuclear production activities performed at the Kansas City Plant, this proposal will be evaluated in a separate NEPA analysis, as was done in the 1990s. NNSA believes that it is appropriate to separate the analyses of the transformation of non-nuclear production from the SEIS because decisions regarding those activities would neither significantly affect nor be affected by decisions regarding the transformation of nuclear production activities.

The SSM PEIS ROD announced NNSA's decision to establish a small interim pit production capacity at LANL. In the 1999 LANL Site-wide EIS ROD, NNSA announced it would achieve a pit production capacity at LANL of up to 20 pits per year. The 2006 draft LANL Site-wide EIS evaluates a proposal for a production capacity of 50 certified pits annually. This proposed capacity is based on an annual production rate of 80 pits per year in order to provide NNSA with sufficient flexibility to obtain 50 certified pits. Any decisions made pursuant to the LANL Site-wide EIS will be included in the Complex 2030 SEIS.

Based upon the studies [5] and analyses that led to NNSA's development of the Complex 2030 scenario, NNSA has developed alternatives that are intended to facilitate public comment on the scope of the SEIS. NNSA's decisions regarding implementation of Complex 2030 will be based on the following alternatives, or a combination of those alternatives.

The Proposed Action—Transform to a More Modern, Cost-Effective Nuclear Weapons Complex (Complex 2030). This alternative would undertake the following actions to continue the transformation of NNSA's nuclear weapons complex:

- Select a site to construct and operate a consolidated plutonium center for long-term R&D, surveillance, and manufacturing operations for a baseline capacity of 125 qualified pits per year at a site with existing Category I/II SNM.
- Reduce the number of sites with Category I/II SNM and consolidate SNM to fewer locations within each given site.
- Consolidate, relocate or eliminate duplicative facilities and programs and improve operating efficiencies, including at facilities for nuclear materials storage, tritium R&D, high explosives R&D, environmental testing, and hydrotesting facilities.
- Identify one or more sites for conducting NNSA flight test operations.

[5] The Stockpile Stewardship Conference in 2003, the Department of Defense Strategic Capabilities Assessment in 2004, the recommendations of the Secretary of Energy Advisory Board (SEAB) Task Force on the Nuclear Weapons Complex Infrastructure in 2005, and the recommendations of the Defense Science Board Task Force on Nuclear Capabilities in 2006.

Existing DOD and DOE test ranges (*e.g.*, White Sands Missile Range in New Mexico and Nevada Test Site in Nevada) would be considered as alternatives to the continued operation of the Tonopah Test Range in Nevada.

• Accelerate dismantlement activities.

The DOE sites that will be considered as potential locations for the consolidated plutonium center and consolidation of Category I/II SNM include: Los Alamos, Nevada Test Site, Pantex Plant, Y–12 National Security Complex, and the Savannah River Site. Other DOE sites are not considered reasonable alternative locations because they do not satisfy certain criteria such as population encroachment, or mission compatibility or synergy with the site's existing mission.

Alternatives to the Proposed Action

No Action Alternative. The No Action Alternative represents the status quo as it exists today and is presently planned. It includes the continued implementation of decisions made pursuant to the SSM PEIS and the Tritium Supply and Recycling PEIS (as summarized above) and related site-specific EISs and EAs. These decisions are contained in RODs and Findings of No Significant Impact (FONSIs), including those discussed above, and copies can be located on the DOE NEPA Document Web page at *http://www.eh.doe.gov/nepa/documents.html.*

The No Action Alternative would also include any decisions made as a result of the new Y–12 Site-wide EIS and the LANL Site-wide EIS once these EISs are finished. NNSA expects to issue RODs on these EISs prior to publication of the draft Complex 2030 SEIS.

The No Action Alternative is illustrated in the following matrix:

Capability	Sites (no action alternative)							
	KCP	LANL	LLNL	NTS	Y–12	PX	SNL	SRS
Weapons assembly/Disassembly				X		X		
Nonnuclear components	X	X					X	
Nuclear components:								
—Pits		X						
—Secondaries and cases					X			
High explosives components						X		
Tritium Extraction, Loading and Unloading								X
High explosives R&D		X	X			X	X	
Tritium R&D		X	X					X
Large Scale Hydrotesting		X	X	X				
Category I/II SNM Storage		X	X	X	X	X	X	X

The No Action Alternative also includes continuation of environmental testing at current locations and flight-testing activities at the Tonopah Test Range in Nevada.

Reduced Operations and Capability-Based Complex Alternative

In this alternative, NNSA would maintain a basic capability for manufacturing technologies for all stockpile weapons, as well as laboratory and experimental capabilities to support stockpile decisions, but would reduce production facilities to a ''capability-based'' [6] capacity. This alternative would not have a production capacity sufficient to meet current national security objectives. This alternative would be defined as follows:

• Do not construct and operate a consolidated plutonium center for long-term R&D, surveillance, and manufacturing operations; and do not expand pit production at LANL beyond 50 certified pits per year.

• Reduce the number of sites with Category I/II SNM and consolidate SNM to fewer locations within a given site.

• Consolidate, relocate or eliminate duplicative facilities and programs and improve operating efficiencies, including at facilities for nuclear materials storage, tritium R&D, high explosives R&D, environmental testing facilities, and hydrotesting facilities.

• Identify one or more sites for conducting NNSA flight test operations. Existing DOD and DOE test ranges (*e.g.* White Sands Missile Range in New Mexico and Nevada Test Site in Nevada) would be considered as potential alternatives to the continued operation of the Tonopah Test Range in Nevada.

• Production capacities at Pantex, Y–12, and the Savannah River Site would be considered for further reductions limited by the capability-based capacity.

• NNSA would continue dismantlement activities.

Proposal Not Being Considered for Further Analysis. The SEAB Task Force on the Nuclear Weapons Complex Infrastructure recommended that NNSA pursue a consolidated nuclear production center (CNPC) as a single facility for all research, development, and production activities relating to nuclear weapons that involve significant amounts (*i.e.* Category I/II quantities) of SNM. The CNPC, as envisioned by the SEAB Task Force, would contain all the nuclear weapons manufacturing, production, assembly, and disassembly facilities and associated weapon surveillance and maintenance activities for the stockpile weapons. The CNPC would include the plutonium activities of the consolidated plutonium center proposed by NNSA in its Complex 2030 vision, as well as the consolidated activities of the uranium, tritium, and high explosive operations. DOE believes that creation of a CNPC is not a reasonable alternative and does not intend to analyze it as an alternative in the SEIS because of the technical and schedule issues involved in constructing a CNPC, as well as associated costs. NNSA invites and will consider comments on this matter during the scoping process.

The SEAB Task Force developed three business cases for transforming the nuclear weapons complex, two of which were characterized as high risk. Its preferred least-risk option was to establish a CNPC ''quickly'' by accelerating site selection, NEPA analyses, regulatory approvals, and construction. The Task Force assumed that NNSA could, under these circumstances, begin operating a CNPC in 2015, start consolidation of SNM shortly thereafter, accelerate dismantlements, and begin other major transformational activities. Until the CNPC was completed, NNSA would have to maintain, and in some cases improve, existing production and research facilities. According to the Task Force's estimates, this option would require an additional 1 billion dollars per year for weapons programs

[6] The capability to manufacture and assemble nuclear weapons at a nominal level.

activities for the next 10 years, and lead to a net savings through 2030 of 15 billion dollars.

Accelerated construction of a CNPC would not allow NNSA to avoid immediate expenditures to restore and modernize interim production capabilities to meet essential Life Extension Program (LEP) schedules and support the existing stockpile during the next decade. LEP is the refurbishment of nuclear weapons parts and components to extend the weapon deployment life. NNSA has concluded that the SEAB Task Force underestimated the nonfinancial challenges of constructing a CNPC. A CNPC would require moving a unique and highly skilled workforce to a new location. It would require NNSA to obtain significant regulatory approvals rapidly, and to construct a unique and complex facility on a tight schedule. It would put many of the significant aspects of the weapons complex transformation into "one basket"—until the CNPC began operations, all the other facilities and activities would be delayed. NNSA's Proposed Action would achieve many of the benefits of the CNPC approach—consolidation of SNM and facilities, integrated R&D and production involving SNM, and aggressive dismantlements—in a way that addresses immediate national security needs in a technically feasible and affordable manner.

Nuclear Materials Consolidation: DOE is pursuing SNM consolidation from all DOE sites including those that comprise the nuclear weapons complex. The SEIS will look at alternatives for the storage and consolidation of nuclear materials within the nuclear weapons complex including materials needed to maintain the United States' nuclear weapons arsenal. There is a potential overlap between the SEIS and the activities of the Department's other nuclear materials consolidation activities, and DOE will ensure that there is appropriate coordination between the two activities.

Supplemental Programmatic Environmental Impact Statement on Stockpile Stewardship and Management for a Modern Pit Facility: NNSA issued a *Draft Supplemental Programmatic Environmental Impact Statement on Stockpile Stewardship and Management for a Modern Pit Facility* (MPF) on June 4, 2003 (68 FR 33487; also 68 FR 33934, June 6, 2003) that analyzed alternatives for producing the plutonium pits that are an essential component of nuclear weapons. On January 28, 2004, NNSA announced that it was indefinitely postponing any decision on how it would obtain a large capacity pit manufacturing facility. Because the Complex 2030 SEIS will analyze alternatives for plutonium-related activities that include pit production, DOE, effective upon publication of this NOI, cancels the MPF PEIS.

Public Scoping Process: The scoping process is an opportunity for the public to assist the NNSA in determining the issues for analysis. NNSA will hold public scoping meetings at locations identified in this NOI. The purpose of these meetings is to provide the public with an opportunity to present oral and written comments, ask questions, and discuss concerns regarding the transformation of the nuclear weapons complex and the SEIS with NNSA officials. Comments and recommendations can also be communicated to NNSA as discussed earlier in this notice.

Complex 2030 PEIS Supplement Preparation Process: The SEIS preparation process begins with the publication of this NOI in the **Federal Register**. NNSA will consider all public comments that it receives during the public comment period in preparing the draft SEIS. NNSA expects to issue the draft SEIS for public review during the summer of 2007. Public comments on the draft SEIS will be received during a comment period of at least 45 days following the U.S. Environmental Protection Agency's publication of the Notice of Availability in the **Federal Register**. Notices placed in local newspapers will specify dates and locations for public hearings on the draft SEIS and will establish a schedule for submitting comments on the draft SEIS, including a final date for submission of comments. Issuance of the final SEIS is scheduled for 2008.

Classified Material: NNSA will review classified material while preparing the SEIS. Within the limits of classification, NNSA will provide the public as much information as possible to assist its understanding and ability to comment. Any classified material needed to explain the purpose and need for the action, or the analyses in the SEIS, will be segregated into a classified appendix or supplement, which will not be available for public review. However, all unclassified information or results of calculations using classified data will be reported in the unclassified section of the SEIS, to the extent possible in accordance with federal classification requirements.

Issued in Washington, DC on October 11, 2006.

Linton F. Brooks,

Administrator, National Nuclear Security Administration.

APPENDIX B
NONRADIOLOGICAL AIR QUALITY

APPENDIX B
NONRADIOLOGICAL AIR QUALITY

Introduction

This appendix provides additional information about the nonradiological air quality analyses presented in Chapter 5 of this Site-Wide Environmental Impact Statement (SWEIS), including details on the modeling and analysis for criteria pollutants and other chemical emissions.

B.1 Assumptions, Data Sources, Standards, and Models

B.1.1 Applicable Guidelines and Standards and Emission Sources

Criteria Pollutants

The Clean Air Act mandates that the U.S. Environmental Protection Agency (EPA) establish primary and secondary National Ambient Air Quality Standards for pollutants of concern. These pollutants, known as criteria pollutants, are carbon monoxide, sulfur dioxide, nitrogen dioxide, ozone, lead, particulate matter less than or equal to 10 microns in aerodynamic diameter (PM_{10}), and particulate matter less than or equal to 2.5 microns in aerodynamic diameter ($PM_{2.5}$).

The State of New Mexico also has established ambient air quality standards for carbon monoxide, sulfur dioxide, nitrogen dioxide, total suspended particulates, hydrogen sulfide, and total reduced sulfur (New Mexico Administrative Code, Title 20, Chapter 2, Part 3). The more restrictive of the State of New Mexico ambient air quality standards and the National Ambient Air Quality Standards, are listed in **Table B–1**.

Criteria pollutants released into the atmosphere from Los Alamos National Laboratory (LANL) operations are emitted primarily from combustion facilities such as boilers, emergency generators, and motor vehicles.

Other Nonradiological Air Pollutants

Chemicals are currently used at LANL in separately located groups of operations or laboratory complexes called "technical areas" (TAs), which comprise large geographic areas. Air pollutants from these TAs may be released into the atmosphere from many ongoing activities, including laboratory, maintenance, and waste management operations. In the 1999 *Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico* (*1999 SWEIS)* (DOE 1999), two types of toxic air pollutants were considered: noncarcinogenic and carcinogenic. Chemical pollutants are classified as hazardous air pollutants or as toxic air pollutants.

Table B–1 Criteria Pollutant Standards

Pollutant	*Time Period*	*Controlling Ambient Air Quality Standards* [a] *(micrograms per cubic meter)*
Carbon Monoxide	8 hours 1 hour	7,961 [b] 11,987 [b]
Nitrogen Dioxide	Annual 24 hours	75 [b] 150 [b]
Sulfur Dioxide	Annual 24 hours 3 hours	42 [b] 209 [b] 1,046 [c]
Total Suspended Particulates	Annual 30-day 7-day 24 hours	60 [b] 90 [b] 110 [b] 150 [b]
PM_{10}	Annual 24 hours	– [c,d] 150 [c]
$PM_{2.5}$	Annual 24 hours	15 [c] 35 [c,d]
Ozone	8 hours	125 [c]
Lead	Calendar quarter	1.5 [c]
Hydrogen sulfide	1 hour	11.1 [b]

PM_n = particulate matter with an aerodynamic diameter less than or equal to *n* micrometers.
[a] Ambient standards for gaseous pollutants are stated in parts per million. These values were converted to micrograms per cubic meter, with appropriate corrections for temperature and pressure (elevation), following New Mexico *Dispersion Modeling Guidelines* (NMED 2003, LANL 2003).
[b] State standard.
[c] Federal standard.
[d] The EPA recently revoked the annual PM_{10} standard and changed the 24-hour $PM_{2.5}$ standard from 65 to 35 micrograms per cubic meter.
Note: The more stringent of the Federal and state standards is presented if both exist for the averaging period. The National Ambient Air Quality Standards (Title 40 *Code of Federal Regulations* [CFR] Part 50), other than those for ozone, particulate matter, lead, and those based on annual averages, are not to be exceeded more than once per year. The annual arithmetic $PM_{2.5}$ mean standard is attained when the expected annual arithmetic mean concentration (3 year average) is less than or equal to the standard. The 24-hour $PM_{2.5}$ standard is met when the 98th percentile over 3 years of 24-hour average concentrations is less than or equal to the standard value. The 24-hour PM_{10} standard is met when the 99th percentile over 3 years of 24-hour concentrations is less than or equal to the standard value.
Sources: NMAC 20.2.3 (New Mexico Administrative Code – Environmental Protection, Air Quality, Ambient Air Quality Standards 2002); 40 CFR Part 50 (National Ambient Air Quality Standards); 71 *Federal Register* (FR) 61143.

For the purpose of this SWEIS, the estimated chemical emissions during recent years were compared to the emissions evaluated in the *1999 SWEIS*. The total emissions of toxic or hazardous air pollutants and volatile organic compounds showed considerable variation over the period 1999 through 2004. Operation of the air curtain destructors resulted in increases of hazardous air pollutants and volatile organic compounds during 2002 and 2003. The air curtain destructors accounted for 2.1 and 22.9 tons (1.9 and 20.8 metric tons) of hazardous air pollutants and volatile organic compounds, respectively, in 2002. In 2003, they accounted for 3.3 and 36.0 tons (3.0 and 32.7 metric tons) of hazardous air pollutants and volatile organic compounds, respectively (LANL 2004b). With the completion of the Cerro Grande Fire Rehabilitation Project tree thinning and removal, emissions of hazardous air pollutants and volatile organic compounds returned to lower levels more typical of prefire conditions.

Toxic and hazardous air pollutant emissions from LANL activities are released primarily from laboratory, maintenance, and waste management operations. Unlike a production facility with well-defined operational processes and schedules, LANL is a research and development facility with great fluctuations in both the types of chemicals emitted and their emission rates. LANL has a program to review new operations for their potential to emit chemicals. Toxic air pollutant emissions from the use of chemicals are generally below the levels for which the State would require a permit for a new source under the New Mexico permit regulations for toxic air pollutant emissions (NMAC 20.2.72.400 - 502). The Title V operating permit limits the emissions of hazardous air pollutants such that operations at LANL are below the major source threshold for hazardous air pollutants. Emissions of hazardous air pollutants are monitored and reported annually to the New Mexico Environmental Department as required by the permit. Past actual emissions of hazardous air pollutants have been well below the threshold (LANL 2004a).

The chemical database information system used to estimate emissions in recent years is called ChemLog. It was used to estimate emissions for the annual *SWEIS Yearbooks* for 2002 through 2005 (LANL 2006). ChemLog includes all chemicals purchased at each LANL facility in each calendar year. Prior to 2002, another inventory system was used to estimate emissions based on chemical use. For the *1999 SWEIS*, 51 of the 382 chemicals evaluated were considered to be carcinogenic. For the purpose of the analysis, it was assumed that air emissions could result from the use of any of the 382 chemicals from any of the TAs that purchased them (DOE 1999). In the *SWEIS Yearbooks* chemical usage was summed by facility. It was then estimated that 35 percent of the chemical used was released to the atmosphere. Emission estimates for some metals were based on an emission factor of less than 1 percent because these metal emissions were assumed to result from cutting or melting activities. Fuels such as propane and acetylene were assumed to be completely combusted; therefore, no emissions were reported. A list of chemicals purchased in 2005 are provided in **Table B–2**.

Noncarcinogens

Short-Term Guideline Values. While no national or State of New Mexico standards have been established for noncarcinogens, the New Mexico Environment Department has developed guideline values for determining whether a new or modified source emitting a toxic air pollutant would be issued a construction permit (New Mexico Environment Department, Air Quality Control Regulations, revised November 17, 1994). These guideline values are 8-hour concentrations that are one-hundredth of the Occupational Exposure Limits established by the American Conference of Governmental Industrial Hygienists or the National Institute of Occupational Safety and Health. The State of New Mexico listing was supplemented with information on the lowest values for Occupational Exposure Limits from these sources. These guideline values were used in this analysis in screening for potential short-term impacts of chemical releases from LANL operations.

Annual Average Guideline Values. The guideline values used in the *1999 SWEIS* analysis were the inhalation reference concentrations from EPA's Integrated Risk Information System. Reference concentrations are daily exposure levels to the human population (including sensitive subgroups) during a lifetime (70 years) that could occur without appreciable risk of deleterious effects.

Table B–2 Chemicals Purchased at Los Alamos National Laboratory – 2005 [a]

Chemical Name	Key Facility

[a] These chemicals are representative of those purchased at LANL. Additional chemicals listed in the New Mexico permit regulations on toxic air pollutants and emission (NMAC 20.2.72.502), listed in the EPA list of hazardous air pollutants, and other chemicals could be used and potentially emitted from activities at LANL as needed.

Source: LANL 2006.

Carcinogens

The guideline values used in the *1999 SWEIS* analysis to estimate potential impacts of carcinogenic toxic air pollutants from LANL operations were based on an incremental cancer risk of one in a million (1.0×10^{-6}) (in other words, one person in a population of a million would develop cancer if this population was exposed to this concentration over a lifetime), a level of concern established in the Clean Air Act. This value was used in the screening for the estimated combined incremental cancer risk associated with all of the carcinogenic pollutants emitted from LANL facilities at any location. For the purpose of screening individual carcinogens, a cancer risk of one in one hundred million (1.0×10^{-8}) was established as the guideline value.

B.1.2 Receptors and Receptor Sets

For the purpose of evaluating the impact of criteria pollutant emissions, the analysis prepared for the LANL operating permit was used (LANL 2003). In this analysis, two sets of receptors (locations where air quality levels were estimated) were considered: 1) a regular Cartesian grid with 329 feet (100-meter) grid spacing, and 2) a discrete Cartesian grid that followed actual fence lines, property boundaries, and roads of interest. The discrete Cartesian grid distance was less than 164 feet (50 meters) between receptor points. The regular Cartesian grid was created large enough to show the full extent of the areas of significant impact and the grid spacing was fine enough that it could serve as the receptor grid for the refined analysis (LANL 2003).

For the purpose of evaluating the impact of criteria pollutant emissions from construction activities for various projects, a discrete Cartesian grid that followed the fence line, property boundary, and public roads of interest was used, plus a regular Cartesian grid with a 1,600-foot (500-meter) spacing to 6,600 feet (2 kilometers) from the boundary and a 3,300-foot (1,000-meter) spacing beyond 6,600 feet (2 kilometers).

For the purpose of the air pollutant analysis in the *1999 SWEIS*, two sets of receptor locations were used: (1) locations representing actual locations of human activity, and (2) fence line locations to which the public has access (DOE 1999).

The potential impacts of air pollutants on workers employed at LANL facilities were not considered as part of the analysis in the *1999 SWEIS*. Different regulations apply to an occupational setting, and the controlled nature of the work, along with surveillance systems associated with those controls, restricts routine exposures for workers. The analysis focused on exposure to the public and was based on a methodology that initially assumed that chemicals that were purchased were entirely available for release to the atmosphere outside the facility in which the chemicals were used.

Air quality standards have been established by the State of New Mexico and the EPA for criteria pollutants for both short-term (1-hour, 3-hour, 8-hour, and 24-hour) and long-term (30-day, quarterly, and annual) time periods. In addition, guideline values were developed for other air pollutants for both short-term (8-hour) and long-term (annual) time periods. Using these standards and guideline values, the potential impacts of the pollutant emissions from LANL operations on these receptor sets were analyzed as discussed in the following paragraphs.

Criteria Pollutants

Short-term and long-term impacts for carbon monoxide, nitrogen dioxide, sulfur dioxide, total suspended particulates, and PM_{10} were estimated at the receptor locations, and the results were compared with applicable air quality standards. Both time frames were analyzed to address the potential short-term (acute) and long-term (chronic) impacts of these pollutants at locations where the public could have both short-term and long-term exposure to emissions from LANL facilities. Hydrogen sulfide and total reduced sulfur emissions are associated mostly with oil and gas industry; therefore, analysis for these pollutants was not necessary at LANL.

Other Air Pollutants

Noncarcinogens. The potential short-term (acute) and long-term (chronic) impacts of these pollutants at locations where the public could have both short-term and long-term exposure to emissions from LANL facilities were considered.

Short-term impacts were analyzed for fence line receptors. Long-term impacts were not considered at these receptor locations because, although it is possible that the public could have access to fence line areas for short periods of time, these locations would not be inhabited or visited on a regular (long-term) basis.

Carcinogens. The annual impacts from the emissions of carcinogenic air pollutants were analyzed for sensitive receptors. Although guideline values for short-term exposure were used in the screening steps, the more meaningful comparisons were to long-term guideline values for sensitive receptors.

B.1.3 Air Quality Dispersion

Models

The EPA's Industrial Source Complex Air Quality Dispersion Model (ISCST3) was used for the nonradiological air pollutant analyses in this SWEIS and the *1999 SWEIS*. ISCST3 is a versatile model that is often used to predict pollutant concentrations from continuous point, area, volume, and open disposal cell sources (EPA 1995, 2002). This versatile model is often used because of the many features that enable the user to estimate concentrations from nearly any type of source emitting nonreactive pollutants.

EPA's PUFF computer model was used for a screening level analysis of emissions from LANL's High Explosive Firing Sites at TA-14, TA-15, TA-36, TA-39, and TA-40. The PUFF model was designed to estimate downwind concentrations from instantaneous releases of pollutants (DOE 1999). The HOTSPOT computer code was used in combination with the ISCST3 computer model for a detailed analysis of emissions from the high explosive firing sites in order to provide a more readily usable input data file than that provided by PUFF for the health effects analysis in the *1999 SWEIS*. The HOTSPOT code was designed for detonation of high explosives, and was used specifically to provide input data to the ISCST3 model (DOE 1999).

B.2 Criteria Pollutants – General Approach

The combustion sources that were evaluated in the facility-wide analysis of criteria pollutants included each permitted emission source, and, for completeness, two of the largest insignificant sources[1]. These sources included boilers, TA-3 and TA-15 carpenter shops, TA-33 generators, TA-52 paper shredder, TA-60 asphalt plant, TA-3 power plant, TA-21 rock crusher, TA-21 steam plant, boilers at TA-9 and TA-35, and air curtain destructors. An atmospheric dispersion modeling analysis was conducted to estimate the combined potential air quality impacts of the emissions from each of these emission sources (DOE 1999).

No quantitative analysis of vehicular-related emissions was performed as part of the analysis for the *1999 SWEIS,* but these emissions were assumed to be included in the background (DOE 1999). The alternatives considered in this SWEIS may have different effects on the travel patterns in the study area as a result of changes in the number of LANL employees and the future population of Los Alamos. Therefore, changes in regional emissions from traffic were considered for each alternative.

B.2.1 Criteria Pollutants – Methodology

The analysis of combustion-related pollutants used standard analytical modeling techniques based on atmospheric dispersion modeling and emissions estimated under the peak and actual annual average operating conditions of each major combustion unit. Estimates of emission rates were based on the potential emissions from each source. For the purpose of the site-wide analysis, it was assumed that all three TA-3 boilers were operating at full capacity, using the fuel with highest air emissions. This approach was taken to obtain a conservative and complete modeling analysis of these emission sources. Emission rates used in the modeling are presented in **Table B–3**. Other details of the modeling are summarized in the *Facility-Wide Air Quality Impact Analysis* report (LANL 2003). With respect to emission rates from the combustion sources, the analysis bounds the air quality impacts from all the alternatives because the analysis is based on the maximum potential emission from the sources.

B.2.2 Results of Criteria Pollutant Analysis

The results of the analysis of criteria pollutants from LANL's combustion sources are presented in Chapter 5, Table 5–8 of this SWEIS. As shown, the highest estimated concentration of each pollutant would be below the appropriate ambient air quality standard. None of the alternatives considered in this SWEIS, therefore, would exceed the applicable ambient air quality standards, and impacts on the public would be minor.

[1] Stationery sources that emit criteria pollutants in quantities smaller than those requiring inclusion in the Title V operating permit are called insignificant sources. The analysis included two of the largest of these insignificant sources.

Table B–3 Criteria Pollutant Emissions Summary [a] (grams per second)

Source	Nitrogen Oxides	Sulfur Oxides	Carbon Monoxide	Total Suspended Particulates	PM_{10}
TA-3 Power Plant, Stack 1 (2 boilers)	2.495	17.312	1.865	0.68	0.68
TA-3 Power Plant, Stack 2 (1 boiler)	1.247	8.656	0.932	0.34	0.34

TA-3-38 Carpenter Shop	0.0	0.0	0.0	0.178	0.178
TA-15-563 Carpenter Shop	0.0	0.0	0.0	0.163	0.163
TA-52-11 Paper Shredder	0.0	0.0	0.0	0.374	0.374

TA = technical area, PM_n = particulate matter with an aerodynamic diameter less than or equal to *n* micrometers.

[a] Emissions represent the values modeled in the *Facility-Wide Air Quality Impact Analysis*. Not included in this table are the results of the analysis for air curtain destructors and a rock crusher that are no longer operated by LANL. About half of the boilers shown are actually backup boilers and would not be operated at the same time as the primary boiler at a facility, but were included for the purpose of bounding the potential impacts considered in the Title V permit.

Source: LANL 2003.

B.3 Other Air Pollutants – General Approach

The approach used to evaluate chemical air pollutants in the *1999 SWEIS* was based on the use of screening level emission values to identify chemicals that would be evaluated in more detail. Screening level emission values were conservatively estimated hypothetical emission rates for each of the air pollutants that could potentially be emitted from each of LANL's TAs and that would not result in air quality levels harmful to human health under current or future conditions. These screening level emission values were compared with conservatively estimated pollutant emission rates on a TA-by-TA basis to determine potential air quality impacts of air pollutants from LANL operations. This process consisted of the following steps:

- From over 2,000 chemical compounds listed as being used at LANL, 382 air pollutants (including 51 carcinogens) were selected for consideration based on chemical properties, volatility, and toxicity.

- A methodology based on screening level emission values was used to estimate the potential worst-case impacts of the air pollutants. Screening level emission values for each chemical for each TA were compared with emission rates conservatively estimated from chemical use rates. If a conservatively estimated emission rate for a given pollutant from a given TA was less than the screening level emission value, that pollutant emission source was deemed not to have the potential to cause significant air quality impacts, and, as such, no detailed analysis was required. If the screening level emission value was less than the estimated emission rate for a given pollutant from a given TA, a more detailed analysis was conducted.

- An additive impact analysis was conducted to estimate the potential total impact from the emissions of each pollutant from more than one TA and the total incremental cancer risk from all of the carcinogenic pollutants combined at any of the sensitive receptor locations considered.

The methodology used in the analysis followed modeling guidelines for toxic pollutants established by the EPA in that it first used screening level evaluations based on conservative assumptions and resulting in maximum potential impacts, followed by more detailed analyses based on more realistic assumptions. The overall procedure used for the air quality assessment, including the development of screening level emission values, is summarized in the *1999 SWEIS* (DOE 1999).

B.3.1 Other Pollutants – Methodology for Individual Pollutants

Screening Level Analysis

The following sections provide more detail on the methodology used for screening and detailed analysis for air pollutants from chemical use in the *1999 SWEIS* (DOE 1999).

Once screening level emission values (both short-term and long-term) were established for each of the air pollutants on a TA-specific basis, a comparison was made between these values and conservatively estimated emission rates. A ratio was developed for each chemical by dividing the screening level emission value by the estimated emission rate (SLEV/Q).

These results, in the form of worksheets, were presented to knowledgeable site personnel who were aware of the activities and processes occurring at each TA, as well as those that might occur in the future. To streamline the process, the relationship between screening level emission values and the estimated emission rates for each TA were presented in two data sets.

The first data set included those chemicals having SLEV/Q ratios greater than 100. For each of these chemicals, a determination was made as to whether the use of that chemical would increase by more than 100 times under future operation(s) of LANL under any of the alternatives considered in this SWEIS. Essentially, this meant that for each TA a determination had to be made as to whether the use of a chemical would increase over current use rates by a factor of 100. If a determination could be made that the future use of that chemical would not increase by this factor, no further evaluation of that chemical was required. If such a determination was not possible, a more detailed analysis was conducted.

The second data set included all chemicals having a SLEV/Q ratio less than 100, and all chemicals having an SLEV/Q ratio greater than 1 but less than 100, and all chemicals having a ratio less than 1. For each chemical having a ratio greater than 1 but less than 100, an evaluation was made as to whether the estimated emissions under any of the future alternatives would exceed the screening level emission values. Essentially, this meant that for each TA a determination had to be made as to whether the use of that chemical would increase over current rates by a factor greater than the SLEV/Q ratio. If a determination could be made that the future use of that chemical would not increase by this factor, no further evaluation of that chemical was required. If such a determination was not possible, a more detailed analysis was conducted. For those chemicals having an SLEV/Q ratio less than 1 (in other words, screening level emission values were potentially being exceeded under current conditions), more detailed analyses were conducted.

Two exceptions to the methodology described above were made. Information on the TAs for high explosive operations were derived using a model more appropriate for screening short-term exposure concentrations under those conditions. The second exception involved screening the emissions of chemicals from the Bioscience Facilities (formerly the Health Research Laboratory Complex) at TA-43. Because of the proximity of the Bioscience Facilities to actual receptors, all analyses for carcinogens, as well as noncarcinogens, were performed for actual receptors rather than fence line receptors.

Detailed Analysis

The detailed air quality analysis consisted of one or both of the following steps:

- Development of emission rates and source term parameters using actual process knowledge, and

- Dispersion modeling using actual stack parameters and receptor locations.

Two consequences may result from detailed analysis of each chemical from each TA: (1) either there is no potential to exceed a guideline value (in which case no additional analyses were required), or (2) there is a potential to exceed a guideline value (in which case additional analyses were required). A pollutant having the potential to exceed a guideline value was subject to evaluation in the health and ecological risk assessment process.

B.3.2 Other Pollutants – Results of Individual Pollutants Analysis

Screening Level

The first data set considered those chemicals having SLEV/Q ratios greater than 100. For more than 90 percent of the air pollutants from chemical use, a determination was made that the use of these chemicals would not increase by more than 100 times under any of the SWEIS alternatives. The second data set included chemicals having SLEV/Q ratios greater than 1 but less than 100, and ratios less than 1. A determination was made as to whether the use of that chemical would increase over current use rates by a factor greater than the SLEV/Q ratio. The list of carcinogens also was reduced from 51 to 35 because some of the chemicals are no longer used and were not projected for future use. Based on worksheets for the chemicals in the data sets, and information on potential future use, operations at 13 locations were identified with the potential to exceed a guideline value, and more detailed analyses were conducted.

Emissions from two sources were referred to the health and ecological risk analysis process. The analysis for TA-43 showed the potential to exceed the guideline values for four chemical carcinogens from the Bioscience Facilities: chloroform, trichloroethylene, formaldehyde, and acrylamide.

The detailed analysis for the High Explosive Firing Sites indicated that the same chemicals that had the potential to exceed a guideline value in the previous screening step would also have the potential to exceed their respective guideline values using somewhat different parameters and a different model than that used in the screening analysis. The HOTSPOT 8.0 and ISCST3 models were used in the detailed analysis in order to provide output data in a form more readily usable for the health risk analysis. Additional information on the following chemicals was referred to the health and ecological risk assessment process for the *1999 SWEIS*:

- Depleted uranium, beryllium, and lead from TA-15;
- Depleted uranium, beryllium, and lead from TA-36;
- Beryllium and lead from TA-39; and
- Depleted uranium and lead from TA-14.

The health risk analysis calculated Hazard Indices for two of the three metals. A Hazard Index equal to or greater than 1 is considered consequential from a human toxicity standpoint. The Expanded Operations Alternative in the *1999 SWEIS* is comparable to the No Action Alternative in this SWEIS. For the Expanded Operations Alternative, the worst-case Hazard Index for lead did not exceed 0.000015, and, for depleted uranium, the worst-case Hazard Index did not exceed 0.000065. Beryllium has no established EPA reference dose from which to calculate the Hazard Index. However it was evaluated as a carcinogen. The estimate of excess latent cancer fatalities for beryllium under the Expanded Operations Alternative in the *1999 SWEIS* was 1 chance in 2.7 million (3.6×10^{-7}) per year (DOE 1999).

B.3.3 Other Pollutants – Methodology for Combined Impacts Analyses

The following analyses were conducted for the *1999 SWEIS* to ensure that the combined effects from the releases of all of the chemicals from all the TAs would not exceed the guideline values.

Noncarcinogens

An analysis of potential short-term impacts at a TA's fence line receptor location showed that the 8-hour impacts from the releases of that TA were greater (more than two orders of magnitude) than the impacts from the releases of a nearby TA. This is because the TAs are relatively far apart compared to the distances between the emission sources of a TA and its fence line receptors. Therefore, it is unlikely that the additive short-term impacts of noncarcinogenic pollutants at the fence line receptors of a TA would be significantly different from the maximum concentrations previously estimated for that TA.

An analysis of annual potential impacts at sensitive receptor locations showed that these impacts were significantly less (less than two orders of magnitude) relative to the appropriate guideline values than the corresponding short-term impacts at the fence line receptors. Therefore, it would be unlikely that the additive annual impacts of the noncarcinogenic pollutants at the sensitive receptor locations would be significant.

Carcinogens

Two different versions of additive impacts for carcinogens were presented. Both versions considered impacts at sensitive receptor locations based on annual ambient concentrations of pollutants. Short-term additive impacts for carcinogens at fence line receptor locations were not considered (for the same reasons as for noncarcinogens). However, long-term impacts at sensitive receptor locations were considered because EPA considers in their standard setting process that risk from carcinogens can be additive for all carcinogenic chemicals.

The first version considered whether emissions of the same chemical from all TAs (whether or not it was actually used at that TA), at the screening level emission value rate (whether or not that maximum rate was actually projected at that TA), would exceed the total guideline risk value of 1×10^{-6}. The risk due to exposure at the maximum concentration over a lifetime for any receptor for each of the TAs was added to the separately calculated maximum concentration for any receptor for each of the other TAs, regardless of whether the same receptor was indicated.

The second version modeled simultaneous emissions of the same chemical at actual projected rates for each of the TAs, and recorded the maximum concentration at any receptor location. The risk due to exposure at that concentration over a lifetime was then added to the risks calculated in a similar fashion for each of the other chemicals. Risks were added regardless of whether the same receptor was involved. That total risk was also compared to the guideline risk value of 1×10^{-6} of any excess cancer from a lifetime of exposure.

B.3.4 Other Pollutants – Results of Combined Impact Analysis

Releases of Each Carcinogenic Pollutant from All TAs

The estimated combined cancer risk associated with releases of each of these pollutants from all TAs was 1.23 in ten million (1.23×10^{-7}), which was below the guideline value of one in a million (1.0×10^{-6}). As such, no potentially significant air quality impacts were estimated.

Releases of All Carcinogenic Pollutants from All TAs

Results of this analysis indicated that the potential combined incremental cancer risk associated with releases of all carcinogenic pollutants from all TAs would be slightly above the guideline value of one in a million (1.0×10^{-6}).

The major contributors to the estimated combined cancer risk values were chloroform, formaldehyde, and trichloroethylene from the Bioscience Facilities at TA-43, and multiple sources for methylene chloride. Of these, the relative contribution of chloroform emissions alone to the combined cancer risk value was more than 87 percent. The impacts of TA-43 emissions were due to a combination of relatively high emission rates, close proximity between receptors and sources, and the elevation of the receptors. A more detailed analysis that considered the impact at each specific receptor location was conducted. This more refined analysis estimated the combined cancer risk at each of the 180 sensitive receptor locations. The health risk analysis concluded that the combined cancer risk at the two receptor locations at the Los Alamos Medical Center was 0.73 to 0.74 in a million (7.3 to 7.4×10^{-7}). This value was below the guideline value for human health consequences from carcinogenic air emissions (DOE 1999).

APPENDIX C
EVALUATION OF HUMAN HEALTH IMPACTS FROM NORMAL OPERATIONS

APPENDIX C
EVALUATION OF HUMAN HEALTH IMPACTS FROM NORMAL OPERATIONS

This appendix provides a brief general discussion of radiation and its effects on human health, as well as the methods and assumptions used for estimating the potential impacts and risks to individuals, workers, and the general public from exposure to releases of radioactivity and hazardous chemicals during normal operations at Los Alamos National Laboratory (LANL). It also discusses methods used to safely control biological material during research activities.

This appendix addresses the methods used to assess human health impacts from normal operations at LANL. To do so, it considers: (1) radionuclides potentially released into the air from Key Facilities as a function of the three alternatives considered in this site-wide environmental impact statement (SWEIS); and (2) radionuclides and chemicals that may be present in environmental pathways (such as ground and surface water and game animals) in and around the LANL environs. In addition, background information is presented regarding the effects on human health from exposure to radiation, biological agents, and hazardous chemicals. Both the methods used to assess impacts and the impacts themselves from the proposed projects that may be implemented at LANL as part of the Expanded Operations Alternative are addressed elsewhere in this SWEIS (see Appendices G, H, I, and J).

The release of pollutants to ambient air is the focus in these analyses because they are projected to dominate possible exposures to the public as a result of future LANL operations. Other releases such as those through outfalls into surface water bodies are not expected to be dominant contributors to future exposures because of the significant reduction in the use of outfalls and the extensive implementation of environmental controls such as those of the National Pollutant Discharge Elimination System. Past releases, however, have resulted in some radiological and chemical contamination in several environmental media, and impacts from this contamination are addressed in this appendix. This approach for evaluating human health impacts from normal operations is consistent with the approach used for the 1999 *Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory, Los Alamos, New Mexico (1999 SWEIS).*

C.1 Impacts on Human Health from Radiological Exposure

Radiation exposure and its consequences are of interest to the public. For this reason, this section provides information on the nature of radiation, emphasizes the consequences of exposure to radiation, and explains the basic concepts used to evaluate radiation health effects.

C.1.1 About Radiation and Radioactivity

C.1.1.1 What Is Radiation?

Radiation is energy transferred in the form of particles or waves. Globally, human beings are exposed constantly to radiation from the solar system and the Earth's rocks and soil. This radiation contributes to the natural background radiation that always surrounds us. Manmade sources of radiation also exist, including medical and dental x-rays, household smoke detectors, and materials released from nuclear and coal-fired power plants.

All matter in the universe is composed of atoms. Radiation comes from the activity of tiny particles within an atom. An atom consists of a positively charged nucleus (central part of an atom) with a number of negatively charged electron particles in various orbits around the nucleus. There are two types of particles in the nucleus: neutrons that are electrically neutral and protons that are positively charged. All atoms of a given chemical element have the same number of protons in their nuclei. There are more than 100 natural and manmade elements. Atoms that have the same number of protons in their nuclei, but different numbers of neutrons, are called isotopes of an element. Elements may have one or more stable isotopes and others that are unstable (decay with time).

Unstable isotopes undergo spontaneous change known as radioactive disintegration or radioactive transformation. The process of continuously undergoing spontaneous transformation is called radioactivity. The radioactivity (number of transformations per second) of a given amount of material decreases with time. Each radioactive isotope is distinguished by the time it takes for a given quantity of the material to lose half of its original radioactivity. This time is its half-life, and is characteristic of the isotope. For example, an isotope with a half-life of 8 days will lose one-half of its radioactivity in that amount of time. In 8 more days, the radioactivity will again decrease by half, to one-fourth of the original value. The half-lives of various radioactive elements can vary from millionths of a second to millions of years.

As unstable isotopes change into more stable forms, they emit electrically-charged particles. The particle may be either an alpha particle (a helium nucleus) or a beta particle (an electron) and have various levels of kinetic energy. Sometimes these particles are emitted in conjunction with gamma rays. The alpha and beta particles and gamma rays are frequently referred to as “ionizing radiation”, a term that reflects the fact that the charged particle or gamma ray can strip or displace electrons away from atoms of matter through which they pass, leaving those atoms with an electrical charge. The ionization caused by radiation can change the chemical composition of many substances, including living tissue, which can affect the way they function.

Ionizing radiation is used in a variety of ways, many of which are familiar to us in our everyday lives. The machines used by doctors to diagnose and treat medical patients typically use x-rays, which are a form of ionizing radiation. The process by which a television displays a picture is by ionizing coatings on the inside of the screen with electrons. Most home smoke detectors use a small source of ionizing radiation to detect smoke particles in room air.

When a radioactive isotope of an element emits a particle, it changes to an entirely different element, one that may or may not be radioactive. Eventually, a stable element is formed. This transformation, which may take several steps, is known as a decay chain. For example, radium, which is a member of the radioactive decay chain of uranium, has a half-life of 1,622 years. It emits an alpha particle and becomes radon, a radioactive gas with a half-life of only 3.8 days. Radon decays first to polonium, then through a series of further decay steps to bismuth, and ultimately to a stable isotope of lead. Meanwhile, the decay products will build up and eventually disappear as time progresses.

The characteristics of various forms of ionizing radiation are briefly described below and in the box to the right.

Alpha (α)—Alpha particles are the heaviest type of ionizing radiation. They can travel only a few centimeters in air. Alpha particles lose their energy almost as soon as they collide with anything. They can be stopped easily by a sheet of paper or by the surface of one's skin.

Radiation Type	*Typical Travel Distance in Air*	*Barrier*
α	Few inches	Sheet of paper or skin's surface
β	Few feet	Thin sheet of aluminum foil or glass
γ	Very large	Thick wall of concrete, lead, or steel
n	Very large	Water, paraffin, graphite

Beta (β)—Beta particles are much (7,330 times) lighter than alpha particles. They can travel a longer distance than alpha particles in the air. A high-energy beta particle can travel a few feet in the air. Beta particles can pass through a sheet of paper, but can be stopped by a thin sheet of aluminum or glass.

Gamma (γ)—Gamma rays (and x-rays), unlike alpha or beta particles, are waves of pure energy. Gamma rays travel at the speed of light. Gamma radiation is very penetrating and requires concrete, lead, or steel shielding to stop it.

Neutrons (n)—The most prolific source of neutrons is a nuclear reactor. Neutrons produce ionizing radiation indirectly by collision with hydrogen nuclei (protons) and when gamma rays and alpha particles are emitted following neutron capture in matter. A neutron has about one-quarter the weight of an alpha particle. It will travel in the air until it is absorbed in another nucleus.

C.1.1.2 Units of Radiation Measure

During the early days of radiological experience, there was no precise unit of radiation measurement. Therefore, a variety of units was used to measure the amount, type, and intensity of radiation. Just as heat can be measured in terms of its intensity or effects using units of calories or degrees, amounts of radiation or its effects can be measured in units of curies, radiation absorbed dose (rad), or dose equivalent (roentgen equivalent man, or rem). The following summarizes these units.

Curie—The curie, named after the French scientists Marie and Pierre Curie, describes the "intensity" (activity) of a sample of radioactive material. The rate of decay of 1 gram of radium was the basis for this unit of measure. Because the measured decay rate kept changing slightly as measurement techniques became more accurate, the curie was subsequently defined as exactly 3.7×10^{10} disintegrations (decays) per second.

Radiation Units and Conversions to International System of Units	
1 curie	= 3.7×10^{10} disintegrations per second
	= 3.7×10^{10} becquerels
1 becquerel	= 1 disintegration per second
1 rad	= 0.01 gray
1 rem	= 0.01 sievert
1 gray	= 1 joule per kilogram

Rad—The rad is used to measure the physical absorption of radiation. The total energy absorbed per unit quantity of tissue is referred to as absorbed dose (or simply dose). As sunlight heats pavement by giving up energy to it, radiation similarly gives up energy to objects in its path. One rad is equal to the amount of radiation that leads to the deposition of 0.01 joule of energy per kilogram of absorbing material.

Rem (roentgen equivalent man)—A rem is a measurement of the dose equivalent from radiation based on its biological effects. The rem is used to measure the effects of radiation on the body as degrees centigrade are used to measure the effects of sunlight heating pavement. Thus, 1 rem of one type of radiation is presumed to have the same biological effects as 1 rem of any other kind of radiation. This allows comparison of the biological effects of radionuclides that emit different types of radiation.

The units of radiation measurement in the International System of Units are becquerels (a measure of source intensity [activity]), grays (a measure of absorbed dose), and sieverts (a measure of dose equivalent).

An individual may be exposed to ionizing radiation externally (from a radioactive source outside the body) or internally (from ingesting or inhaling radioactive material). The external dose is different from the internal dose because an external dose is delivered only during the actual time of exposure to the external radiation source, while an internal dose continues to be delivered as long as the radioactive source is in the body. The dose from internal exposure is calculated over 50 years following the initial exposure. Both radioactive decay and elimination of the radionuclide by ordinary metabolic processes decrease the dose rate with the passage of time.

C.1.1.3 Sources of Radiation

The average American receives a total of approximately 360 millirem per year from all sources of radiation, both natural and manmade, of which approximately 300 millirem per year are from natural sources. A person living in Los Alamos receives an average background dose between 300 and 500 millirem, depending on where they live (LANL 2004d). The sources of radiation can be divided into six different categories: cosmic radiation, terrestrial radiation, internal radiation, consumer products, medical diagnosis and therapy, and other sources (NCRP 1987). These categories are discussed in the following paragraphs.

Cosmic Radiation—Cosmic radiation is ionizing radiation resulting from energetic charged particles from space continuously hitting the Earth's atmosphere. Cosmic radiation comprises these particles and the secondary particles and photons they create. Because the atmosphere provides some shielding against cosmic radiation, the intensity of this radiation increases with the altitude above sea level. The average dose to people in the United States from this source is approximately 27 millirem per year. Doses from cosmic radiation range from 50 millirem per year at lower elevations near the Rio Grande River to about 90 millirem per year in the mountains near Los Alamos (LANL 2004d).

External Terrestrial Radiation—External terrestrial radiation is the radiation emitted from the radioactive materials in the Earth's rocks and soils. The average dose from external terrestrial radiation is approximately 28 millirem per year. Doses from terrestrial radiation in Los Alamos range from about 50 to 150 millirem a year, depending on the amounts of natural uranium, thorium, and potassium in the soil (LANL 2004d).

Internal Radiation—Internal radiation results from radioactive material that has entered the body by inhalation or ingestion and is retained by the affected organs or tissues. Natural radionuclides in the body include isotopes of uranium, thorium, radium, radon, polonium, bismuth, potassium, rubidium, and carbon. The major contributors to the annual dose equivalent for internal radioactivity are the short-lived decay products of radon, which contribute approximately 200 millirem per year. The average dose from other internal radionuclides is approximately 40 millirem per year.

Consumer Products—Consumer products also contain sources of ionizing radiation. In some products, such as smoke detectors and airport x-ray machines, the radiation source is essential to the product's operation. In other products, such as televisions and tobacco, the radiation source is a byproduct of the product's function. The average dose from consumer products is approximately 10 millirem per year.

Radiation Source	***Average Annual Dose (millirem)***
Cosmic	50-90
External Terrestrial	50-150
Internal	240
Consumer Products	10
Medical Diagnostic and Treatment	50
Other	1 +

Medical Diagnosis and Therapy—Radiation is an important diagnostic medical tool and cancer treatment. Diagnostic x-rays result in an average exposure of 50 millirem per year. Nuclear medical procedures result in an average exposure of 14 millirem per year.

Other Sources—There are a few additional sources of radiation that contribute minor doses to individuals in the United States. The dose from nuclear fuel cycle facilities (for example, uranium mines, mills, and fuel processing plants) and nuclear power plants has been estimated to be less than 1 millirem per year. Radioactive fallout from atmospheric atomic bomb tests, emissions from certain mineral extraction facilities, and transportation of radioactive materials contribute less than 1 millirem per year to the average dose to an individual. Air travel contributes approximately 1 millirem per year to the average dose.

C.1.1.4 Exposure Pathways

As stated earlier, an individual may be exposed to ionizing radiation both externally and internally. The different ways that an individual can be exposed to radiation are called exposure pathways. Each type of exposure is discussed separately in the following paragraphs.

External Exposure—External exposure can result from a number of different pathways where the exposure is external to the body. These pathways include exposure to a cloud of radiation passing over the receptor (an exposed individual), standing on ground that is contaminated with radioactivity, and swimming or boating in contaminated water. If the receptor leaves the source of radiation exposure, the dose rate will be reduced. It is assumed that external exposure occurs uniformly during the year. The appropriate dose measure is called the effective dose equivalent.

Internal Exposure—Internal exposure results from a radiation source entering the human body through either inhalation of contaminated air or ingestion of contaminated food or water. In contrast to external exposure, once a radiation source enters the body, it remains there for a period of time that varies depending on its physical decay and biological half-life. The absorbed dose to each organ of the body is calculated for a period of 50 years following the intake. The calculated absorbed dose is called the committed dose equivalent. Various organs have different susceptibilities to damage from radiation. The committed effective dose equivalent takes these different susceptibilities into account and provides a broad indicator of risk to the health of an individual from radiation. The committed effective dose equivalent is a weighted sum of the committed dose equivalent in each major organ or tissue. The concept of committed effective dose equivalent applies only to internal pathways.

C.1.1.5 Limits of Radiation Exposure

Limits of exposure to members of the public and radiation workers are derived from International Commission on Radiological Protection recommendations. The U.S. Environmental Protection Agency (EPA) uses the National Council on Radiation Protection and Measurements and the International Commission on Radiological Protection recommendations to set specific annual exposure limits (usually less than those specified by the Commission) in *Radiation Protection Guidance to Federal Agencies* documents. Each regulatory organization then establishes its own set of radiation standards. The various exposure limits set by the U.S. Department of Energy (DOE) and EPA for radiation workers and members of the public are given in **Table C–1**.

Table C–1 Exposure Limits for Members of the Public and Radiation Workers

Guidance Criteria (Organization)	*Public Exposure Limits at the Site Boundary*	*Worker Exposure Limits*
10 CFR Part 835 (DOE)	Not applicable	5,000 millirem per year [a]
DOE Order 5400.5 (DOE) [b]	10 millirem per year (all air pathways) 4 millirem per year (drinking water pathway) 100 millirem per year (all pathways)	Not applicable
40 CFR Part 61 (EPA)	10 millirem per year (all air pathways)	Not applicable
40 CFR Part 141 (EPA)	4 millirem per year (drinking water pathways)	Not applicable

CFR = *Code of Federal Regulations*, EPA = U.S. Environmental Protection Agency.

[a] Although this limit (or level) is enforced by DOE, worker doses must be managed in accordance with as low as reasonably achievable (ALARA) principles. An annual limit of 2,000 millirem per year was established by DOE to assist in achieving its goal to maintain radiological doses at ALARA levels (DOE 1999b).

[b] Derived from 40 CFR Part 61, 40 CFR Part 141, and 10 CFR Part 20.

C.1.2 Health Effects

To provide a background for discussing impacts, this section explains the basic concepts used to evaluate radiation effects.

Radiation can cause a variety of damaging health effects in people. The most significant effects are induced cancer fatalities. These effects are referred to as "latent" cancer fatalities because the cancer may take many years to develop. In the discussions that follow, all fatal cancers are considered latent; therefore, the term "latent" is not used.

The National Research Council prepared a series of reports to advise the U.S. Government on the health consequences of radiation exposures. The most recent of these, *Health Effects from Exposure to Low Levels of Ionizing Radiation, BEIR VII-Phase 2* (National Research Council 2005), provides current estimates for excess mortality from leukemia and other cancers that are expected to result from exposure to ionizing radiation. Biological Effects of Ionizing

Radiation (BEIR) VII provides estimates that are not significantly different from those in its predecessor, BEIR V, and recent United Nations Scientific Committee on the Effects of Atomic Radiation and International Commission on Radiological Protection reports. The report, however, concludes that recent data and analyses have reduced the uncertainties associated with the risk estimates. BEIR V developed models in which the excess relative risk was expressed as a function of age at exposure, time after exposure, and sex for each of several cancer categories. The models were based on the assumption that the relative risks are comparable between the atomic bomb survivors and the U.S. population.

The models and risk coefficients in BEIR VII are derived through review of the most current information on the biological mechanisms of radiation tumorigenesis as well as analyses of relevant epidemiologic data that includes the Japanese atomic bomb survivors, medically-exposed persons, and large-scale occupational radiation studies. The BEIR VII Committee concluded that the balance of evidence tends to support a simple proportionate relationship at low doses between radiation dose and risk. This conclusion essentially affirms the Linear-No-Threshold model that has long been the basis for the regulation and control of occupational and environmental radiation exposure in the United States.

The National Council on Radiation Protection and Measurements (NCRP 1993), based on the radiation risk estimates provided in BEIR V and the International Commission on Radiological Protection (ICRP 1991), estimates the total detriment resulting from low dose[1] or low dose rate exposure to ionizing radiation to be 0.00076 per rem for the working population and 0.00083 per rem for the general population. The total detriment includes fatal and nonfatal cancers as well as severe hereditary (genetic) effects. The major contribution to the total detriment is from fatal cancer, estimated to be 0.0006 per rem for both radiation workers and the general population. For comparison, the BEIR VII Committee's preferred estimates of lifetime attributable risk of mortality for all solid cancers and leukemia are 0.00048 for males and 0.00066 for females. The breakdowns of the risk estimators for both workers and the general population are given in **Table C–2**. Nonfatal cancers and genetic effects are less probable consequences of radiation exposure.

Table C–2 Nominal Health Risk Estimators Associated with Exposure to 1 Rem of Ionizing Radiation

Exposed Individual	*Fatal Cancer* [a, c]	*Nonfatal Cancer* [b]	*Genetic Disorders* [b]	*Total*
Worker	0.0006	0.00008	0.00008	0.00076
Public	0.0006	0.0001	0.00013	0.00083

[a] For fatal cancer, the health effect coefficient is the same as the probability coefficient. When applied to an individual, the units are the lifetime probability of a cancer fatality per rem of radiation dose. When applied to a population of individuals, the units are the excess number of fatal cancers per person-rem of radiation dose. These factors are from DOE 2003a.
[b] In determining a means of assessing health effects from radiation exposure, the International Commission on Radiological Protection has developed a weighting method for nonfatal cancers and genetic effects. These factors are from NCRP 1993.
[c] For high individual exposures (greater than or equal to 20 rem), the health factors are multiplied by a factor of 2.
Sources: NCRP 1993, DOE 2003a.

[1] *Low dose is defined as the dose level where deoxyribonucleic acid (DNA) repair can occur in a few hours after irradiation-induced damage. Currently, a dose level of about 0.2 grays (20 rad), or a dose rate of 0.1 milligrays (0.01 rad) per minute is considered low enough to allow the DNA to repair itself in a short period (EPA 1994).*

EPA, in coordination with other Federal agencies involved in radiation protection, issued *Federal Radiation Guidance Report No. 13, Cancer Risk Coefficients for Environmental Exposure to Radionuclides*, in September 1999 (EPA 1999). This document is a compilation of risk factors for doses from external gamma radiation and internal intakes of radionuclides. *Federal Radiation Guidance Report No. 13* is the basis for the radionuclide risk coefficients used in the EPA Health Effects Assessment Summary Tables (EPA 2001) and in computer dose codes. The Interagency Steering Committee on Radiation Standards (ISCORS) issued a technical report entitled, *A Method for Estimating Radiation Risk from TEDE* (DOE 2003a). ISCORS technical reports are guidance to Federal agencies to assist them in preparing and reporting the results of analyses and implementing radiation protection standards in a consistent and uniform manner. This report provides dose-to-risk conversion factors where doses are estimated using total effective dose equivalent (TEDE). It is recommended for use by DOE personnel and contractors when computing potential radiation risk from calculated radiation dose for comparison purposes. For situations in which a radiation risk assessment is required for making risk management decisions, however, the radionuclide-specific risk coefficients in Federal Guidance Report No. 13 should be used.

DOE and other agencies regularly conduct dose assessments using models and codes that calculate radiation dose from exposure or intake using dose conversion factors and do not compute risk directly. In those cases where it is necessary or desirable to estimate risk for comparative purposes (for example, comparing the risk associated with alternative actions), it is common practice to simply multiply the calculated TEDE by a risk-to-dose factor. DOE previously recommended a TEDE-to-fatal cancer risk factor of 0.0005 per rem for the public and 0.0004 per rem for working-age populations. ISCORS recommends that agencies use a conversion factor of 0.0006 fatal cancers per TEDE (rem) for mortality and 0.0008 cancers per rem for morbidity when making qualitative or semi-quantitative estimates of risk from radiation exposure to members of the general public[2] (DOE 2003a).

The ISCORS report notes that the recommended risk coefficients used with TEDE dose estimates generally produce conservative radiation risk estimates (they overestimate risk). Regarding the ingestion pathway for the 11 radionuclides included in the report, the risks are overestimated compared to the values in Federal Radiation Guidance Report No. 13 for about 8 radionuclides and significantly overestimated (by up to a factor of 6) for 4 of these. The Office of Environmental Policy and Guidance also compared the TEDE-to-cancer risk conversion factor approach to Federal Radiation Guidance Report No. 13 for the inhalation pathway and found a bias toward overestimating risk, although it was not as severe as for ingestion. For 16 radionuclides and chemical states evaluated, 7 were overestimated (by more than a factor of 2) and 5 were underestimated. The remainder agreed within about a factor of two. Generally, these differences were within the uncertainty of transport and the uptake portions of dose or risk modeling; therefore, the approach recommended is fully acceptable for comparative assessments. It is recommended, however, that the more rigorous approach using Federal Radiation Guidance Report No. 13 cancer risk coefficients be employed wherever possible (DOE 2003a).

Different methods of extrapolation to the low-dose region could yield higher or lower numerical estimates of fatal cancers. Studies of human populations exposed to low doses are inadequate to

---

[2] *Such estimates should not be stated with more than one significant digit.*

demonstrate the actual level of risk. There is scientific uncertainty about cancer risk in the low-dose region below the range of epidemiologic observation, and the possibility of no risk cannot be excluded (CIRRPC 1992).

C.1.2.1 Health Effect Risk Estimators Used in this SWEIS

Health impacts from radiation exposure, whether from external or internal sources, generally are identified as "somatic" (affecting the exposed individual) or "genetic" (affecting descendants of the exposed individual). Radiation is more likely to produce somatic effects than genetic effects. The somatic risks of most importance are induced cancers. Except for leukemia, which can have an induction period (the time between exposure to a carcinogen and a cancer diagnosis) of as little as 2 to 7 years; most cancers, however, have an induction period of more than 20 years.

For a uniform irradiation of the body, the incidence of cancer varies among organs and tissues; the thyroid and skin demonstrate a greater sensitivity than other organs. Such cancers, however, also produce relatively low mortality rates because they are relatively amenable to medical treatment. Because fatal cancer is the most probable serious effect of environmental and occupational radiation exposures, estimates of cancer fatalities rather than cancer incidence are presented in this new SWEIS. The numbers of fatal cancers can be used to compare the risks among the various alternatives.

The fatal cancer estimators are used to calculate the statistical expectation of the effects of exposing a population to radiation. For example, if 100,000 people were each exposed to a one-time radiation dose of 100 millirem (0.1 rem), the collective dose would be 10,000 person-rem. The exposed population would then be expected to experience 6 additional cancer fatalities from the radiation (10,000 person-rem times 0.0006 lifetime probability of cancer fatalities per person-rem = 6 cancer fatalities).

Calculations of the number of excess fatal cancers associated with radiation exposure do not always yield whole numbers. These calculations may yield numbers less than 1, especially in environmental impact applications. For example, if a population of 100,000 were exposed to a total dose of only 0.001 rem per person, the collective dose would be 100 person-rem (100,000 persons times 0.001 rem = 100 person-rem). The corresponding estimated number of cancer fatalities would be 0.06 (100 person-rem times 0.0006 cancer fatalities per person-rem = 0.06 cancer fatalities). This estimate of 0.06 cancer fatalities means that there is 1 chance in 16.6 that the exposed population would experience 1 fatal cancer. In other words, 0.06 cancer fatalities is the *expected* number of deaths that would result if the same exposure situation were applied to many different groups of 100,000 people. In most groups, no person would incur a fatal cancer from the 0.001 rem dose each member would have received. In a small fraction of the groups, 1 cancer fatality would result; in exceptionally few groups, 2 or more cancer fatalities would occur. The *average* expected number of deaths over all the groups would be 0.06 cancer fatalities (just as the average of 0, 0, and 0 added to 1 is 1/4, or 0.25). The most likely outcome is no cancer fatalities.

C.1.2.2 Material of Interest at Los Alamos National Laboratory

LANL scientists have a large involvement in nuclear science and its applications. Therefore, many types of radioactive materials and radiation sources are in use at LANL; however, many of these uses require only very small amounts of material. Note that all radioactive materials are considered in this new SWEIS, but three radionuclides tend to dominate the human health effects at LANL due to their particular radioactive and biological characteristics, the quantities of material being used, or the potential for dispersion in an accident. These radionuclides are plutonium, uranium, and tritium.

Plutonium is a manmade element that has several applications in weapons, nuclear reactors, and space exploration. There are several types of plutonium atoms, called isotopes, which are distinguished by the different numbers of neutrons in their nucleus. (Note that isotopes of a particular element all behave the same chemically.) In most cases, the isotopes of plutonium decay by alpha particle emission and have radioactive half-lives ranging from tens to thousands of years. Plutonium that is taken into the body tends to be deposited in certain organs (notably the bone, liver and lung) and is excreted very slowly. Because alpha particles have a very short range in tissue, the radiation dose from plutonium in the body is largely delivered to the organs where the material is deposited.

Uranium is a naturally-occurring radioactive element. The discovery that an atom of uranium could be fissioned with neutrons was the starting point of the Nuclear Age. Uranium-235 is one of several fissile materials that fission with the release of energy. Various applications require the use of different isotopes of uranium. Because isotopes cannot be chemically separated, processes have been developed to enrich uranium to various isotopic ratios. Natural uranium consists mostly of uranium-238, with very small amounts of uranium-234 and uranium-235. Enriched uranium is enhanced in the isotope uranium-235 above its natural concentration of 0.72 percent. Highly enriched uranium has a greater than 20 percent concentration of uranium-235 or greater. Depleted uranium results from the enrichment process, where most of the uranium-235 is removed.

Most uranium isotopes of interest here have very long half-lives and are alpha-emitters. Their half-lives are much longer than plutonium isotopes; as a result, uranium is generally of lower radiological concern than plutonium. Its actual radiological concern, however, varies with its enrichment. As a heavy metal, uranium can be chemically toxic to the kidneys. Depending on the enrichment and chemical form, either chemical or radiological considerations dominate.

Tritium is a radioactive isotope of hydrogen. It is generated at low levels in the environment by interactions of cosmic radiation with the upper atmosphere, but for practical applications, it is normally produced in a nuclear reactor. The radioactive properties of tritium are very useful. By mixing tritium with a chemical that emits light in the presence of radiation, a phosphor, a continuous light source, is created. This can be applied to situations where a dim light is needed but using batteries or electricity is not possible. Rifle sights and exit signs are common applications. Tritium has a half-life of around 12 years and decays by emitting a low-energy beta particle that cannot penetrate the outer layer of human skin. The main hazard associated with tritium is internal exposure. Because tritium is an isotope of hydrogen, it can be incorporated into a water molecule, forming tritiated water. In the environment, tritium is most often found in its elementary form as a gas, or as water. Tritiated water is a concern to the human body because the body is composed mostly of water. Tritiated water will easily and rapidly enter the body and irradiate it rather uniformly; however, it also is removed from the body rather quickly because it can be easily displaced with regular water and has a biological half-life of about 12 days under normal conditions.

C.1.3 Methods Used to Estimate Radiological Impacts from Normal Operations

Dose assessments for members of the public were performed at LANL to determine the incremental doses that would be associated with the alternatives addressed in this SWEIS. This section provides supplemental information regarding those assessments. Incremental doses for members of the public were calculated for the following types of receptors:

- *Facility-Specific Maximally Exposed Individual (MEI)*—The facility-specific MEI represents a location near a facility where the greatest modeled dose to a hypothetical public individual would be received from all modeled emissions.
- *LANL Site-Wide MEI*—The LANL MEI represents the location where the single highest modeled dose would be received by a hypothetical public individual. The highest facility-specific MEI becomes the LANL MEI.
- Collective dose to the population within a 50-mile (80-kilometer) radius from LANL.

C.1.3.1 Key Facilities Modeled

Several facilities at LANL release radioactive materials to the ambient air through stacks, vents, or diffuse emissions. The facilities modeled for this SWEIS are listed in **Table C–3**. Those facilities not modeled were eliminated from detailed analysis because they either have historically low emission rates or would not be expected to operate during the period analyzed in this SWEIS. In addition, all of the facilities modeled in the *1999 SWEIS* as non-Key Facilities (High Pressure Tritium Facility [Technical Area (TA) 33] and Nuclear Safeguards Research Facilities [TA-35]) no longer have facility emissions. The following are changes from the *1999 SWEIS* to the list of Key Facilities:

- The Pajarito Site (TA-18) was removed from the LANL Key Facility list in both the Reduced and Expanded Operations Alternatives of this SWEIS (see Chapter 3, Section 3.1.3.9). Because the normal operational releases will still be applicable for the No Action Alternative at the Pajarito Site, a dose assessment was performed for this SWEIS.
- The Tritium Facilities in TA-21 were removed from the LANL Key Facilities list in the Expanded Operations Alternative. The buildings will continue to have radioactive air emissions until the decontamination, decommissioning, and demolition process has begun. Since these air emissions will result in potential doses to the MEI and public, a dose assessment was performed for the Tritium Facilities in TA-21 in this SWEIS.

Table C–3 Los Alamos National Laboratory Key Facilities

Technical Area	*Facility Name*
TA-3-29	Chemistry and Metallurgy Research Building
TA-3-66	Sigma Complex
TA-3-102	Machine Shops
TA-11	High Explosives Processing Facilities
TA-15 and TA-36	High Explosives Testing Facilities
TA-16	Tritium Facility [a]
TA-18	Pajarito Site [b]
TA-48	Radiochemistry Facility
TA-53	Los Alamos Neutron Science Center
TA-54	Waste Management Operations [c]
TA-55	Plutonium Facility Complex
Non-Key (TA-21)	TA-21 Non-Key Facilities [a]

[a] The Tritium Facility includes the Weapons Engineering Tritium Facility at TA-16. The non-Key Facilities at TA-21 were formerly part of the Tritium Facilities and include the Tritium Science and Fabrication Facility and the Tritium Systems Test Assembly that will continue to produce emissions while awaiting decontamination, decommissioning, and demolition and are under non-Key Facilities.
[b] A LANL Key Facility in the No Action Alternative, it will continue to produce emissions until the Solution High-Energy Burst Assembly moves to another DOE site.
[c] Area G and the Decontamination and Volume Reduction System.

The new LANL Key Facilities were reviewed for potential radiological air releases. It was determined that no significant air emissions from these facilities would produce doses that could affect the public. In addition, the radiological air emissions from the Radioactive Liquid Waste Treatment Facility at TA-50 were considered in the *1999 SWEIS* to be minimal (DOE 1999a) relative to other sources at LANL and therefore were not modeled. It was anticipated that the replacement Radioactive Liquid Waste Treatment Facility also would have minimal radiological air emissions; therefore, it was not modeled in this SWEIS (Appendix G).

As part of LANL's zero liquid discharge program, two concrete basins located at the east end of TA-53 are used to evaporate radioactive liquid discharge from the Los Alamos Neutron Science Center (LANSCE) facility. LANSCE radioactive liquid is first placed in a collection tank for decay. Measurement of the radioisotope concentration of the liquid in this tank after decay is used to determine when it can be released to one of the evaporation basins. Each basin has a 125,000-gallon (473,125-liter) capacity and is lined with a nonpermeable material. The measured radioisotope concentrations in liquid released to the evaporation basin in 2006 were used to calculate the dose to the MEI residing at the East Gate at State Highway 502 located 800 meters (2,625 feet) from the evaporation basins. The calculation used the Clean Air Act Assessment Package – 1988 (CAP88) computer code (EPA 2002) and assumed that all radioisotopes present in the liquid in the evaporation basin during the year, regardless of physical form, were released to the air. The resulting calculated dose to the MEI was 0.035 millirem per year. This 0.035 millirem evaporation basin MEI dose is less than 0.5 percent of the LANL MEI dose of 7.8 millirem for the No Action Alternative. The effect of these evaporation basins on the 50-mile (80-kilometer) population dose from normal operations was calculated to be 0.0278 person-rem per year, which is small (0.13 percent) compared to the population dose from LANSCE emissions (22 person-rem per year).

C.1.3.2 Clean Air Act Assessment Package – 88 Model

CAP88-PC Version 3.0 computer code was used for this SWEIS to calculate population radiation doses from normal releases of radioisotopes (EPA 2002). There were significant changes in dose calculations between the (CAP88-PC) DOS Version 1.0 used in the *1999 SWEIS* and the Version 3.0 used here, including:

- Incorporation of the new Federal Guidance Report No. 13 dose and risk factors;
- Incorporation of options to choose different chemical forms for each radionuclide;
- Addition of pathways, such as drinking water ingestion and external exposure from multiple depths of soil contamination;
- Ability to account for the effect of humidity; and
- Addition of more than 800 isotopes, consistent with those in Federal Guidance Report No. 13.

C.1.3.3 Model Input Parameters

The CAP88 model requires many input parameters to perform dose calculations. Most of these parameters are built into the model and require no input from the user. The user-defined inputs are discussed below, along with how the data were derived.

Population Data

The evaluation of collective offsite dose considers the population living within 50 miles (80 kilometers) of LANL. Potential doses to the local population from airborne radioactive emissions at each Key Facility at LANL were estimated using a 50-mile radius centered on the facility whose emissions were being analyzed. The 50-mile radius is typically used in EISs to evaluate impacts from both emissions from normal operations and releases from postulated accidents. Dose calculations using emissions from LANSCE were performed to support the use of the 50-mile distance. In this analysis, in addition to the dose to the MEI, the dose to an individual was calculated in the direction of the highest dose (north-northeast) for various distances out to 50 miles. As shown in **Figure C–1**, the dose dropped dramatically with increasing distance from the source, due primarily to the dispersion of the emitted contaminants, which reduced their concentrations. Therefore, anywhere beyond 50 miles in any direction, the dose would be smaller than the dose at 50 miles (0.035 millirem per year).

The Sector Population, Land Fraction, and Economic Estimation Program (NRC 2003) was used to create population distribution files that were then configured to work as data input files for CAP88. The SECPOP2000 software can calculate estimated population and economic data about any point (specified by longitude and latitude) that lies within the continental United States. SECPOP2000 used the latest (2000) census data. Population estimates were made using block level census data.

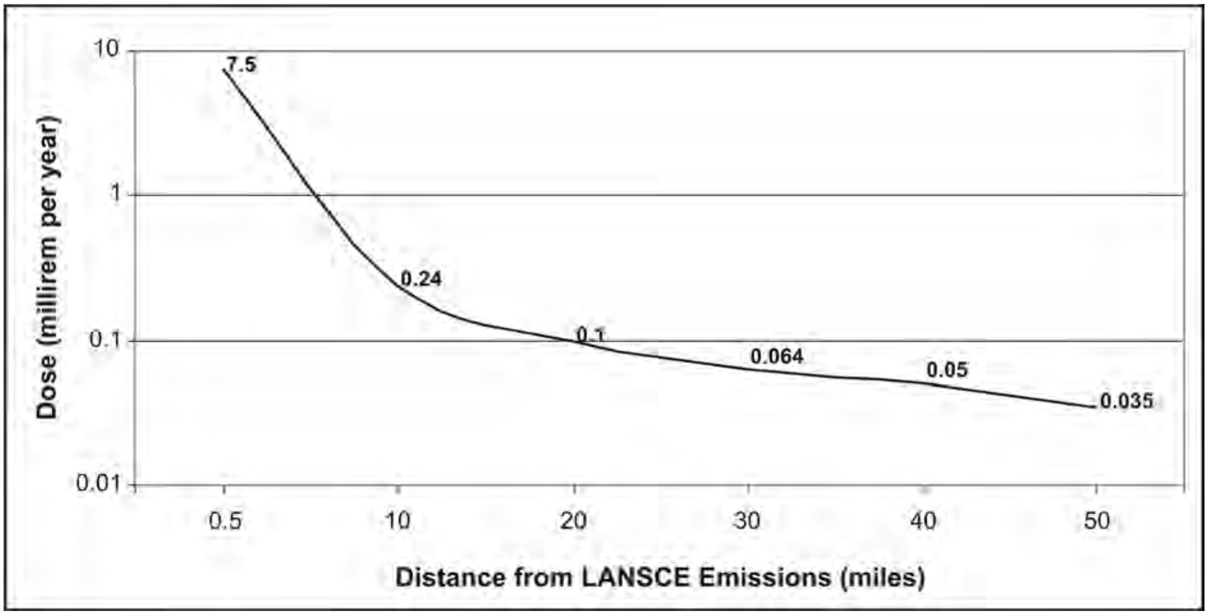

Figure C–1 Maximum Dose to an Individual at Selected Distances

In its population files, CAP88 uses edgepoints for each sector, which are entered in the population file in kilometers. The edgepoints used for CAP88 were consistent with those used for the accident analyses (1, 2, 3, 4, 5, 10, 20, 30, 40, 50 miles). Each CAP88 population file was subsequently analyzed for residents inappropriately listed as residing on LANL property. One block of 184 individuals was consistently listed on a LANL-only sector. Those 184 individuals were manually moved to the adjoining sector to ensure no individuals were assessed as living on LANL property.

Maximally Exposed Individual Locations

The facility-specific MEI represents the location near a specific facility where a hypothetical person receives the greatest dose. These locations do not represent actual residences or individuals, but rather a hypothetical receptor (see Chapter 5, Section 5.6). Some points at the LANL boundary do have residences close to them. This is especially true for those TAs located in the northern part of the LANL site, such as TA-3 and TA-53.

The facility-specific MEI locations remained the same in this SWEIS as those in the *1999 SWEIS*. Due to the expected changes in LANL boundaries near TA-21 and TA-54, the MEIs for TA-21 and TA-54 were reviewed. The review of the TA-21 MEI location included the conveyance of segments A-5-1, A-6, A-8, A-9, A-10, A-11, and A-15. The review of the TA-54 MEI location included the conveyance of segments A-19-1, A-19-2, A-19-3, B-1 and C-1, all of which are near White Rock (LANL 2006a). Since the highest dose for TA-54 in the *1999 SWEIS* was located northeast of the site at the boundary with San Ildefonso Pueblo, the conveyance of land near White Rock, further away, did not affect the TA-54 MEI location.

For some Key Facilities, there are areas nearby that are not populated by LANL workers (such as the Los Alamos County Landfill). These areas were not considered populated by public receptors. Some modeled facilities share the same MEI location. The Chemistry and Metallurgy

Research Building (TA-3-29) and the Sigma Complex (TA-3-66) share the same MEI location, as do the Radiochemistry Facility (TA-48) and the Plutonium Facility Complex (TA-55).

Meteorological Data

There are six towers that gather meteorological data. Four of the towers are located on mesa tops and are used with the CAP88 model to estimate air dispersion of emitted nuclides. The data used for each tower covered an average of 9 years (January 1, 1995 through December 31, 2003) of actual meteorological data. Using average meteorological data over a period of time better reflects conditions than data from any individual year. The tower nearest to the modeled facility was used for data input.

Tower	***Key Facility Locations***
TA-6	TA-3, TA-16, TA-48, TA-55
TA-49	TA-11, TA-15, TA-36
TA-53	TA-21, TA-53
TA-54	TA-18, TA-54

The other meteorological data used in CAP88 is listed below. Previous versions of CAP88 used a default value of 8 grams per cubic meter for the Average Absolute Humidity. For this SWEIS, a value of 3.85 grams per cubic meter (LANL 2004a) was used. All other parameters were confirmed from the *1999 SWEIS*.

- Annual precipitation = 19 inches (48 centimeters) per year.
- Annual ambient temperature = 48 degrees Fahrenheit (8.8 degrees Celsius).
- Height of lid (atmosphere mixing level) = 5,000 feet (1,525 meters).
- Average absolute humidity = 4 grams per cubic meter (3.85 grams per cubic meter rounded up by CAP88).

Emissions Data

For this SWEIS, all actual emissions from 1999 through 2004 (LANL 2000, 2001, 2002a, 2003a, 2004c, 2005a) were reviewed and analyzed to ensure that the projected emissions from the *1999 SWEIS* were bounding. Based on the above review and additional data from LANL, some changes were made to the projected air emissions. Specific changes can be found in the appropriate Radiological Air Emissions **Tables C–4** through **C–15**. In addition, each Key Facility's activities were reviewed for the three alternatives considered in this SWEIS (No Action, Reduced Operations, and Expanded Operations). The projected releases are based on those activities. A complete description of the alternatives can be found in Chapter 3.

Changes to CAP88 Version 3.0 included the ability of the user to choose the specific chemical form and type. The chemical form used in the assessments was based on each facility's process knowledge. For example, LANSCE produces a variety of materials generated through the process of activation; consequently, emissions occur as gaseous mixed activation products. Other activation products occur in particulate and vapor form.

Gaseous mixed activation product emissions included argon-41, carbon-11, nitrogen-13, nitrogen-16, oxygen-14, and oxygen-15. Various radionuclides such as mercury-193, mercury-197, germanium-68, and bromine-82 made up the majority of the particulate and vapor form emissions (LANL 2004c). Tritium can be released in different forms, either as tritium oxide (vapor) or as elemental tritium (gas), at each facility where it is present. Area G at TA-54, for instance, is a known source of diffuse emissions of tritium vapor (LANL 2004c). These forms are noted in Tables C–4 through C–15.

At some Key Facilities, the emissions were modeled using the most conservative radioisotope. For example, actinide emissions at the Chemistry and Metallurgy Research Building include plutonium, uranium, thorium, and americium isotopes. Of these isotopes, plutonium-239 was used for modeling purposes to conservatively represent all of the actinides released. By using plutonium-239, the estimated dose for members of the public presented in this SWEIS is higher than would be experienced if the actual actinides were used in the model calculations.

Some Key Facility projected emissions included radionuclides that are not in the dose conversion factor database of CAP88 Version 3.0. Impacts from these radionuclides would be minimal due to their extremely short half-lives and small inventory amounts. All of the radionuclides omitted from the dose assessment have half-lives of less than 2 minutes. Chlorine-39, whose portion among the LANSCE air emissions was negligible (less than 0.01 percent per year), also was omitted from the dose assessment.

Table C–4 Radiological Air Emissions (curies per year) from the Chemistry and Metallurgy Research Building (Technical Area 3-29) [a]

Radionuclide	*No Action*	*Reduced Operations*	*Expanded Operations*
Stack ES-14 Height (meters) = 15.9 Diameter (meters) = 1.07 Exit velocity (meters per second) = 6.8			
Actinides [b]	0.00076	0.00003	Same as No Action
Stack ES-46 [c] Height (meters) = 16.5 Diameter (meters) = 1.88 Exit velocity (meters per second) = 1.9			
Krypton-85	100	Same as No Action	Same as No Action
Xenon-131m	45	Same as No Action	Same as No Action
Xenon-133	1,500	Same as No Action	Same as No Action

[a] Projected emission rates are from the *CMRR EIS* (DOE 2003b). For the No Action and Expanded Operations Alternatives, because of the start of the Chemistry and Metallurgy Research Replacement Facility Project, there would be no emissions from the Chemistry and Metallurgy Research Building after approximately 2014. The actinide processes and resulting emissions would move to a new facility near TA-55 and the Wing 9 processes would move to the Radiological Sciences Institute. The support for hydrodynamic testing and tritium separation activities would remain at TA-55.
[b] Actinides were not broken down by isotope and were represented by plutonium-239. Actinides are emitted from almost all wings. The most conservative stack (ES-14) was chosen to model these emissions. The most conservative lung absorption rate for plutonium-239 (moderate) was chosen.
[c] Fission products are emitted from Wing 9. The most conservative stack (ES-46) was chosen for modeling.
Note: To convert meters to feet, multiply by 3.2808.

Table C–5 Radiological Air Emissions (curies per year) from the Sigma Complex (Technical Area 3-66)

Radionuclide	*No Action*	*Reduced Operations*	*Expanded Operations*
All Stacks [a] Height (meters) = 15.2 Diameter (meters) = 1.2 Exit velocity (meters per second) = 1			
Uranium-234 [b]	0.0000660	Same as No Action	Same as No Action
Uranium-238 [b, c]	0.0018	Same as No Action	Same as No Action

[a] Stacks are no longer monitored. Emissions now based on process knowledge and inventory. Depleted uranium is considered as uranium-238 and enriched uranium is considered as uranium-234.
[b] The most conservative lung absorption rate (slow) was chosen for all uranium and thorium isotopes. A moderate lung absorption rate was used for protactinium.
[c] All uranium-238 is assumed to be in equilibrium with thorium-234 and protactinium-234m.
Note: To convert meters to feet, multiply by 3.2808.

Table C–6 Radiological Air Emissions (curies per year) from the Machine Shops (Technical Area 3-102)

Radionuclide	*No Action*	*Reduced Operations*	*Expanded Operations*
Stack ES-22 Height (meters) = 13.4 Diameter (meters) = 0.91 Exit velocity (meters per second) = 0.8			
Uranium-238 [a]	0.00015	Same as No Action	Same as No Action

[a] Uranium-238 was used to model all uranium. Protactinium-234m and thorium-234 are in equilibrium with uranium-238. The most conservative lung absorption rate (slow) was chosen for uranium and thorium. A moderate lung absorption rate was used for protactinium.
Note: To convert meters to feet, multiply by 3.2808.

Table C–7 Radiological Air Emissions (curies per year) from High Explosives Processing Facilities (Technical Area 11)

Radionuclide	*No Action*	*Reduced Operations* [a]	*Expanded Operations*
Area size (square meters) = 10,000 [b]			
Uranium-234 [c]	3.71×10^{-7}	2.97×10^{-7}	3.71×10^{-7}
Uranium-235 [d, c]	1.89×10^{-8}	1.51×10^{-8}	1.89×10^{-8}
Uranium-238 [e, c]	9.96×10^{-7}	7.97×10^{-7}	9.96×10^{-7}

[a] For Reduced Operations, a 20 percent reduction in operations was assumed to result in a 20 percent reduction in air emissions.
[b] No stack emissions. This is an area source.
[c] The most conservative lung absorption rate (slow) was chosen for all uranium and thorium. A moderate lung absorption rate was used for protactinium.
[d] Thorium-231 is in equilibrium with uranium-235.
[e] Thorium-234 and protactinium-234m are in equilibrium with uranium-238.
Note: To convert square meters to square feet, multiply by 10.764.

Table C–8 Radiological Air Emissions (curies per year) from High Explosives Testing Facilities (Technical Area 15 and Technical Area 36) [a]

Radionuclide	No Action	Reduced Operations [b]	Expanded Operations
Area size (square meters) = 100 [c]			
Uranium-234 [f]	0.0345	0.0276	0.0345
Uranium-235 [d, f]	0.0015	0.0012	0.0015
Uranium-238 [e, f]	0.114	0.0912	0.114

[a] Depleted uranium was modeled as 27 percent uranium-234, 1 percent uranium-235, and 72 percent uranium-238 per curie of release, per LANL guidance in *Dose Assessment Using CAP88*, RRES-MAQ-501, R6 (LANL 2003b).
[b] For Reduced Operations, a 20 percent reduction in operations was assumed to result in a 20 percent reduction in air emissions. The reduction of experiments with special nuclear material at the Dual Axis Radiographic Hydrodynamic Test Facility was assumed to have no effect on air emissions.
[c] No stack emissions. This is an area source.
[d] Thorium-231 is in equilibrium with uranium-235.
[e] Thorium-234 and protactinium-234m are in equilibrium with uranium-238.
[f] The most conservative lung absorption rate (slow) was chosen for all uranium and thorium. A moderate lung absorption rate was used for protactinium.
Note: To convert square meters to square feet, multiply by 10.764.

Table C–9 Radiological Air Emissions (curies per year) from the Tritium Facility (Technical Area 16)

Radionuclide	No Action	Reduced Operations	Expanded Operations
Stack FE-04 Height (meters) = 18.3 Diameter (meters) = 0.46 Exit velocity (meters per second) = 19.3			
Tritium (gas)	300	Same as No Action	Same as No Action
Tritium (water vapor)	500	Same as No Action	Same as No Action

Note: To convert meters to feet, multiply by 3.2808.

Table C–10 Radiological Air Emissions (curies per year) from the Pajarito Site (Technical Area 18)

Radionuclide	No Action	Reduced Operations [a]	Expanded Operations [a]
Area size (square meters) = 45,200 [b]			
Argon-41	102	Same as No Action	Same as No Action

[a] Under reduced and expanded operations, the Solution High-Energy Burst Assembly would be removed from TA-18 in about 2009, thereafter there would be no radiological air emissions.
[b] No stack emissions. This is an area source from operations that activate argon atoms in the air surrounding the assembly.
Note: To convert square meters to square feet, multiply by 10.764.

Table C–11 Radiological Air Emissions (curies per year) from the Radiochemistry Facility (Technical Area 48)

Radionuclide [a]	***No Action***	***Reduced Operations***	***Expanded Operations***
Fan Exhaust FE-51/54 [b] Height (meters) = 13.1 Diameter (meters) = 0.91 Exit velocity (meters per second) = 7.9			
Plutonium-239 [c]	0.0000121	Same as No Action	Same as No Action
Uranium-235 [c]	0.000000484	Same as No Action	Same as No Action
Mixed Fission Products [d]	0.000154	Same as No Action	Same as No Action
Fan Exhaust FE-63/64 [e] Height (meters) = 13.4 Diameter (meters) = 0.3 Exit velocity (meters per second) = 12.5			
Arsenic-72 [f]	0.000121	Same as No Action	Same as No Action
Arsenic-73 [f]	0.00255	Same as No Action	Same as No Action
Arsenic-74 [f]	0.00133	Same as No Action	Same as No Action
Beryllium-7 [f]	0.0000165	Same as No Action	Same as No Action
Bromine-77 [f]	0.000935	Same as No Action	Same as No Action
Germanium-68 [f, h]	0.00897	Same as No Action	Same as No Action
Rubidium-86 [g]	0.000000308	Same as No Action	Same as No Action
Selenium-75 [g]	0.000385	Same as No Action	Same as No Action
Other Activation Products [i]	0.00000558	Same as No Action	Same as No Action

[a] All radionuclides at TA-48 were increased 10 percent (over *1999 SWEIS* amounts or highest actual emission rate, whichever was higher).
[b] Actinides are emitted through several unmonitored stacks at TA-48. The most conservative stack (Fan Exhaust FE-51/54 exits through stack 54) was chosen to model emissions from these stacks.
[c] The most conservative lung absorption rates (moderate for plutonium and slow for uranium) were chosen.
[d] Mixed Fission Products were not broken down by isotopes and were represented by strontium-90 and yttrium-90 in equilibrium. The default lung absorption rate (moderate) was used.
[e] Activation products are emitted through several stacks at TA-48. The most conservative stack (Fan Exhaust FE-63/64 exits through stack 7) was chosen to model emissions from these stacks.
[f] The lung absorption rate (moderate) was used.
[g] The default lung absorption rate (fast) was used
[h] Germanium-68 was assumed to be in equilibrium with gallium-68.
[i] Other Activation Products are a mixed group of activation products represented by strontium-90 and yttrium-90 in equilibrium. The default lung absorption rate (moderate) was used.
Note: To convert meters to feet, multiply by 3.2808.

Table C–12 Radiological Air Emissions (curies per year) from the Los Alamos Neutron Science Center (LANSCE) (Technical Area 53) [a, b]

Radionuclide	*No Action*	*Reduced Operations*	*Expanded Operations*
Stack ES-2 Height (meters) = 13.1 Diameter (meters) = 0.91 Exit velocity (meters per second) = 7			
Argon-41	453	0	453
Carbon-11 (dioxide)	18,400	0	18,400
Mercury-193	30.1	0	30.1
Nitrogen-13	2,860	0	2,860
Oxygen-15	3,820	0	3,820
Stack ES-3 [c] Height (meters) = 33.5 Diameter (meters) = 0.91 Exit velocity (meters per second) = 12.5			
Argon-41	431	0	431
Carbon-11[d] (dioxide)	4,090	0	4,090
Nitrogen-13	240	0	240
Oxygen-15	60	0	60
Area size (square meters) = 1,432 [e]			
Argon-41	3.2	0	3.2
Carbon-11 (dioxide)	76.8	0	76.8

[a] The total curies emitted changed from the *1999 SWEIS* emission rates based on a revised curie per microamp-hour ratio. Under the Reduced Operations Alternative, there would be no emissions due to the shutdown of all activity at LANSCE.
[b] Carbon-10 and oxygen-14 were not modeled. They both are very short-lived nuclides (less than 2 minutes) and have no published dose conversion factor. They would have minimal health impacts.
[c] Emission projections for the Isotope Production Facility were modeled as being released from stack ES-3 in addition to evacuations from experimental areas A, B, and C and associated lines B and C tunnels. Expanded Operations include emissions for up to 100 irradiated targets for medical isotope processing.
[d] Total carbon-11 from stack ES-3 and the Isotope Production Facility.
[e] These are fugitive sources created at the accelerator target cells that have migrated into room air and into the environment.
Note: To convert meters to feet, multiply by 3.2808.

Table C–13 Radiological Air Emissions (curies per year) from Waste Management Operations (Technical Area 54)

Radionuclide	*No Action*	*Reduced Operations*	*Expanded Operations*
Area size (square meters) = 5,000 [a]			
Tritium (water vapor)	60.9	Same as No Action	Same as No Action
Americium-241 [b]	6.6×10^{-7}	Same as No Action	Same as No Action
Plutonium-238 [c]	4.80×10^{-6}	Same as No Action	Same as No Action
Plutonium-239 [c]	6.80×10^{-7}	Same as No Action	Same as No Action
Uranium-234 [c]	8.00×10^{-6}	Same as No Action	Same as No Action
Uranium-235 [c]	4.10×10^{-7}	Same as No Action	Same as No Action
Uranium-238 [c]	4.00×10^{-6}	Same as No Action	Same as No Action
Stack 54-412 (DVRS) Height (meters) = 10.7 Diameter (meters) = 0.69 Exit velocity (meters per second) = 16.6			
Americium-241 [b]	3.53×10^{-6}	Same as No Action	Same as No Action
Plutonium-238 [c]	1.76×10^{-5}	Same as No Action	Same as No Action
Plutonium-239 [c]	7.78×10^{-6}	Same as No Action	Same as No Action

DVRS = Decontamination and Volume Reduction System.

[a] These emissions are from an area source. They are conservatively based on a 5-year average plus two standard deviations of nearby environmental concentration measurements.

[b] The default lung absorption rate (moderate) was used.

[c] The most conservative lung absorption rates (moderate for plutonium and slow for uranium) were chosen.

Note: To convert meters to feet, multiply by 3.2808; to convert square meters to square feet, multiply by 10.764.

Table C–14 Radiological Air Emissions (curies per year) from the Plutonium Facility Complex (Technical Area 55)

Radionuclide	*No Action*	*Reduced Operations*	*Expanded Operations* [a]
Stack ES-15 Height (meters) = 9.5 Diameter (meters) = 0.93 Exit velocity (meters per second) = 6.8			
Plutonium-239 [b]	0.0000025	Same as No Action	Same as No Action
Stack ES-16 Height (meters) = 9.5 Diameter (meters) = 0.94 Exit velocity (meters per second) = 10.8			
Plutonium-239 [b]	0.000017	Same as No Action	0.000036
Tritium (gas)	250	Same as No Action	Same as No Action
Tritium (water vapor)	750	Same as No Action	Same as No Action

[a] Expanded operations include pit production (80 pits), pit surveillance (65 pits), actinide processing 1,764 pounds (800 kilograms), and pit disassembly capacity (500 pits).

[b] No isotopic breakdown of particulates was available; therefore all particulates were represented by plutonium-239. The most conservative lung absorption rate (moderate) was chosen.

Note: To convert meters to feet, multiply by 3.2808.

Table C–15 Radiological Air Emissions (curies per year) from Non-Key Facilities (Technical Area 21)

Radionuclide	*No Action* [a]	*Reduced Operations* [a]	*Expanded Operations* [a]
Stack ES-1 (TA-21 Tritium Science and Fabrication Facility) Height (meters) = 22.9 Diameter (meters) = 1.22 Exit velocity (meters per second) = 10.3			
Tritium (water vapor) [b]	50	Same as No Action	Same as No Action
Stack ES-5 (TA-21 Tritium Systems Test Assembly) Height (meters) = 29.9 Diameter (meters) = 0.79 Exit velocity (meters per second) = 7.8			
Tritium (gas)	100	Same as No Action	Same as No Action
Tritium (water vapor) [c]	400	Same as No Action	Same as No Action

TA = technical area.

[a] Emissions from TA-21 stacks were stopped in September 2006 as part of TA-21 shutdown activities. Decontamination, decommissioning, and demolition of TA-21 under the Expanded Operations Alternative would permanently eliminate this potential source of emissions.

[b] Tritium emissions are based on LANL estimates of neutron target tube loading operations through the end of 2006 while awaiting decontamination, decommissioning, and demolition. The more conservative water vapor form of tritium was used.

[c] Tritium emissions (water vapor) were increased from the *1999 SWEIS* based on actual emission data (1999 through 2004) and expected emission rate while awaiting decontamination, decommissioning, and demolition.

Note: To convert meters to feet, multiply by 3.2808.

Stack Parameters

The height and diameter measurements of monitored stacks were taken from the 2003 LANL Radionuclide Air Emissions Report (LANL 2004c). The same exit velocities for those stacks were used as in the *1999 SWEIS*. The parameters used for unmonitored stacks were obtained from LANL staff (LANL 2006a). Stack parameters are listed in Tables C–4 through C–15.

Agricultural Data

One pathway of exposure modeled by CAP88 is emission of radionuclides to the air and their subsequent ingestion through food crops. CAP88 uses average agricultural productivity data for New Mexico based on the address of LANL when determining the agricultural data. The EPA Food Source Scenario used in CAP88 describes the fraction of vegetables, milk, and meat produced in the area. The ingestion (consumption) rates are the same for all scenarios. The "rural" scenario was used and included the following fractions.

Fraction	***Vegetable***	***Milk***	***Meat***
Produced at home	0.7	0.399	0.442
From the region (not imported)	0.3	0.601	0.558

C.1.3.4 Results of Analyses

The sequence of analyses performed to generate the radiological impact estimates from normal operations included selection of normal operational modes, estimation of source terms, estimation of environmental transport and uptake of radionuclides, calculation of radiation doses to exposed individuals, and estimation of health effects. There are uncertainties associated with each of these steps. Uncertainties exist in the way the physical systems being analyzed are represented by the computational models and in the data required to exercise the models (due to measurement, sampling, or natural variability).

The analysis was designed to ensure—through judicious selection of release scenarios, models, and parameters—that the results represent the potential risks. This was accomplished by making conservative assumptions in the calculations at each step. The models, parameters, and release scenarios used in the calculations were selected such that most intermediate results and, consequently, final estimates of impacts, were greater than would be expected. As a result, even though the range of uncertainty in a quantity might be large, the value calculated for any one modeled dose would be close to one of the extremes in the range of possible values, so the chance of the actual dose being greater than the calculated value would be low. The goal of the radiological assessment for normal operations in this SWEIS is to produce conservative results in order to capture any uncertainties in normal operations.

Maximally Exposed Individual

The facility-specific MEI represents a location near a facility that was modeled as having the greatest dose to a hypothetical public individual from all modeled emissions. This location was determined for each Key Facility and was calculated based on meteorological data for the site, as well as the type and amount of radiological air emissions from the Key Facility. For the purposes of this analysis, it was very conservatively assumed that the MEI is a person who stays in the same location 24 hours a day, 365 days a year. Furthermore, it was assumed that this person is not shielded from emissions by clothing or shelter (for example, a building, auto, home, etc.).

The doses were then calculated at each facility-specific MEI location from all other modeled facilities; thus, the facility-specific MEI represents the estimated dose to an individual near the specified facility from all modeled facilities. **Table C–16** summarizes the dose to each facility MEI from emissions from all modeled facilities. **Tables C–17** through **C–19** compare the facility-specific MEI for each of the three alternatives considered in this SWEIS. Each facility-specific MEI was totaled and the facility-specific MEI with the highest total dose was designated the LANL site-wide MEI for that alternative. Therefore any facility-specific MEI dose would be less than the LANL site-wide MEI for that alternative.

Table C–16 Summary of Facility-Specific Maximally Exposed Individual Dose (millirem per year) [a, b]

	No Action Alternative	*Reduced Operations Alternative*	*Expanded Operations Alternative*
Chemistry and Metallurgy Research Building and Sigma Complex [c]	0.46	0.13	0.46
Machine Shops	0.37	0.08	0.37
High Explosives Processing Facilities	0.38	0.11	0.38
High Explosives Testing Facilities	2.9	0.78	2.9
Tritium Facility	0.32	0.09	0.32
Pajarito Site [d]	2.9	0.78	2.9
Radiochemistry Facility and Plutonium Facility Complex [e]	0.78	0.20	0.78
Los Alamos Neutron Science Center [f]	14	0.24	14
Waste Management Operations	1.2	0.33	1.2
Non-Key Facilities (TA-21) [g]	1.9	0.29	1.9

TA = technical area.

[a] Doses are from all modeled facilities.

[b] Under the No Action Alternative and the Expanded Operations Alternative, the LANL site-wide MEI would be located near LANSCE. Under the Reduced Operations Alternative, the LANL site-wide MEI would be located near the Firing Sites at TA-36.

[c] Chemistry and Metallurgy Research Building and Sigma Complex had the same MEI location.

[d] Under the Reduced and Expanded Operations Alternatives, Pajarito Site (TA-18) would not be operational after about 2009, thereby eliminating the need for a designated facility-specific MEI dose.

[e] Radiochemistry Facility and Plutonium Facility Complex had the same MEI location.

[f] As a mitigating measure, operational controls at LANSCE would limit their portion of the MEI dose to 7.5 millirem, resulting in lower doses.

[g] Emissions from TA-21 stacks were stopped in September 2006 as part of TA-21 shutdown activities. Decontamination, decommissioning, and demolition of TA-21 under the Expanded Operations Alternative would permanently eliminate this potential source of radiation dose.

LANL site-wide MEI dose impacts for the No Action (Table C–17) and Expanded Operations (Table C–19) Alternatives reflect the change in location of the actinide processes at the Chemistry and Metallurgy Research Building to the new Chemistry and Metallurgy Research Replacement Facility near TA-55. These impacts on the doses were determined by calculating the net dose (removal of the dose from operations at the Chemistry and Metallurgy Research Building and addition of the dose from operations at the new Chemistry and Metallurgy Research Replacement Facility). These impacts to the MEI were minimal. For the Reduced Operations Alternative (Table C–18), LANL site-wide MEI dose impacts reflect the continued operations at the existing Chemistry and Metallurgy Research Building in TA-3.

Under the No Action and Expanded Operations Alternatives, operational controls at LANSCE would limit the amount of radiological air emissions. It is assumed that there is a dose limit of 7.5 millirem to the MEI from LANSCE emissions. This dose limit, when added to the doses from operations at all other Key Facilities, would result in a LANL site-wide MEI dose of 7.8 millirem under the Expanded Operations Alternative. The regulatory limit of 10 millirem per year (Title 40 *Code of Federal Regulations* [CFR] 61.92) to a member of the public, therefore, would not be exceeded under any of the SWEIS alternatives. The highest estimated dose to the MEI from normal LANL operations, 8.2 millirem per year, would be under the Expanded Operations Alternative and includes the additional dose (0.42 millirem per year) from remediation activities (see Chapter 5, Section 5.6 and Appendix I, Section I.5.6).

TA-21 Non-Key Facilities [a]	0.00266	0.00252	0.00242	0.00705	0.00209	0.00478	0.00374	0.0115	0.00277	0.0223
Total (millirem per year)	**0.46**	**0.37**	**0.38**	**2.85**	**0.32**	**2.92**	**0.78**	**13.56** [b, c]	**1.21**	**1.93**

CMR = Chemistry and Metallurgy Research, MEI = maximally exposed individual, TA = technical area, LANSCE = Los Alamos Neutron Science Center.

[a] TA-18 and TA-21 are expected to be decontaminated, decommissioned, and demolished under this alternative and would not produce emissions after that time. These values are applicable for the first few years.

[b] As a mitigating measure, operational controls at LANSCE would limit their portion of the MEI dose to 7.5 millirem resulting in a LANL site-wide MEI dose of 7.8 millirem.

[c] After approximately 2014, actinide emissions will move from the Chemistry and Metallurgy Research Building to the Chemistry and Metallurgy Research Replacement Facility near TA-55. The resulting dose (an additional 0.0023 millirem) will have minimal impact on the LANL MEI dose.

Collective Population Dose

The collective dose to the population living within a 50-mile (80-kilometer) radius from normal operations at LANL was calculated based on emissions from all modeled facilities. The population doses from emissions at each Key Facility were compared and then totaled in **Table C–20**. The majority of the population dose comes from emissions at the High Explosives Testing Facilities and LANSCE under both the No Action and Expanded Operations Alternatives. Under the Reduced Operations Alternative, LANSCE would not be operating; therefore, it would produce no emissions contributing to a population dose.

Table C–20 Collective Population Dose Summary (person-rem per year)

Source	*No Action Alternative Estimated Dose*	*Reduced Operations Alternative Estimated Dose*	*Expanded Operations Alternative Estimated Dose*
Chemistry and Metallurgy Research Building [a]	0.43	0.11	0.43
Sigma Complex	0.16	0.16	0.16
Machine Shops	0.01	0.01	0.01
High Explosives Processing Facilities	0.00005	0.00004	0.00005
High Explosives Testing Facilities	6.4	5.2	6.4
Tritium Facility	0.09	0.09	0.09
Pajarito Site	0.23	0.23 [b]	0.23 [b]
Radiochemistry Facility	0.01	0.01	0.01
Los Alamos Neutron Science Center	22	0.00	22
Waste Management Operations	0.04	0.04	0.04
Plutonium Facilities Complex	0.19	0.19	0.20
Non-Key Facilities (TA-21)	0.09	0.09	0.09 [b]
Total Dose (person-rem per year)	**30**	**6.1**	**36.2** [c]

TA = technical area.

[a] For the No Action and Expanded Operations Alternatives, because of the start of the Chemistry and Metallurgy Research Replacement project there would be no emissions from the Chemistry and Metallurgy Research Building after approximately 2014. The actinide processes and resulting emissions would move to a new facility near TA-55 and the Wing 9 processes would move to the Radiological Sciences Institute. There would be no change in the population dose impact from this move.

[b] TA-18 and TA-21 would be decontaminated, decommissioned, and demolished under these alternatives and would not produce emissions after that time. These values are applicable for the first few years.

[c] The population dose includes 6.2 person-rem that is the maximum annual contribution that may occur from material disposal area remediation (see Appendix I).

Minority and Low-Income Population Dose

Radiological impacts of normal operations on minority, Hispanic, American Indian[3], and low-income populations are determined by applying a methodology similar to that used to determine dose to the total population. This approach is discussed in detail in Section C.1.3. It should be noted that the exposure scenario used to model the minority, Hispanic, American Indian, and low-income populations assumes that these individuals would be exposed in the same manner as

[3] *The term American Indian is used in this environmental justice analysis to reflect definitions used in the 2000 Census. The term Native American is used elsewhere in this SWEIS.*

the general population, that is, by external exposure to a radioactive plume and deposited radioactive materials and by internal exposure from inhalation and from ingestion of foodstuffs.

For purposes of evaluating potential for disproportionately high and adverse impacts caused by radiological emissions from normal operations, an annual collective dose was calculated for each of the subsets of the population being evaluated (minority, Hispanic, American Indian, and low-income) within 50 miles (80 kilometers) of the emission source. **Table C–21** shows the population estimates used for this environmental justice analysis. The average dose to an individual of the minority or low-income population is then calculated to compare to the average dose to an individual from the remainder of the population. The average dose to an individual of the population subset being evaluated is derived by dividing the annual collective dose for the subset by the number of people in the subset.

Table C–21 Potentially Affected Populations

Source Location	*Total Population*	*Total Minority Population*	*Hispanic Population*	*American Indian Population*	*Low-Income Population*
TA-53	283,766	155,261	127,641	17,811	35,826
TA-36	375,495	185,474	151,110	21,263	39,206

The result is then compared to the average dose to an individual who is not a member of the subset being evaluated. The average dose to a member of the remaining population is derived by dividing the annual collective dose to the remainder of the population (collective dose to the total population minus the collective dose to the subset population) by the number of people within 50 miles (80 kilometers) that are not in the population subset. The total minority population includes all Hispanic persons regardless of race. In addition, the American Indian population may include persons who indicated that they were of Hispanic ethnicity in the 2000 Census.

As shown in Table C–20, the total population within 50 miles (80 kilometers) of LANL is projected to receive an annual dose of about 30 person-rem under the No Action Alternative, and 36 person-rem under the Expanded Operations Alternative. Because the majority of these doses (22 person-rem) result from operations at LANSCE, the environmental justice analysis for these alternatives uses the 50-mile (80-kilometer) population centered on LANSCE in TA-53. For the Reduced Operations Alternative, the majority of the collective dose of 6.4 person-rem results from operations at the High-Explosive Testing firing sites at TA-36, therefore, the environmental justice analysis for this alternative uses the 50-mile (80-kilometer) population centered on TA-36.

Table C–22 shows the collective and annual average individual doses used to examine the potential for disproportionately high and adverse impacts on minority, Hispanic, American Indian, and low-income populations. The collective population dose is highest for those populations with the highest number of individuals. Under all alternatives, the largest population is associated with the white, non-Hispanic, and non-low-income populations. The differences, if any, would be most evident on the basis of average individual doses to members of the different population groups. As shown in Table C–22, there are no appreciable differences between the average dose to any minority, Hispanic, American Indian, or low-income individual and the comparable non-minority or non-low-income individual under any of the alternatives. Therefore, these alternatives would not pose disproportionately high and adverse impacts on minority and low-income populations or individuals surrounding each facility site.

Table C–22 Comparison of Total Minority, Hispanic, American Indian and Low-income Population and Average Individual Annual Doses

	No Action [a] *Alternative*	*Reduced* [a] *Operations Alternative*	*Expanded* [a] *Operations Alternative*
Collective Population Dose (person-rem) [b]	29.2	4.9	29.2
Average Individual Dose (millirem)	0.10	0.013	0.10
White (non-Hispanic) Population Dose (person-rem)	15.0	2.7	15.0
Non-Minority Average Individual Dose (millirem)	0.11	0.014	0.11
Minority Population Dose (person-rem)	14.1	2.2	14.1
Minority Average Individual Dose (millirem)	0.088	0.012	0.088
Hispanic Population Dose (person-rem) [c]	11.3	1.9	11.3
Hispanic Average Individual Dose (millirem)	0.086	0.012	0.086
American Indian Population Dose (person-rem) [d]	1.8	0.20	1.8
American Indian Average Individual Dose (millirem)	0.092	0.0094	0.092
Non-low-income Population Dose (person-rem)	25.9	4.4	25.9
Non-low-income Average Individual Dose (millirem)	0.10	0.013	0.10
Low-Income Population Dose (person-rem)	3.0	0.44	3.0
Low-Income Average Individual Dose (millirem)	0.082	0.011	0.082

[a] The collective population dose displayed in this table, accounts for the estimated dose from LANSCE at TA-53 and the High Explosive Testing firing sites at TA-36 for the No Action and Expanded Operations Alternatives, and the firing sites at TA-36 for the Reduced Operations Alternative.

[b] The collective population doses for this environmental justice analysis differ by plus or minus 3 to 6 percent from those in Table C–20. This difference is due to different models used to estimate the populations; both estimates are based on data drawn from the 2000 decennial census. The SECPOP computer program used for the analysis for Table C–20 does not allow for the identification of minority and low-income populations. Therefore an alternate method that uses a more refined distribution of the population is used for this analysis. The minor differences do not affect the conclusions supported by the analyses.

[c] The total Hispanic population includes all Hispanic persons regardless of race.

[d] The American Indian population may include persons who indicated that they were of Hispanic ethnicity in the 2000 census.

Under all alternatives, the annual population and average individual dose would be highest for the white (non-Hispanic) population. Similarly the projected annual population and average individual dose for persons living above the poverty level (non-low-income populations) would be higher than for those living below the poverty threshold. These data indicate that under all alternatives there would not be disproportionately high and adverse impacts on minority, Hispanic, American Indian, and low-income populations surrounding LANL.

C.1.4 Impacts to Offsite Resident, Recreational User, and Special Pathways Receptors from Radionuclides and Chemical Contaminants in the Environment

C.1.4.1 Methodology

Earlier investigation of exposure pathways in the vicinity of LANL (DOE 1999a) concluded that ingestion of foodstuffs and water and incidental ingestion of soil and sediment were of primary interest. Several other contact exposure pathways (including dermal absorption of contaminants from clays used in pottery, bathing or ceremonial use of springs, and smoking of native vegetation) were examined at that time and were not found to be significant contributors to risk. Recent environmental surveillance results and other reports on conditions following the 2000 Cerro Grande Fire indicated that diet, land use, and cultural practices remain largely unchanged from conditions noted in the *1999 SWEIS* analysis, and that, apart from inhalation, ingestion continues to be the only significant pathway by which people in the region adjacent to LANL might be exposed to radioactive and other contaminants resulting from operations at the site. Risks from radionuclides and chemicals in the environment, therefore, were evaluated for three receptors and ingestion exposure scenarios, collectively referred to as “specific receptors.” The specific receptors and the rationale for the selection of ingestion exposure parameters for this analysis are as follows:

- **Offsite Resident.** This receptor represents the resident of Los Alamos County whose living habits and diet tend to produce higher than average exposures to radioactive materials and chemicals in the local environment. The resident also was assumed to use water from the Los Alamos County water supply and to have a garden at their home that produced the fruit and vegetables that they consumed. The resident also was assumed to consume local game animals, game fish, honey, and pinyon nuts, as well as beef and milk produced on local farms and ranches. Accordingly, the pathways considered for this resident include ingestion of groundwater and the above-listed foods, plus inadvertent ingestion of soils and sediments on produce, such as leafy greens and root vegetables. The assumption that the offsite resident consumes all components of the diet and that all the foodstuffs are produced locally (that is no dilution by store-bought or processed foods from outside the area) tends to raise the intake of contaminants well above that of the average person living near LANL. In fact, at the 95th percentile consumer (high-intake) rates published by EPA for each foodstuff, a diet consisting of locally-raised beef, milk, fruits, and vegetables, plus local big game animals and fish, fairly approximates a “subsistence” diet (over 4 pounds [1.83 kilograms] of fruits and vegetables, 1.2 pounds [0.55 kilograms] of meat and fish, and 1.7 pints [0.8 liters] of milk per day), particularly when combined with the additional foods described under “specials pathways”. The 95th percentile consumer eats these foodstuffs at a rate greater than 95 percent of the population.

- **Recreational User of Wildlands.** The recreational user represents a hypothetical outdoor enthusiast who regularly uses the canyons on and near LANL for recreation (as a hiker, rockhound, photographer, etc.). This receptor was assumed to make an average of two visits per month to the canyons, spending 8 hours per visit. This receptor was assumed to be exposed to environmental contaminants by consumption of surface water and the incidental ingestion of soils and sediments at concentrations typical of the LANL canyons. Ingestion of sediments and soils occurs from consuming surface water and from swallowing inhaled dust. It is reasonable to assume that the recreational user is a local resident and that, in the extreme case, exposures received in the course of outdoor recreation might be *additional to* those depicted by the offsite resident.

- **Special Pathways – Subsistence Consumption of Fish and Wildlife**. Section 4–4 of Executive Order 12898 directs that "Federal agencies whenever practicable and appropriate, shall collect, maintain, and analyze information on the consumption patterns of populations who principally rely on fish and/or wildlife for subsistence" and that "Federal agencies shall communicate to the public the risks of those consumption patterns." Therefore, special exposure and diet pathways were evaluated to assess the potential impacts to Native American, Hispanic, and other residents whose traditional living habits and diets could cause larger exposures to environmental contaminants than those experienced by the hypothetical offsite resident. The foodstuffs and pathways of specific interest for this group are ingestion of game animals, including consumption of some organ meats not assumed for the "resident" receptor, ingestion of game fish and other fish taken from local waters, and ingestion of native vegetation through use of Indian Tea (Cota). In general, these intakes can be assumed to be *in addition to* the meat, milk, produce, water, and soil and sediment consumption reflected in the offsite resident plus recreational user pathway assumptions.

The types and amounts of foods represented in the offsite resident diet package suggested that consumption of all items at the *high* intake rates, plus the three additional special pathways components (non-game fish, herbal teas, organ meats), approximates a subsistence diet for someone living in the vicinity of LANL. To confirm that proposition, a trial was done in which the combined intakes (offsite resident plus recreational user plus special pathways) were adjusted to create a model diet consisting entirely of items that would likely be staple foods for a person living a subsistence life near Los Alamos. Milk, beef, and game fish were removed from the offsite resident diet package and groundwater was replaced by surface (stream) water as the sole source of drinking water. The intakes of the remaining foods – deer, elk, non-game fish; produce (beans, corn, squash, and greens); fruit (plums, apricots, and apples); honey and pinyon nuts – were then scaled up to deliver a total of 2,700 calories per day. The radiation dose from consumption of this subsistence diet was determined to be 9.1 millirem per year, consistent with the special pathways consumer at the high intake rates.

Concentrations of radionuclides and chemicals in environmental media reported in LANL Environmental Surveillance Reports for 2001 through 2004 (LANL 2002b, 2004b, 2004d, 2005b) were used in the dose and risk analysis except where noted in the table (see Tables C–24 through C–40). Chemical and radionuclide concentrations in the *2005 LANL Environmental Surveillance Report* (LANL 2006b) were reviewed and found to be enveloped by the 2001 through 2004 measurements. For each environmental medium, the mean and 95 percent upper confidence limit[4] of the reported values were calculated. Data from locations near the LANL boundary, identified in the reports as "perimeter" locations, were used to calculate dose and risk to the offsite resident receptor. For the special pathways receptor, data from bottom-feeder fish

[4] *Calculated using the methodology described in Appendix F.*

taken at locations downstream from LANL were used to represent the maximum impact of LANL emissions and runoff. Data from the limited number of published LANL analysis results for elk heart and liver and Indian Tea (Cota) were used to complete the intake for the special pathways receptor. For the recreational user receptor, soil, sediment and surface water analysis results for onsite locations accessible to the public were used.

Because of the small number of samples reported for some media (all items are not necessarily sampled every year) calendar year 1999 and 2000 results for foodstuffs were also considered, thereby increasing the number of data points used to develop the 95 percent upper confidence limit values and reducing uncertainty. Uncertainties associated with measured contaminant concentrations in environmental media may be quite large, and the 95 percent upper confidence limit values were used when calculating dose to hypothetical individuals to help ensure that the dose and risk estimates were conservative. For radionuclides, additional conservatism was introduced by calculating the 95 percent upper confidence limit values using only those reported values that were greater than zero. This was performed for several reasons. First, the same method was used to develop the 95 percent upper confidence limit values for calculating ingestion doses in the *1999 SWEIS.* By using the same approach, the results of the current analysis can be compared directly with the 1999 results for each pathway component. Second, concentrations of the radionuclides of interest in environmental media are typically quite low (near the threshold of detection) and, when corrected for counting background radiation, negative concentrations of some radionuclides were reported. Setting the negative values to zero or to the limit of detection for a particular radionuclide is complicated by the fact that analytical methods, detection limits, and data reporting formats may vary from year to year. Finally, the ingestion pathway doses are quite small even when they are biased upwards by eliminating the zero and negative sample results. When calculating 95 percent upper confidence limit values for nonradioactive contaminants, a similar conservatism was introduced by using a value *equal to the lower limit of detection* for all samples reported as below the detection limit.

Based on a review of LANL environmental surveillance data and the results of ingestion pathway exposure calculations published in the *1999 SWEIS*, it was determined that consumption of water, soil, sediment, fish, and produce would account for essentially all ingestion exposure to nonradioactive contaminants. Accordingly, only those five pathway components were analyzed for contribution to nonradiological risk. **Table C–23** summarizes the ingestion exposure pathway components that were evaluated for each receptor.

The consumption rate of each component of the ingestion pathway was assumed to equal the average adult daily intake. The average adult daily intake of each foodstuff is defined as the 50^{th} percentile. The "high" daily consumer is defined as the 95^{th} percentile consumer. In other words, 95 percent of the population eats at a rate less than the high daily consumption rate. These rates and doses are typically 2-3 times higher than for the average case. The intake rates, their sources, and the doses for both intake rates are reported in the notes following the dose calculation tables for the various components of the ingestion pathway. For chemicals, the health hazard index and cancer risk were calculated using the most current Reference Doses and Slope Factors published by EPA Region 6 (EPA 2005b).

Table C–23 Ingestion Exposure Pathway Components Evaluated for Offsite Resident, Recreational User, and Special Pathways Receptors

Exposure Pathway Component	*Offsite Resident* [a]	*Recreational User* [b]	*Special Pathways* [c]
Produce	✓	✓	✓
Meat (free-range beef)	✓	✓	✓
Milk	✓	✓	✓
Fish (game)	✓	✓	✓
Elk	✓	✓	✓
Deer	✓	✓	✓
Honey	✓	✓	✓
Pinyon nuts	✓	✓	✓
Groundwater	✓	✓	✓
Soil	✓	✓	✓
Sediment	✓	✓	✓
Surface water		✓	✓
Soil [d]		✓	✓
Sediment [d]		✓	✓
Fish (non-game)			✓
Elk (heart, liver)			✓
Indian Tea (Cota)			✓

[a] A hypothetical person who is conservatively assumed to intake various foodstuffs, water, soil and sediments with concentrations of contaminants at the 95 percent upper confidence limit for each contaminant.
[b] Assumed to visit the canyons on and near LANL 24 times per year, 8 hours per visit.
[c] Assumed to have traditional Native American or Hispanic lifestyles and diet.
[d] Soil and sediments from onsite locations.

C.1.4.2 Estimates of Ingestion Pathway Radiation Dose and Risk

The results of the radiation dose calculations for each of the receptors and components of the ingestion pathway are summarized in **Tables C–24** through **C–40**. Except where noted, all intake rates are in grams dry weight per year. The total doses from all pathway components are presented in **Table C–41**.

Table C–24 Dose from the Consumption of Produce

Exposure Pathway: Produce Ingestion				
Intake (grams per year)	*Nuclide*	*Concentration (picocuries per gram)*	*Dose Conversion Factor (rem per picocurie)*	*Dose (rem per year)*
32,200	Americium-241	0.000858	4.50×10^{-6}	0.000124
32,200	Cesium-137	0.0175	5.00×10^{-8}	0.0000282
32,200	Plutonium-238	0.00128	3.80×10^{-6}	0.000156
32,200	Plutonium-239, Plutonium-240	0.000430	4.30×10^{-6}	0.0000595
32,200	Strontium-90	0.129	1.30×10^{-7}	0.000541
32,200	Tritium	1.04	6.30×10^{-11}	2.11×10^{-6}
32,200	Uranium	0.0167	2.60×10^{-7}	0.000140
Total		–	–	**0.00105**

Notes: Average annual intakes are (4.5 grams per kilogram-day for vegetables + 3.7 grams per kilogram-day for fruits) × (a dry to wet weight ratio of 0.15) × 71.8-kilogram adult × (365 days per year) = 32,200 grams dry weight per year (EPA 2003). The *1999 SWEIS* reported 0.00162 rem per year (average intake) from combined fruit and vegetable consumption. High intake is 25.5 grams wet weight per kilogram-day. Thus, dose at high intake is (25.5/8.2) × 0.00105 or 0.00327 rem per year. To convert grams to ounces, multiply by 0.035274. To convert grams to ounces, multiply by 0.035274.

Table C–25 Dose from the Consumption of Free Range Beef

Exposure Pathway: Meat Ingestion				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
14,900	Americium-241	0.000301	4.50×10^{-6}	0.0000202
14,900	Cesium-137	0.0560	5.00×10^{-8}	0.0000417
14,900	Plutonium-238	0.000230	3.80×10^{-6}	0.0000130
14,900	Plutonium-239, Plutonium-240	0.000218	4.30×10^{-6}	0.0000140
14,900	Strontium-90	0.0843	1.30×10^{-7}	0.000163
14,900	Tritium	0.00	6.30×10^{-11}	0.00
14,900	Uranium	0.00105	2.60×10^{-7}	4.07×10^{-6}
Total		–	–	**0.000256**

Notes: Average annual intake is 2.1 grams per kilogram-day × 0.27 dry to wet ratio × 71.8 kilogram adult × 365 days per year = 14,900 grams dry weight per year (EPA 1997). Concentration values are from the 1999 LANL Environmental Surveillance Report, Table 6-14 (mean plus 2 sigma). The *1999 SWEIS* reported 0.00027 rem per year from this source and pathway. High intake is 5.1 grams per kilogram-day. Thus, dose at high intake is (5.1/2.1) × 0.000256 or 0.000622 rem per year. To convert grams to ounces, multiply by 0.035274.

Table C–26 Dose from the Consumption of Milk

Exposure Pathway: Milk Ingestion				
Intake (liters per year)	***Nuclide***	***Concentrations (picocuries per liter)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
110	Americium-241	0.0785	4.50×10^{-6}	0.0000388
110	Cesium-137	25.8	5.00×10^{-8}	0.000142
110	Plutonium-238	0.00710	3.80×10^{-6}	2.97×10^{-6}
110	Plutonium-239, Plutonium-240	0.0856	4.30×10^{-6}	0.0000405
110	Strontium-90	3.76	1.30×10^{-7}	0.0000538
110	Tritium	450	6.30×10^{-11}	3.12×10^{-6}
110	Uranium	0.120	2.60×10^{-7}	3.43×10^{-6}
Total		–	–	**0.000284**

Notes: Average annual intake is 0.3 liters per day × 365 days per year 110 liters per year. Uranium total is 0.065 (U-234) + 0.013 (U-235) + 0.042 (U-238) = 0.120 picocuries per liter. The *1999 SWEIS* reported 0.0000733 rem per year (0.000195 for high intake) from this source and pathway. High intake is 0.8 liters per day. Thus, dose at high intake is (0.8/0.3) × 0.000284 or 0.000757 rem per year (DOE 1999a). To convert liters to gallons, multiply by 0.26418.

Table C–27 Dose from the Consumption of Fish

Exposure Pathway: Fish Ingestion				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
1,880	Americium-241	0.000764	4.50×10^{-6}	6.46×10^{-6}
1,880	Cesium-137	0.0226	5.00×10^{-8}	2.13×10^{-6}
1,880	Plutonium-238	0.000517	3.80×10^{-6}	3.69×10^{-6}
1,880	Plutonium-239, Plutonium-240	0.000315	4.30×10^{-6}	2.55×10^{-6}
1,880	Strontium-90	0.0462	1.30×10^{-7}	0.0000113
1,880	Tritium	0.669	6.30×10^{-11}	7.92×10^{-8}
1,880	Uranium	0.00678	2.60×10^{-7}	3.31×10^{-6}
Total		–	–	**0.0000295**

Notes: Average annual intake is 20.1 grams per day (5.15 grams per day dry weight × 365 days = 1,880 grams per year dry weight). High intake is 53 grams per day (13.6 grams per day dry weight). Thus, dose at high intake is (53/20.1) × 0.0000295 or 0.0000778 rem per year (EPA 1997). The *1999 SWEIS* reported 0.0000542 rem per year (average intake) from this source and pathway (DOE 1999a). Uranium concentration of 9.55 nanograms per gram dry weight (0.00955 micrograms per gram dry weight) equates to 0.00678 picocuries per gram. Applying the reported 0.23 picocuries per milliliter tritium concentration value to the water fraction (1-0.256) yields: 0.744/0.256 or 2.91 grams water per gram dry weight × 0.23 picocuries per milliliter × 1 milliliter per gram water = 0.669 picocuries tritium per gram dry weight. To convert grams to ounces, multiply by 0.035274.

Table C–28 Dose from the Consumption of Elk

Exposure Pathway: Elk Ingestion				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
2,420	Americium-241	0.000221	4.50×10^{-6}	2.40×10^{-6}
2,420	Cesium-137	0.0208	5.00×10^{-8}	2.52×10^{-6}
2,420	Plutonium-238	0.0000518	3.80×10^{-6}	4.76×10^{-7}
2,420	Plutonium-239, Plutonium-240	0.000210	4.30×10^{-6}	2.18×10^{-6}
2,420	Strontium-90	0.0315	1.30×10^{-7}	9.92×10^{-6}
2,420	Tritium	1.00	6.30×10^{-11}	1.52×10^{-7}
2,420	Uranium	0.00570	2.60×10^{-7}	3.59×10^{-6}
Total		–	–	**0.0000212**

Notes: Average annual intake is 26 grams per day × 0.255 dry to wet ratio × 365 days per year = 2,420 grams per year. Uranium concentration of 8.04 nanograms per gram dry weight (0.00804 micrograms per gram) equates to 0.00570 picocuries per gram. The *1999 SWEIS* reported 0.0000773 rem per year (average intake) from this source and pathway. High intake is 63 grams per day . Thus, dose at high intake is 63/26 × 0.0000212 or 0.0000514 rem per year (DOE 1999a). To convert grams to ounces, multiply by 0.035274.

Table C–29 Dose from the Consumption of Deer

Exposure Pathway: Deer Ingestion				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
2,370	Americium-241	0.000150	4.50×10^{-6}	1.60×10^{-6}
2,370	Cesium-137	0.0351	5.00×10^{-8}	4.16×10^{-6}
2,370	Plutonium-238	0.000132	3.80×10^{-6}	1.19×10^{-6}
2,370	Plutonium-239, Plutonium-240	0.000297	4.30×10^{-6}	3.03×10^{-6}
2,370	Strontium-90	0.0386	1.30×10^{-7}	0.0000119
2,370	Tritium	4.86	6.30×10^{-11}	7.26×10^{-7}
2,370	Uranium	0.00162	2.60×10^{-7}	9.98×10^{-7}
Total		–	–	**0.0000236**

Notes: Average annual intake is 26 grams per day × 0.25 dry to wet ratio × 365 days per year = 2,370 grams per year (dry weight). High intake is 63 grams per day. Thus, dose at high intake is 63/26 × 0.0000236 or 0.0000572 rem per year. Uranium concentration of 2.28 nanograms per gram dry weight (0.00228 micrograms per gram) equates to 0.00162 picocuries per gram. Tritium concentration on a dry weight basis equals picocuries per milliliter of water × milliliters of water per gram dry weight. If the dry to wet ratio is 0.25, 0.75 grams water (0.75 milliliter) is present for each 0.25 grams dry weight. Tritium concentration is 1.62 picocuries per milliliter × 0.75 milliliters/0.25 grams or 4.86 picocuries per gram dry weight. The *1999 SWEIS* reported 0.0000181 rem per year (average intake) from this source and pathway (DOE 1999a). To convert grams to ounces, multiply by 0.035274.

Table C–30 Dose from the Consumption of Honey

Exposure Pathway: Honey Ingestion				
Intake (milliliters per year)	***Nuclide***	***Concentration (picocuries per milliliter)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
989	Americium-241	0.000599	4.50×10^{-6}	2.67×10^{-6}
989	Cesium-137	0.0177	5.00×10^{-8}	8.73×10^{-7}
989	Plutonium-238	0.0000294	3.80×10^{-6}	1.10×10^{-7}
989	Plutonium-239, Plutonium-240	0.0000728	4.30×10^{-6}	3.10×10^{-7}
989	Strontium-90	0.00406	1.30×10^{-7}	5.22×10^{-7}
989	Tritium	2.07	6.30×10^{-11}	1.29×10^{-7}
989	Uranium	0.00712	2.60×10^{-7}	1.83×10^{-6}
Total		–	–	$\mathbf{6.44 \times 10^{-6}}$

Notes: Average intake is 3.84 grams per day. At a specific gravity of 1.4171 (18 percent water, 20 degrees centigrade) this equates to 2.71 milliliters per day or 989 milliliters per year. High intake is 13.7 grams per day or 3,528 milliliters per year. Thus, dose at high intake is 13.7/3.84 × 6.44×10^{-6} or 0.0000230 rem per year. Uranium value is 0.00356 (uranium-234) plus 0.000394 (uranium-235) plus 0.00317 (uranium-238) = 0.00712 picocuries per milliliter. The *1999 SWEIS* reported 7.37×10^{-7} rem per year from this source and pathway (average intake), but addressed only tritium and did not include the contributions from the other nuclides reported here (DOE 1999a).

Table C–31 Dose from the Consumption of Pinyon Nuts

Exposure Pathway: Pinyon Nut Ingestion				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
1,410	Beryllium-7	0.140	1.10×10^{-10}	2.17×10^{-8}
1,410	Americium-241	0.00	4.50×10^{-6}	0.00
1,410	Cesium-137	0.0200	5.00×10^{-8}	1.41×10^{-6}
1,410	Plutonium-238	0.0170	3.80×10^{-6}	0.0000911
1,410	Plutonium-239, Plutonium-240	0.0130	4.30×10^{-6}	0.0000788
1,410	Strontium-90	0.230	1.30×10^{-7}	0.0000422
1,410	Tritium	0.364	6.30×10^{-11}	3.23×10^{-8}
1,410	Uranium	0.0568	2.60×10^{-7}	0.0000208
Total		–	–	**0.000234**

Notes: Calculated using concentrations from *1999 SWEIS* Table D.3.3-50 corrected for dry to wet ratio of 0.94 versus 0.06 (NutritionData 2006). Average intake of 1,500 grams per year corresponds to 1,410 grams per year dry weight. Tritium concentration is (0.06/0.94) × (1 milliliter per gram water) × (5.7 picocuries per milliliter) = 0.364 picocuries per gram. The *1999 SWEIS* reported 0.0000155 rem per year for from this source and pathway (DOE 1999a). No high intake was found. Thus, dose at high intake equals dose at average intake. To convert grams to ounces, multiply by 0.035274.

Table C–32 Dose from the Consumption of Groundwater

Exposure Pathway: Groundwater Ingestion				
Intake (liters per year)	***Nuclide***	***Concentration (picocuries per liter)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
551	Americium-241	0.0551	4.50×10^{-6}	0.000137
551	Cesium-137	6.49	5.00×10^{-8}	0.000179
551	Plutonium-238	0.0127	3.80×10^{-6}	0.0000267
551	Plutonium-239, Plutonium-240	0.0244	4.30×10^{-6}	0.0000577
551	Strontium-90	0.101	1.30×10^{-7}	7.26×10^{-6}
551	Tritium	311	6.30×10^{-11}	1.08×10^{-5}
551	Uranium	0.866	2.60×10^{-7}	0.000124
Total		–	–	**0.000542**

Notes: Average intake is 1.51 liters per day (551 liters per year). High intake is 2.44 liters per day. Thus, dose at high intake is (2.44/1.51) × 0.000542 or 0.000876 rem per year. Calculated using groundwater composite data (95 percent upper confidence limit) for 2001-2004 for "Water Supply Wells" (see Appendix F of this SWEIS). The *1999 SWEIS* reported 0.00234 rem per year for the offsite Los Alamos County resident from this source and pathway (DOE 1999a). To convert liters to gallons, multiply by 0.26418.

Table C–33 Dose from the Consumption of Soil

Exposure Pathway: Soil Ingestion				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
36.5	Americium-241	0.0126	4.50×10^{-6}	2.07×10^{-6}
36.5	Cesium-137	0.346	5.00×10^{-8}	6.31×10^{-7}
36.5	Plutonium-238	0.00358	3.80×10^{-6}	4.96×10^{-7}
36.5	Plutonium-239, Plutonium-240	0.0671	4.30×10^{-6}	0.0000105
36.5	Strontium-90	0.177	1.30×10^{-7}	8.39×10^{-7}
36.5	Tritium	1.04	6.30×10^{-11}	2.39×10^{-9}
36.5	Uranium	2.39	2.60×10^{-7}	0.0000227
Total		–	–	**0.0000372**

Notes: Average intake is 36.5 grams per year. High intake is 146 grams per year. Thus, dose at high intake is (146/36.5) × 0.0000372 or 0.000149 rem per year. Calculated using 2001-2004 composite data (95 percent upper confidence limit) for perimeter stations (see Appendix F of this SWEIS). The *1999 SWEIS* reported 0.000313 rem per year for the offsite resident from this source and pathway (DOE 1999a). To convert grams to ounces, multiply by 0.035274.

Table C–34 Dose from the Consumption of Sediment

Exposure Pathway: Sediment Ingestion				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
36.5	Americium-241	0.365	4.50×10^{-6}	0.0000600
36.5	Cesium-137	0.327	5.00×10^{-8}	5.97×10^{-7}
36.5	Plutonium-238	0.220	3.80×10^{-6}	3.05×10^{-5}
36.5	Plutonium-239, Plutonium-240	0.947	4.30×10^{-6}	0.000149
36.5	Strontium-90	0.244	1.30×10^{-7}	1.16×10^{-6}
36.5	Tritium	127	6.30×10^{-11}	2.92×10^{-7}
36.5	Uranium	1.77	2.60×10^{-7}	0.0000168
Total		–	–	**0.000258**

Notes: Average intake is 36.5 grams per year. High intake is 146 grams per year. Thus, dose at high intake is (146/36.5) × 0.000258 or 0.00103 rem per year. Calculated using 2001-2004 composite data (95 percent upper confidence limit) for perimeter stations (see Appendix F of this SWEIS). The *1999 SWEIS* reported 0.00262 rem per year for the offsite resident from this source and pathway (DOE 1999a). To convert grams to ounces, multiply by 0.035274.

Table C–35 Dose to the Recreational User Receptor from the Consumption of Surface Water

Exposure Pathway: Surface Water Ingestion (Recreational User)				
Intake (liters per year)	***Nuclide***	***Concentration (picocuries per liter)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
5.34	Americium-241	17.7	4.50×10^{-6}	0.000426
5.34	Cesium-137	13.9	5.00×10^{-8}	3.72×10^{-6}
5.34	Plutonium-238	20.4	3.80×10^{-6}	0.000415
5.34	Plutonium-239, Plutonium-240	14.6	4.30×10^{-6}	0.000336
5.34	Strontium-90	3.97	1.30×10^{-7}	2.75×10^{-6}
5.34	Tritium	380	6.30×10^{-11}	1.28×10^{-7}
5.34	Uranium	16.6	2.60×10^{-7}	0.0000230
Total		–	–	**0.00121**

Notes: Average intake is 5.34 liters per year. High intake is 8.64 liters per year. Thus, dose at high intake is (8.64/5.34) × 0.00121 or 0.00195 rem per year. Calculated using surface water onsite stations 2001-2004 composite data (95 percent upper confidence limit). The *1999 SWEIS* reported 0.000740 rem per year for the "resident recreational user" from this source and pathway (DOE 1999a). To convert liters to gallons, multiply by 0.26418.

Table C–36 Dose to the Recreational User Receptor from the Consumption of Soil

Exposure Pathway: Soil Ingestion (Recreational User)				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
1.07	Americium-241	0.0176	4.50×10^{-6}	8.49×10^{-8}
1.07	Cesium-137	0.365	5.00×10^{-8}	1.95×10^{-8}
1.07	Plutonium-238	0.00236	3.80×10^{-6}	9.60×10^{-9}
1.07	Plutonium-239, Plutonium-240	0.0669	4.30×10^{-6}	3.08×10^{-7}
1.07	Strontium-90	0.154	1.30×10^{-7}	2.14×10^{-8}
1.07	Tritium	1.14	6.30×10^{-11}	7.71×10^{-11}
1.07	Uranium	2.34	2.60×10^{-7}	6.51×10^{-7}
Total		–	–	$\mathbf{1.09 \times 10^{-6}}$

Notes: Average intake is 1.07 grams per year. High intake is 4.27 grams per year. Thus, dose at high intake is (4.27/1.07) × 1.09×10^{-6} or 4.37×10^{-6} rem per year. Calculated using 2001-2004 composite data (95 percent upper confidence limit) for onsite stations (see Appendix F of this SWEIS). The *1999 SWEIS* reported 0.0000125 rem per year for the "resident recreational user" from this source and pathway (DOE 1999a). To convert grams to ounces, multiply by 0.035274.

Table C–37 Dose to the Recreational User Receptor from the Consumption of Sediment

Exposure Pathway: Sediment Ingestion (Recreational User)				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
1.07	Americium-241	0.696	4.50×10^{-6}	3.35×10^{-6}
1.07	Cesium-137	1.48	5.00×10^{-8}	7.89×10^{-8}
1.07	Plutonium-238	0.422	3.80×10^{-6}	1.72×10^{-6}
1.07	Plutonium-239, Plutonium-240	0.692	4.30×10^{-6}	3.18×10^{-6}
1.07	Strontium-90	0.286	1.30×10^{-7}	3.98×10^{-8}
1.07	Tritium	352	6.30×10^{-11}	2.37×10^{-8}
1.07	Uranium	1.86	2.60×10^{-7}	5.17×10^{-7}
Total		–	–	$\mathbf{8.91\times 10^{-6}}$

Notes: Average intake is 1.07 grams per year. High intake is 4.27 grams per year. Thus, the dose at high intake is (4.27/1.07) × 8.91×10^{-6} or 0.0000356 rem per year. Calculated using 2001-2004 composite data (95 percent upper confidence limit) for onsite stations (see Appendix F of this SWEIS). The *1999 SWEIS* reported 0.000176 rem per year for the “resident recreational user” from this source and pathway (DOE 1999a). To convert grams to ounces, multiply by 0.035274.

Table C–38 Dose to the Special Pathways Receptor from the Consumption of Fish

Exposure Pathway: Fish Ingestion (Special Pathways)				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
6,540	Americium-241	0.000482	4.50×10^{-6}	0.0000142
6,540	Cesium-137	0.00866	5.00×10^{-8}	2.83×10^{-6}
6,540	Plutonium-238	0.000653	3.80×10^{-6}	0.0000162
6,540	Plutonium-239, Plutonium-240	0.000210	4.30×10^{-6}	5.90×10^{-6}
6,540	Strontium-90	0.0450	1.30×10^{-7}	0.0000382
6,540	Tritium	1.16	6.30×10^{-11}	4.78×10^{-7}
6,540	Uranium	0.0184	2.60×10^{-7}	0.0000313
Total		–	–	**0.000109**

Notes: Calculated using average intake of 70 grams per day (17.92 grams per day dry weight). High intake is 170 grams per day (43.52 grams per day dry weight.). Thus, dose at high intake is (170/70) × 0.000109 or 0.000265 rem per year (EPA 1997). The *1999 SWEIS* reported 0.000189 rem per year (average intake) from this source and pathway. Uranium concentration of 24.5 nanograms per gram dry weight. (0.0245 micrograms per gram) equates to 0.0174 picocuries per gram. Applying the reported 0.40 picocuries per milliliter tritium concentration value to the water fraction (1-0.256) yields: 0.744 grams water per 0.256 grams dry weight × 0.40 picocuries per milliliter × 1 milliliter per gram water = 1.163 picocuries per gram dry weight. To convert grams to ounces, multiply by 0.035274.

Table C–39 Dose to the Special Pathways Receptor from the Consumption of Elk Heart and Liver

Exposure Pathway: Elk Ingestion (Special Pathways)				
Intake (grams per year)	***Nuclide***	***Concentration (picocuries per gram)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
436	Americium-241	0.00	4.50×10^{-6}	0.00
436	Cesium-137	0.0679	5.00×10^{-8}	1.48×10^{-6}
436	Plutonium-238	0.00	3.80×10^{-6}	0.00
436	Plutonium-239, Plutonium-240	0.000655	4.30×10^{-6}	1.23×10^{-6}
436	Strontium-90	0.00650	1.30×10^{-7}	3.68×10^{-7}
436	Tritium	0.00	6.30×10^{-11}	0.00
436	Uranium	0.0347	2.60×10^{-7}	3.93×10^{-6}
Heart Total		–	–	$\mathbf{7.01 \times 10^{-6}}$
763	Americium-241	0.00	4.50×10^{-6}	0.00
763	Cesium-137	0.596	5.00×10^{-8}	0.0000227
763	Plutonium-238	0.0000750	3.80×10^{-6}	2.17×10^{-7}
763	Plutonium-239, Plutonium-240	0.0000950	4.30×10^{-6}	3.12×10^{-7}
763	Strontium-90	0.00820	1.30×10^{-7}	8.13×10^{-7}
763	Tritium	0.00	6.30×10^{-11}	0.00
763	Uranium	0.0160	2.60×10^{-7}	3.17×10^{-6}
Liver Total		–	–	**0.0000273**
Heart + Liver Total		–	–	**0.0000343**

Notes: This represents consumption of heart and liver in addition to the meat consumption calculated for the resident. Average heart intake is based on 3.2 pounds per year for an individual × 454 grams per pound × 0.30 (wet to dry ratio). Average liver intake is based on 5.6 pounds per year for an individual × 454 grams per pound × 0.30 (wet to dry ratio). The *1999 SWEIS* reported 0.0000343 rem per year from this source and pathway (no new data were found – same data and consumption rates were used here as for *1999 SWEIS*) (DOE 1999a). To convert grams to ounces, multiply by 0.035274.

Table C–40 Dose to the Special Pathways Receptor from the Consumption of Indian Tea (Cota)

Exposure Pathway: Indian Tea (Cota) Ingestion (Special Pathways)				
Intake (liters per year)	***Nuclide***	***Concentration (picocuries per liter)***	***Dose Conversion Factor (rem per picocurie)***	***Dose (rem per year)***
213	Americium-241	0.0362	4.50×10^{-6}	0.0000347
213	Cesium-137	21.2	5.00×10^{-8}	0.000226
213	Plutonium-238	0.0250	3.80×10^{-6}	0.0000202
213	Plutonium-239, Plutonium-240	0.0302	4.30×10^{-6}	0.0000277
213	Strontium-90	0.642	1.30×10^{-7}	0.0000178
213	Tritium	117	6.30×10^{-11}	1.58×10^{-6}
213	Uranium	0.780	2.60×10^{-7}	0.0000432
Total		–	–	**0.000371**

Notes: Average intake is 0.58 liters per day (213 liters per year). High intake is 2.03 liters per day (741 liters per year). Thus, dose at high intake is (2.03/0.58) × 0.000371 or 0.00130 rem per year. The *1999 SWEIS* reported 0.000749 rem per year (average intake) from this source and pathway (DOE 1999a). To convert liters to gallons, multiply by 0.26418.

Table C–41 Summary of Ingestion Pathway Doses for Offsite Resident, Recreational User, and Special Pathways Receptors

Exposure Pathway	*Dose to Receptor (rem per year)*		
	Offsite Resident [a]	*Recreational User* [b]	*Special Pathways* [c]
Produce	0.00105	0.00105	0.00105
Meat (free-range beef)	0.000256	0.000256	0.000256
Milk	0.000284	0.000284	0.000284
Fish (game)	0.0000294	0.0000294	0.0000294
Elk	0.0000212	0.0000212	0.0000212
Deer	0.0000236	0.0000236	0.0000236
Honey	6.44×10^{-6}	6.44×10^{-6}	6.44×10^{-6}
Pinyon nuts	0.000234	0.000234	0.000234
Groundwater	0.000542	0.000542	0.000542
Soil	0.0000372	0.0000372	0.0000372
Sediment	0.000258	0.000258	0.000258
Surface water	–	0.00121	0.00121
Soil [d]	–	1.09×10^{-6}	1.09×10^{-6}
Sediment [d]	–	8.91×10^{-6}	8.91×10^{-6}
Fish (non-game)	–	–	0.000109
Elk (heart, liver)	–	–	0.0000343
Indian Tea (Cota)	–	–	0.000371
Totals	**0.00274**	**0.00396**	**0.00448**

[a] A hypothetical person who is conservatively assumed to intake various foodstuffs, water, soil and sediments with concentrations of contaminants at the 95 percent upper confidence limit for each contaminant.
[b] Assumed to visit the canyons on and near LANL 24 times per year, 8 hours per visit.
[c] Assumed to have traditional Native American or Hispanic lifestyles and diet.
[d] Soil and sediments from onsite locations.

The offsite resident receptor was estimated to receive a dose of about 0.00274 rem, or about 2.7 millirem, per year from the ingestion exposures reported here. Eliminating all zero and negative values when calculating the 95 percent upper confidence limit concentration from the reported environmental surveillance results adds a degree of conservatism. It is also quite unlikely that any given individual would derive all of their diet from local sources, as was assumed in this consumption model. Additional exposures to a person whose diet and activities reflect those of the recreational user and special pathways receptors would bring their total doses to about 4.0 and 4.5 millirem per year, respectively. Using a risk estimator value of 0.0006 lifetime probability of fatal cancer per person-rem, 4.5 millirem (0.0045 rem) per year would equate to a probability of fatal cancer of 2.7×10^{-6}, or just under a 3 in 1 million chance of developing a fatal cancer from the ingestion pathway. The high consumption rates for all components of the ingestion pathway are detailed in their respective tables (C–24 through C–40). The total doses to each receptor as a result of potential consumption at these higher rates would be increased by less than a factor of three. Using the high consumption rates, the lifetime probability of developing a fatal cancer would be about 4.3×10^{-6} for the offsite resident total dose of 0.0072 rem; 5.5×10^{-6} for the recreational user total dose of 0.0091 rem; and 6.4×10^{-6} for the special pathways receptor total dose of 0.0107 rem per year of exposure.

For perspective, the ingestion pathway doses of 2.7 to 10.7 millirem per year calculated here for the offsite resident and other specific receptors should be viewed against the dose of about 400 millirem (dose ranges from 300 to 500 millirem) per year that the average Los Alamos resident receives from all background radiation sources (see Section C.1.1.3). That average includes about 240 millirem from radioactive material that has entered the body by inhalation or ingestion. The largest fraction of the internal dose (about 200 millirem on average) is due to the short-lived decay products of naturally-occurring radon gas. It is also important to compare these ingestion pathway doses to the more significant inhalation pathway dose, where the bulk of the radiological air emissions and resulting dose come from LANSCE and the High Explosives Testing Key Facility (see Chapter 5, Section 5.6).

As shown in Table C–41, the highest estimated ingestion pathway dose to any specific receptor is about 4.5 millirem per year from radionuclides in the environment resulting from past LANL operations, global fallout, and naturally-occurring geologic sources. If a particular specific receptor also were to receive the maximum impact from projected future radionuclide LANL emissions to the atmosphere (see Tables C–19, C–20, and C–21), that specific receptor might receive a total annual dose from past and future site operations ranging from about 5.3 millirem (4.5 millirem plus the dose to the MEI of 0.79 millirem) for the Reduced Operations Alternative to about 12.3 millirem (4.5 millirem plus the dose to the MEI of 7.8 millirem) for the No Action and Expanded Operations Alternatives. The fatal cancer risk associated with these doses ranges from about 3 in 1 million to 7 in 1 million. To place these doses in perspective, that same individual would be expected to receive an annual dose from background sources of about 400 millirem. In addition, these are conservatively calculated doses because no one person would actually consume such a large concentration from each pathway component. These large concentrations are found at scattered locations around LANL.

When calculating ingestion pathway radiation doses, river surface water was considered as a potential dose source for certain recreational user and special pathways receptors. Surface water radioisotope concentrations were measured at locations both upstream and downstream of LANL on the Rio Grande and Jemez River during 2005 (LANL 2006b). The 95 percent upper confidence limit values of these measurements were used to calculate the radiation dose to an individual that consumed all their drinking water, at the rate of 2 liters per day, from these surface water sources. The total surface drinking water doses are presented in **Table C–42**. This table shows the location of the sampling station relative to LANL (that is, upstream or downstream), as well as the fraction of the EPA 4 millirem per year drinking water limit that the calculated dose at each location represents. Consumption of all drinking water from all of the river locations around LANL resulted in doses of less than 10 percent of the EPA limit. There was no trend between upstream and downstream locations relative to LANL.

The doses calculated here are generally lower than those reported in the *1999 SWEIS* for the same ingestion pathway components. Only 5 of the 17 pathway component doses are greater than those reported in the *1999 SWEIS*. The dose from honey consumption is greater than that reported in the *1999 SWEIS* because the 1999 dose calculation considered only the dose from tritium, whereas this calculation includes the dose from tritium and all other radionuclides reported in the LANL environmental surveillance data for honey. The dose from pinyon nut consumption reported here is higher because this calculation makes use of a higher dry to wet weight ratio than was assumed in the *1999 SWEIS* calculation. The doses from consumption of surface water (recreational user), milk, and deer are also higher, but not remarkably so. The calculated dose from consumption of elk heart and liver is unchanged from the *1999 SWEIS* because no more current radionuclide concentration data were found. The lower doses calculated here for the other 12 pathway components are due to lower average radionuclide concentrations in environmental media reported during the 2001 through 2004 period compared to the 1991 through 1996 data used in the *1999 SWEIS* calculations.

Table C–42 Total Los Alamos National Laboratory River Surface Water Consumption Radiation Doses

Surveillance Sample River Site	*Location Upstream or Downstream of LANL*	*Total Annual (2 liters per day) Drinking Water Dose (millirem)*	*Percent of Annual EPA Drinking Water Dose Limit of 4 Millirem*
Jemez River	Upstream	0.384	9.6%
Embudo at Rio Grande	Upstream	0.118	3.0%
Otowi at Rio Grande	Upstream	0.159	4.0%
Chamita at Rio Grande	Upstream	0.236	5.9%
Frijoles at Rio Grande	Downstream	0.297	7.4%
Cochiti at Rio Grande	Downstream	0.172	4.3%

C.2 Impacts on Human Health from Nonradioactive Contaminants in the Environment

Many nonradioactive substances (chemical elements, compounds, and mixtures) found in the environment are potentially harmful to human health. Some substances, small amounts of which are beneficial or necessary for good health, may be harmful in larger amounts or higher concentrations (examples: iron, selenium, zinc). Even at very low concentrations or levels of intake, exposure to some substances may cause long-term health effects or increase the likelihood of developing certain diseases, particularly when the exposure continues over a long period of time (that is, chronic exposure). The health impact (harmful effect) of taking any substance into the body depends on the toxicity of the material (a measure of the amount needed to produce a given harmful effect) and the dose or intake (the rate at which the substance was taken into the body). For many substances, humans have the capacity to metabolize, excrete, or otherwise detoxify small quantities or small chronic intakes without showing ill effects. Substances that accumulate in the body over time, however, may cause harm that becomes evident only after many years of exposure.

Humans may be exposed to toxic substances in their environment by several different routes, of which ingestion, inhalation, and skin contact are usually most important. At concentrations typically found in the general living environment, acute health effects (those having a rapid onset followed by a short, severe course of symptoms) are seldom observed. Elevated levels of some contaminants in air, water, soil, and other environmental media, however, have been linked statistically to the occurrence rate (or frequency) of specific health problems in populations exposed to those media. The health effects from exposure to carcinogenic substances are evaluated using risk factors from the EPA Integrated Risk Information System database (EPA 2005a). The risk factor for a substance is an estimate of the upper-bound lifetime probability, per unit oral intake or concentration in the air, of an individual developing cancer from exposure to the substance. The potential for noncancer health effects from exposure to a toxic substance is evaluated by dividing the estimated average daily intake of that substance by its Oral Reference Dose value (RfD) to obtain a hazard index. The Oral Reference Dose is an estimate of the average daily oral intake that is believed to pose no appreciable risk of harmful health effects (EPA 2005b). If the calculated hazard index is greater than 1, the individual is considered to be at some risk of adverse health effects as a result of exposure to the substance.

C.2.1 Methods Used to Estimate Risks from Ingestion of Nonradioactive Contaminants

Environmental media and foodstuffs collected on and near LANL are regularly analyzed for various nonradioactive contaminants. Measured concentrations of contaminants in food, water, soils and sediments are used here to calculate the health risks to residents and special pathways receptors from the ingestion of those materials. The same dietary intake assumptions used to calculate radiation dose and risk were used to estimate health risk from a range of nonradioactive contaminants, some of which occur naturally in the LANL environment and others that are a result of past LANL operations, natural processes, or human activities in the region.

Naturally-occurring contaminants with possible health implications for residents include metals derived from local soil and rock that are consumed via ingestion of groundwater, surface water, soil, sediment and various foodstuffs. As part of this group, arsenic and beryllium are known to be present in concentrations that represent a significant increment of ingestion risk. Contaminants known to have been released to the environment from site operations include nitrates and perchlorate, as well as various high explosives and organics. These materials are present in groundwater and surface water on and near LANL, and therefore represent a potential direct impact on the health of the current population from past LANL operations. Finally, residues from environmentally persistent pesticides used in the surrounding forests and agricultural land can be detected in various media, as can organic contaminants of natural (such as wildland fires) or undetermined origin. These substances and others have been monitored, either regularly or episodically as part of the LANL Environmental Surveillance Program.

Groundwater Ingestion

To estimate human health impacts to the public, only contaminants that could be ingested by the postulated receptors were included in the impact calculations. For the groundwater component of the ingestion pathway, only analysis results from the water supply wells were used to calculate the 95 percent upper confidence limit concentration.

Groundwater at LANL occurs as a regional aquifer at depths ranging from 600 to 1,200 feet (180 to 370 meters) and as perched groundwater of limited thickness and horizontal extent, either in canyon alluvium or at intermediate depths of a few hundred feet. All water produced by the Los Alamos County water supply system comes from the regional aquifer and meets Federal and state drinking water standards. No drinking water is supplied from the alluvial and intermediate groundwater sources. Water supply wells are present in Guaje Canyon, Pueblo Canyon, upper Los Alamos Canyon, Mortandad Canyon, Pajarito Canyon, and White Rock Canyon.

Liquid effluent disposal is the primary means by which LANL contaminants have had an effect, albeit limited, on the regional aquifer. Liquid effluent disposal at LANL has significantly degraded the quality of alluvial groundwater in some canyons. Because flow through the underlying approximately 900-foot-thick (270-meter-thick) zone of unsaturated rock is slow, the impact of effluent disposal is seen to a lesser degree in intermediate-depth perched groundwater and is only seen in a few wells that draw from the regional aquifer. In general, groundwater quality would improve as outfalls are eliminated, the volume of liquid discharges is reduced, and the water quality (concentrations of contaminants) of the discharges is improved.

During the last decade, EPA has recognized the potential for perchlorate toxicity at concentrations in the parts per billion range. No EPA regulatory limit exists for perchlorate in drinking water, though several states have set limits in the range of 10 to 20 parts per billion. EPA Region VI has established a level of 3.7 parts per billion.

LANL and the New Mexico Environment Department DOE Oversight Bureau have found perchlorate in most groundwater samples analyzed from across northern New Mexico at concentrations below 1 part per billion. At LANL, perchlorate was the byproduct of the perchloric acid used in nuclear chemistry research. Water samples from most LANL locations show low perchlorate concentrations, but samples taken downstream from inactive perchlorate release sites show distinctly higher values.

As indicated by the LANL environmental surveillance program (LANL 2005b), the presence of high metal values (compared with regulatory standards) in groundwater samples is believed to be due to ubiquitous well-sampling-related issues rather than to contamination resulting from LANL operations. Well-drilling fluids; the metal in well casings, fittings, and pump housings; dissolved surface minerals from the aquifer's rock framework; and alterations to aquifer water chemistry due to the presence of a well all may contribute to increases of some metal values.

Arsenic was detected in measurable amounts in some water supply wells. As noted in Appendix D of the *1999 SWEIS*, the primary sources of arsenic in food and water sources in the LANL area are naturally-occurring soil and basalt. The concentrations of arsenic in groundwater supply wells are not significantly different between Los Alamos and San Ildefonso. The main use of arsenic in the United States is pesticide formulation, and LANL does not use large amounts of arsenic in any of its research and development or processing activities.

Some supply wells have shown elevated levels of nitrate. LANL environmental surveillance program results (LANL 2005b) indicate that a possible source of these contaminants is effluent from a local sewage treatment plant. In addition, some past effluent discharges from the Radioactive Liquid Waste Treatment Facility contained high levels of nitrates (LANL 2004b).

The LANL environmental surveillance program analyzed samples from selected springs and wells for organic constituents. Samples were analyzed for some or all of the following types of organics: volatile organic compounds, semivolatile organic compounds, polychlorinated biphenyls, pesticides, diesel-range organics, and high explosives (HMX, RDX, TNT). Certain organic compounds used in analytical laboratories are frequently detected in samples, probably as a result of contamination introduced by the laboratory process. These compounds include acetone, methylene chloride, 2-butanone, and bis(2-ethylhexyl)phthalate. Since there was no definitive evidence that these compounds were introduced as part of the laboratory process, they were conservatively retained as part of the group of organics considered as contributing to risk from ingestion of groundwater.

Volatile and semi-volatile organic compounds were not found in any of the water supply wells in significant concentrations; therefore, they were not included in the group of compounds that contribute to risk from groundwater consumption.

High-explosive compounds also were not found in statistically significant quantities in the water supply wells. They have been found in other regional aquifer wells, however, and are a known contaminant in surface waters and sediments. As a result, any supply well sample results containing high-explosive compounds were conservatively retained for consideration.

In August 2004, the LANL environmental surveillance program identified several positive pesticide results, notably results for 4,4'-DDT and 4,4'-DDE, in LANL samples. These results were not supported by previous data or by process knowledge at the sample locations. Subsequent examination of the data revealed that some glassware used in the process was only rinsed, without further cleaning, between uses. This finding meant that pesticide contamination could be transferred from one sample to another during the sample preparation. As a result, all pesticide results for 2004 are considered unusable (LANL 2005b).

Table C–43 shows the contribution to health risk to the offsite resident receptor from ingestion of trace metals, nitrates, perchlorate, and organic compounds in groundwater. Arsenic, the contaminant with the highest Hazard Index and cancer risk, occurs naturally at relatively high concentrations in soil and groundwater throughout northern New Mexico. Arsenic is not known to have been used in significant quantities at LANL and the elevated groundwater concentrations do not appear to be related to any past or current LANL operations or effluents. Vanadium, the contaminant with the second-highest Hazard Index, is also a naturally-occurring trace element in the region. Elevated concentrations of vanadium seen in surface water and groundwater samples do not appear to be related to any past or current LANL operations or effluents. See Section C.2 for additional information.

Surface Water and Sediment Ingestion

LANL personnel monitor surface water and stream sediments in northern New Mexico and southern Colorado to evaluate the potential environmental effects of LANL operations. LANL personnel analyze samples for radionuclides, high explosives, metals, a wide range of organic compounds, and (for surface water) general chemistry.

Watercourses that drain from LANL property are dry most of the year. No perennial surface water extends completely across LANL in any canyon. The canyons consist of over 85 miles (140 kilometers) of watercourses located within LANL and Los Alamos Canyon upstream of the site. Of the 85 (140 kilometers) miles of watercourse, approximately 2 miles (3.2 kilometers) are naturally perennial, and approximately 3 miles (4.8 kilometers) are perennial waters created by effluent. The remaining 80 or more miles (130 kilometers) of watercourse dry out for varying lengths of time. The driest segments may flow only in response to local precipitation or snowmelt. Although most of the watercourses are dry throughout the year, occasional floods can redistribute sediment in a streambed to locations far downstream from where a release or spill occurs.

kg = kilogram, L = liter, mg = milligram, µg = microgram, RDx = hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine, RfD = Reference Dose, UCL = upper confidence limit.

Notes: Chronic Intake (mg/kg-day) = Water Concentration (µg/L) × Consumption rate (L/day) × 1×10^{-3} (mg/µg) × 1/Body Weight (1/71.8 kg). Shaded cells in Slope Factor and Cancer Risk columns indicate no known human chemical cancer risk.

The overall quality of most surface water in the Los Alamos area is very good, with very low levels of dissolved solutes. Of the more than 100 analytes tested in sediment and surface water within LANL, most are at concentrations far below regulatory standards or risk-based advisory levels. Nearly every major watershed, however, shows indications of some effect from LANL operations, often for just a few analytes.

Although many of the above-background results in sediment and surface water are from the major liquid effluent discharges, other possible sources include isolated spills, former photographic-processing facilities, highway runoff, and residual ash from the Cerro Grande Fire. At monitoring locations below other industrial or residential areas, particularly in the Los Alamos and Pueblo Canyon watersheds, above-background contaminant levels reflect contributions from non-LANL sources such as urban runoff.

Guaje Canyon is a major tributary in the Los Alamos Canyon watershed that heads in the Sierra de los Valles and lies north of LANL. The canyon has not received any effluent from LANL activities. Concentrations of metals, organics, and radionuclides in Guaje Canyon base flow and sediments were below regulatory limits or screening levels. Active channel sediments contained background ranges of metals and radionuclides.

Los Alamos Canyon, including Bayo, Acid, Pueblo, and DP Canyons, has a large drainage that heads in the Sierra de los Valles. Land in the Los Alamos Canyon watershed has been continuously used since the mid-1940s, with operations conducted at some time in all of the subdrainages. Each of the canyons draining the watershed also receives urban runoff from the Los Alamos town site.

Nonradiological contaminants detected at significant concentrations in the Los Alamos Canyon watershed include polychlorinated biphenyls, benzo(a)pyrene, mercury, copper, lead, and zinc. Analysis detected benzo(a)pyrene in sediment samples from Acid Canyon above Pueblo; the LANL environmental surveillance staff concluded that the major source of benzo(a)pyrene in the drainage was urban runoff rather than a LANL-related source (LANL 2005b).

Mercury was detected in Los Alamos Canyon above DP Canyon. LANL sources of mercury and polychlorinated biphenyls are known to exist in the drainage system, and erosion control features have been installed near the sources to minimize downstream movement. Elevated concentrations of copper, lead, and zinc were detected in DP Canyon above LANL facilities and are likely derived from urban runoff sources rather than LANL operations.

Sandia Canyon begins on the Pajarito Plateau within TA-3 and has a total drainage area of about 5.5 square miles. This relatively small drainage extends eastward across the central part of LANL and crosses San Ildefonso Pueblo land before joining the Rio Grande. Effluent discharges primarily from power plant blowdown support perennial flow conditions along a 2-mile (3.2-kilometer) reach. The upper portion of the canyon contains some of the highest polychlorinated biphenyl concentrations of any watercourse within LANL boundaries. Downstream sediment concentrations of polychlorinated biphenyls decline quickly and are near background ranges at the LANL downstream boundary. Along an approximately 2-mile (3.2-kilometer) segment are found above-background concentrations of chromium, copper, mercury, and zinc in surface water and sediments. Measurements in 2004 also found concentrations of dissolved copper and lead above regulatory standards.

Mortandad Canyon begins on the Pajarito Plateau near the main complex at TA-3. The canyon crosses San Ildefonso Pueblo land before joining the Rio Grande. Analysis detected dissolved copper concentrations and benzo(a)pyrene above screening levels; potential sources are many and include road runoff, ash from the Cerro Grande Fire, and industrial sources.

Pajarito Canyon begins on the flanks of the Sierra de los Valles on U.S. Forest Service lands. The canyon crosses the south-central part of LANL before entering Los Alamos County lands in White Rock. Dissolved copper concentrations greater than the regulatory standards were detected in channels throughout the Pajarito Canyon watershed. A review of sediment data from the drainage did not indicate a LANL source for the copper. In 2004, a sediment sample from Pajarito Canyon contained many metals and radionuclides at concentrations two to five times above background levels (LANL 2005b). Concentrations of organic compounds in sediments from Pajarito Canyon are far below EPA residential soil screening levels, with the exception of benzo(a)pyrene. Low levels of polychlorinated biphenyls were detected in sediments. Polychlorinated biphenyls were not detected in stormwater runoff samples.

Water Canyon heads on the flanks of the Sierra de los Valles on U.S. Forest Service land and extends across LANL to the Rio Grande. Water Canyon and its tributary Cañon de Valle pass through the southern portion of LANL where explosives development and testing has been conducted in the past and continues to take place. Elevated concentrations of barium, HMX, and RDX have been measured in sediment and surface water.

Tables C–44 and **C–45** show the contribution to health risk to the recreational user receptor from ingestion of metals, nitrates, perchlorate, and organic compounds in surface water and sediment. **Table C–46** shows the health risk to the offsite resident receptor from ingestion of contaminants in sediment that may be transported offsite by streams and seasonal runoff.

Soil Ingestion

In the past, soils within and around LANL were analyzed for 22 light, heavy, and nonmetal trace elements (occurrence in amounts less than 1,000 micrograms per gram in soil) and 3 light and heavy abundant elements (occurrence in amounts greater than 1,000 micrograms per gram in soil). Most of these elements, with the exception of barium, beryllium, mercury, and lead, were either below the limits of detection or within the regional statistical reporting limits. Therefore, recent analyses only address the four metals that were consistently detected above the limit of detection in past years (barium, beryllium, mercury, and lead). In general, very few individual sites from either perimeter or onsite areas had barium, beryllium, mercury, or lead concentrations above the regional statistical reporting limits, and these concentrations were far below the screening action levels.

A comparison of the means of these elements collected in soils from perimeter and onsite areas with those from regional areas shows that the concentrations of beryllium, mercury, and lead in soils collected from onsite areas were significantly higher than concentrations from regional soils. Although beryllium, mercury, and lead concentrations in soils from onsite areas were statistically higher than in regional soils, the differences were very small.

Tables C–47 and **C–48** show the contribution to health risk to the offsite resident and the recreational user receptors from the ingestion of trace metals in surface soil.

Produce and Fish Ingestion

A wide variety of wild and domestic edible vegetable, fruit, grain, and animal products are harvested in the area surrounding LANL. Ingestion of foodstuffs constitutes an important pathway by which nonradioactive contaminants can be transferred to humans. Therefore, foodstuff samples are routinely collected (fruits, vegetables, grains, fish, milk, eggs, honey, herbal teas, mushrooms, pinyon nuts, domestic animals, and large and small game animals) from the surrounding area and communities to determine the impacts of LANL operations on the human food chain.

The metal elements analyzed in food were either those that have been consistently detected above the limit of detection in past years, those that have a history of use at LANL, or those that have been detected in significantly higher concentrations in soils. Of the five metals analyzed in produce collected from perimeter and onsite areas, only three (barium, lead, and selenium) were found to be above their limits of detection; beryllium and mercury were below the limits of detection. Of the three elements that were found to be above their limits of detection, all were within regional statistical reporting limits. As a group, the levels of all of the metal elements analyzed in produce from all perimeter and onsite areas were not significantly higher than those in produce collected from regional areas. Of special note is that beryllium and lead were found at significantly higher levels in soils collected in perimeter and onsite areas, but were not found at significantly higher levels in produce collected from perimeter or onsite areas than in produce collected from around the region.

Monitoring results reported in 2002 (LANL 2004b) show trace elements in produce collected before and after the Cerro Grande Fire. From almost all sites, only selenium was present in higher concentrations in produce collected after the Cerro Grande Fire than in produce collected before the fire. It is hard to say that selenium concentrations in produce collected from these sites increased because of the Cerro Grande Fire because (1) no other trace elements were elevated after the fire, and (2) selenium concentrations in soil samples collected from these same sites in 2000 and 2002 were not significantly higher than in soils collected in 1999.

The 2003 Environmental Surveillance Report presents the results of a special study on perchlorates found in vegetables and irrigation waters (LANL 2004d). Perchlorates are used at LANL in explosive and actinide research and were released into the environment as treated and untreated effluent discharges. They are highly soluble, mobile, and long-lived, and they have migrated from shallow depths to deeper groundwater levels within LANL lands. Perchlorates are

g = grams, kg = kilogram, L = liter, mg = milligram, μg = microgram, RfD = Reference Dose, UCL = upper confidence limit.
Notes: Chronic Intake (mg/kg-day) = Soil Concentration (μg/g) × Consumption rate (g/day) × 1×10^{-3} (mg/μg) × 1/Body Weight (1/71.8 kg). Shaded cells in Slope Factor and Cancer Risk columns indicate no known human chemical cancer risk.

readily taken up by plants, and the major source of water for home garden irrigation in the Los Alamos vicinity is from deep groundwater sources. Perchlorates inhibit thyroid function, but there is no current Federal standard for protection of human health. Therefore, a special study was conducted to evaluate the possible existence of perchlorates in locally grown foods. Results showed no perchlorate concentrations in any of the vegetable samples or water samples above the minimum reporting level or the minimum detection level.

The 2004 Environmental Surveillance Report (LANL 2005b) discussed the results of a special monitoring study to identify polychlorinated biphenyls in the Rio Grande. Polychlorinated biphenyls are extensively distributed worldwide and are ubiquitous in the environment. Concern has existed for years that LANL has released polychlorinated biphenyls into the environment that may have reached the Rio Grande. From 1997 to 2002, studies were conducted on polychlorinated biphenyls in fish taken from the Rio Grande and from Cochiti and Abiquiu reservoirs. One of the goals of the studies was to determine whether LANL has contributed to the polychlorinated biphenyl burdens. Results showed only a small amount of similarity between the type of aroclors indicated in the Rio Grande below LANL and aroclors known to exist at LANL. In addition, the studies concluded that, for the particular time period studied, LANL was not likely contributing polychlorinated biphenyls to the Rio Grande as indicated by the statistically similar total polychlorinated biphenyls concentrations at the two stations above LANL and the station immediately below LANL. This same conclusion was made in reports on the previous fish studies.

Fish normally collected each year include two types: predators and bottom-feeders. In any given year, predator fish may include the following: northern pike (*Esox lucius*), largemouth bass (*Micropterus salmoides*), smallmouth bass (*Micropterus dolomieui*), white crappie (*Pomoxis annularis*), brown trout (*Salmo trutta*), white bass (*Morone chrysops*), and walleye (*Stizostedion vitreum*). Similarly, bottom-feeding fish may include the following: white sucker (*Catostomus commersoni*), channel catfish (*Ictalurus punctatus*), carp (*Cyprinus carpio*), and carp sucker (*Carpiodes carpio*). Bottom-feeding fish are better indicators of environmental contamination than predator game fish because the bottom-feeding fish forage on the bottom where contaminants readily bind to sediments.

In general, most of the trace elements in both predator and bottom-feeding fish collected upstream and downstream of LANL were below the limit of detection. Concentrations of the elements that were above the limit of detection (barium, mercury, and selenium) were within historical regional background concentrations and were statistically similar to concentrations in fish from other bodies of water in the region. Mercury concentrations, a major problem in New Mexico fisheries, were statistically significant in most fish collected. The levels of mercury in predator and bottom-feeding fish muscle (fillets) collected were still below the U.S. Food and Drug Administration's ingestion limit.

Tables C–49 and **C–50** show the contributions to health risk to the offsite resident from the ingestion of trace metals in produce and predator fish. **Table C–51** shows the contribution to health risk to the special pathways receptor from ingestion of trace metals in non-predator (bottom-feeding) fish.

Lead	0.168	0.000163	0.000397	0.0014		0.117	0.284		
Antimony	0.4	0.00039	0.000948	0.0004		0.975	2.37		
Selenium	0.866	0.000844	0.00205	0.005		0.169	0.41		

g = grams, kg = kilogram, L = liter, mg = milligram, µg = microgram, RfD = Reference Dose, UCL = upper confidence limit.
Notes: Chronic Intake (mg/kg-day) = Fish Concentration (µg/g wet weight) × Consumption rate (g/day) × 1×10^{-3} (mg/µg) × 1/Body Weight (1/71.8 kg). Shaded cells in Slope Factor and Cancer Risk columns indicate no known human chemical cancer risk.

C.3 Impacts on Human Health from Biological Agents

C.3.1 Introduction

The research capacity of LANL deals with a multitude of world-class scientific topics and is focused on advancing environmental and biomedical knowledge and supporting both the DOE mission and the national bio-defense mission. Current biological research covers a range of topics including, but not limited to, genomic (or genetic) and proteomic (the study of proteins generated by the genes of a particular cell) science, measurement science and diagnostics, molecular synthesis, structural biology, cell biology, computational biology, and environmental microbiology. All of these divisions are focused on understanding the interaction between humans, the microbial world, and the environment. This task is accomplished by the detailed study of microorganisms and their characteristics using technology specific to each of the groups mentioned above. Microorganisms are found naturally in the environment; they are living things that have or can develop the ability to act or function independently. There are different categories of microorganisms, including bacteria, viruses, and fungi. Bacteria are single-celled organisms that can multiply rapidly and live anywhere in the environment. Only a very small percentage of these can cause infection and mild-to-severe disease in humans. Bacteria are also capable of producing toxins that can be harmful to humans, animals, and plants. A virus is an acellular organism (that is, a single particle) that depends on the host cell's metabolic functions to multiply. Most but not all viruses can infect humans. Fungi are plant-like organisms that lack chlorophyll; a small number of these organisms are capable of causing disease in humans.

C.3.2 Principles of Biosafety

All laboratories within the United States, including LANL, follow a specific set of guidelines for all laboratory practices that is issued by the Centers for Disease Control and Prevention and the National Institutes of Health. These guidelines are safety protocols that provide a baseline for all laboratory work.

The term "containment" is used to describe safe methods of managing infectious materials in the laboratory environment where they are being handled or maintained. The purpose of containment is to reduce or eliminate exposure of laboratory workers, other persons, and the outside environment to potentially hazardous agents (HHS 2007).

Primary containment, the protection of personnel and the immediate laboratory environment from exposure to infectious agents, is provided by both good microbiological technique and the use of appropriate safety equipment. Secondary containment, the protection of the environment external to the laboratory from exposure to infectious materials, is provided by a combination of facility design and operational practices. Therefore, the three elements of containment include laboratory practice and technique, safety equipment, and facility design. The risk assessment of the work to be performed with a specific agent will determine the appropriate combination of these elements (HHS 2007).

C.3.2.1 Safety Equipment (Primary Barriers)

Safety equipment includes biological safety cabinets, enclosed containers, and other engineering controls designed to remove or minimize exposures to hazardous biological materials. The biological safety cabinet is the principal device used to provide containment of infectious splashes or aerosols generated by many microbiological procedures. Three types of biological safety cabinets (Class I, II, and III) are used in microbiological laboratories. Open-fronted Class I and Class II biological safety cabinets are primary barriers that offer significant levels of protection to laboratory personnel and the environment when used with good microbiological techniques. The Class II biological safety cabinet also provides protection from external contamination of the materials (for example, cell cultures, microbiological stocks) being manipulated inside the cabinet. The gas-tight Class III biological safety cabinet provides the highest attainable level of protection to personnel and the environment. Safety equipment also may include items for personal protection such as gloves, coats, gowns, shoe covers, boots, respirators, face shields, safety glasses, or goggles. Personal protective equipment is often used in combination with biological safety cabinets and other devices that contain the agents, animals, or materials being handled (HHS 2007).

C.3.2.2 Facility Design and Construction (Secondary Barriers)

The design and construction of the facility contributes to laboratory workers' protection, provides a barrier to protect persons outside the laboratory, and protects persons or animals in the community from infectious agents that may be accidentally released from the laboratory. Laboratory management is responsible for providing facilities commensurate with the laboratory's function and the recommended biosafety level for the agents being manipulated.

The recommended secondary barrier(s) will depend on the risk of transmission of specific agents. For example, the exposure risks for most laboratory work in Biosafety Level 1 and 2 facilities will be direct contact with the agents or inadvertent contact exposures through contaminated work environments. Secondary barriers in these laboratories may include separation of the laboratory work area from public access, availability of a decontamination facility, and handwashing facilities. When the risk of infection by exposure to an infectious aerosol is present, higher levels of primary containment and multiple secondary barriers may be necessary to prevent infectious agents from escaping into the environment. Such design features include specialized ventilation systems to ensure directional airflow, air treatment systems to decontaminate or remove agents from exhaust air, controlled access zones, airlocks at laboratory entrances, or separate buildings or modules to isolate the laboratory. Design engineers for laboratories may refer to specific ventilation recommendations such as those found in the Applications Handbook for Heating, Ventilation, and Air-Conditioning published by the American Society of Heating, Refrigerating, and Air-Conditioning Engineers (HHS 2007).

C.3.2.3 Waste

Biological waste being removed from a laboratory is disinfected with a 10 percent Clorox solution or by autoclaving (a process using temperature and pressure to produce steam) regardless of the safety level. These processes, when implemented correctly, ensure that all waste is decontaminated before it leaves the confinement of the facility (HHS 2007). Normal laboratory waste is handled in an appropriate manner in accordance with the type of waste being discarded via the LANL Safety Plan.

C.3.2.4 Biological Release

LANL operates Biosafety Level 1 and 2 (see the discussion of Biosafety Levels in Section C.3.3) facilities as discussed in Chapter 3, Section 3.1.3.11, of this SWEIS. If released into the environment, Biosafety Level 1 material at LANL would pose little to no risk to the workers, public, or environment in general because this biological material is not known to consistently cause disease and is not contagious. Biosafety Level 2 facilities use an extensive set of procedures, safety equipment, and containment facilities that prevent any releases of Biosafety Level 2 agents that would affect workers or the public. Laboratory personnel are still subject to non-biological hazards that are associated with all workplaces and are subject to Occupational Safety and Health Administration regulations.

C.3.3 Biosafety Levels

Four biosafety levels represent combinations of laboratory practices and techniques, safety equipment, and laboratory facilities. Each combination is specifically appropriate for the operations performed, the documented or suspected routes of transmission of the infectious agents, and the laboratory function or activity. The recommended biosafety level(s) for specific organisms represent those conditions under which the agent(s) ordinarily can be safely handled. When specific information is available to suggest that the human body's ability to resist the type, strength, and rate of infection is insufficient, or that antibiotic resistance patterns, vaccine and treatment availability, or other factors are significantly altered, more (or less) stringent practices may be specified (HHS 2007).

C.3.3.1 Biosafety Level 1

Biosafety Level 1 practices, safety equipment, and facility design and construction are appropriate for undergraduate and secondary educational training and teaching laboratories, as well as other laboratories in which work is performed with defined and characterized strains of viable microorganisms that are not known to consistently cause disease in healthy adult humans. *Bacillus subtilis, Naegleria gruberi,* infectious canine hepatitis virus, and exempt organisms under the National Institutes of Health Recombinant DNA Guidelines represent microorganisms that meet these criteria. Vaccine strains that have undergone multiple in vivo (that is, within a living organism) passages should not be considered infectious simply because they are vaccine strains. Biosafety Level 1 represents a basic level of containment that relies on standard microbiological practices with no special primary or secondary barriers recommended, other than a sink for handwashing (HHS 2007).

C.3.3.2 Biosafety Level 2

Biosafety Level 2 practices, equipment, and facility design and construction are applicable to clinical, diagnostic, teaching, and other laboratories in which work is performed with the broad spectrum of naturally occurring moderate-risk agents that are present in the community and associated with human disease of varying severity. With good microbiological techniques, these agents can be used safely in activities conducted on the open bench, provided the potential for producing splashes or aerosols is low. Hepatitis B virus, HIV, *salmonellae*, and *Toxoplasma spp.* (a parasite that spreads from animals to humans) are representative of microorganisms assigned to this containment level. Biosafety Level 2 is appropriate when work is performed with any human-derived blood, body fluids, tissues, or primary human cell lines where the presence of an infectious agent may be unknown. (Laboratory personnel working with human-derived materials should refer to the Occupational Safety and Health Administration Bloodborne Pathogen Standard for specific required precautions.) Primary hazards to personnel working with these agents relate to accidental skin absorption, mucous membrane exposures, or ingestion of infectious materials. Extreme caution should be taken with contaminated needles or sharp instruments. Even though organisms routinely manipulated at Biosafety Level 2 are not known to be transmissible by the aerosol route, procedures with aerosol or high splash potential that may increase the risk of such personnel exposure must be conducted in primary containment equipment or in devices such as a biological safety cabinet. Other primary barriers should be used as appropriate, such as splash shields, face protection, gowns, and gloves. Secondary barriers such as handwashing sinks and waste decontamination facilities must be available to reduce potential environmental contamination (HHS 2007).

C.3.3.3 Biosafety Level 3

Biosafety Level 3 practices, safety equipment, and facility design and construction are applicable to clinical, diagnostic, teaching, research, or production facilities in which work is performed with indigenous or exotic agents with a potential for respiratory transmission, and thus may cause serious and potentially lethal infection. *Mycobacterium tuberculosis*, St. Louis encephalitis virus, and *Coxiella burnetii* are representative of the microorganisms assigned to this level. Primary hazards to personnel working with these agents relate to autoinoculation (that is, inoculation with a vaccine made from microorganisms obtained from the recipient's own body), ingestion, and exposure to infectious aerosols. At Biosafety Level 3, more emphasis is placed on primary and secondary barriers to protect personnel in contiguous areas, the community, and the environment from exposure to potentially infectious aerosols. For example, all laboratory manipulations should be performed in a biological safety cabinet or other enclosed equipment such as a gas-tight aerosol generation chamber. Secondary barriers for this level include controlled access to the laboratory and ventilation requirements that minimize the release of infectious aerosols from the laboratory (HHS 2007). The Biosafety Level 3 work being proposed for LANL is being addressed in a separate environmental impact statement and is not addressed in this SWEIS.

C.3.3.4 Biosafety Level 4

Biosafety Level 4 practices, safety equipment, and facility design and construction are applicable to work with dangerous and exotic agents that pose a high individual risk of life-threatening disease, may be transmitted via the aerosol route, and have no available vaccine or therapy. Agents with similar genetics to Biosafety Level 4 agents also should be handled at this level. When sufficient data are obtained, work with these agents may continue at this level or at a lower level. Viruses such as Marburg or Congo-Crimean hemorrhagic fever are manipulated at Biosafety Level 4 (HHS 2007). No Biosafety Level 4 work is currently performed or proposed to be performed at LANL. **Table C–52** delineates containment design practices and levels of biological agents for each Biosafety Level Facility.

Table C–52 Containment Design Practices and Levels of Biological Agents for Each Biosafety Level Facility

Biosafety Level	*Agents*	*Practices*	*Safety Equipment (Primary Barriers)*	*Facilities (Secondary Barriers)*
1	Not known to consistently cause disease in healthy adults.	Standard Microbiological Practices	None required.	Open bench top sink required.
2	Associated with human disease; hazard = percutaneous injury (that is, injury obtained through the skin or skin puncture), ingestion, and mucous membrane exposure.	Biosafety Level 1 practices plus: - Limited access, - Biohazard warning signs, - "Sharps" precautions, and - Biosafety manual defining any needed waste decontamination or medical surveillance policies	Primary barriers = Class I or II biological safety cabinets or other physical containment devices used for all manipulations of agents that cause splashes or aerosols of infectious materials; personal protective equipment: laboratory coats; gloves; and face protection as needed.	Biosafety Level 1 plus: - Autoclave (a strong, pressurized, steam-heated vessel, used for sterilization).
3	Indigenous or exotic agents with potential for aerosol transmission; disease may have serious or lethal consequences.	Biosafety Level 2 practices plus: - Controlled access, - Decontamination of all waste, - Decontamination of lab clothing before laundering, and - Baseline serum.	Primary barriers = Class I or II biological safety cabinets or other physical containment devices used for all open manipulations of agents; personal protective equipment: protective lab clothing; gloves; and respiratory protection as needed.	Biosafety Level 2 plus: - Physical separation from access corridors; - Self-closing, double-door access; - Exhausted air not recirculated; and - Negative airflow into laboratory.
4	Dangerous or exotic agents which pose high risk of life-threatening disease from aerosol-transmitted lab infections or related agents with unknown risk of transmission.	Biosafety Level 3 practices plus: - Clothing change before entering, - Shower on exit, and - All material decontaminated on exit from facility.	Primary barriers = All procedures conducted in Class III biological safety cabinets or Class I or II biological safety cabinets in combination with full-body, air-supplied, positive pressure personnel suit.	Biosafety Level 3 plus: - Separate building or isolated zone; - Dedicated supply and exhaust, vacuum, and decontamination systems; and - Other requirements outlined in Section C.3.3.3.

Source: HHS 2007.

C.3.4 Detection

Unlike chemical or radiological hazards, biological organisms cannot be recognized instantaneously due to the complexity of differentiating normal background organisms from potentially deadly organisms. Therefore, the scientific community has been working diligently to develop methods and assays that will allow collection and identification of an organism within any sample within an acceptable time. The detection of a biological agent starts with being able to collect samples from surfaces, air, water, soil, or bodily fluids that contain the potentially harmful organism. The next step in detection is identifying the presence of a harmful organism and its identification. These assays must be capable of utilizing specificity, time, and accuracy to identify the unknown agent; the more specific assays take a longer period of time. The methods that are most commonly used are Polymerase Chain Reaction, Enzyme-Linked Immunosorbent Assay, and Culturing. Polymerase Chain Reaction is a method in which specific DNA sequences are amplified to identify the presence or absence of a given organism. Enzyme-Linked Immunosorbent Assay is a method that determines the presence of antibodies to a foreign substance. Culturing, the gold standard method for many reference laboratories, is a method in which a given sample is spread on a nutrient culture plate containing the appropriate media for the organism of interest and allowed to grow for a given length of time at a given temperature. This method allows investigators to identify all living organisms within a sample, unlike the previous methods that cannot distinguish between living or dead organisms. All of these methods together are being developed to help protect the public from a biological attack.

C.3.5 Select Biological Agents

Select agents are specifically regulated pathogens and toxins as defined in 42 CFR Part 73, including pathogens and toxins regulated by both the U.S. Department of Health and Human Services and U.S. Department of Agriculture (specifically overlapping agents or toxins). These agents are select agents because they have been or could be used by a nation state or terrorist group to attack the United States in the form of biological warfare; therefore they are a risk to national security. These select agents are a concern because:

- They can be easily or moderately disseminated or transmitted from person to person;
- They result in high mortality rates, moderate morbidity rates, and have the potential for a major public health impact;
- They might cause public panic and social disruption;
- They require special action for public health preparedness;
- They require specific enhancements of the Center for Disease Control and Prevention’s diagnostic capacity and enhanced disease surveillance;
- Their ease of production and dissemination; and
- They can be engineered for mass dissemination in the future.

C.3.6 Transmission

These different types of agents are also categorized by route of infection or transmission; that is, how they are passed via an animal (zoonotic), a host – mosquito (vector-borne), or a human. A “zoonotic disease is a disease caused by infectious agents that can be transmitted between (or are shared by) animals and humans” (Olsen 2000). These categories of agents also can be described by whether or not they just cause infection in the person that had contact with that organism (infectious) and whether the infection is passed from person to person (contagious).

C.4 Key Differences Between Biological, Radiological, and Chemical Agents

Although each is always present in our environment and can be both beneficial and detrimental to human health, there are several important distinctions between biological, radiological, and chemical agents, including those listed below:

- Biological organisms have the capability to survive and replicate within a given environment, whereas both radiological and chemical agents will decay or remain constant over time.
- Detection time for chemicals and ionizing radiation is faster than for biological materials (minutes versus hours).
- Only biological materials are capable of contagious spread from person to person.
- There are levels of radiation and concentrations of chemicals below which there are no discernible health effects; but even at minute concentrations, certain biological agents may cause health effects ranging from mild illness (morbidity) to fatal illness (mortality).
- All chemical agents and some biological agents can be neutralized by the use of other chemicals, but radiation cannot be neutralized; it can only be shielded or contained.

APPENDIX D
EVALUATION OF HUMAN HEALTH IMPACTS FROM FACILITY ACCIDENTS

APPENDIX D
EVALUATION OF HUMAN HEALTH IMPACTS FROM FACILITY ACCIDENTS

D.1 Introduction

This appendix provides additional information and details to support the analysis of the impacts of potential facility accidents presented in Chapter 5. It includes, in Section D.2, an evaluation of the present applicability of the methodology and accident data that were reported in the *Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory, Los Alamos, New Mexico (1999 SWEIS)* (DOE 1999a) to inform the public of the differences in analyses between that document and the current site-wide environmental impact statement (SWEIS) for continued operation of Los Alamos National Laboratory (LANL). This is followed in Section D.3 with a discussion of the postulated radiological and chemical accident scenarios and their estimated impacts to workers and the public. Section D.4 discusses site-wide seismic impacts. Wildfires in the LANL vicinity and their potential for causing the release of hazardous radiological and chemical materials are a subject of public concern. A wildfire accident scenario was analyzed and its potential impacts to workers and the public are discussed in Section D.5. The impact discussions in Sections D.3 through D.5 address the general population and specific bounding individuals (the noninvolved worker and the maximally exposed individual [MEI]). Section D.6 discusses the impacts to the worker directly involved in the operation being analyzed, that is, the involved worker. Section D.7 presents impacts on individuals at various distances up to 3,281 yards (3,000 meters) from each hypothesized accident source. Two computer codes were used to analyze the postulated accidents and to estimate their impacts: (1) MACCS for radiological releases; and (2) ALOHA for chemical releases. These codes are described in Sections D.8 and D.9, respectively.

D.2 Data and Analysis Changes from the *1999 SWEIS*

Accident scenarios are generally chosen for analysis in an environmental impact statement to represent the range of possible initiating events and impacts. Accidents resulting in severe (often bounding) consequences and risks are typically presented as well. In the case of the current SWEIS, scenarios from the *1999 SWEIS* were considered. Changes to LANL operations since 1999 and any new information that could change the scenarios evaluated in 1999 were incorporated. In addition, operations that are planned or have been initiated since 1999 were included. Scenarios for these changed and new operations were chosen to demonstrate the range of possible accidents and to describe the bounding impacts.

The differences between accidents analyzed in the *1999 SWEIS* and this SWEIS are provided in **Table D–1**. Most of the differences are the result of updated environmental information (such as population and meteorology data) and changes in facility operations (facilities added, deleted, or material at risk [MAR] changes). Additional, relevant aspects of the overall study that pertain to other environmental resource areas are addressed elsewhere in this SWEIS.

The first column of Table D–1 refers to an accident topic or issue discovered during the review of documented information. Designations such as RAD-01, CHEM-01, and SITE-01 refer to specific accidents that were postulated and analyzed in the *1999 SWEIS*. The relevant facilities are also identified in the column, where applicable. The second column contains a qualitative description to reflect any changes in scenarios since the *1999 SWEIS* was issued. The third column is an evaluation of the current information on the listed topic or issue. The information contained in Table D–1 played a dominant role in directing the course of the facility accident analyses performed for this SWEIS.

Much of the background data, such as meteorology or plume characteristics, and its use in the present analysis are described in **Table D–2**. As indicated in the table, an offsite population distribution based on the 2000 census was determined for each LANL technical area (TA); this distribution was then applied to any releases from that area. Populations were considered to a distance of 50 miles (80 kilometers) from the TA.

D.3 Radiological and Chemical Accidents

This section provides information and data that supports the analysis of radiological and chemical impacts of facility accidents for each alternative presented in Chapter 5. It includes the accident frequency of occurrence and impacts, scenarios, material at risk, source terms, and factors used in the calculation of source terms.

These scenarios represent potential accidents at individual facilities. Earthquakes and wildfires that could impact multiple facilities are considered in Sections D.4 and D.5, respectively.

D.3.1 Radiological and Chemical Scenarios and Source Terms

The accident scenarios and source terms used to calculate the radiological and chemical accident impacts are shown in **Table D–3**. The evolution of choosing these scenarios is described in Table D–1. As described there, most of these scenarios evolved from those analyzed in the *1999 SWEIS*.

The Decontamination and Volume Reduction System (DVRS) is a new operation that was not considered in the *1999 SWEIS*. The impacts from an operational spill at DVRS are presented to depict the consequences of a relatively high probability operational accident. The forklift collision and spill associated with the building fire scenario are included because they represent high consequence and high risk (relative to other DVRS scenarios) impacts to the general public and workers.

Table D–1 Evaluation of Accident Data from the *1999 SWEIS*

Topic/Issue	*Scenario Notes*	*Evaluation*
Offsite population	None	Offsite population has increased in magnitude by 20 to 30 percent.
Modeling Methodology		Dose-to-LCF factor has increased by 20 percent (public) and 50 percent (worker). Other SWEIS modeling parameters that were not specified in the *1999 SWEIS* can affect MEI and population doses.
Meteorological Data		Post-*1999 SWEIS* meteorological data are available through 2003. Sensitivity analysis using more recent data show increases in population dose of up to 20 percent. Chemical accident impacts would also increase.
RAD-01 TA-54, RANT	Increased source term	Reanalyzed based on scenario changes including increased source term from 2006 BIO. Now noted as RANT Lightning Strike Fire.
RAD-02 TA-3, CMR	New CMR scenario	The *CMRR EIS* (DOE 2003a) was published after the *1999 SWEIS*. The maximum risk no action accident from that document was selected to represent CMR. The scenario is called CMR HEPA filter fire.
RAD-03 TA-18, GODIVA IV	No longer operating	Not analyzed because this TA-18 mission is being relocated to the Nevada Test Site. MAR that was formerly at TA-18 has been moved to the TA-55 SST Facility and is considered part of the site-wide seismic scenarios.
RAD-04 TA-15, DARHT	Nonnuclear	Not analyzed; now a nonnuclear facility.
RAD-05 TA-21, TSFF	MAR moved to WETF	Replaced with WETF Fire. Remaining MAR analyzed as part of site-wide seismic scenarios.
RAD-06 TA-50-37, RAMROD	Radiological facility	Not analyzed; facility is no longer a nuclear facility and thus would not impact offsite receptors.
RAD-07 TA-50-69, WCRR	Increased Source Term	Now called WCRR Lightning Strike Fire. New accident scenario from 2006 BIO.
RAD-08 TA-54, TWISP	New transuranic waste storage scenario	Replaced with Waste Storage Dome Fire. Major risk accident from the Safety Evaluation Report for TA-54 Area G (DOE 2003b).
RAD-09 TA-54, TWISP	New waste storage domes scenario	Replaced with Onsite Transuranic Waste Fire Accident. Major risk accident from the Safety Evaluation Report for TA-54 Area G (DOE 2003b).
RAD-10 TA-55-4, Plutonium Facility	Increased Source Term	Now called Plutonium Facility Materials Staging Area Fire.
RAD-11 TA-15, DARHT	Nonnuclear	Not analyzed; now a nonnuclear facility.
RAD-12 TA-16-411	Radiological facility	Not analyzed; facility is no longer a nuclear facility and thus would not impact offsite receptors. Remaining MAR analyzed as part of Site-wide Wildfire.
RAD-13 TA-18, Pajarito Site, Kiva #3	No longer operating	Replaced with scenario for only operating reactor, SHEBA Hydrogen Detonation. Scenario is major risk SHEBA accident scenario from the *TA-18 Relocation EIS* (DOE 2002a). MAR that was formerly at TA-18 has been moved to the TA-55 SST Facility and is considered part of the site-wide seismic scenarios.
RAD-14 TA-55-4, Plutonium Facility	Deleted	Replaced by Materials Staging Area Fire Accident Scenario.

Topic/Issue	***Scenario Notes***	***Evaluation***
RAD-15 TA-3-29 CMR	New CMR scenario	See RAD02. Wing Fire now considered part of Radiological Sciences Institute.
RAD-16 TA-3-29, CMR	New CMR scenario	See RAD02.
SITE-01 (Rad) Site-wide Earthquake	Change in source term and components	Renamed Seismic 1. CMR source term replaced based on CMR EIS (DOE 2003a). TA-18 source term changed based on TA-18 Relocation EIS (DOE 2002a), plus movement of material from TA-18 to TA-55 (see Seismic 02). RAMROD deleted because it is no longer a nuclear facility. Decrease in TA-21 source term. Change in scenario and increase in RANT source term. No release from waste storage domes during this event (DOE 2003b). DVRS glovebox processing campaign added (DOE 2004b). Nominally PC-2.
SITE-02 (Rad) Site-wide Earthquake	Change in source term and components	Renamed Seismic 2. Seismic 1 changes (above) carry to this scenario. Increase in WETF source term. TWISP (now Domes) scenario revised; source term increase based on all domes (DOE 2003b). Plutonium Facility releases based on 2002 BIO. Added SST Facility (material moved from TA-18 and awaiting shipment to the Nevada Test Site). Nominally PC-3. All else unchanged from *1999 SWEIS* with exception of new higher source term for TA-50-69 and TA-55-4.
SITE-03 (Rad) Site-wide Earthquake	Deleted	No significant scenarios beyond those of Seismic 2. Surface rupture not considered in source document (DOE 2003a).
SITE-04 (Rad) Site-wide Wildfire	Change in source term and components	Renamed Wildfire. TA-21 source terms decreased. Sigma Complex, Radiochemistry Laboratory, waste storage domes added.
CHEM-01 TA-00-1109	Deleted	Accident is no longer applicable because MAR has been moved offsite (LANL 2004).
CHEM-02 TA-3-476	Deleted	Chlorine no longer stored for water treatment (LANL 2004).
CHEM-03 TA-3-476	Deleted	Chlorine no longer stored for water treatment (LANL 2004).
CHEM-04 TA-54-216	No change	Now labeled 75 liters selenium hexafluoride from waste cylinder storage at TA-54-216 (LANL 2004).
CHEM-05 TA-54-216	No change	Now labeled 300 pounds sulfur dioxide from waste cylinder storage at TA-54-216 (LANL 2004).
CHEM-06 TA-55-4	No change	Now labeled 150 pounds of chlorine gas released outside of Plutonium Facility (LANL 2004).
Helium at TA-55-41	New	Added to represent possible asphyxiant release accident.
SITE-01 (Chem) Site-wide Earthquake	Change in source term and components	Renamed Seismic 1. Chlorine at TA-00 and TA-3 deleted; no longer at site. Phosgene and formaldehyde sources decreased.
SITE-02 (Chem) Site-wide Earthquake	Change in source term and components	Renamed Seismic 2. Seismic 1 changes carry over to this scenario.
SITE-03 (Chem) Site-wide Earthquake		Same scenario as Seismic 2. SITE-03 was combined with SITE-02 to create Seismic 2.

Topic/Issue	*Scenario Notes*	*Evaluation*
SITE-04 (Chem) Site-wide Wildfire	Change in source term and components	Renamed Wildfire. Hydrogen cyanide from Sigma Complex added.
TA-54, DVRS	New	DVRS glovebox processing campaign scenarios are added (DOE 2004b).
Sealed Sources at CMR	New	Sealed source MAR at CMR added.
MDA G	New	Scenario (explosion) that could potentially affect offsite receptors chosen (see Appendix I).
Aircraft Crash	New	*1999 SWEIS* aircraft crash scenarios changed because either MAR moved (see RAD-05); facilities are no longer operating (see RAD-06); or a more bounding, non-aircraft crash scenario was chosen for analysis (see RAD-08 and RAD-16). Aircraft crash scenario analyzed in Appendix J (Human Health Impacts section) of this SWEIS for Sealed Sources in Waste Storage Domes at TA-54, Area G. Highest-risk sealed source scenario (Sealed Sources at CMR) brought forward to this appendix (see Sealed Sources at CMR above).
CMRR	Bounded by CMR	DOE 2003a considered accidents from both CMR (No Action) and the CMRR (Preferred Action). Results (Tables C–3 and C–5 of that document) show that CMRR accident risks are bounded by those of CMR. Therefore, the latter is analyzed here.
WORK-01 thru -05	Not included	Involved worker accident consequences were addressed qualitatively in the *1999 SWEIS*. Designations Work-01 through -05 were dropped and replaced with discussion in Section D.6.
Criticality Scenario	Involved worker issue	Considered in *1999 SWEIS* for TA-18 (facility not operating in the alternatives for this SWEIS) and qualitatively for involved workers (WORK-03). SHEBA (TA-18) criticality considered in the TA-18 Relocation EIS (DOE 2002a) and risks to the public and non-involved worker shown (Table C–6 of that document) to be inconsequential and bounded by the SHEBA Hydrogen Detonation scenario analyzed in this SWEIS. Criticality scenario impacts are short range and affect involved workers only. Involved worker impacts are discussed in Section D.6.
Detonation of High Explosives Scenario	Involved worker issue	Considered qualitatively in *1999 SWEIS* for involved workers (WORK-01). No potential for associated radionuclide or toxic chemical release consequences to public. High explosive detonation scenario impacts are short range and affect involved workers only. Involved worker impacts are discussed in Section D.6.

LCF = latent cancer fatality; MEI = maximally exposed individual; TA = technical area; RANT = Radioassay and Nondestructive Testing; BIO = basis of interim operation; CMR = Chemistry and Metallurgy Research Building; CMRR EIS = *Final Environmental Impact Statement for the Chemistry and Metallurgy Research and Replacement Project at Los Alamos National Laboratory, Los Alamos, New Mexico*; HEPA = high-efficiency particulate air; GODIVA = fast burst reactor formerly operating in TA-18; MAR = material at risk; SST = Safe Secure Transport; DARHT = Dual-Axis Radiographic Hydrodynamic Test; TSFF = Tritium Science and Fabrication Facility; WETF = Weapons Engineering Tritium Facility; RAMROD = Radioactive Materials Research, Operations, and Demonstration; WCRR = Waste Characterization, Reduction, and Repackaging Facility; TWISP = Transuranic Waste Inspectable Storage Project; SHEBA = Solution High-Energy Burst Assembly; DVRS = Decontamination and Volume Reduction System; PC = performance category; MDA = material disposal area; CMRR = Chemistry and Metallurgy Research Replacement Facility.

Table D–2 General Analysis Assumptions Independent of Scenario

Parameter	*General Population*	*MEI, Workers*	*Comments*
MACCS2			**Version 1.13.1**
Population	SECPOP2000 (NRC 2003) 2000 census. General population distribution centered at accident source facility.	Noninvolved worker at 100 meters from source.	Facility locations from LANL 2006. MEI and noninvolved worker using "peak dose at a distance" MACCS2 results.
Population Ring Boundaries	1, 2, 3, 4, 5, 10, 20, 30, 40, 50 miles	Not applicable	General population to 50 miles.
Inhalation and external exposure from plume	Yes	Yes	
Inhalation and external exposure from deposition and resuspension	Yes	No	MEI and noninvolved worker are short-term exposures.
Breathing rate	0.000347 cubic meters per second	0.000347 cubic meters per second	DOE 1992.
Exposure from agricultural pathway, except tritiated water, strontium-90 and cesium-137	No	No, due to short exposure time.	Plutonium and uranium chief inhalation risks.
Exposure from agricultural pathway, tritiated water, strontium-90, and cesium-137	Yes, HTO estimated using CAP88. Derived factor.	No, due to short exposure time.	Ratio of ingestion to inhalation as determined from unit release of HTO using CAP88 (EPA 2005). No worker or individual ingestion pathway.
Evacuation	No	No	Assume no protective actions taken.
Relocation	No	No	Assume no protective actions taken.
Cloud shielding factor	0.75	1	General population from Chanin and Young 1997.
Protection factor for inhalation	0.41	1	General population from Chanin and Young 1997.
Skin protection factor	0.41	1	General population from Chanin and Young 1997.
Ground shielding factor	0.33	1	General population from Chanin and Young 1997. No deposition for workers.
Groundshine weathering coefficients	0.5, 0.5	0.5, 0.5	Chanin and Young 1997. Not applicable to workers.
Groundshine weathering coefficient half-lives	1.6×10^{7}, 2.8×10^{9} seconds	1.6×10^{7}, 2.8×10^{9} seconds	Chanin and Young 1997. Not applicable to workers.
Resuspension concentration coefficient	10^{-5}, 10^{-7}, 10^{-9} per meter	10^{-20}, 10^{-20}, 10^{-20} per meter	General population from Chanin and Young 1997. No resuspension for workers.
Resuspension concentration coefficient half-lives	1.6×10^{7}, 1.6×10^{8}, 1.6×10^{9} seconds	1.6×10^{7}, 1.6×10^{8}, 1.6×10^{9} seconds	0.5, 5, and 50 years, respectively (Chanin and Young 1997). Not applicable to workers.
Wet deposition	Yes	No	No wet deposition for workers. No wet deposition of noble gases (Chanin and Young 1997).
Dry deposition	Yes	No	No dry deposition for workers (conservative). No dry deposition of noble gases (Chanin and Young 1997).

Parameter	***General Population***	***MEI, Workers***	***Comments***
Washout coefficient	0.000095, 0.8	0.000095, 0.8	Chanin and Young 1997. Not applicable to workers and MEI.
Deposition velocity	.01, .005, .001 meters per second	.01, .005, .001 meters per second	Unfiltered particulates, tritiated water, filtered particulates, respectively. Not applicable to workers and MEI.
Long-term exposure period (resuspension)	317 years (1×10^{10} sec)	317 years (1×10^{10} sec)	Maximum allowed by MACCS2. Not applicable to workers and MEI.
Sigma-y, Sigma-z (dispersion parameters)	Tadmor-Gur Tables	Tadmor-Gur Tables	Chanin and Young 1997.
Surface roughness length correction	1.27	1.66	Corresponds to z0=10 centimeters (rural) for general population and z0=38 centimeters (DOE 2004b) for workers.
Plume meander time base	600 seconds	600 seconds	Chanin and Young 1997.
xpfac1	0.2	0.01	Plume meander exponential factor for time less than break point (1 hour). General population from DOE 1992, workers set to .01 (minimum value allowed by MACCS), so no plume meander for 1 hour (conservative).
xpfac2	0.25	0.25	Chanin and Young 1997; plume meander exponential factor for times greater than 1 hour.
Plume segment reference time	0	0	Plume segment reference at leading edge of plume (for dispersion, deposition, decay calculations).
TA releases for which TA-6 Meteorological Tower data are used	[3], 6, 8, 9, [16], 22, 35, 40, 43, 48, [50], 52, [55], 59, 60, 61, 63, 64, 66, 69	[3], 6, 8, 9, [16], 22, 35, 40, 43, 48, [50], 52, [55], 59, 60, 61, 63, 64, 66, 69	Closest Meteorological Tower to TAs. All TAs with workers listed; TAs with accident releases in *1999 SWEIS* indicated with brackets [ ].
TA releases for which TA-49 Meteorological Tower data are used	11, [15], 33, 36, 39, 49	11, [15], 33, 36, 39, 49	Closest Meteorological Tower to TAs. All TAs with workers listed; TAs with accident releases in *1999 SWEIS* indicated with brackets [ ].
TA releases for which TA-53 Meteorological Tower data are used	0, [21], 46, 51, 53	0, [21], 46, 51, 53	Closest Meteorological Tower to TAs. All TAs with workers listed; TAs with accident releases in *1999 SWEIS* indicated with brackets [ ].
TA releases for which TA-54 Meteorological Tower data are used	[18], [54]	[18], [54]	Closest Meteorological Tower to TAs. All TAs with workers listed; TAs with accident releases in *1999 SWEIS* indicated with brackets [ ].

Parameter	General Population	MEI, Workers	Comments
Meteorological dataset	2003	2003	Overall year of maximum worker and general population dose for the years 1995 through 2003 for unit ground level release of plutonium-239. All TA Meteorology data for 2003 within 11 percent of maximum year (1995 through 2003) except TA-46 (16 percent).
Atmospheric mixing height	350, 550, 500, 380; 1,500, 3,400, 4,000, 2,200 meters	350, 550, 500, 380; 1,500, 3,400, 4,000, 2,200 meters	Corresponding to the numbers in the previous two columns: morning-winter, spring, summer, fall; afternoon-winter, spring, summer, fall (Holzworth 1972).
Wind shift without rotation	Yes	Yes	Plume direction follows wind direction every hour.
metcod	5	5	Stratified random samples for each day of the year (see nsmpls below).
nsmpls	24	24	24 Meteorology samples per day (sample each hour).
Boundary conditions used in last ring	Yes	No	General population boundary conditions (rainfall) conservatively chosen so that releases are accounted for within modeled area. Sensitivity shows that not including boundary conditions (open boundary) results in decrease of 12 percent in median population dose and no change in extreme population dose for TA-6.
Model boundary mixing height	1,600 meters	1,600 meters	Average of seasonal mixing heights as given in Meteorology files.
Model boundary stability class and wind speed	D-2.2 meters per second	D-2.2 meters per second	50 percent MET conditions (see average Meteorology conditions below). Not applicable to workers.
Model boundary rain fall rate	23 millimeters per hour	0 millimeters per hour	Conservative maximum hourly rate from all 2003 Meteorology files (noted at TA-53 and 54). Not applicable to workers.
Dose conversion factors	FGR 11,12	FGR 11,12	Increase tritiated water inhalation by 50 percent to account for skin absorption (EPA 1988, EPA 1993).
Presented dose results	TEDE-mean	TEDE-mean	
Health risk	0.0006	0.0006	Fatal cancers per rem (total effective dose equivalent) (DOE 2003c).
ALOHA			**Version 5.3.1.**
Ground roughness length	38 centimeters	38 centimeters	DOE 2004b. ALOHA defaults to vertical dispersion parameter (Sigma-z) values consistent with urban environment for the indicated roughness length, z0, of 38 centimeters. For z0 less than 20 centimeters,

Parameter	General Population	MEI, Workers	Comments
			ALOHA defaults to a rural environment. Distances of interest expected to be close to release. General population uses same parameters as workers.
Meteorological measurement height	10 meters	10 meters	Consistent with MACCS MET data files.
Humidity	50 percent	50 percent	DOE 2004c. Within range for LANL (LANL 2006).
Median MET conditions	D-2.2	D-2.2	Stability class and wind speed in meters per second. 50 percent x/q at 2,000 meters, typical distance of interest. Minimum median wind speed from any MET Tower for 2003 (noted at TA-6). Other areas range up to D-2.8.
Median MET conditions (Wildfire)	D-3.5	D-3.5	Stability class and wind speed in meters per second. 50 percent x/q at 2,000 meters, typical distance of interest. Minimum median wind speed from any MET Tower for cumulative period 2000 through 2003 (noted at TA-49) for months of April through June. Other areas range up to D-4.0 (for TA-53).
Date and time, median MET conditions	June 22 - 1 p.m.	June 22 - 1 p.m.	DOE 2004c (summer, midday). Consistent with hours of average MET conditions from 2003 TA-6 MET tower data.
Air temperature, median MET conditions	81 degrees Fahrenheit	81 degrees Fahrenheit	LANL 2006.
Cloud cover, median MET conditions	10 tenths	10 tenths	Complete cloud cover; chosen to be consistent with other median meteorological conditions and stability class D.
Inversion height (mixing height), median MET conditions	4,000	4,000	(Meters) Summer afternoon mixing height (see "Atmospheric Mixing Height" above) consistent with date and time.
Presented effects	Distance to ERPG-2 and 3	Distance to ERPG-2 and 3	DOE 2004c.

MEI = maximally exposed individual, MET = meteorological, HTO = tritiated water, TA = technical area, FGR = Federal Guidance Report, TEDE = total effective dose equivalent, ERPG = Emergency Response Planning Guideline.
Note: To convert meters to feet, multiply by 3.2808; from miles to kilometers, multiply by 1.609.

MAR = material at risk, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, HEPA = high-efficiency particulate air filter.

[a] Damage ratios less than 1 indicate that all or part of the inventory is in a waste form such as concrete that would not release respirable particles in this accident scenario.

Storage of sealed sources represents a potential source of radionuclides that were not included in the earlier *1999 SWEIS*. These radionuclides (for example, cobalt-60 and cesium-137) represent external gamma radiation dose risks that are unlike those in most other scenarios (for example, tritium, uranium, and transuranics), which represent chiefly internal dose risks. A scenario that results in the largest risk from these sources, seismic event and fire at the Chemistry and Metallurgy Research Building impacting sealed sources, is included. Doses to individuals located close to the sources (for example, the noninvolved worker) include a component from direct (external) exposure to exposed source material. Appendix J describes the calculation of direct exposure to sealed sources in an accident and includes additional sealed source scenarios.

Material Disposal Area (MDA) cleanup was not considered in the *1999 SWEIS*. Appendix I of the current SWEIS describes proposed environmental remediation of MDAs and contains estimated impacts to offsite and worker receptors from severe accidents (relative to other MDA scenarios) at MDA G (maximum inventory MDA) and MDA B (close proximity to offsite receptors). The consequences and risks from the greater of the two are included in the discussion of the Expanded Operations Alternative in Section D.3.2.3.

D.3.2 Radiological Accident Impacts

Estimated facility accident impacts are represented in terms of consequences and risks. All consequences assume that the accident has occurred; therefore, the probability or frequency of the accident occurring is not taken into account. The risk of an accident does reflect the probability or frequency of occurrence and is calculated by multiplying the accident's frequency of occurrence by its consequences. Dose consequences are estimated for the MEI (reported in rem) located at the nearest site boundary, a noninvolved worker (reported in rem) located 328 feet (100 meters) from the accident, and the offsite population (reported in person-rem) out to a distance of 50 miles (80 kilometers). The MACCS offsite population dose calculation for radiological accidents includes an assumption that forces a conservatively large amount of radioactive material to be deposited in the last 10 miles (16 kilometers) of the 50-mile (80-kilometer) distance. This assumption results in a significantly higher calculated population dose than would be calculated if the real meteorology was used in this area. For the largest population dose radiological accident, the TA-54 waste storage dome wildfire, this MACCS methodology results in a 15 percent higher dose as compared to using real meteorology. Applying this conservative MACCS methodology to the population within 100 miles (160 kilometers) resulted in an increase of only 3 percent in the population dose even though the population increased by 194 percent. This comparison demonstrates the conservative nature of the methodology used in calculating the population dose, which encompasses radiological consequences for the population out to greater distances. Impacts at locations of public access closer than the nearest site boundary are also discussed.

Consequences are also expressed in terms of the likelihood of a latent cancer fatality (LCF) for the MEI and noninvolved worker and in terms of the number of additional LCFs for the offsite population. A conversion factor, 0.0006 LCFs (or the number of LCFs) per rem (or person-rem), is used to convert rem (or person-rem) to the likelihood of an LCF (or number of LCFs); this factor is doubled for doses to an individual in excess of 20 rem. The calculated doses and associated LCFs do not take into account any medical intervention that could be taken to lower the consequences of exposure.

D.3.2.1 No Action Alternative

The estimated consequences and annual risks of postulated accidents for the No Action Alternative are shown in **Tables D–4** through **D–6**. The maximum consequences and risks from facility accidents are chiefly a result of Plutonium Facility Operations at TA-55-4 and TA-54 operations (Radioassay and Nondestructive Testing [RANT], waste storage domes, DVRS).

The nearest public access to the Chemistry and Metallurgy Research Building, located on Diamond Drive approximately 170 feet (50 meters) from the CMR Building, is closer than the nearest site boundary to this facility. Doses were calculated for an individual at Diamond Drive during the duration of the high-efficiency particulate air (HEPA) filter fire at the Chemistry and Metallurgy Research Building. The same assumptions used to calculate the dose to the MEI were applied to this individual. The dose to an individual at Diamond Drive would be 8.1 rem, more than 10 times the value indicated in Table D–4. The consequences and risks at this location also would be 10 times the value indicated in Tables D–4 and D–6 for this scenario.

The relatively large RANT and Waste Characterization, Reduction, and Repackaging Facility (WCRR) lightning strike fire accident annual frequency is based on the conservative assumption that any lightning strike on these facilities, regardless of lightning energy or strike location on the facility, would result in a fire with the same source term as the largest building fire from the facility accident analysis.

D.3.2.2 Reduced Operations Alternative

Accident impacts under the Reduced Operations Alternative are similar to those under the No Action Alternative, as shown in Tables D–4 through D–6. Solution High-Energy Burst Assembly (SHEBA) operations at LANL would cease. The tables show that SHEBA operations are a small component of the facility impacts at LANL; its elimination would not significantly alter the overall risk profile from individual facility operations. All other impacts in the No Action Alternative tables are equally applicable for this alternative.

D.3.2.3 Expanded Operations Alternative

Accident impacts under the Expanded Operations Alternative are shown in **Tables D–7** through **D–9**. SHEBA operations at LANL would cease under the Expanded Operations Alternative, so its relatively small impacts, have been eliminated from the tables. Additional or replacement risks from accident impacts would result from expanded waste management activities. Transuranic waste at DVRS and the waste storage domes would be moved offsite or to a new facility, the TRU (Transuranic) Waste Facility (formerly the Transuranic Waste Consolidation Facility), which would be located in a TA along the Pajarito Road Corridor. The impacts to the public of this new facility would be less than those of the existing facilities because of the new location and because less material would be stored while the rest would be moved offsite. Tables D–7 through D–9 reflect the present DVRS and waste storage domes operations because they would be active for most of the time period of interest and would bound the impacts of the new TRU Waste Facility. Accident impacts for the new facility are described in Appendix H.

Table D–4 Radiological Accident Offsite Population Consequences for the No Action and Reduced Operations Alternatives

Accident Scenario	MEI		Population to 50 Miles (80 kilometers)	
	Dose (rem) [a]	LCF [b]	Dose (person-rem)	LCF [c, d]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	410	0.49	11,000	6 (6.3)
Weapons Engineering Tritium Facility Fire (TA-16-205)	5.9	0.0036	190	0 (0.11)
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	46	0.055	4,800	3 (2.9)
Waste Storage Dome Fire (TA-54)	420	0.50	4,200	3 (2.5)
Onsite Transuranic Waste Fire (TA-54)	190	0.22	5,700	3 (3.4)
Plutonium Facility Materials Staging Area Fire (TA-55-4)	73	0.087	9,000	5 (5.4)
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	20	0.012	190	0 (0.11)
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	320	0.39	6,100	4 (3.7)
SHEBA Hydrogen Detonation (TA-18-168) [e]	0.88	0.00053	69	0 (0.041)
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.77	0.00046	200	0 (0.12)

MEI = maximally exposed individual, LCF = latent cancer fatality, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, HEPA = high-efficiency particulate air filter.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Increased number of LCFs for the offsite population, assuming the accident occurs; value in parentheses is the calculated result.

[d] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, and TA-21-209), 302,000 (TA-50-69), 343,100 (TA-54-38, TA-54-412, Domes), 301,900 (TA-55-4).

[e] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduce Operations Alternative.

Table D–5 Radiological Accident Onsite Worker Consequences for the No Action and Reduced Operations Alternatives

Accident Scenario	Noninvolved Worker at 110 Yards (100 meters)	
	Dose (rem) [a]	LCF [b]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	1,900	2.2 [c]
Weapons Engineering Tritium Facility Fire (TA-16-205)	8.9	0.0054
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	1,100	1.3 [c]
Waste Storage Dome Fire (TA-54)	2,000	2.3 [c]
Onsite Transuranic Waste Fire (TA-54)	760	0.91
Plutonium Facility Materials Staging Area Fire (TA-55-4)	1,600	1.9 [c]
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	51	0.062
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	890	1.1 [c]
SHEBA Hydrogen Detonation (TA-18-168) [d]	15	0.0092
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	5.4	0.0032

LCF = latent cancer fatality, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, HEPA = high-efficiency particulate air filter.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Based on a dose-risk-conversion factor of 0.0006 LCF per rem, the indicated dose yields an LCF value greater than 1.0 as shown. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For calculation purposes, the actual value is shown here; however, because the exposed recipient is an individual, the equivalent tables in Chapter 5, Section 5.12 show an LCF of 1.0.

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduce Operations Alternative.

Table D–6 Radiological Accident Offsite Population and Worker Risks for the No Action and Reduced Operations Alternatives

Accident Scenario	*Frequency (per year)*	*Onsite Worker*	*Offsite Population*	
		Noninvolved Worker at 110 Yards (100 meters) [a]	*MEI* [a]	*Population to 50 Miles (80 kilometers)* [b, c]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	0.12 [d]	0.12	0.059	0.76
Weapons Engineering Tritium Facility Fire (TA-16-205)	1.1×10^{-5}	6.0×10^{-8}	4.0×10^{-8}	1.3×10^{-6}
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	0.14 [d]	0.14	0.0077	0.4
Waste Storage Dome Fire (TA-54)	0.001	0.001	0.0005	0.0025
Onsite Transuranic Waste Fire (TA-54)	0.001	0.00091	0.00022	0.0034
Plutonium Facility Materials Staging Area Fire (TA-55-4)	0.01	0.01	0.00087	0.054
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	0.02	0.0012	0.00024	0.0022
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	0.001	0.001	0.00039	0.0037
SHEBA Hydrogen Detonation (TA-18-168) [e]	0.0054	0.00005	2.8×10^{-6}	0.00022
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.01	0.000032	4.6×10^{-6}	0.0012

MEI = maximally exposed individual, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, HEPA = high-efficiency particulate air filter.

[a] Increased risk of an LCF to an individual per year.

[b] Increased number of LCFs in the offsite population per year; value in parentheses is the calculated result.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-69), 343,100 (TA-54-38, TA-54-412, Domes), 301,900 (TA-55-4).

[d] The lightning strike fire accident scenarios conservatively assumes that any lightning strike on the facility will result in a source term equivalent to a structure fire.

[e] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduce Operations Alternative.

Table D–7 Radiological Accident Offsite Population Consequences for the Expanded Operations Alternative

Accident Scenario	*MEI*		*Population to 50 Miles (80 kilometers)*	
	Dose (rem) [a]	*LCF* [b]	*Dose (person-rem)*	*LCF* [c, d]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	410	0.49	11,000	6 (6.3)
Weapons Engineering Tritium Facility Fire (TA-16-205)	5.9	0.0036	190	0 (0.11)
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	46	0.055	4,800	3 (2.9)
Waste Storage Dome Fire (TA-54)	420	0.50	4,200	3 (2.5)
Onsite Transuranic Waste Fire (TA-54)	190	0.22	5,700	3 (3.4)
Plutonium Facility Materials Staging Area Fire (TA-55-4)	73	0.087	9,000	5 (5.4)
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	20	0.012	190	0 (0.11)
Explosion at Material Disposal Area G (TA-54)	55	0.066	770	0 (0.46)
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	320	0.39	6,100	4 (3.7)
Chemistry and Metallurgy Research Building Fire Involving Sealed Sources (TA-3-29)	0.099	0.000059	12,000	7.0
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.77	0.00046	200	0 (0.12)

MEI = maximally exposed individual, LCF = latent cancer fatality, TA = technical area, HEPA = high-efficiency particulate air filter.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Increased number of LCFs for the offsite population, assuming the accident occurs; value in parentheses is the calculated result.

[d] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 271,600 (TA-21-155, -209), 302,000 (TA-50-69), 343,100 (TA-54-38, TA-54-412, Domes), 301,900 (TA-55-4).

Table D–8 Radiological Accident Onsite Worker Consequences for the Expanded Operations Alternative

Accident Scenario	***Noninvolved Worker at 110 Yards (100 meters)***	
	Dose (rem) [a]	***LCF*** [b]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	1,900	2.2 [c]
Weapons Engineering Tritium Facility Fire (TA-16-205)	8.9	0.0054
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	1,100	1.3 [c]
Waste Storage Dome Fire (TA-54)	2,000	2.3 [c]
Onsite Transuranic Waste Fire (TA-54)	760	0.91
Plutonium Facility Materials Staging Area Fire (TA-55-4)	1,600	1.9 [c]
Decontamination and Volume Reduction System Operational Spill (TA-54-412)	51	0.062
Explosion at Material Disposal Area G (TA-54)	410	0.49
Decontamination and Volume Reduction System Building Fire and Spill due to Forklift Collision (TA-54-412)	890	1.1 [c]
Chemistry and Metallurgy Research Building Fire Involving Sealed Sources (TA-3-29)	1.2	0.00073
Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	5.4	0.0032

LCF = latent cancer fatality, TA = technical area, HEPA = high-efficiency particulate air filter.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF, assuming the accident occurs.

[c] Based on a dose-risk-conversion factor of 0.0006 LCF per rem, the indicated dose yields an LCF value greater than 1.0 as shown. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For calculation purposes, the actual value is shown here; however, because the exposed recipient is an individual, the equivalent tables in Chapter 5, Section 5.12, show an LCF of 1.0.

Table D–9 Radiological Accident Offsite Population and Worker Risks for the Expanded Operations Alternative

Accident Scenario	*Frequency (per year)*	*Onsite Worker*	*Offsite Population*	
		Noninvolved Worker at 110 Yards (100 meters) [a]	*MEI* [a]	*Population to 50 Miles (80 kilometers)* [b, c]
Radioassay and Nondestructive Testing Facility Lightning Strike Fire (TA-54-38)	0.12 [d]	0.12	0.059	0.76
Weapons Engineering Tritium Facility Fire (TA-16-205)	1.1×10^{-5}	6.0×10^{-8}	4.0×10^{-8}	1.3×10^{-6}
Waste Characterization, Reduction, and Repackaging Facility Lightning Strike Fire (TA-50-69)	0.14 [d]	0.14	0.0077	0.4

Chemistry and Metallurgy Research Building HEPA Filter Fire (TA-3-29)	0.01	0.000032	4.6×10^{-6}	0.0012

MEI = maximally exposed individual, TA = technical area, HEPA = high-efficiency particulate air filter.

[a] Increased risk of an LCF to an individual per year.

[b] Increased number of LCFs for the offsite population per year.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-69), 343,100 (TA-54-38, TA-54-412, Domes), 301,900 (TA-55-4).

[d] The lightning strike fire accident scenarios conservatively assumes that any lightning strike on the facility will result in a source term equivalent to a structure fire.

MDA cleanup is a component of the Expanded Operations Alternative. A number of scenarios were considered for this activity, and an explosion during cleanup operations that breaches the MDA enclosure and bypasses the HEPA filtration was chosen for analysis. MDA G, because of its relatively large inventory, was found to bound the accident impacts from MDA cleanup. The consequences and risks from this scenario are included in Tables D–7 through Table D–9. As with the No Action Alternative, TA-54 operations generally dominate the accident risks from Expanded Operations. Cleanup of MDA G, although not bounding, adds a component to this risk. Appendix I includes more details about MDA cleanup accident impacts.

Another component of the Expanded Operations Alternative (but not of the No Action Alternative) is the onsite storage of sealed sources. The important exposure pathways are different for some of the radionuclides that might be released from the sealed sources. Previously, sources received for management at LANL consisted chiefly of alpha emitters such as americium and plutonium that are chiefly internal risks with doses to the body that are delivered over an extended time period. The nuclides associated with other sealed sources now being considered for management at LANL can be strong gamma emitters and thus may result in significant prompt external as well as internal exposure in the event of an accident.

A number of different radionuclides are present in the sealed sources, as shown in Table D–3. The MARs shown there represent the maximum allowable inventory of each of the nuclides if that individual nuclide only were present. Each of the nuclides was separately analyzed. It was found that cobalt-60 would lead to maximum exposure of the individuals closest to the release, such as the noninvolved worker, from exposure to source material as well as plume exposure. Transuranics such as californium-252 would lead to maximum exposure of individuals further from the release, such as the MEI at the Chemistry and Metallurgy Research Building, from plume exposure. Cesium-137 would lead to maximum exposure of the general public from ground exposure to deposited material, internal exposure from ingestion of foodstuffs, and exposure to the release plume. The dose to an individual outside at Diamond Drive during the hypothetical fire at the Chemistry and Metallurgy Research Building involving sealed sources scenario would be 4.3 rem, 42 percent of which would be from external exposure to gamma radiation. Such a dose would result in an increased chance of a fatal cancer during the lifetime of the individual of 0.0026, or approximately 1 chance in 385.

The accident analysis for sealed sources conservatively assumes that the maximum allowable limit of one single radioisotope is present instead of a more realistic expected mix of several radioisotopes at lower activity levels. This assumption provides a bounding consequence in the event of a postulated accident that releases sealed source inventory or exposes gamma or neutron emitters so that direct radiation affects the dose to individuals close to the source. The analysis also assumes that the shipping containers that hold the source and the building within which the containers are stored both fail, resulting in external exposure and release of these radionuclides. Appendix J, Section J.3.3.2, contains further discussion of sealed source accident scenarios and risks.

D.3.3 Chemical Accident Impacts

This section provides data that support the impacts of facility accidents presented in Chapter 5, including estimated accident frequencies of occurrence, scenarios, and materials released.

The chemicals of concern at LANL facilities and their potential impacts under the No Action, Reduced, and Expanded Operations Alternatives are shown in **Table D–10**. These were selected from a complete set of chemicals used onsite based on their quantities, chemical properties, and human health effects. The tables show the impact of each postulated chemical release and the applicable concentration guidelines. The first guideline is the concentration of a substance in air at a level that generally requires action to prevent or mitigate exposures. The second guideline is the concentration above which severe irreversible health effects or a fatality may occur. Emergency Response Planning Guideline (ERPG) -2 and -3 values published by the American Industrial Hygiene Association (AIHA 2005) are used in this analysis to represent those levels of impact, consistent with DOE emergency management hazards assessment and planning practices (DOE 2005a, DOE 1997).[1] ERPG-2 and ERPG-3 are defined in terms of the expected health impacts from a 1-hour exposure, as follows:

> *ERPG-2: The maximum concentration in air below which it is believed nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action.*
>
> *ERPG-3: The maximum concentration in air below which it is believed nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects.*

ERPGs are used throughout industry and government to assess chemical hazards and plan for emergencies; however, ERPGs have been issued for fewer than 120 chemicals as of 2005. To provide its sites and facilities with impact criteria for other chemicals, DOE commissions the development of alternative values, termed Temporary Emergency Exposure Limits (TEELs). As of late 2005, TEEL values have been issued for nearly 3,000 chemicals (DOE 2005b). The TEEL levels of TEEL-2 and TEEL-3 are defined in the same words as the corresponding ERPGs, but without reference to any duration of exposure. When no ERPGs have been published for a substance, the TEEL-2 and -3 values are used in this analysis to represent the ERPG-2 and ERPG-3 levels of health impact.

---

[1] *Beginning with the recent issuance of DOE Order 151.1C (November 2005) Acute Exposure Guideline Levels published by the U.S. Environmental Protection Agency (EPA) are specified as the chemical impact criteria of first choice, and these values are being incorporated into hazards assessments and emergency plans throughout DOE. Acute Exposure Guideline Levels are defined in terms of several different exposure times ranging from 10 minutes to 8 hours. In general, the Acute Exposure Guideline Levels-2 and -3 values for a 60-minute exposure are about the same as the ERPGs used in this analysis.*

Table D–10 Chemical Accident Impacts

Chemical	Frequency (per year)	Quantity Released	ERPG-2 [a]		ERPG-3 [b]		Concentration	
			Value	Distance to Value (meters)	Value	Distance to Value (meters)	Noninvolved Worker at 100 Meters	MEI at Site Boundary
Selenium hexafluoride from waste cylinder storage at TA-54-216	0.0041	75 liters (20 gallons)	0.6 ppm [c]	2,800	5 ppm [c]	880	140 ppm	12 ppm at 491 meters
Sulfur dioxide from waste cylinder storage at TA-54-216	0.00051	300 pounds (136 kilograms)	3 ppm	1,650	15 ppm	690	310 ppm	27 ppm at 491 meters
Chlorine gas released outside of Plutonium Facility (TA-55-4)	0.063	150 pounds (68 kilograms)	3 ppm	1,080	20 ppm	380	170 ppm	3.4 ppm at 1,016 meters
Helium at TA-55-41	0.063	9,230,000 cubic feet (261,366 cubic meters) (at STP)	280,000 ppm [c]	186	500,000 ppm [c]	139	greater than ERPG-3	10,000 ppm at 1,048 meters

ERPG = Emergency Response Planning Guideline, MEI = maximally exposed individual, TA = technical area, ppm = parts per million, STP = standard temperature and pressure, TEEL = Temporary Emergency Exposure Limits.

[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their ability to take protective action (DOE 2004a).

[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2004a).

[c] The TEEL value is used. ERPGs have not been issued for this substance.

Note: To convert meters to yards, multiply by 1.0936.

D.3.3.1 No Action Alternative

The chemicals of concern at LANL facilities under the No Action Alternative are shown in Table D–10. Selenium hexafluoride, sulfur dioxide, and chlorine are all toxic gases that, at elevated levels, can cause respiratory dysfunction as well as other health effects. Helium is an asphyxiant that can cause health effects by displacing breathable oxygen.

Table D–10 shows the concentrations of each chemical, if released, at specified distances. The inventory of each chemical is assumed to be released from a break in a line over a 10-minute interval. The cause of the break could be mechanical failure, corrosion, mechanical impact, or natural phenomena. The noninvolved worker, if directly downwind from the release and unable to take evasive action, would be exposed to levels in excess of ERPG-3 for these releases. Under the same circumstances, the MEI located at the LANL and San Ildefonso Pueblo boundary would be exposed to selenium hexafluoride and sulfur dioxide in excess of ERPG-3 levels.

D.3.3.2 Reduced Operations Alternative

The chemicals of concern that could be released in a facility accident are the same for the Reduced Operations Alternative as for the No Action Alternative. None of the chemicals identified for the latter are eliminated in this alternative. The information in Table D–10, then, is applicable to the Reduced Operations Alternative.

D.3.3.3 Expanded Operations Alternative

The chemicals of concern that could be released in a facility accident for the No Action Alternative apply equally to the Expanded Operations Alternative. In addition, MDA cleanup is a component of the Expanded Operations Alternative that has a potential for accidental releases of toxic chemicals. A fire during excavation that breaches the MDA enclosure and bypasses the HEPA filtration was chosen as a severe scenario. There is a great deal of uncertainty regarding which chemicals and quantities were disposed of in the MDAs. MDA B, the MDA closest to the public (and thus with the potential for the greatest impact on the public), was chosen to bound the chemical accident impacts for MDA cleanup. Two chemicals, sulfur dioxide (a gas) and beryllium (assumed in powder form), were chosen based on their restrictive ERPG values to bound the impacts of an extensive list of possible chemicals disposed of in the MDAs. **Table D–11** shows that both of these chemicals, if present in MDA B at the quantities assumed, would dissipate to below ERPG-3 levels very close to the release. Appendix I includes more details about MDA cleanup chemical accident impacts.

Table D–11 Chemical Accident Impacts for the Expanded Operations Alternative

Chemical	Frequency (per year)	Quantity Released	ERPG-2 [a]		ERPG-3 [b]		Concentration	
			Value	Distance to Value (meters)	Value	Distance to Value (meters)	Noninvolved Worker at 100 Meters	MEI at Site Boundary
Selenium hexafluoride from waste cylinder storage at TA-54-216	0.0041	75 liters (20 gallons)	0.6 ppm [c]	2,800	5 ppm [c]	880	140 ppm	12 ppm at 491 meters
Sulfur dioxide from waste cylinder storage at TA-54-216	0.00051	300 pounds (136 kilograms)	3 ppm	1,650	15 ppm	690	310 ppm	27 ppm at 491 meters
Chlorine gas released outside of Plutonium Facility (TA-55-4)	0.063	150 pounds (68 kilograms)	3 ppm	1,080	20 ppm	380	170 ppm	3.4 ppm at 1,016 meters
Helium at TA-55-41	0.063	9,230,000 cubic feet (261,366 cubic meters) (at STP)	280,000 ppm [c]	186	500,000 ppm	139	> ERPG-3	10,000 ppm at 1,048 meters
Sulfur dioxide at MDA B	Unknown	1 pound (0.45 kilogram)	3 ppm	83	15 ppm	34	2.1 ppm	9.2 ppm at 45 meters
Beryllium powder at MDA B	Unknown	22 pounds [d] (10 kilograms)	0.025 mg/cu m	23	0.1 mg/cu m	9	0.0025 mg/cu m	0.0088 mg/cu m at 45 meters

ERPG = Emergency Response Planning Guideline, MEI = maximally exposed individual, TA = technical area, ppm = parts per million, STP = standard temperature and pressure, MDA = material disposal area, mg/cu m = milligrams per cubic meter.

[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their ability to take protective action (DOE 2004a).

[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2004a).

[c] The TEEL value is used. ERPGs have not been issued for this substance.

[d] This quantity represents the total material at risk. A fraction (6×10^{-5}) of this solid would be released as respirable particles in the hypothesized scenario.

Note: To convert meters to yards, multiply by 1.0936.

D.4 Site-Wide Seismic Impacts

Two site-wide seismic events, Seismic 1 and Seismic 2, were postulated to estimate the effects of potential radiological and chemical releases. Seismic 1 is nominally represented by a Performance Category-2 (PC-2) earthquake. Such an event is characterized by a return period of 1,000 years (annual probability of exceedance of 1×10^{-3}) with a peak horizontal ground acceleration of 0.22 g (gravitational acceleration).[2] Seismic 2 is nominally represented by a PC-3 earthquake with a return period of 2,000 years (annual probability of exceedance of 5×10^{-4}) and a peak horizontal ground acceleration of 0.31 g (Cuesta 2004). Were such a seismic event to occur, simultaneous radiological and chemical releases from multiple locations could result. The rationale for choosing these scenarios is described in Table D–1. Most of these scenarios evolved from those analyzed in the *1999 SWEIS*. Revisions to the seismic releases in that earlier document (called site releases there) were based on information that became available subsequent to the writing of the *1999 SWEIS*. This new information was reviewed and significant scenarios were added as appropriate. One example is the addition of the Safe Secure Transport Facility (TA-55-355). That facility houses material that was at TA-18 at the time of the *1999 SWEIS*. The current document considers the new location and storage design, while deleting the TA-18 buildings that are no longer operating.

The health effects calculated for these two postulated seismic events should be considered within the context of the nonradiological human health impacts expected. These seismic events would cause widespread failures of both nonnuclear LANL structures and structures outside of LANL. A much larger number of fatalities and injuries from structure collapse would be expected for these seismic events.

Effects of Updated Probabilistic Seismic Hazards Analysis

An updated probabilistic seismic hazard analysis that uses new geotechnical, geologic, and geophysical data collected at the Chemistry and Metallurgy Research Replacement Facility location (particularly of the Bandelier Tuff) and current seismic hazard analysis methodology has been developed for the LANL site (LANL 2007a). Probabilistic seismic hazards were calculated for specific locations, the Chemistry and Metallurgy Research Replacement Facility, TA-3, TA-16, and TA-55. The envelope of these site-specific hazards can be applied in a generic fashion to other locations at the LANL site. The seismic accident scenarios (Seismic 1 and 2) analyzed in the SWEIS were developed based on the *Seismic Hazards Evaluation of the Los Alamos National Laboratory (February 24, 1995)*. LANL nuclear structures, systems, and components were evaluated specifically for peak horizontal ground accelerations of 0.22g and 0.31g corresponding to an annual earthquake return period of 1,000 and 2,000 years or annual probabilities of exceedance of 0.001 (1 in 1000) and 0.0005 (1 in 2000), respectively. The updated seismic hazards analysis (LANL 2007a) results indicate a site-wide peak horizontal ground acceleration of about 0.27g with a corresponding expected return period of 1,000 years and about 0.45g with an expected return period of 2,000 years. The expected return periods for the 0.22g and 0.31g peak horizontal ground acceleration are now established at about 700 and 1,250 years, respectively. The revised annual probabilities of exceedance are thus 0.0015 and

---

[2] *The term "g" stands for the acceleration of an object due to gravity at a rate of 32 feet per second (9.8 meters per second) and is used as a standard measure of ground movement associated with seismic events.*

0.0008, respectively. Using these larger probabilities, however, the seismic accident risks for the MEI, the noninvolved worker, and the population are less than 1 percent of accident risks for other types of accidents in the SWEIS such as fires at the Radioassay and Nondestructive Testing Facility, the Waste Characterization, Reduction, and Repackaging Facility, and the TA-54 waste storage domes.

For many facilities involved in the Seismic 1 and 2 accident scenarios, a conservative assumption is made that there is a complete failure of structures, systems, and components (given the Seismic 1 and 2 ground shaking) thereby resulting in the maximum possible radioisotope or chemical release to the environment. Higher seismic accelerations at the same annual frequency of exceedance based on the updated probabilistic seismic hazard analysis would result in identical consequences for these facilities. Therefore, larger seismic peak ground acceleration associated with the updated probabilistic seismic hazard analysis would not increase the consequence of these accident scenarios. The facilities for which the consequences would be the same include: the Chemistry and Metallurgy Research Building, the Weapons Engineering Test Facility, the Tritium Science and Fabrication Facility, the Tritium System Test Assembly, the Radioactive Liquid Waste Treatment Facility, Waste Characterization, Reduction, and Repackaging Facility, and the Radioassay and Nondestructive Testing Facility. Facilities for which the consequences of higher ground acceleration may be greater include: the Plutonium Facility, the TA-55 Storage Facility, the Decontamination and Volume Reduction System, Waste Storage Domes, and the Safe Secure Transport Facility.

Typically, structures are designed with considerable factors of safety against failure of the structure subjected to a variety of loads (including earthquake loads). These factors of safety produce reliable structures. For the LANL facilities that are not assumed to completely fail (given the Seismic 1 and Seismic 2 levels of ground shaking), it is not possible to state the impacts of different peak horizontal ground accelerations without detailed structural analysis of facilities using the updated probabilistic seismic hazard analysis results. A bounding approach was used to estimate the maximum expected effect of the updated seismic hazards on the SWEIS seismic accident risks. The revised annual probabilities of exceeding the peak ground horizontal accelerations used in the accident analysis of 0.22g and 0.31g are approximately 1.5×10^{-3} and 8×10^{-4}. Using the accident source terms that were developed for the Seismic 1 and Seismic 2 accident scenarios, the effect of the revised estimates of annual probability of exceedance would be an increase in the radiological risk of 50 percent for Seismic 1 scenarios and 60 percent for Seismic 2 scenarios. This results in a maximum risk of an LCF of 0.00012 for the MEI, 0.0015 for the noninvolved worker and 0.0077 for the total population for the Seismic 1 accident scenario. The comparable MEI, noninvolved worker, and population risks for the Seismic 2 accident scenario are: 0.00045, 0.0008, and 0.0144, respectively. These estimated higher seismic accident risks do not take credit for facilities in which complete failure has already been assumed and therefore no larger accident source term would be expected at higher seismic ground accelerations. Although these seismic risks have increased due to the results of the updated seismic analysis, they remain less than 1 percent of the highest MEI, noninvolved worker, and population risks for other types of accidents that are analyzed in the SWEIS.

Just as the updated probabilistic seismic hazards analysis used new data and advanced methods to calculate LANL seismic hazards, revised structural analysis methods tied to damage states credited in the safety assessments will be used to update the seismic structural integrity evaluation of LANL facilities. The effect of the higher values of peak horizontal ground acceleration on calculated seismic accident consequences and risks will be analyzed in future facility safety analyses and incorporated as appropriate into future National Environmental Policy Act (NEPA) documents. The LANL management and operating contractor has developed and NNSA has accepted a site-wide justification for continued operation as a result of the estimates of increased seismic event frequency and acceleration associated with the updated probabilistic seismic hazards analysis. The justification for continued operation presents a qualitative evaluation of the effect of this increased seismic hazard on site-wide transportation and on the following LANL facilities: Chemistry and Metallurgy Research Building, Beryllium Technology Facility, Dual-Axis Radiographic Hydrodynamic Test Facility, Weapons Engineering Test Facility, Radioactive Liquid Waste Treatment Facility, Waste Characterization, Reduction, and Repackaging Facility, TA-53 underground spent resin tank, LANSCE, Area G waste operations, Radioassay and Nondestructive Testing Facility, Plutonium Facility, Safe and Secure Transport Facility, and the nuclear environmental sites (MDA A, MDA B, MDA C, MDA H, MDA T, MDA W, TA-35 Wastewater Treatment Plant, TA-35 Pratt Canyon, and MDA AB). The justification for continued operation determined that existing bounding seismic accident analyses; new facility safety analyses; compensatory measures of limiting radioactive material inventory, new programs, and procedures; and the low probability of a seismic event during the anticipated time period for detailed quantitative analysis of each facility's safety documentation provide the basis for an acceptable risk for continued operation of LANL (LANL 2007b, NNSA 2007).

The Los Alamos Site Office directed the LANL management and operating contractor to develop a project execution plan to perform specific detailed facility seismic analyses; incorporate necessary changes to facility safety bases; and develop a list of potential facility modifications to address deficiencies identified in the seismic analyses (NNSA 2007c). If necessary, facility-specific justifications for continued operation will be developed as part of this process. This project will provide for the evaluation of each LANL facility using the updated probabilistic seismic hazard analysis seismic accelerations and frequencies and in accordance with appropriate LANL structural engineering standards for seismic events using all applicable industry, federal government, and international standards, codes, and criteria.

D.4.1 Source Term Data

Table D–12 shows the source term data used to calculate impacts to workers and the public that could result from a site-wide earthquake. A single table is presented for the two earthquake scenarios (Seismic 1 and 2); the scenario corresponding to each release is indicated under the facility name.

MAR = material at risk, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, MEI = maximally exposed individual, PC = performance category.

[a] Separate analyses were performed for the population and for the MEI and noninvolved worker because releases from all of the doses would affect the population, but an individual would be affected by only a subset of doses that are close to each other.

D.4.2 No Action Alternative Impacts

D.4.2.1 Site-Wide Seismic 1 – Radiological Impacts

Site-wide Seismic 1 is associated with seismic events up to approximately PC-2 in severity. **Tables D–13** and **D–14** show the potential consequences (dose and probability of an LCF) should such an earthquake occur under the No Action Alternative. **Table D–15** shows the health risk (frequency multiplied by the LCF consequence) per year of operation. The largest risk from this event is from potential Chemistry and Metallurgy Research Building releases.

If a Seismic 1 event were to occur, all of the releases shown in Table D–15 could emanate simultaneously. Accordingly, the sum of the health risk from each facility to the general population is indicated at the bottom of that table. This sum can be thought of as the overall health risk to the general population from a Seismic 1 event. The overall risk is seen to be approximately 0.005 per year; that is, a mean of one cancer fatality in the entire general population (out to 50 miles [80 kilometers] from each release) every 200 years of LANL operation.

Table D–13 Site-Wide Seismic 1 Radiological Accident Offsite Population Consequences for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 1 Event	MEI		Population to 50 Miles (80 kilometers)	
	Dose (rem)	LCF [a]	Dose (person-rem)	LCF [b, c]
Chemistry and Metallurgy Research Building (TA-3-29)	62	0.075	6,100	4 (3.7)
SHEBA (TA-18-168) [d]	0.03	0.000018	0.77	0 (0.00046)
Tritium System Test Assembly (TA-21-155)	0.0015	8.8×10^{-7}	0.049	0 (0.00003)
Tritium Science and Fabrication Facility (TA-21-209)	0.013	7.5×10^{-6}	0.43	0 (0.00026)
Radioactive Liquid Waste Treatment Facility (TA-50-1)	3	0.0018	520	0 (0.31)
Radioassay and Nondestructive Testing Facility (TA-54-38)	64	0.077	1,100	1 (0.67)
Storage Facility (TA-55-185)	6	0.0036	590	0 (0.35)
Decontamination and Volume Reduction System (TA-54-412) (PC-2 Seismic)	2.8	0.0017	49	0 (0.03)
	Max 64	Max 0.077	Sum 8,400	Sum 5 (5.1)

MEI = maximally exposed individual, LCF = latent cancer fatality, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Increased risk of an LCF to an individual, assuming the accident occurs.

[b] Increased number of LCFs for the offsite population, assuming the accident occurs; value in parentheses is the calculated result.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-1), 343,100 (TA-54-38, TA-54-412).

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduce Operations and Expanded Operations Alternatives.

Table D–14 Site-Wide Seismic 1 Radiological Accident Onsite Worker Consequences for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 1 Event	Noninvolved Worker at 110 Yards (100 meters)	
	Dose (rem) [a]	LCF [b]
Chemistry and Metallurgy Research Building (TA-3-29)	2,000	2.4 [c]
SHEBA (TA-18-168) [d]	1.1	0.00064
Tritium System Test Assembly (TA-21-155)	0.011	6.7×10^{-6}
Tritium Science and Fabrication Facility (TA-21-209)	0.097	0.000058
Radioactive Liquid Waste Treatment Facility (TA-50-1)	120	0.15
Radioassay and Nondestructive Testing Facility (TA-54-38)	580	0.69
Storage Facility (TA-55-185)	240	0.29
Decontamination and Volume Reduction System (TA-54-412) (PC-2 Seismic)	10	0.0061

LCF = latent cancer fatality, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Based on a dose-risk-conversion factor of 0.0006 LCF per rem, the indicated dose yields an LCF value greater than 1.0 as shown. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For calculation purposes, the actual value is shown here; however, since the exposed recipient is an individual, the equivalent tables in Chapter 5, Section 5.12, show an LCF of 1.0.

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduce Operations and Expanded Operations Alternatives.

Table D–15 Site-Wide Seismic 1 Radiological Accident Offsite Population and Worker Risks for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 1 Event	Frequency (per year)	Onsite Worker	Offsite Population	
		Noninvolved Worker at 110 Yards (100 meters) [a]	MEI [a]	Population to 50 Miles (80 kilometers) [b, c]
Chemistry and Metallurgy Research Building (TA-3-29)	0.001	0.001	0.000075	0.0037
SHEBA (TA-18-168) [d]	0.001	6.4×10^{-7}	1.8×10^{-8}	4.6×10^{-7}
Tritium System Test Assembly (TA-21-155)	0.001	6.7×10^{-9}	8.8×10^{-10}	3×10^{-8}
Tritium Science and Fabrication Facility (TA-21-209)	0.001	5.8×10^{-8}	7.5×10^{-9}	2.6×10^{-7}
Radioactive Liquid Waste Treatment Facility (TA-50-1)	0.001	0.00015	1.8×10^{-6}	0.00031
Radioassay and Nondestructive Testing Facility (TA-54-38)	0.001	0.00069	0.000077	0.00067
Storage Facility (TA-55-185)	0.001	0.00029	3.6×10^{-6}	0.00035
Decontamination and Volume Reduction System (TA-54-412) (PC-2 Seismic)	0.001	6.1×10^{-6}	1.7×10^{-6}	0.00003
		Max 0.001 [e]	Max 0.000077 [e]	Sum 0.0051 [e]

MEI = maximally exposed individual, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Increased risk of an LCF to an individual per year.

[b] Increased number of LCFs for the offsite population per year.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-1), 343,100 (TA-54-38, TA-54-412).

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduce Operations and Expanded Operations Alternatives.

[e] See the discussion in Section D.4 regarding the impacts of the 2007 update of the probabilistic seismic hazard analysis.

Risks to individuals, on the other hand, cannot be summed because a single individual likely would not be exposed to multiple facility releases. Instead, only releases upwind from the individual's location would result in exposure. Table D–15, therefore, indicates the maximum health risk to the MEI from a release at any facility.

There is a potential for an individual at publicly accessible Diamond Drive, approximately 55 yards (50 meters) from the Chemistry and Metallurgy Research Building, to receive an exposure from that facility in excess of the MEI exposure. MACCS2 dispersion calculations, the underlying basis for this result, are generally considered to be conservatively high within 330 feet (100 meters) of a release. The calculated dose at Diamond Drive is 6,400 rem, 100 times the Chemistry and Metallurgy Research Building MEI dose indicated in Table D–13. Depending on the specific radionuclides released and the route of human exposure, a radiation dose of this magnitude would result in near-term health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose to the exposed individual or mitigating any health impacts. The dose calculated for an individual on Diamond Drive is based on an assumption that no protective action is taken during the entire time of exposure and that no subsequent medical intervention occurs.

D.4.2.2 Site-Wide Seismic 2 – Radiological Impacts

Site-wide Seismic 2 is associated with events up to approximately PC-3 in severity. **Tables D–16** and **D–17** show the potential consequences (dose and probability of an LCF) should such an earthquake occur under the No Action Alternative. **Table D–18** shows the health risk (frequency multiplied by the LCF consequence) per year of operation. All of the releases from the Seismic 1 event would, of course, be released during this event as well. The waste storage domes would be among the facilities that would have no releases during a Seismic 1 event, but would have releases in the event of the larger Seismic 2 event. This facility, TA-55, and the Chemistry and Metallurgy Research Building represent the major sources of risk for this event. The overall health risk to the general population from this event is approximately 0.009 per year; that is, a mean of one LCF in the entire general population (out to 50 miles [80 kilometers] from each release) every 111 years of LANL operation. Therefore, the risk from a Seismic 1 or 2 event is roughly equivalent.

Table D–16 Site-Wide Seismic 2 Radiological Accident Offsite Population Consequences for the No Action, Reduced Operations, and Expanded Operations Alternatives

Facility Impacted by Seismic 2 Event	*MEI* Dose (rem)[a]	*MEI* LCF[b]	*Population to 50 Miles (80 kilometers)* Dose (person-rem)	*Population to 50 Miles (80 kilometers)* LCF[c, d]

MEI = maximally exposed individual, TA = technical area, SHEBA = Solution High-Energy Burst Assembly, PC = performance category.

[a] Increased risk of an LCF to an individual per year.

[b] Increased number of LCFs for the offsite population per year.

[c] Offsite population size out to a 50-mile (80-kilometer) radius is approximately 297,000 (TA-3-29), 404,900 (TA-16-205), 334,100 (TA-18-168), 271,600 (TA-21-155, -209), 302,000 (TA-50-1, -69), 343,100 (TA-54-38, TA-54-412, Domes), 301,900 (TA-55-4, -185, -355).

[d] The SHEBA accident scenario is applicable only to the No Action Alternative. Operation of SHEBA would cease under the Reduce Operations and Expanded Operations Alternatives.

[e] Different frequency than other seismic events due to assumption of other additional failures.

[f] See the discussion in Section D.4 regarding the impacts of the 2007 update of the probabilistic seismic hazard analysis.

The consequence to an individual at publicly accessible Diamond Drive from a Seismic 2 release from the Chemistry and Metallurgy Research Building could exceed that from the nearest site boundary. This consequence is the same as for the Seismic 1 event; the effects of the Chemistry and Metallurgy Research Building release are discussed in detail under that heading.

D.4.2.3 Site-Wide Seismic 1 – Chemical Impacts

The facilities and chemicals of concern under site-wide Seismic 1 conditions are shown in **Table D–19**. There are numerous chemicals in small quantities onsite that could be released under these conditions. The listed chemicals were selected from a complete set of chemicals used onsite based on their larger quantities, chemical properties, and human health effects.

Table D–19 shows the ERPG concentration values for which excess concentrations could have harmful health or life-threatening implications as defined in the table's footnotes. Hydrogen cyanide, phosgene, and formaldehyde are toxic gases that, at elevated levels, can cause respiratory or cardiovascular (in the case of hydrogen cyanide) dysfunction. The hypothetical MEI could be exposed to formaldehyde concentrations in excess of ERPG-3 values in the event of such an earthquake, depending on the meteorological conditions at the time. This high exposure is a result of the proximity of TA-43-1 to the site border with the Los Alamos townsite.

Table D–19 Chemical Accident Impacts Under Seismic 1 Conditions

Chemical	Frequency [c] (per year)	Quantity Released	ERPG-2 [a]		ERPG-3 [b]		Concentration	
			Value	Distance to Value (meters)	Value	Distance to Value (meters)	Noninvolved Worker at 100 Meters	MEI at Site Boundary
Hydrogen Cyanide at TA-3-66 (Sigma Complex)	0.001	13.5 pounds (6 kilograms)	10 ppm	140	25 ppm	86	19 ppm	0.25 ppm at 924 meters
Phosgene at TA-9-21	0.001	1 pound (0.45 kilogram)	0.2 ppm	280	1 ppm	120	1.4 ppm	0.025 ppm at 823 meters
Formaldehyde at TA-43-1 (Bioscience Facilities)	0.001	14.1 liters (3.7 gallons)	10 ppm	180	25 ppm	110	31 ppm	Exceeds ERPG-3 at 12 meters

ERPG = Emergency Response Planning Guideline, MEI = maximally exposed individual, TA = technical area, ppm = parts per million.
[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their ability to take protective action (DOE 2004a).
[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2004a).
[c] Based on the updated 2007 update of the probabilistic seismic hazard analysis, the annual probability of exceedance for this earthquake is estimated to be 0.0015 (1 chance in 670). See discussion in Section D.4.
Note: To convert meters to yards, multiply by 1.0936.

The noninvolved worker could be exposed to phosgene or formaldehyde in excess of ERPG-3 values if located directly downwind of the releases and unable to take evasive action.

Table D–19 shows the concentration of each chemical, if it were released, at specified distances. The estimated frequency of this seismic event is shown in the table.

D.4.2.4 Site-Wide Seismic 2 – Chemical Impacts

The facilities and chemicals of concern under site-wide Seismic 2 conditions are shown in **Table D–20**. There are numerous chemicals in small quantities onsite that could be released under these conditions. The listed chemicals were selected from a complete set of chemicals used onsite based on their larger quantities, chemical properties, and human health effects. The table shows the ERPG concentration values for which excess concentrations could have harmful health or life-threatening implications, as defined in the table's footnotes.

Table D–20 Chemical Accident Impacts Under Seismic 2 Conditions

Chemical	Frequency [c] (per year)	Quantity Released	ERPG-2 [a]		ERPG-3 [b]		Concentration	
			Value	Distance to Value (meters)	Value	Distance to Value (meters)	Noninvolved Worker at 100 Meters	MEI at Site Boundary
Hydrogen cyanide at TA-3-66 (Sigma Complex)	0.0005	13.5 pounds (6.1 kilograms)	10 ppm	137	25 ppm	86	18.6 ppm	0.25 ppm at 924 meters
Phosgene at TA-9-21	0.0005	1 pound (0.45 kilogram)	0.2 ppm	276	1 ppm	118	1.38 ppm	0.025 ppm at 823 meters
Formaldehyde at TA 43-1 (Bioscience Facilities)	0.0005	14.1 liters (3.7 gallons)	10 ppm	178	25 ppm	112	31.3 ppm	Exceeds ERPG-3 at 12 meters
Chlorine gas released outside of TA-55-41 Plutonium Facility	0.0005	150 pounds (68 kilograms)	3 ppm	1,080	20 ppm	380	165 ppm	3.4 ppm at 1,016 meters
Nitric acid spill at TA-55-4 (Plutonium Facility)	0.0005	6,100 gallons (23,090 liters)	6 ppm	49	78 ppm	6.6	1.61 ppm	0.019 ppm at 1,016 meters
Hydrochloric acid spill at TA-55-249	0.0005	5,200 gallons (19,684 liters)	20 ppm	185	150 ppm	64.5	65.9 ppm	0.65 ppm at 1,117 meters
Beryllium at TA-3-141 (Beryllium Technology Facility)	0.0005	110 pounds (49 kilograms) (powder) [d]	0.025 milligrams per cubic meter	282	0.1 milligrams per cubic meter	116	0.126 ppm	0.0043 milligrams per cubic meter at 880 meters

ERPG = Emergency Response Planning Guideline, MEI = maximally exposed individual, TA = technical area, ppm = parts per million.

[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action (DOE 2004a).

[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2004a).

[c] Based on the updated 2007 update of the probabilistic seismic hazard analysis, the annual probability of exceedance for this earthquake is estimated to be 0.0008 (1 chance in 1,250). See discussion in Section D.4.

[d] This quantity represents the total material at risk. A fraction (0.0006) of this solid would be released for the hypothesized scenario.

Note: To convert meters to yards, multiply by 1.0936.

The Seismic 1 chemical releases would be repeated here. In addition, because of the increased severity of this event, beryllium, chlorine, nitric acid, and hydrochloric acid could be released in sufficient quantities to create plausible health effects near the release site. Exposure to beryllium can result in acute lung damage; elevated levels of chlorine and acids can cause respiratory dysfunction. The beryllium powder release could result from a Beryllium Technology Facility structural failure in a Seismic 2 earthquake with subsequent container breaching. Chlorine could be released as a result of line or tank failures. The integrity of the nitric and hydrochloric acid tanks could be compromised. It is assumed that their entire contents spill and are contained within the seismically qualified berms surrounding each tank. Release from these acid pools would be by evaporation.

Table D–20 shows the concentration of each chemical, if released, at specified distances. The estimated frequency of the Seismic 1 event is shown in the table. The hydrogen cyanide, phosgene, and formaldehyde releases projected during a Seismic 1 event also would occur during the more severe Seismic 2 event; the distances and environmental concentration levels would be unchanged from the former event. None of the additional releases would result in MEI exposure in excess of ERPG-3 levels. A noninvolved worker, if directly downwind from the release and unable to take evasive action, could be exposed to beryllium or chlorine in excess of ERPG-3 levels. The additional releases (except beryllium) are from TA-55, and its distance from the site boundary, together with the quantities potentially released, would prevent ERPG-3 exposure to the public. The inventory of beryllium kept at TA-3-141 is limited to minimize accident impacts.

D.4.3 Reduced Operations Alternative Impacts

The site-wide seismic radiological accident impacts from the Reduced Operations Alternative would be similar to those from the No Action Alternative, as given in Tables D–13 through D–18. SHEBA operations at LANL would cease under this alternative. Inspection of the tables shows that SHEBA operations are a small component of the site-wide seismic accident impacts at LANL; its elimination would not significantly alter the overall site risk profile from such an event. All other impacts in the tables are equally applicable for this alternative.

The chemicals of concern that could be released in a site-wide seismic event are the same for the Reduced Operations Alternative as for the No Action Alternative. None of the chemicals identified for the latter are eliminated in this alternative. The information in Tables D–19 and D–20, then, is applicable to the Reduced Operations Alternative.

D.4.4 Expanded Operations Alternative Impacts

D.4.4.1 Site-Wide Seismic 1 – Radiological Impacts

The Seismic 1 accident impacts from the Expanded Operations Alternative would be similar to those from the No Action Alternative. SHEBA operations at LANL would cease under the Expanded Operations Alternative. Its impacts are relatively small; deleting SHEBA impacts would not change the overall Seismic 1 risk profile of this alternative. Replacement risks from accident impacts would result from expanded waste management activities. Transuranic waste managed at DVRS would be moved offsite or to a new facility, the TRU Waste Facility, which would be located in a TA along the Pajarito Road Corridor. The impacts from this new facility would be less than those of the existing facility because of the new location. The entries in Tables D–13 through D–15 reflect present DVRS operations because it could be active for most of the time period of interest. The accident impacts from DVRS bound the impacts of its replacement facility. Accident impacts for the new facility are described in Appendix H.

D.4.4.2 Site-Wide Seismic 2 – Radiological Impacts

The Seismic 2 accident impacts from the Expanded Operations Alternative would be similar to those from the No Action Alternative. SHEBA operations at LANL would cease under the Expanded Operations Alternative. Its impacts are relatively small; deleting its impacts would not change the overall Seismic 2 risk profile of this alternative. Replacement risks from accident impacts would result from expanded waste management activities. Transuranic waste managed at DVRS and the waste storage domes would be moved offsite or to a new facility, the TRU Waste Facility, located in a TA along the Pajarito Road Corridor. The impacts from this new facility would be less than those of the existing facility because of the new location and because less material would be stored, the rest being moved offsite. The entries in Tables D–16 through D–18 reflect present DVRS and the waste storage domes operations because they could be active for most of the time period of interest and because their accident impacts bound the impacts of the new facility. The TRU Waste Facility accident impacts are described in Appendix H.

D.4.4.3 Site-Wide Seismic 1 – Chemical Impacts

The chemicals of concern that could be released in a site-wide Seismic 1 event are the same under the Expanded Operations Alternative as under the No Action Alternative. No additional chemicals were identified in this alternative that would have impacts exceeding those for the No Action Alternative. The information in Table D–19, then, is applicable to the Expanded Operations Alternative.

D.4.4.4 Site-Wide Seismic 2 – Chemical Impacts

The chemicals of concern that could be released in a site-wide Seismic 2 event are the same under the Expanded Operations Alternative as under the No Action Alternative. No additional chemicals were associated with this alternative that would have impacts exceeding those under the No Action Alternative. The information in Table D–20, then, is applicable to the Expanded Operations Alternative.

D.5 Wildfire Accidents

This section discusses the potential for a wildfire at LANL (LANL 2004) that could cause the release of hazardous radioactive and chemical materials that would affect the health and safety of LANL workers and the public.

D.5.1 Background

Wildfires were evaluated in the *1999 SWEIS* and were studied further following the Cerro Grande Fire in May 2000. The following sections provide background information on the potential for LANL wildfires since the *1999 SWEIS* was prepared.

D.5.1.1 Consuming Combustible Structures and Vegetation

A theoretical wildfire resulting in the exposure of humans to airborne radiation was one of several operational site-wide accident scenarios analyzed and reported in the *1999 SWEIS*. The health impact of the wildfire accident was 0.34 LCFs, resulting from an estimated population dose of 675 person-rem. The dose to the MEI member of the public was less than 25 rem, and the estimated frequency of occurrence was approximately once every 10 years. While the estimated radiological dose consequence of a wildfire accident was small, the high frequency of occurrence resulted in a risk (the product of the frequency and consequence) that was surpassed by only one other postulated accident in the *1999 SWEIS*.

The wildfire accident analysis assumed multiple source releases, including radiological inventories from buildings, suspended soils with environmental (very low) levels of contamination, and ash from burned vegetation (this ash also had very low levels of contamination). Since the analysis in 1999, radiological inventories in buildings have changed; the vulnerability of buildings to ignition by wildfire has changed as a result of tree thinning; more accurate and more comprehensive data have been compiled on concentrations of radionuclides in vegetation; vegetation fuel loads have changed; and the frequency of occurrence has possibly changed.

The LANL site and surrounding vicinity are generally forested areas with high fuel loading (Balice, Oswald, and Martin 1999; Balice et al. 2000). Wildfires are frequent occurrences on nearby U.S. Forest Service land and have an obvious potential for encroaching on the LANL site, as demonstrated by recent events (Balice, Oswald, and Martin 1999, Balice et al. 2000). Recently, an analysis was completed to help determine areas of concern for continued wildfire risk at LANL that consider the extensive environmental changes since 1999. Based on the results of this analysis, areas of concern were determined that are consistent with those found in another recent wildfire risk analysis (Balice et al. 2005). A particular scenario, a wildfire starting southwest of LANL near the border of the Bandelier National Monument and the Dome Wilderness Area, was postulated. While there is a potential for initiation of a wildfire at many locations within and near the LANL site, this location was considered to have the greatest potential for widespread environmental impacts to LANL because continuous fuel is available from these offsite locations near the southwest corner of LANL.

D.5.1.2 Recent Widespread Environmental Changes

Since completion of the *1999 SWEIS* wildfire analysis, the Cerro Grande Fire occurred. On May 4, 2000, the National Park Service initiated a prescribed burn on the flanks of Cerro Grande Peak within the boundary of Bandelier National Monument. The intended burn was a meadow of about 300 acres (120 hectares), located 3.5 miles (5.6 kilometers) west of TA-16, near the southwest corner of LANL. The prescribed burn began in the evening; by 1:00 p.m. the following day, the burn was declared a wildfire.

LANL’s meteorological data showed above–average temperatures and low humidity for the first 10 days of the wildfire, with wind speeds averaging 6 to 17 miles per hour (10 to 27 kilometers per hour) and gusting from 27 to 54 miles per hour (44 to 87 kilometers per hour). Generally, winds tended to be from the southwest to west during this period. By May 8, day 5 of the wildfire, spot fires began to occur on LANL lands. By May 10, the fire moved into the Los Alamos townsite and proceeded north and east across the TA-16 mesa top. The fire moved eastward down Water Canyon, Cañon de Valle, Pajarito Canyon, and Cañada del Buey by May 11. Eventually the fire extended northward on LANL lands to Sandia Canyon and eastward down Mortandad Canyon into San Ildefonso Pueblo lands. The residential areas of Los Alamos and White Rock were in the fire’s path, and more than 18,000 residents were evacuated. By the end of the day on May 10, the fire had burned 18,000 acres (7,280 hectares), destroyed 235 homes, and damaged many other structures. The fire also spread toward LANL; although the fire moved onto LANL land, all major structures were secured and no releases of radiation occurred. The wildfire was declared fully contained on June 6, after burning nearly 43,000 acres (17,400 hectares) of land extending to Santa Clara Canyon on Santa Clara Pueblo lands to the north of the townsite. LANL had approximately 6,757 acres (2,734 hectares) of low-burn severity; 844 acres (342 hectares) of moderate-burn severity; and 50 acres (20 hectares) of high-burn severity (Balice, Bennett, and Wright 2004).[3]

[3] *The sum of these areas is approximately equal to 7,700 acres as cited elsewhere in this SWEIS.*

The Cerro Grande Fire had enormous adverse impacts on forests around LANL. Immediately there were concerns about increased erosion and flooding and the potential impacts on contaminated soil and sediment. Seventy-seven contaminant potential release sites and two nuclear facilities at LANL that contain hazardous and radioactively contaminated soils and materials are located within floodplain areas. Without DOE action, these potential release sites and nuclear facilities could have released contaminants and materials downstream during rainfall events. In addition, numerous cultural resource sites and traditional cultural properties are located in canyons or along drainage areas and were at increased risk of flood damage.

LANL conducted assessments and implemented on-the-ground rehabilitation efforts. Under the DOE Special Environmental Assessment (DOE 2000), LANL was to conduct mitigation measures and monitor the condition of the burned area annually. In all, LANL treated over 1,800 acres (728 hectares) with techniques similar to those used by the Burned Area Emergency Rehabilitation team. The project was successful, increasing vegetative cover on the severely burned units from around 0 percent to almost 45 percent. Most of the straw wattles that were installed held sediment onsite and allowed vegetation to grow. The LANL management and operating contractor developed best management practices for all potential release sites that were potentially impacted by the fire to eliminate contaminant transport.

The drought that began in 2000 in the southwestern United States, although not unprecedented, has been one of the more severe in 50 years (Breshears et al. 2005). Precipitation for this region was 25 percent below average during 2000 and 2001, and 65 percent below average through the summer months. The combined effects of prolonged drought and severe outbreak of bark beetles (*Ips confusus*) resulted in tens of millions of dead trees over thousands of square miles in Arizona, New Mexico, Colorado, and Utah (McHugh, Kolb, and Wilson 2003). Highest mortality levels have been seen in ponderosa pine (*Pinus ponderosa*), douglas-fir (*Pseudotsuga menziesii*) and pinyon (*Pinus edulis*) pine trees. In many areas of pinyon-juniper habitat, entire stands of pinyon have died, leaving only juniper (*Juniperus monosperma*). Bark beetle infestations in western North America has been documented to cause large areas of high tree mortality that has been linked to both drought and fire in the region (USDA 2002). The Pajarito Plateau, where LANL is located, had an average 85 percent tree mortality for trees over 5 feet (1.5 meters) tall from 2002 to 2003, leaving a mosaic of live and dead trees.

To decrease the risk from catastrophic environmental fire, LANL began a tree-thinning project in January 2002. The goals of this project were to reduce the threat of wildfire to forested areas and structures on LANL property, to enhance and maintain wildlife habitat and tree species diversity by ensuring vertical and horizontal heterogeneity of age class and structure throughout the forest, and to promote forest health. Tree thinning has been completed on 7,283 acres (2,947 hectares), including both ponderosa pine and pinyon–juniper habitats (LANL 2005). Tree thinning and environmental changes were incorporated into the wildfire risk analysis of this SWEIS.

D.5.1.3 Wildfire Occurrence

D.5.1.3.1 General Approach

The following analysis of the risk of wildfire initiation and spread was taken from the *Information Document in Support of the Five-Year Review and Supplement Analysis for the Los Alamos National Laboratory Site-Wide Environmental Impact Statement* (LANL 2004).

This analysis was largely based on data produced during earlier studies and field monitoring activities. A dataset of lightning strike locations and intensities was used to represent wildfire ignitions. Polygons (multi-sided geometric shapes) of previously modeled fires were used to evaluate the relative potential for fires to burn within the study area. Fuels data and an existing land cover map were used to characterize the fuels and fire hazards in the study region. It was assumed that lightning, modeled fires, and fuels characterizations represent ignitions, fire spread, and flammability, respectively. These are all important components of wildfire risk. The three intermediate results were weighted and combined in the geographical information system (GIS) software to create a preliminary relative risk rating for each cell in the study region. All analyses were completed using ArcView 3.2a GIS software. Cell (a term used in ArcView for a specific bounded surface area) resolution was set at 49 feet by 49 feet (15 meters by 15 meters).

D.5.1.3.2 Region of Interest

The study region was based on an area used for previous analyses of wildfire behavior (Balice et al. 2000). This included most of LANL and all of its areas west of TA-18. To the west, north, and south, the region of interest extends to the crest of the Sierra de los Valles and the eastern portion of the Valles Caldera National Preserve, the northern extent of the Los Alamos townsite, and Frijoles Canyon, respectively. Typical vegetation in this area consists of pinyon-juniper woodlands, ponderosa pine forests, mixed conifer forests, aspen forests and grasslands. Occasional barren areas, shrub lands, and spruce-fir forests also are found in the study region. Numerous developed areas, including the Los Alamos townsite and the TAs at LANL, are also interspersed throughout the study region.

D.5.1.3.3 Lightning Strike Densities and Intensities

Lightning strikes that were less than 100,000 amps in intensity were removed from the dataset. Lightning strikes that were located outside of a test region were also removed from the dataset. The 131 remaining lightning strike locations and their relative intensities were analyzed in ArcView. From these point locations, a map of densities by relative strike intensities was created and scaled from 0 to 1, with 1 representing the greatest combined strike density and intensity. The cell-based output of scaled values represents the relative tendencies that fires would be ignited within the polygons.

D.5.1.3.4 Modeled Fire Polygons

To assess the potential for fires to burn within each ArcView cell, wildfires were simulated from each lightning strike location using scenarios that reflected conditions in the Los Alamos region for the 1999 time period (57 lightning strikes) and the 2002 time period (49 lightning strikes), respectively. FARSITE was used as the modeling software (USDA 1998). FARSITE was previously parameterized with locally collected data representing the fuels and fire hazards of the Los Alamos region. The parameterized fire behavior modeling system also was validated against the burn histories of known fires.

The databases representing the 1999 time period were derived from vegetation and fuels conditions that were present in the Los Alamos region before the Cerro Grande Fire, before the initiation of major thinning and fire hazard reduction activities, and before the initiation of drought-induced mortality. All other conditions for fire behavior simulations were assumed to be those that existed immediately before or during the Cerro Grande Fire. The databases representing the 2002 time period incorporated changes that resulted from the Cerro Grande Fire, large-scale forest thinning activities, and tree mortality.

Each simulation produced a polygon representing the potential area burned by a wildfire. These multiple theme layers or polygons were then superimposed in the GIS, and the total number of fire polygons that occurred in each cell was summed. For both the 1999 time period and the 2002 time period, the greatest number of simulated fires in any given cell was 11. Cell values were then scaled from 0 to 1 based on these values, with 1 representing those cells where 11 simulated fires occurred. The final scaled values represent the relative tendency of a fire to burn through a cell under the conditions of the simulation. Those cells with more fires were assumed to be at greater risk of a fire actually burning through that cell.

D.5.1.3.5 Fuel Conditions

The fuel model concept, canopy heights, and percent canopy cover were used to model the fuel conditions at each ArcView cell. Values for these parameters were established from previous field sampling conducted throughout the Los Alamos region from 1997 through 2004. The fuel models were ranked by their relative ability to support more intense fires. Similarly, 100 feet (30 meters) was assumed to be the maximum canopy height, and all other canopy heights were ranked proportionally to this maximum value and scaled from 0 to 1. For canopy cover, 100 percent cover was set as the maximum possible, and the actual percent canopy cover values were rated proportionately between 0 and 1.

Previously developed land cover classification systems for assignment of fuel model, canopy heights, and percent canopy cover values to each land cover class were used. This was performed for conditions that were typical of the 1999 and 2002 time period. These scaled class assignments were applied to ArcView versions of land cover maps that were developed before and after the Cerro Grande Fire.

D.5.1.3.6 Wildfire Model Development

The five data layers of lightning, modeled fires, and fuel conditions (three layers) for each time period were mathematically combined in the GIS to assess spatial trends of fire risk across the study region. Equal weight was given to each of these three major risk groups according to the following relationship:

> {Density of lightning strikes by their relative intensity + relative number of simulated fires + [relative canopy height + relative percent canopy cover + relative fuel model]/3}/3.

Finally, the values for these calculated fire risks were scaled from 0 to 1. The analysis was repeated for conditions that existed in approximately 1999. This was before the Cerro Grande Fire, before extensive thinning was initiated, before rehabilitation treatments were applied to the forests of the region, and before the onset of major mortality events. Then the process was repeated for the 2002 conditions, after the Cerro Grande Fire, after the thinning of approximately 7,000 additional acres (2,800 hectares), and after the onset of tree mortality.

D.5.1.3.7 Wildfire Model Results

Results indicate that the risk of wildfires within the study region is not homogeneous through space and time. With regard to time, the relative wildfire risks are seen to decrease from the 1999 time period (see **Figure D–1**) to the 2002 time period (see **Figure D–2**). The greatest decrease in the wildfire risk appears to have taken place in the mountainous regions on the western boundary of LANL and further to the west, as well as in the mesa and canyon regions of the western and central portions of LANL.

Spatial variations in wildfire risk for the 2002 time period show a general decrease in risk from the mountainous regions in the west to the lower elevations in the eastern portion of the study region. A general ranking of the specific areas for their relative risk is also possible.

First, the greatest fire risk occurs along the Pajarito Ridge from New Mexico (NM) 501 to the Pajarito Ski Area.

Second, the next greatest fire risk occurs in the southwest corner of LANL, adjacent to the Back Gate.

Third, relatively high fire risks occur in the intervening areas along NM 501 and the western boundary of LANL.

Fourth, relatively high fire risks occur along portions of the mesa-canyon areas between TA-40 and TA-21. This is particularly true for the north-facing slopes of the canyons, although some of the other topographic positions in this area resulted in lower fire risk levels.

Fifth, the remaining portions of LANL and its immediate surroundings are at relatively less risk from wildfires.

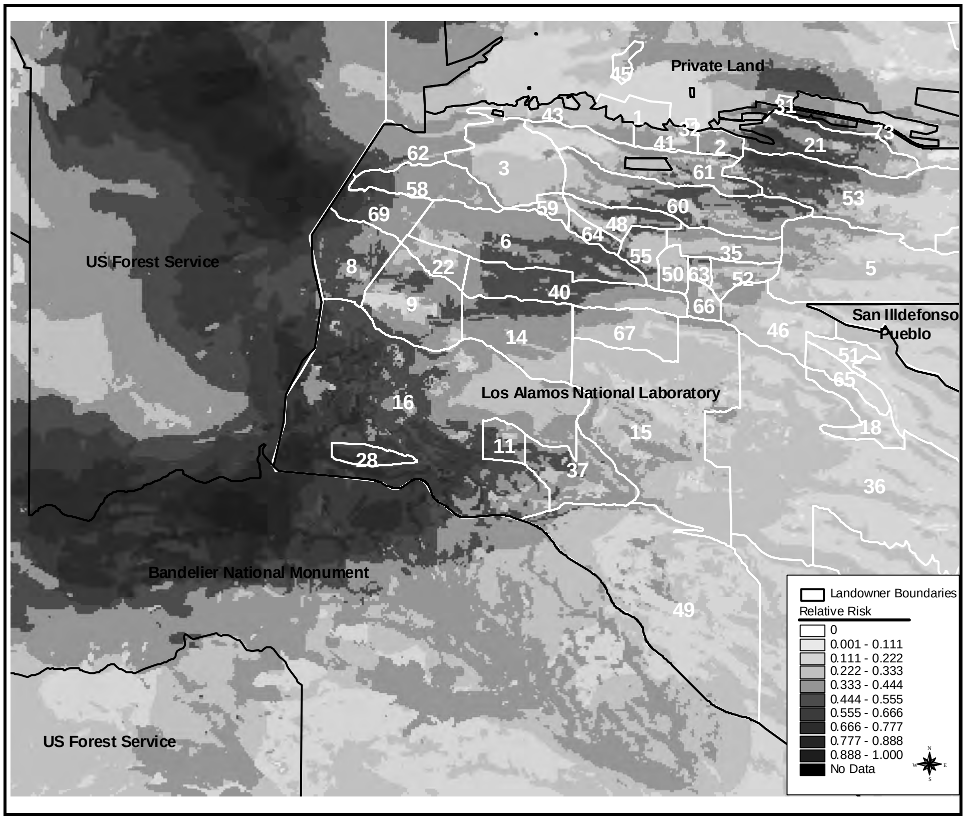

Figure D–1 Relative Risk of Wildfire in the Los Alamos Region (1999)

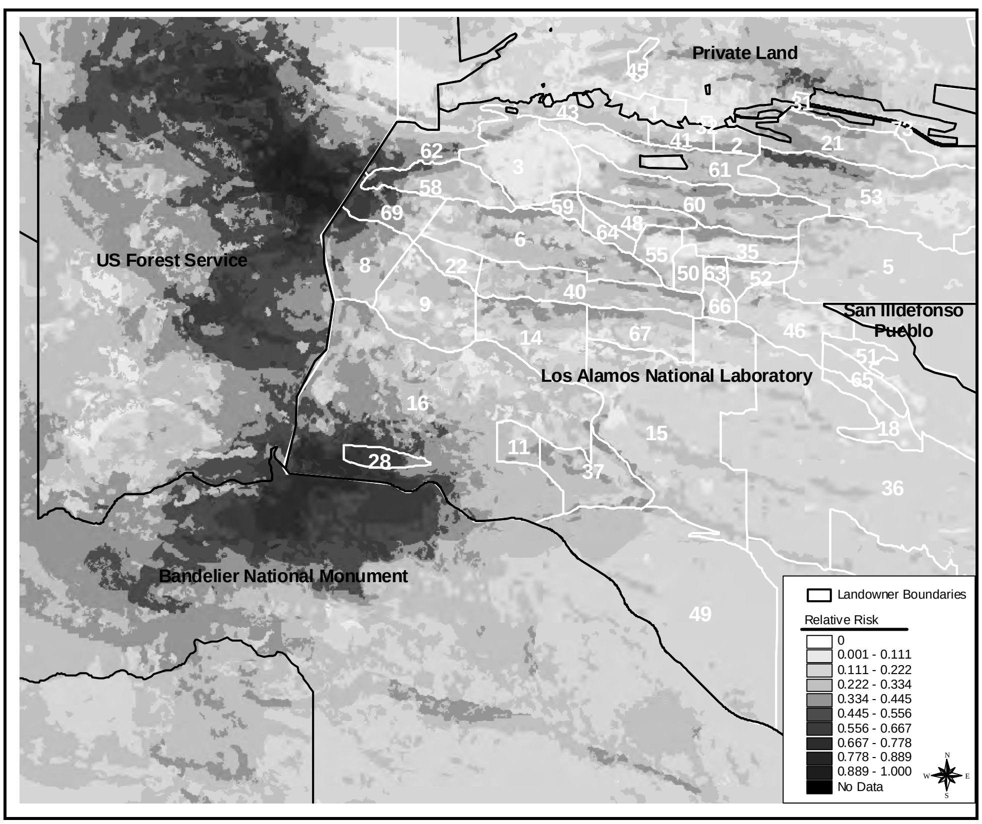

Figure D–2 Relative Risk of Wildfire in the Los Alamos Region (2002)

D.5.2 Current Wildfire Hazard Conditions

This section discusses the current wildfire hazard conditions and likelihood, reflecting changes that have occurred since the late 1990s. The analysis is taken from LANL 2004.

D.5.2.1 Changes to the Fuels and Fire Hazard Conditions in the Past 5 Years

Current fuels and fire hazard conditions in the Los Alamos region are not the same as those that existed in the late 1990s. This is reflected in the most credible wildfire scenario that would be expected in the present time period, which is considerably different from what would have been expected before 2000. In the wildfire scenario reported in the *1999 SWEIS* (DOE 1999a), fuels were heavy and continuous throughout most of the mixed conifer forests of the Sierra de los Valles and extended eastward to the ponderosa pine forests on most of the western portions of LANL property. As ponderosa pine forests transitioned to pinyon-juniper woodlands toward the eastern half of LANL, the canopy heights and the total fuel loads were reduced somewhat, but maintained the continuous nature of their overstory cover. These heavy and continuous fuels, especially in the mountainous environments, coupled with the southwest-to-northeast wind patterns that are typically prevalent during the fire season, suggested a general wildfire scenario that was validated by the Dome Fire and the Cerro Grande Fire.

In the general wildfire scenario of the 1990s, fire would be ignited by lightning or by humans in the mountains during high to extreme fire danger levels. A small fire of this type would burn lightly for a day or two until the combination of temperature, humidity, and wind worsened to the point that the fire extended from the ground surface through the fuel ladders into the forest overstory. At this time, the winds would carry the fire through the tree crowns from the mountains in a northeasterly direction toward LANL. The fire would continue to spread across LANL for up to 10 days. During this time, all unprotected buildings and facilities in its path would be destroyed. Suppression of the fire would be impossible until the weather conditions moderated sufficiently to allow the application of effective suppression measures.

Since the writing of the *1999 SWEIS*, several aspects of the wildfire conditions in the Los Alamos region have changed significantly; however, some aspects of the wildfire conditions in the region have not changed. For example, ignition sources have not changed since the *1999 SWEIS*. During both time periods, fires most likely would be ignited by lightning or by humans. Moreover, ignitions would typically occur most prevalently in the mountainous environments to the west of LANL. Topographic conditions in the Los Alamos region also have not changed since the *1999 SWEIS*. The mountainous environments to the west of LANL and the canyon-mesa environments at LANL present difficulties in managing and suppressing fires and create safety and management issues related to transportation and movements across these topographic barriers. In addition, the patchwork of land management agencies in the Los Alamos region has not changed since the *1999 SWEIS*, which creates unique problems for wildfire hazard management that can only be resolved through strong interaction and collaboration among the individual agencies.

Some aspects of weather have changed since the *1999 SWEIS* and some have not. Severe wildfire weather conditions tend to occur from mid-April to early July, and these have not been altered since 1999. Similarly, there is still a significantly strong tendency for intense winds to occur during this time period, and the direction of these winds tends to be from the southwest to the northeast. Moreover, the density of lightning strikes is high during the latter portions of the wildfire season, and this has altered since the writing of the *1999 SWEIS*. What has changed with respect to weather conditions since the *1999 SWEIS* is that the climate has grown significantly hotter and drier. Precipitation levels are somewhat similar to the 1950s drought; however, recent temperatures have been significantly higher (Breshears et al. 2005).

The wildfire hazard that changed extensively since the *1999 SWEIS* is fuel levels in the Los Alamos region. First, the Cerro Grande Fire greatly reduced fuels in more than 42,000 acres (17,000 hectares) of forested landscape at LANL and to the west of LANL. This was especially true in the severely burned areas where re-establishment of fuels has been limited to regrowth from sprouting shrubs and from seeded grasses. In contrast, regrowth of vegetation in the lightly burned and moderately burned sections of the Cerro Grande Fire has resulted in very little net change in fuel levels in these areas. Moreover, reseeding with grasses in the severely burned areas of the Cerro Grande Fire and other rehabilitation techniques have resulted in major changes to the post-fire fuel conditions. Immediately after the fire, severely burned forests were essentially unburnable; however, with the establishment of seeded grasses and with the addition of dead trees that have fallen to the ground, many of these areas can now support a surface fire.

In addition to past fires, fire hazard reduction activities in forests and adjacent to facilities at LANL have altered the fuel structures. Before 1997, the forests and woodlands at LANL were essentially unmanaged and severely overstocked with trees and shrubs. The result was a situation that was dangerously high in fuels and fire hazards throughout most of the forests and woodlands at LANL. Between 1997 and 1999, approximately 800 acres (324 hectares) of ponderosa pine forest on the western perimeter of LANL and near critical facilities were thinned from below. These fire hazard reduction activities increased dramatically after the Cerro Grande Fire. Between 2001 and 2003, approximately 6,000 acres (2,428 hectares) of ponderosa pine forests and pinyon-juniper woodlands were thinned. These fire hazard reduction activities focused on creating defensible space around critical buildings and facilities, underneath power lines and along transportation corridors, and in the surrounding forests and woodlands.

D.5.2.2 Potential Wildfire Scenarios

The results of the wildfire risk analysis incorporating altered fuel conditions that have occurred in the past few years suggest the heightened likelihood that some general wildfire scenarios will occur compared to other scenarios at LANL. Wildfires that occur today would still be ignited by lightning or by humans. These fires would tend to be ignited in the mountainous regions to the west of LANL, but fires also could be started on the LANL site. High winds during the fire season from mid-April to early July would still tend to carry actively burning wildfires from the southwest to the northeast. This general scenario is consistent with another recent wildfire risk analysis for LANL (Balice et al. 2005). Early suppression of wildfires is important to the successful protection of buildings and facilities. Once these fires enter the canopy of forests, they are difficult to control until weather conditions moderate.

The major impact of fire hazard reduction activities in recent years at LANL is that fires would tend to remain on the ground surface and would more readily drop from the canopies back to the ground surface. This, in combination with the creation of defensible space adjacent to LANL facilities, would facilitate management and suppression with the result that buildings and facilities would be easier to protect.

With the greatest modeled risk from wildfires occurring along the Pajarito Ridge and along the margins of the Frijoles Canyon, the risk to LANL would still largely arise from the west and the southwest. TA-16, TA-28, TA-58, TA-62, and TA-69 would be at the greatest risk from wildfires. The second greatest risk from wildfires would occur along the western borders of LANL; TA-8 and TA-9, and portions of TA-16 would be at risk from wildfires arising in this area. Secondarily, TA-3, TA-6, TA-11, TA-14, TA-22, TA-37, TA-40, and TA-59 also would be at risk from fires arising along the western boundary at LANL. In all of these cases, fires would enter the canyon environments on LANL property. This would create difficulties for control and management and increase the danger to adjacent buildings and facilities.

Fires that originate from within the boundaries of LANL likely would be ignited at firing sites at central locations of the site. These would primarily impact TA-14, TA-15, TA-40, and TA-67. Numerous canyons dissect this area, which would add to the difficulties of suppressing these fires as they spread across adjacent mesas from canyon to canyon. In addition, the canyon environments contain conditions (topographic barriers, heavy fuel loads on north-facing aspects, and modified canyon wind patterns) that would complicate the direction of wildfire spread. The result would be that fires would tend to spread readily in down-canyon and up-canyon directions and travel across mesas or via airborne embers to adjacent canyons.

D.5.2.3 Frequency of Wildfires

The probability component of the risk equation reported in the *1999 SWEIS* only considered the advancement of a large wildfire to the LANL boundary and assumed that this fire would continue on a path through LANL, reaching and igniting LANL buildings and causing a radiological release.

The frequency of a large fire encroaching on LANL (1 in 10 years) was estimated in 1999 as the joint probability of ignition in the adjacent forests, high to extreme fire danger, failure to promptly extinguish the fire, and fire-favorable weather. The frequency estimate for ignition in the adjacent forests was based on a 21-year period (1976 to 1996) and probably has not changed appreciably in the years since. Fire ignitions have continued to occur in adjacent forests. Periods of high to extreme fire danger have continued to occur frequently during the summer months, and fire-favorable conditions have continued as well. The estimated likelihood of a fire reaching a LANL boundary did not include the likelihood of a fire advancing across LANL to encroach on buildings containing radiological materials (in appreciable amounts), the likelihood of buildings igniting, and the likelihood of a release occurring once buildings are assumed to ignite. The likelihood of a fire encroaching on a building containing radioactive material depends on, among other factors, fuel load and continuity of fuel leading up to the space surrounding the buildings. The likelihood of a nuclear facility igniting depends on the joint probability of fuel load indices for fuel adjacent to buildings, the slope on which the adjacent fuel loads exist, and the combustibility of buildings. This factor was quantified in 1999 and has been updated recently. The likelihood of a release would be related to the damage ratio (likelihood that the material at risk was actually impacted by the accident) and the leak path factor (likelihood that confinement, if any, is breached). While the probability of a large fire encroaching on LANL remains moderate to high depending on location, probably still on the order of 1 in 10 years (0.1 per year), the probability of a LANL facility containing an appreciable radiological inventory being ignited by a wildfire and releasing some or all of the inventory has been reduced somewhat by the "defensible space" thinning and by the reductions in fuel caused by the Cerro Grande Fire.

Since the probability estimate for the *1999 SWEIS* stopped at the LANL boundary, there is no value for the probability of the fire advancing across LANL to nuclear facilities, igniting buildings, and causing a release. Without this value, an assessment of how this probability might have changed cannot be made. Gonzales, Ladino, and Valerio (2004) conservatively estimated that there is a 50 percent chance that the three factors just mentioned occur and combined this probability value (0.5) with the assumed probability for a wildfire reaching the LANL boundary (0.1). This resulted in a conservative estimate of the probability that a release would occur due to a wildfire and result in radiological exposures of 0.05 per year. This translates to a 5-in-100-year chance of occurrence, which is equal to 1 in 20 years. This estimate is in agreement with the draft Documented Safety Analysis for Area G. The fact that the Cerro Grande Fire did not result in the ignition of a LANL nuclear facility is evidence that thinning works and preventative maintenance will keep key facilities safer from wildfire than in the past.

D.5.2.4 Conditions that Favor Wildfire

In view of the present density and structure of fuel surrounding and within LANL and the occurrence of five major fires in the past 50 years it is evident that there is the potential for wildfire occurrence at LANL. Some protection is afforded LANL by the fire scars of the previous Dome and La Mesa Fires, but there is ample fuel continuity remaining to bring an offsite wildfire to the southwest and western boundary of LANL. The current analysis accounts for the environmental changes and fuel reduction mitigation that have occurred due to the Cerro Grande Fire.

The probability of high to extreme fire danger is determined by the frequency of meteorological conditions of low precipitation for 2 to 3 weeks preceding; low relative humidity for 3 consecutive days; and high temperatures. When the high to extreme fire danger exists in New Mexico in May through July, there are certain to be multiple ignition sources (from lightning and human causes). The high frequency of lightning and lightning-caused fires in the Jemez Mountains was used in the analysis of fire risk. The frequency of a large fire encroaching on LANL is estimated as the joint probability of ignition in the adjacent forests, high to extreme fire danger, failure to promptly extinguish the fire, and a 3-day spell of southwesterly to westerly wind over 11 miles per hour (5 meters per second), low humidity, and no precipitation.

D.5.2.5 Determining the Joint Probability of Occurrence of Weather and Fire Danger Conditions

The probability of occurrence of the weather and fire conditions needed for a wildfire were determined using wind and fire danger data for April through June, the months when fire risk and frequency are greatest, of 1980 through 1998. Note that site-wide fires also are possible, but less probable, in other months besides April through June; thus, the annual frequency of fire–favorable weather is somewhat greater than quantified for April through June.

In general, wind direction at any location varies and does not persist in a single direction for a few days. LANL is no exception. At LANL, persistent daytime winds are interrupted for a few hours when nighttime drainage winds occur; however, granting short interludes of drainage flow, there are many instances in which a dominant direction, such as southwesterly, westerly, northerly, can exist for 3 days without precipitation.

To determine a fire-favorable weather frequency, 15-minute average wind data from the lower level of the TA-6 and TA-59 meteorological towers was used. For each day in April through June of 1980 through 1998, an average afternoon wind was calculated from the 15-minute data to eliminate the local diurnal changes in wind speed and direction that are common to the area. Average afternoon wind speeds of greater than 10 miles per hour (4.5 meters per second) are chosen to represent strong winds. While this threshold may seem low for a strong wind, wind gusts of over 30 miles per hour (13 meters per second) and sometimes over 40 miles per hour (18 meters per second) are seen on most days when the afternoon average wind is above 10 miles (16 kilometers) per hour. The wind direction thresholds are set at 180 degrees (southerly) through 292.5 degrees (west-northwesterly). Three-day periods from the same dataset were then examined to determine whether the precipitation, wind speed, and wind direction fell above or within set limits. All 3-day periods falling within the set limits were then extracted.

The results show that it is not uncommon to see a 3-day period exhibiting the selected characteristics in a given year and that, when such a 3-day period appears, it is likely that more than one such period will occur within that year. Specifically, the resulting statistics show that, of the 19 years examined, 5 displayed at least one 3-day period within the limits, or one every 4 years. Of these 5 years, 4 had an average of 3.6 3-day periods (an instance of 5 days in a row is counted as three 3-day periods.) This comes to 15.4 instances in 19 springs.

In summary, fire-favorable weather conditions occur on the order of once per year; the ignition sources are prevalent; and firefighting is hampered by limited accessibility. Therefore, analysis concludes that a major fire moving up to the edge of LANL is not only credible but likely, probably on the order of 0.10 per year. This frequency is the same for all alternatives.

D.5.3 General Wildfire Scenario

D.5.3.1 Description

The SWEIS wildlife scenario used in 1999 predicted a path and outcome very similar to the Cerro Grande Fire. Due to the extent and size of the Cerro Grande Fire and subsequent fire mitigation actions completed since the *1999 SWEIS*, a new fire risk analysis was completed to incorporate the environmental changes and lessons learned from the Cerro Grande Fire.

The scenario fire begins midday in the late April through June timeframe, at a time of high or extreme fire danger, and is not extinguished in the first hour. The initial location is in an area populated with heavy ponderosa pine fuels that is found at between roughly 6,500 and 8,200 feet (1,980 and 2,500 meters) elevation. As the fire grows, local jurisdictions respond to the fire, but are not effective due to characteristics such as remoteness, travel time, lack of road access, and fire behavior. Resources from more distant jurisdictions are alerted, but cannot arrive in a short time because of distance, limited roads, and opposing evacuation traffic. It proves impossible to put out the fire with the available resources and existing forest access before it enters LANL. Unlike the Water Canyon Fire (greater than 3,000 acres [1,214 hectares] in June 1954), La Mesa Fire (15,300 acres [6,191 hectares] in June 1977), Dome Fire (16,500 acres [6,677 hectares] April 25 to May 5, 1996), and Oso Fire (greater than 5,000 acres [2,023 hectares] in June 1998), but very much like the Cerro Grande Fire in May 2000 (43,000 acres [17,401 hectares]), the weather does not change in time to prevent the fire from sweeping across the western part of LANL and into the townsite.

This specific analysis assumes a common meteorological situation that favors the fire. In this scenario, the fire begins about 10 a.m., reaches a size of 1,000 acres (400 hectares) in 3 hours, and becomes a well-developed crown fire on a broad fire front containing 6,000 acres (2,400 hectares) on the second day. Like the La Mesa Fire, at times it advances at a rate of 0.5 miles (0.7 kilometers) per hour. It starts spot fires 0.5 to 1.25 miles (0.8 to 2.0 kilometers) in advance, aided by prevailing southwest winds of 20 miles per hour (9 meters per second) and low daytime humidity. It easily jumps canyons and existing fuel break lines around LANL and the townsite, similar to the Cerro Grande Fire.

The daytime convection column reaches to 20,000 to 25,000 feet (6,000 to 7,600 meters). In the Oso Fire, the fire burned as actively at night as in the day, with flame heights on the order of 100 feet (30 meters). In this scenario, in order to have a conservative (low height) plume rise, at night the temperature drops and the relative humidity increases. The nighttime plume rise is then about 2,000 feet (600 meters). The fire regains its intensity at 10:00 a.m. each day. Following fire passage, the smoldering remains of vegetation and structures emit smoke and contaminants at the surface level.

The fire reaches NM 4 and NM 501, the southwest edge of LANL, at noon on the second day. Protective actions are already being undertaken by LANL management, such as relocating some radionuclides, barricading some windows, and releasing nonessential personnel following existing emergency plans. The fuel break along these roads proves inadequate. At this point, the fire has progressed in areas where access is limited, hampering fire suppression activities due to concern for the safety of the firefighters. A control line is established at Pajarito Road and resources are concentrated there. Consequently, Pajarito Road is closed and is not available for public evacuation. The fire burns forest to the west of and within LANL, but its eastern extent within LANL is constrained by pinyon-juniper woodlands and defined by fuel continuity and density.

From the completed specific analysis of fuel loads and prediction of fire risks, it is estimated the TAs most at risk include TA-8, TA-16, TA-28, TA-58, TA-62, and TA-69. This differs slightly from the previous wildfire scenario, in which TA-15, TA-37, and TA-66 were used. Following the continuous fuel lines and steered somewhat by southwesterly winds, the fire enters and crosses Pajarito Canyon and Twomile Canyon; by 1:00 a.m. on the third day, it burns up to the Pajarito Road control line just west of TA-66.

Although the control line would be expected to contain most fires, in this conservative accident scenario, an adverse meteorological situation exists where the wind picks up to 54 mph (24 meters per second), as it did in the Cerro Grande Fire, causing the fire to cross NM 501. On the LANL site, the fire is assumed to consume all combustible structures in its path that are evaluated to be at moderate or higher risk from wildfire under the LANL Building Appraisal Program. The fire also exposes the surface of contaminated earth that was previously protected by vegetation in the firing sites and canyons. This text separately discusses exposures from fire that burns the soil cover and suspends the underlying soil and exposures from burning structures. Exposures from the latter are calculated individually, enabling the assessment of fires of lesser extent than the site-wide fire.

This accident analysis does not consider offsite damage directly caused by the flames and smoke from LANL fires or the direct effects of the fire on the townsite. It is recognized that continuous fuel joins the National Forest and the residential areas, and that fires in the canyons at LANL also could propagate into the townsite.

D.5.3.2 Dispersion Meteorology, Thermal Energy, and Soil Resuspension Following the Fire

The wildfire radiological release exposure analysis was performed using MACCS2, the same computer code used on the other radiological release scenarios described in this appendix. That code was exercised stochastically, sampling each hour of an annual meteorological dataset and using that hour as the initial conditions for plume transport. The reported doses are the mean values of each of these trials. Because the wildfire is more likely to occur in April through June, the meteorology for those months was extracted from a recent 4-year dataset (2000 through 2003) of hourly meteorology to form a synthetic annual dataset consisting of April through June 2000 through 2003 (with meteorology from July 1, 2003, filling out the final day of the set). The MACCS2 wildfire analysis used this synthetic meteorology dataset.

The wildfire chemical release exposure analysis was performed using ALOHA, the same code used in the other chemical release scenarios described in this appendix. That code uses deterministic meteorology such as a single wind speed and stability class to calculate downwind dispersion. Table D-2 shows that stability class D and 7.8 mph (3.5 meters per second) wind speed represent median dispersion conditions for the synthetic dataset used in the MACCS2 analysis.

Exposures were calculated at 330 feet (100 meters) and the nearest public access to a release. These exposure locations are consistent with those chosen for the other scenarios included in this appendix. In the event of a wildfire scenario such as that considered here, the location of the public and onsite personnel such as firefighters might not correspond to those associated with the other scenarios considered. Chemical exposure at an additional location, 3,300 feet (1,000 meters) from each release, is therefore included. Radiological exposures at additional downwind distances, including 3,300 feet (1,000 meters), from each release are given in Section D.7.

The thermal energy of the contaminant plumes is a strong determinant of plume exposure; the greater the energy, the greater the plume buoyancy and the less impact on receptors along the ground. As described in the previous subsection, the daytime plume rise could reach up to 25,000 feet (7,600 meters), while the nighttime plume rise is conservatively assumed to be only 2,000 feet (600 meters). MACCS2 was run with the meteorological dataset described above and a plume heat input of 20 megawatts was found to result in a plume rise of approximately 2,000 feet (600 meters). That heat input was used for the fire phase of all radiological releases. ALOHA conservatively assumes no heat input; therefore, no buoyant rise due to heat is included in the chemical exposure calculations.

Following the fire release, a 24-hour wind suspension release period was assumed. It is thought that after the fire has passed, mitigation may not occur for this time period. An airborne release rate, 4×10^{-6} (4 parts per million) per hour, was chosen to reflect that contamination remaining at the source will likely be covered with fire debris.

D.5.3.3 Exposures from Burning Vegetation and Suspended Soil

Suspended ash from vegetation and suspended soil contributed about 7 percent (approximately 50 person-rem) of the total population radiological dose reported in the *1999 SWEIS*. Concentrations of radionuclides in vegetation at LANL were largely unavailable when that SWEIS analysis was performed in the late 1990s. Given plant and soil uptake coefficients for some radionuclides in the published literature, concentrations of radionuclides in plants were largely based on concentrations in soil. Since the *1999 SWEIS*, data have been compiled on concentrations of radionuclides in vegetation at LANL. Comparing data used in the *1999 SWEIS* with more recent data on concentrations of radionuclides in plants, perspective can be gained on the change in vegetation as a radiation source term for wildfire. One concentration used in the *1999 SWEIS* was 320 micrograms (μg) uranium per gram (g) of dry vegetation, which was taken from a sample collected in 1975 where uranium concentrations in surface soils were 20 to 3,500 times background levels. This compares to maximum concentrations of 0.65 μg/g-dry in the bark of shrubs that were rooted in transuranic waste material; 0.073[4] μg/g-dry in understory vegetation collected at one of 12 LANL Environmental Surveillance Program onsite locations in 1998; 0.066[3] μg/g-dry in overstory vegetation at one of the same 12 locations in the same year; 0.05[3] μg/g-dry in pine needles from TA-16 in 1985; 0.72[5] μg/g-dry in overstory vegetation at the Dual-Axis Radiographic Hydrodynamic Test (DARHT) Facility in 2002; and 1.5[6] μg/g-dry in pinyon tree bark at a firing site in 2001 (Gonzales et al. 2004). Other than total uranium, the *1999 SWEIS* does not identify the concentrations used in source term calculations. Ignoring the other radionuclides and based on comparison of the total uranium concentration assumed in the earlier SWEIS with other, more recent data on concentrations of total uranium in plants, the source term from vegetation used in the *1999 SWEIS* is still bounding of any that would be calculated using more recent concentration data. The predicted MEI dose from vegetation and soil in a site-wide fire remains less than 1 millirem. Although the Cerro Grande Fire burned only about 7,500 acres (3,040 hectares) of forest within LANL, the estimated inhalation dose to an MEI based on measurements of 0.2 millirem (LANL 2001) supports the hypothesis that vegetation and soil contribute very little radiation dose.

The effect of the existing radioisotope concentration in the soil in and around LANL on the calculated radiological consequences of a postulated wildfire was evaluated. Environmental

---

[4] *Computed using an ash/dry weight ratio of 0.1 from Fresquez and Ferenbaugh (1999).*
[5] *Computed using an ash/dry weight ratio of 0.08 from Fresquez and Ferenbaugh (1999).*
[6] *Computed by converting radioisotopic data to uranium mass data and using an ash/dry weight ratio of 0.029 for bark from Gonzales et al. (2004).*

surveillance data from the top 2 inches of soil measured in the 2001 through 2004 time period were used. These measurements were made for the following radioisotopes: tritium, strontium-90, cesium-137, uranium-234, uranium-235, uranium-238, plutonium-238, plutonium-239, plutonium-240, and americium-241. Assuming a wildfire occurred that burned the same 43,000 acres (17,400 hectares) as the Cerro Grande Fire and that the mean radioisotope soil concentration was the same as the mean measured for the onsite LANL areas, the airborne respirable source term was calculated to be approximately 10 curies of tritium and 0.2 curies of uranium and transuranic radioisotopes. The total released respirable source term for all of the buildings affected by the postulated wildfire accident in Appendix D is approximately 1.45×10^6 curies of tritium and 100 curies of uranium and transuranic radioisotopes. Therefore, the conservatively calculated soil-released source term from a Cerro Grande-size fire is a factor of about 500 to 100,000 times smaller than the source term released by buildings affected by the fire. This much smaller magnitude of source term, coupled with the fact that it would be released over a very large distributed area, shows that the radiological effect of releasing radioisotopes in the soil during a large fire at LANL is insignificant compared to the radiological consequence of the fire's effects on certain buildings at LANL.

D.5.4 Methodology

D.5.4.1 Evaluation of Building Fires

The *1999 SWEIS* analyzed potential individual and population radiological and chemical exposures from buildings burning as a result of wildfire initiation. Each building was first screened for its vulnerability to wildfire. Building vulnerabilities were updated in 2004 for this analysis. The building vulnerabilities at TA-54 and the Weapons Engineering Tritium Facility in TA-16 were validated in the field to incorporate the many fuel load mitigations that occurred in the recent past. Those buildings that were evaluated as vulnerable were then screened for chemical and radiological inventories that were updated in May 2004.

Criteria and Process for Determining Building Vulnerability to Wildfire

The evaluation of vulnerability to wildfire is based on building construction, materials and exposure, slope, and the quantity and structure of external fuel as described below. The total wild land fire vulnerability of over 500 buildings is frequently updated by the LANL Fire Protection Group. The vulnerability is the product of the structure hazard times the sum of the fuel hazard and slope hazard, as defined below.

Structure Hazard

The structure hazard rating considers the combustibility of the exterior structure:

- Underground – 0
- Noncombustible exterior (windowless) – 1
- Noncombustible exterior (window exposures) – 2
- Combustible exterior – 3

Fuel Hazard

The fuel hazard is the product of two components, fuel loading and distance factor. Fuel loading is taken as 0 for short grass and asphalt; for other conditions, it is determined by the fuel model type, as described in *Aids to Determining Fuel Models For Estimating Fire Behavior* (Anderson 1982).

The distance factor (DF) expresses the distance of the fuel from the structure:

- DF–0 – distance is greater than 4 times the height of the fuel.
- DF–1 – distance is greater than 2 times the height of the fuel.
- DF–2 – distance is the height of the fuel.
- DF–3 – distance is less than one-half the height of the fuel.

Slope Hazard

Exposing slopes are rated as follows:

Slope Hazard	***Slope***
5	Mild (0 to 5 percent)
10	Moderate (6 to 20 percent)
15	Steep (21 to 40 percent)
20	Extreme (41 percent and greater)

The total vulnerability is then calculated as the product of the structure hazard times the sum of the fuel hazard and slope hazard. This number is converted to a word description as follows:

Numerical Rating	***Vulnerability***
0 to 5	None
6 to 49	Very Low
50 to 79	Low
80 to 149	Moderate
150 to 259	High
260 and above	Extreme

Note that this method does not estimate the probability that a wildfire will consume the building. Rather, it quantifies the relative vulnerability of a building to wildfire on the basis of the conditions immediately surrounding a building and the construction type for each building. **Table D–21** lists the buildings that have a moderate or higher risk. Other buildings have no significant amounts of MAR and were not evaluated for this accident analysis.

Since 1999 when the results of this vulnerability assessment were first reported, a reduction in vulnerability from 51 to 21 buildings classified as moderate or higher has been achieved, largely as the result of clearing or thinning the forested areas (defensible space) immediately adjacent to the buildings. More importantly, buildings of concern that are located in the wildfire high-risk area, such as Weapons Engineering Tritium Facility in TA-16, have been downgraded to low vulnerability.

The *1999 SWEIS* analysis assumed that buildings with a moderate, high, or extreme wildfire vulnerability burned and released their entire content of radiological inventories. A reduction in the wildfire vulnerability of key buildings through reductions in the fuel load around the buildings could substantially reduce the likelihood of the buildings igniting and could also reduce the release of radiological materials by lowering the intensity of the fire. Since 1999, however, the wildfire vulnerabilities of two formerly high risk waste storage domes (Buildings 229 and 230) at TA-54 have been lowered to moderate. The Weapons Engineering Tritium Facility wildfire vulnerability has been reduced from moderate to very low.

Table D–21 Evaluation of Vulnerability of Los Alamos National Laboratory Buildings to Wildfire

Technical Area	*Building*	*Wildfire Risk*	*Nuclear Facility*	*Hazards*	*Construction Type* [a]
03	0016 and 0208	Moderate	No	Radiological	2
03	0040	Moderate	No	Radiological	2
03	0066 and 0451	High	No	Radiological, Chemical	2
03	0169	Moderate	No	Radiological	
08	0023	High	No	Radiological	2
21	0155	Moderate	No	Radiological	
21	0209	Extreme	No	Radiological, Chemical	2
36	0001	Moderate	No	Radiological	
41	0001 and 0004	Moderate	No	Radiological	
43	0001	Extreme	No	Radiological, Chemical	2
54	0033	High	Yes	Radiological	
54	0048	Moderate	Yes	Radiological	
54	0049	Moderate	Yes	Radiological	
54	0153	Moderate	Yes	Radiological	3
54	0215	Moderate	No	Radiological	3
54	0224	Moderate	No	Radiological	3
54	0226	Moderate	Yes	Radiological	3
54	0229	Moderate	Yes	Radiological	3
54	0230	Moderate	Yes	Radiological	3
54	0231	Moderate	Yes	Radiological	3
54	0232	Moderate	Yes	Radiological	3

[a] Construction type: 2 = noncombustible exterior with window exposures, 3 = combustible exterior.

Current sources of information were consulted for data on the relative quantities of radiological material at risk of potentially being impacted and released in an accident situation. By definition, only Hazard Category 1 and 2 nuclear facilities can have offsite impacts from their radiological material inventories when considered on an individual basis. However, because site-wide accidents can involve releases from several facilities, Hazard Category 3 nuclear facilities and nonnuclear (radiological) facilities were also considered. Nuclear facilities that are rated extreme, high, or moderate vulnerability in Table D–21 and were within relatively high wildfire risk areas were selected for quantitative contaminant risk assessment. Three additional facilities in TA-16, Building 205 (WETF), Building 411 (Device Assembly), and TA-50-69 (WCRR Transportainer) were also included because, even though individual facilities may have low vulnerabilities, TA-16 is among the TAs at greatest risk from a wildfire and TA-50 has an outside vulnerable transportainer.

D.5.4.2 Public Exposure from Burning Buildings

The individual exposures assume no sheltering inside buildings or vehicles and no protective actions taken by the individual at those locations. Although Area G is not in the direct path of the fire, it borders a canyon and could be susceptible to a canyon fire even in the absence of a site-wide fire. The results of the *1999 SWEIS* found that Area G contributed 75 percent of the total population exposure. Therefore, it was again included in the wildfire analysis.

D.5.4.3 Effects of Hazardous Chemicals

Vulnerable buildings and the outdoors in the fire path were screened for their chemical inventories and updated for 2004. Six of the 12 facilities included in the *1999 SWEIS* eliminated their chemical inventories. Only TA-3-66 increased its inventory from 11.5 pounds (5.2 kilograms) of hydrogen cyanide to 13.5 pounds (6.1 kilograms) of hydrogen cyanide. For fire-vulnerable facilities, the earthquake scenario chemical results are acceptable representations of the site-wide fire because the entire inventories are assumed to be released.

D.5.4.4 Onsite Workers and Offsite Population

In the event of a wildfire approaching from the south, LANL would begin evacuation of the southern area of LANL as soon as it was determined that the fire posed a threat and would proceed north with the evacuation. Personnel deemed essential to shutdown operations would remain until such actions were completed. Some emergency response personnel and security personnel would remain at all times in some areas. In 1999, there were 10,200 LANL employees (including contractors), of which approximately 4,000 lived outside of Los Alamos County and 6,200 within Los Alamos County. The *1999 SWEIS* reported that the Main Hill Road (New Mexico 502) could evacuate 800 cars per hour, and the combination of the East Jemez and Pajarito Roads could evacuate another 800 cars per hour.

During the Cerro Grande Fire, it was decided that, if the fire jumped Los Alamos Canyon, the entire town of Los Alamos would have to be evacuated. Shortly after noon on May 10, the fire jumped Los Alamos Canyon, which was the last natural barrier before the townsite. At 1:15 p.m., county emergency personnel broadcast the directive for all of the people of Los Alamos to evacuate their homes immediately. Although some projections indicated that it would take up to 12 hours to get all 12,000 Los Alamos residents down the mountain using the single road (New Mexico 502), the entire town evacuated in 4 hours, directed by the small police force. On May 10, 2000, the fire burned over 15,500 acres (62,700 hectares) in 9 hours—in other words, the Cerro Grande Fire consumed in 9 hours the same amount of acreage that the 1996 Dome Fire consumed in 9 days. By late afternoon, the wind-whipped 200-foot (60-meter) wall of flame reached the western edge of town; by 6:00 p.m., the first reports of loss of houses came in to the Emergency Operations Center.

In the aftermath of the Cerro Grande Fire, there was considerable interest in describing the potential radiological impacts of the fire itself and of the radionuclides of LANL origin that may have dispersed during the fire. Radiological dose calculations were performed based on air monitoring data collected by the LANL AIRNET system during the Cerro Grande Fire. The dose calculated was the committed effective dose equivalent, which is the dose received during the 50 years following the inhalation of radionuclides. The inhalation dose to an MEI in Los Alamos was 0.2 millirem (LANL 2001). A dose of similar magnitude was conservatively calculated for Rio Grande water use, chiefly from assumed irrigation during peak runoff from a storm event (LANL 2002). These doses can be considered in the context of exposure to naturally occurring radioactivity in the LANL area of at least 400 millirem per year (see Chapter 4, Section 4.6.1.2, of this SWEIS).

All workers in threatened areas would be evacuated prior to arrival of the fire front. Aircraft crashes with fatalities have occurred while dropping slurry on wildfires. Firefighters on the ground are at risk if they enter an area without an alternate escape route, and there have been historical fatalities from such events. However, because life safety is given priority over protection of property at LANL, it is not likely that there would be worker fatalities. Some firefighters and other emergency personnel could have significant, but transient, effects from smoke inhalation.

D.5.5 Wildfire Accident Impacts Analysis

There are no significant impact differences among the wildfire risks for the three alternatives, No Action, Reduced Operations, and Expanded Operations. Therefore, only a single set of wildfire impacts are presented. The radiological impact section, D.5.5.2, includes a discussion of the alternatives.

D.5.5.1 Facility Source Terms

A wildfire accident scenario was postulated for evaluation of impacts to onsite workers and the offsite population. Details of this scenario are given in the preceding sections. **Table D–22** shows the LANL buildings that could be affected by the wildfire, inventory of hazardous radiological materials, source term factors, and estimated source terms.

D.5.5.2 Radiological Impacts

The estimated consequences for the public and workers as a result of a wildfire are shown in **Tables D–23** and **D–24** for each listed facility. The values shown assume that a wildfire has occurred and therefore do no reflect any credit for the probability of a wildfire occurrence. The estimated annual risks for the wildfire scenario are shown in **Table D–25**. The values shown in that table take credit for the probability of a wildfire's occurrence. The risk from a wildfire is dominated by the TA-54 waste storage domes. The second largest risk (although significantly less than the domes) is also from TA-54, DVRS.

Table D–22 Wildfire Accident Source Term Data

Accident Phase	*Nuclide*	*MAR (curies or grams)*	*MAR*	*Damage Ratio*	*Airborne Release Fraction*	*Respirable Fractions*	*Airborne Release Rate (per hour)*	*Leak Path Factor*	*Source Term (in units of MAR)*	*Release Duration (Delta T) (minutes)*	*Heat (mega-watts)*	*Release Height (meters)*	*Wake?*

MAR = material at risk, TA = technical area, MEI = maximally exposed individual.

Table D–23 Radiological Accident Offsite Population Consequences for a Wildfire Accident

Facility Impacted by Wildfire	MEI		Population to 50 Miles (80 kilometers)	
	Dose (rem) [a]	LCF [b]	Dose (person-rem)	LCF [c, d]
Sigma Complex (TA-3-66/451)	0.0039	2.3×10^{-6}	4.8	0 (0.0029)
Weapons Engineering Tritium Facility (TA-16-205)	0.061	0.000036	110	0 (0.067)
Radiochemistry Facility (TA-48-1)	0.0011	6.4×10^{-7}	0.44	0 (0.00026)
Waste Storage Domes (TA-54)	1,900	2.3 [e]	91,000	55 (54.8)
Device Assembly (TA-16-411)	1.6×10^{-6}	8.9×10^{-10}	0.00017	0 (1×10^{-7})
Decontamination and Volume Reduction System (TA-54-412)	4.9	0.003	1,200	0 (0.7)
Radiography (TA-8-23)	0.00033	2×10^{-7}	0.56	0 (0.00034)
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	27	0.032	6,900	4 (4.2)

MEI = maximally exposed individual, LCF = latent cancer fatality, TA = technical area.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Increased number of LCFs for the offsite population, assuming the accident occurs; value in parentheses is the calculated result.

[d] Offsite population size is approximately 297,030 for TA-03-66/451; 404,913 for TA-16-205 and TA-16-411; 299,508 for TA-48-1; 343,069 for Domes and TA-54-412; and 349,780 for TA-8-23.

[e] Based on a dose-risk-conversion factor of 0.0006 LCF per rem, the indicated dose yields an LCF value greater than 1.0 as shown. This means that it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For calculation purposes, the actual value is shown here; however, since the exposed recipient is an individual, the equivalent tables in Chapter 5, Section 5.12 show an LCF of 1.0.

Table D–24 Radiological Accident Onsite Worker Consequences for a Wildfire Accident

Accident	Noninvolved Worker at 110 Yards (100 meters)	
	Dose (rem) [a]	LCF [b]
Sigma Complex (TA-3-66/451)	0.076	0.000046
Weapons Engineering Tritium Facility (TA-16-205)	0.33	0.0002
Radiochemistry Facility (TA-48-1)	0.016	9.3×10^{-6}
Waste Storage Domes (TA-54)	8,700	11 [c]
Device Assembly (TA-16-411)	0.000017	1×10^{-8}
Decontamination and Volume Reduction System (TA-54-412)	16	0.0098
Radiography (TA-8-23)	0.0019	1.2×10^{-6}
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	440	0.53

LCF = latent cancer fatality, TA = technical area.

[a] Individual radiation doses in excess of a few hundred rem would result in acute (near-term) health effects or even death from causes other than cancer. In some cases, medical intervention may be effective in reducing the dose, mitigating health impacts, or both. The listed doses are calculated assuming that the exposed individual takes no protective action during the period of exposure and that no subsequent medical intervention occurs.

[b] Increased risk of an LCF to an individual, assuming the accident occurs.

[c] Based on a dose-risk-conversion factor of 0.0006 LCF per rem, the indicated dose yields an LCF value greater than 1.0 as shown. This means it is likely that an individual exposed to the indicated dose would develop a latent fatal cancer. For calculation purposes, the actual value is shown here; however, because the exposed recipient is an individual, the equivalent tables in Chapter 5, Section 5.12 show an LCF of 1.0.

Table D–25 Radiological Accident Offsite Population and Worker Risks for a Wildfire Accident

Accident	Frequency (per year)	Onsite Worker	Offsite Population	
		Noninvolved Worker at 110 Yards (100 meters) [a]	MEI [a]	Population to 50 Miles (80 kilometers) [b, c]
Sigma Complex (TA-3-66/451)	0.05	2.3×10^{-6}	1.2×10^{-7}	0.00014
Weapons Engineering Tritium Facility (TA-16-205)	0.05	1×10^{-5}	1.8×10^{-6}	0.0034
Radiochemistry Facility (TA-48-1)	0.05	4.7×10^{-7}	3.2×10^{-8}	1.3×10^{-5}
Waste Storage Domes (TA-54)	0.05	0.05	0.05	2.7
Device Assembly (TA-16-411)	0.05	5.2×10^{-10}	4.4×10^{-11}	5.2×10^{-9}
Decontamination and Volume Reduction System (TA-54-412)	0.05	0.00049	0.00015	0.035
Radiography (TA-8-23)	0.05	5.7×10^{-8}	1×10^{-8}	1.7×10^{-5}
Waste Characterization, Reduction, and Repackaging Facility (TA-50-69)	0.01 [d]	0.0053	0.00032	0.042

MEI = maximally exposed individual, TA = technical area.
[a] Increased risk of an LCF to an individual per year.
[b] Increased number of LCFs for the offsite population per year; value in parentheses is the calculated result.
[c] Offsite population size is approximately 297,030 for TA-03-66/451; 404,913 for TA-16-205 and TA-16-411; 299,508 for TA-48-1; 343,069 for Domes and TA-54-412; and 349,780 for TA-8-23.
[d] Assumes additional failures for source term used in calculation.

Inventories at TA-48-1 (Radiochemistry Laboratory) and TA-8-23 (Radiography Facility) were assumed to be at the building limits. Radiological source material would be at these locations only during material testing. The impacts and risks presented in this section conservatively assume the presence of this material at the allowable limits.

The health risks in Table D–25 (and consequences in D–23 and D–24) are given for individual building releases; it is unlikely that a wildfire would impact all of these facilities. For the case of a wildfire impacting all of these facilities, the overall health risk to the general population, dominated by waste storage domes and DVRS releases, is 2.7 per year, equivalent to a mean of 14 cancer fatalities in the entire general population (out to 50 miles [80 kilometers] from each release) every 5 years of LANL operation. This risk can be contrasted with the more than 2,500 normally occurring cancer fatalities to this same population over 5 years (see Chapter 4, Section 4.6.1). Risks to individuals, on the other hand, cannot be summed, because a single individual would not be exposed to multiple facility releases. Instead, only releases upwind from the individual's location would result in exposure. The maximum health risk to the MEI from any facility's release for exposure at the nearest Pueblo boundary to the waste storage domes is 0.05 probability (5 chances in 100) of an LCF per year of operation. It is highly unlikely that an individual would remain at this location during the entire wildfire event; therefore, this risk is thought to be very conservative.

Each of the building releases (except for the WCRR) was ascribed the same frequency of occurrence, 0.05. Section D.5.2 describes the potential of a wildfire affecting the various onsite technical areas. TA-54 is considered at a low (but not 0) risk of wildfire impacts relative to the other areas.

Tables D–23, D–24 and D–25 are strictly applicable to the No Action Alternative. The Reduced Action Alternative would include a 20 percent reduction in high explosives processing and a likely reduction in risk from the Device Assembly Building. However, the consequences and risk from that facility are insignificant; a decrease in its risk would not affect the overall wildfire risk.

Replacement risks from wildfire accident impacts would result from implementation of the Expanded Operations Alternative. Transuranic waste storage at DVRS and waste storage domes in TA-54 would be moved to a new facility, the TRU Waste Facility, located in TA-50 or TA-63. The impacts of this new facility would be less than those of the existing facilities because of the new location and because less material would be stored and the rest would be moved offsite. The entries in Tables D–23 through D–25 reflect present DVRS and waste storage domes operations because they would be active for part of the time period of interest and because their accident impacts bound the impacts of the new facility. TRU Waste Facility accident impacts are described in Appendix H.

D.5.5.3 Chemical

The chemicals of concern at LANL facilities under the No Action, Reduced Operations, and Expanded Operations Alternatives are shown in **Table D–26**. These have been selected from a complete set of chemicals used onsite based on their quantities, chemical properties, and human health effects. The table shows the ERPG concentration values for which excess concentrations could have harmful health or life-threatening implications, as defined in the table's footnote.

Table D–26 Chemical Accident Impacts under Wildfire Conditions

Chemical	Frequency (per year)	Quantity Released	ERPG-2 [a]		ERPG-3 [b]		Concentration		
			Value (ppm)	Distance to Value (meters)	Value (ppm)	Distance to Value (meters)	Noninvolved Worker at 100 Meters (ppm)	MEI at 1,000 Meters (ppm)	Nearest Site Boundary (12 m TA-43) (924 m TA-3)
Formaldehyde at TA-43-1	0.05	3.7 gallons (14.1 liters)	10	141	25	89	20	0.23	Exceeds ERPG-3
Hydrogen Cyanide at TA-3-66	0.05	13.5 pounds (6 kilograms)	10	108	25	68	12	0.14	0.16 ppm

ERPG = Emergency Response Planning Guideline, ppm = parts per million, MEI = maximally exposed individual, m = meters, TA = technical area.

[a] ERPG-2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their ability to take protective action (DOE 2004a).

[b] ERPG-3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects (DOE 2004a).

Note: To convert meters to yards, multiply by 1.0936.

Table D–26 shows the concentrations of each chemical, if it were released, at specified distances. For a formaldehyde release, the distances to the ERPG-2 and ERPG-3 levels of concern are 154 yards (141 meters) and 97 yards (89 meters), respectively. For a hydrogen cyanide release, the distances to the ERPG-2 and ERPG-3 levels of concern are 118 yards (108 meters) and 74 yards (68 meters), respectively. Depending on the magnitude of the release and plume characteristics, workers and members of the public could be exposed to harmful concentrations of each chemical within these distances from the point of release. Table D–26 also shows the estimated concentration of each chemical at a distance of about 110 yards (100 meters) from the release point where a representative noninvolved worker is assumed to be located. The seriousness of the exposure of a noninvolved worker at this distance is determined by comparing the concentration at that distance to the ERPG-2 and ERPG-3 levels of concern. In addition, Table D–26 also shows the estimated concentration at the nearest site boundary located at a distance from the release point of 13 yards (12 meters) and 1,010 yards (924 meters) for TA-43 and TA-3, respectively. The accident evaluation assumes a hypothetical member of the public is located at this site boundary. As in the case of the noninvolved worker, the seriousness of the exposure of a member of the public located at the nearest site boundary is determined by comparing the concentration at that distance to the ERPG-2 and ERPG-3 levels of concern. If concentration levels exceeding ERPG-2 and ERPG-3 were estimated to occur at distances beyond the site boundary, a segment of the offsite population could be exposed to harmful levels of the released chemical. The direction traveled by the chemical plume would depend upon meteorological conditions at the time of the accident.

D.5.5.4 Additional Environmental Effects

Firewater. Firewater (water used in fighting building fires) at nonnuclear facilities is captured by outdoor containment and temporary dikes erected for firefighting. Firewater at nuclear facilities is captured by the drain system and is sent to TA-50 for processing. Conceivably, some radioactively contaminated water from the nuclear facilities could reach the outdoor environment, but would be of such small volume that it would not leave the building environs. If there were a fire at TA-50, most of the firewater would wash off down the roads. If fire trucks had to spray water, some of that water would go to the adjacent canyon. Resultant contaminated soil would be eroded, pending the return of vegetative cover. As with other contaminated soils, the environmental and human health threat from the new contamination would be assessed and mitigated.

Loss of Protective Cover. The charred plant remains following a severe wildfire are the only immediate visual consequences. The consequences of a wildfire are diverse, continuous through time and space, and frequently include significant changes in geomorphology and biological communities and processes. LANL is perhaps unique in potential consequences because, in addition to a rich presence of biological communities and cultural remains and resources, the site contains soil-bearing legacy contaminants from historical operations.

Trees, grass and herbaceous cover, and forest litter are important features in stabilizing soils by: (1) reducing the velocity and impact of falling raindrops; (2) reducing the velocity of runoff, thereby encouraging infiltration and discouraging its transport by water and wind; and (3) reducing runoff quantities. Loss of vegetative cover will create a setting that can have pronounced effects on flow dynamics, soil erosion, and sediment deposition. These changes also can have significant ramifications for plant and animal communities and cultural resources.

Runoff, Soil Erosion, and Sedimentation. It has been well established through studies around the world that runoff and sediment yields can dramatically increase following wildfires. Accompanying these physical changes are changes in the composition or quality of runoff water. At Los Alamos, these changes may be severe due to the steepness of the burned terrain and the high severity of the burn, creating water-shedding hydrophobic soils. These higher runoff quantities would be discharged into the Rio Grande where they would contribute to the overall floodwater storage of Cochiti Lake. Modified hydrologic conditions likely would cause some watercourses that have only rarely had sufficient flows to reach the Rio Grande to increase their frequency of discharge.

Commensurate with higher runoff quantities and velocities would be an increase in soil erosion. Sheetflow would begin transporting soil suspended by rainfall droplet impact. Both rills and gullies would form on sloping ground surfaces with the first significant rainfall event. Higher channel volumes and velocities would promote both downward and lateral scouring of channels in the steeper portions of the watershed and sediment deposition in the lower portions. (These conditions depend on the quantity of runoff discharges and resulting changes in channel hydraulics.) Headcutting would increase throughout the channel system. Delta formation would increase at the confluence of watercourses and tributaries to the Rio Grande, and added sediment would contribute to the depletion of the sediment reserve of Cochiti Lake.

The gradual establishment of ground cover would correspondingly retard soil erosion and a more stabilized hydrologic regime would return. Extensive rehabilitation after the Cerro Grande Fire minimized runoff, soil erosion, and sedimentation. To understand the possible impact to downstream water bodies, runoff events after the fire were monitored and sampled by LANL staff. An extensive network of automated samplers and stream gages served as the cornerstone of this effort. Due to a general lack of intense “monsoon-like” rainfall during the summer of 2000, severe runoff passing across LANL was limited to a single event on June 28. Record peak discharges were recorded for several drainages leading onto LANL during that event. For example, in Water Canyon above NM 501, the estimated peak of 840 cubic feet (23,800 liters) per second dwarfed the prefire maximum of 0.3 cubic feet (8.5 liters) per second. Concentrations of most metals dissolved in stormwater remain below the Environmental Protection Agency or New Mexico drinking water standards; however, a few (for example, aluminum, barium, manganese) are above the standards in many samples. Dissolved manganese concentrations increased by about 50 times above prefire levels; barium by 20. Concentrations of radionuclides dissolved in stormwater are slightly elevated or comparable to prefire levels.

Effects on Legacy Contaminants. Active erosion processes have moved some contaminants bound to sediment from the watershed into the Rio Grande, mainly as suspended sediment and bedload sediment. Conversely, many of the remaining legacy contaminants at LANL are present in situ, have not been transported far from their origin, or remain onsite. Water transport is a major mechanism for the transport of contaminants in both the dissolved and suspended sediment phases. Because vegetation acts to hold soil and reduce erosion, its loss, however short-term, may significantly increase the potential for erosion and the transportation of contaminants. Some watercourses only rarely have had sufficient flow to reach the Rio Grande; as a result, they have become “discharge sinks” for some contaminants. Increases in runoff amounts and frequency would increase the potential to remove and transport contaminants from LANL’s ground surface, subsurface, and stream channels into the Rio Grande and downstream to Cochiti Lake.

Effects on Biological Systems. Although fire is a natural part of biological systems, anthropogenic influences such as grazing, logging, and fire suppression have produced conditions that have had pronounced adverse effects on forest ecosystems. Natural high-frequency, low-intensity fire regimes have been replaced with low-frequency, high-intensity fires that consume a higher percentage of vegetation. As reflected in other nearby areas that have experienced severe wildfires in the past (for example, the Water Canyon, La Mesa, Dome, and Oso Complex Fires), a wildfire at LANL would result in a period of disequilibrium with a reversion to early seral development and a corresponding change in animal use (Allen 1996). Fire debris, fallen trees, and needle cast would gradually begin to check erosion and develop soil conditions that would promote the establishment of grasses and herbaceous vegetation that would further reduce erosion. This gradual re-establishment of ground cover would begin the dynamic process of seral progression toward a wooded or forested plant community.

A loss of forest or woodland habitat would result in a temporary loss of habitat for a broad spectrum of animals. As vegetation is re-established, an altered community of animal species would follow, its composition changing with the evolution of the plant community. The pattern of burned vegetation would play a significant role in renewed wildlife use. Early plant communities of grasses and herbaceous growth can have a high biomass and species diversity, as exhibited by nearby areas affected by recent wildfires. This expansion of grass and herbaceous growth could provide additional forage for the large elk population in and around LANL and contribute to existing management concerns.

Impacts on threatened and endangered species (such as the Mexican spotted owl, *Strix occidentalis lucida*) would depend on several factors such as the burn pattern, the time of day the burn occurs, the type of fire, topography, and whether nesting is occurring. Threatened and endangered species have remained in or returned to nearby areas that have experienced recent burns. Individual response to fire also would vary. Perhaps the most significant impact to threatened and endangered species precipitated by a wildfire would be the general disturbance caused by the firefighting effort itself (firefighting crews, aircraft, and vehicular traffic).

As discussed previously, increased runoff discharges would result in a commensurate increase in channel scouring, enlargement, and headcutting. This process and any accompanying sedimentation would have the potential to degrade or remove the limited riparian vegetation on LANL. Wetlands associated with watercourses also would be affected, and perhaps several would be removed for a period because of changes in channel morphology. The degradation of riparian vegetation and wetlands would result in a reduction or loss of habitat for a variety of invertebrates, small and large mammals, amphibians, reptiles, and diverse bird species.

Effects on Cultural Resources. LANL is located in a region of abundant and culturally significant prehistoric and historic resources, including traditional cultural properties. As stated, fire is a normal feature of the landscape that has played and continues to play a natural role in the culture of regional communities. Because of anthropogenic influences, the character of recent fires will be different from historic fires and will affect resources differently. The need to protect property and life from wildfire will necessitate measures that can affect cultural resources.

As discussed, high intensity fires can burn an appreciable amount of ground cover and accelerate erosion. Surface erosion can physically disturb surface features and confuse and distort the contextual integrity of the site. More pronounced erosion in the form of gully formation and lateral bank cutting can permanently remove site features. A high-intensity fire also can scorch organic remains located near the ground surface, decreasing their interpretive value. Historical structures can suffer through direct incineration. Damage to these resources also can occur as a consequence of vehicular traffic and mechanical disturbance (from bulldozers and fire trucks for example) and other soil-disturbing activities connected with the firefighting effort.

Traditional cultural properties present on and adjacent to LANL include ceremonial and archaeological sites, natural features, ethnobotanical sites, artisan material sites, and subsistence features. These resources are an integral part of the landscape and almost certainly are and have been affected by natural fires. Because of the altered character of fires, these resources may be affected to a greater extent. Depending on the characteristics of these properties, they could be either permanently or temporarily affected by a wildfire and its subsequent ancillary effects, such as erosion.

D.5.6 Mitigation

After the *1999 SWEIS* was completed, actions were initiated to reduce the wildfire risk to major facilities with significant radiological inventories. Specifically, considerations were given to reducing the risk to low or very low for the following facilities:

- TA-3 Building 66/451, Sigma Complex
- TA-54 (Area G) Pads
- TA-21 Building 209, Tritium Science and Fabrication Facility
- TA-21 Building 155, Tritium Storage and Test Assembly
- TA-16 Building 205/205A, Weapons Engineering Tritium Facility

The planning, evaluation, and beginning of fire mitigation (described in DOE 1999b) that was completed prior to the Cerro Grande Fire undoubtedly contributed to minimizing the impacts to facilities and, possibly, human lives. There is an ongoing, interagency, collaborative program to reduce the threat of catastrophic wildfire occurring at LANL and the townsite by thinning and removing vegetation at the perimeter and in the surrounding Santa Fe National Forest and Bandelier National Monument. This will reduce the frequency and intensity of wildfires that could impact LANL.

D.6 Involved Worker Hazards

Facility workers generally fall into two groups: noninvolved worker and involved worker. Noninvolved workers have assigned duties on the site at a location beyond the general vicinity of an accident. The impacts of postulated accidents to the noninvolved worker are evaluated in this appendix and are presented in Chapter 5. Involved workers actively participate or support operation of the facilities directly involved with the Proposed Action. The analysis to determine involved worker risks are usually presented qualitatively due to the dynamics and potential worker proximity. In general, involved workers are protected by design safety features and operational procedures. Involved workers who are at the greatest risk of serious injury or fatality are those that are located in the immediate vicinity of where an accident takes place. Factors such as the time of the accident, an individual’s distance from the accident, and the effects of shielding mechanisms are highly variable. Given the severity of some accidents, involved worker fatalities could be expected. The number of fatalities could range from zero to the maximum number of workers involved within the facility. For example, an accident involving spills and exposure to contamination could lead to an individual receiving a measurable dose, but not lead to a fatality; however, in a severe earthquake accident, involved workers are likely to be hurt and killed by the collapse of a building before they can be evacuated.

No attempt is made in this SWEIS to evaluate the involved worker effects of such accidents for the following reasons. There is limited information on the circumstances that cause such accidents and the hazardous conditions they involve are difficult to characterize in a manner that would differentiate between alternatives and provide meaningful information for decisionmakers. Modeling methods such as those used for radiological and chemical accidents exposures are not accurate at close distances. Quantitative or qualitative representation of such accidents would introduce data uncertainties that would complicate the decisionmaking process.

The analyses performed by the authors of this SWEIS carefully considered the provisions of NEPA, Council on Environmental Quality Guidelines, and DOE NEPA Guidelines regarding acceptable procedures for estimating the environmental impacts of events where the available data are both uncertain and limited. These provisions and guidelines permit the use of the "sliding scale approach" (DOE 2002b), which allows the analyst to consider specified key factors for determining an appropriate level of technical analysis for estimating impacts.

According to DOE NEPA Guidelines, the key factors to consider in applying a sliding scale approach to accident analyses include:

- Probability that accidents will occur;
- Severity of the potential accident consequences;
- Context of the Proposed Action and alternatives;
- Degree of uncertainty regarding the analyses (for example, whether sufficient engineering design information is available to support detailed analysis); and
- Level of technical controversy regarding the potential impacts.

More recent DOE guidance was also used for the preparation of this SWEIS (DOE 2004e).

D.7 Maximally Exposed Individual-Type Doses versus Distance

Sections D.3, D.4, and D.5 describe various facility and site-wide accident scenarios and the estimated exposures to the accident releases, were such accidents to occur. Exposure to radiological releases is described by dose, measured in rem, to an individual. Exposure to a population is generalized by summing the dose to each individual of that population; the population dose is thus measured in person-rem.

Exposures of the hypothetical noninvolved worker and MEI have been given in the previous sections. These are conservative representations of the exposure to any single individual from the plume that could emanate as a result of an accident. They are mean values, and thus include components of exposure to all of the meteorological conditions that could be experienced throughout the year. A number of assumptions are employed in the calculation of these exposures to individuals (see Table D–2) which result in conservatively large doses.

Foremost, is the assumption that the individual is always downwind of the plume. That is, the direction from the release to the individual is not taken into account (although the distance is); such a dose is sometimes called a sector independent representation of the exposure to the individual. In reality, were there to be an accident resulting in a release, the probability of the plume blowing toward a particular individual would be small. A second conservative assumption is that the individual lies directly in the path of the plume centerline, meaning the portion of the plume in which the release concentration is greatest. Again, even if the wind were blowing from the release in the general direction of the individual, the probability that the individual would be exposed directly to the plume centerline is small. Other conservative assumptions governing the calculation of exposure to the individual include his remaining at the nearest site boundary to the release (MEI) or 100 meters downwind from the release (noninvolved worker) for the duration of the event; no protection (the individual is assumed to remain outside directly in the path of the plume); no deposition (thereby maximizing the inhalable plume concentration), no plume meander (the individual is assumed to be exposed to the plume centerline for the entire event); and use of an annual Meteorology (MET) dataset (2003), which maximizes downwind plume concentrations.

The downwind location of the noninvolved worker, 100 meters from the hypothesized release, does not vary among scenarios. The downwind location at which each MEI exposure is calculated (at the nearest site boundary to a hypothesized release) is specific to each scenario and release location. Although the scenarios and exposure locations correspond to the actions analyzed in this SWEIS, MEI-type doses at other locations could be of present or future interest. An example could be associated with the site-wide wildfire event. In a wildfire event, the locations of the public and onsite personnel such as firefighters may not correspond to those associated with the other accident scenarios. Another example could be interest in the MEI dose at an onsite, publicly accessible location such as a road. These data would also be useful if NNSA were considering changing public accessibility to portions of the site or if the site boundaries were to change.

Table D–27 gives the MEI-type doses at various downwind distances for the accident scenarios considered in this SWEIS. The scenarios are grouped by their section in this and other appendices. Some of the action-specific scenarios (for example, the MDA G explosion scenario) are reported both in this appendix and in the appendix discussing the action.

Table D–27 Maximally Exposed Individual-Type Doses versus Downwind Distance by Accident Scenario

[a] Doses include component from external exposure to source.

[b] See Appendix I, Section I.5.12.1 regarding a revision to the material at risk; conclusions of this analysis remain valid.

Note: To convert meters to yards, multiply by 1.0936.

D.8 MACCS2 Code Description

The MACCS2 computer code is used to estimate the radiological doses and health effects that could result from postulated accidental releases of radioactive materials to the atmosphere. The specification of the release characteristics, designated a "source term," can consist of up to four Gaussian plumes that are often referred to simply as "plumes."

The radioactive materials released are modeled as being dispersed in the atmosphere while being transported by the prevailing wind. During transport, particulate material can be modeled as being deposited on the ground. The extent of this deposition can depend on precipitation. If contamination levels exceed a user-specified criterion, mitigating actions can be triggered to limit radiation exposures.

Atmospheric conditions during an accident scenario's release and subsequent plume transport are taken from the annual sequential hourly meteorological data file. Scenario initiation is assumed to be equally likely during any hour contained in the file's dataset, with plume transport governed by the succeeding hours. The model was applied by calculating the exposure to each receptor for accident initiation during each hour of the 8,760 hour-dataset. The mean results of these samples, which include contributions from all meteorological conditions, are presented in this SWEIS.

Two aspects of the code's structure are important to understanding its calculations: (1) the calculations are divided into modules and phases; and (2) the region surrounding the facility is divided into a polar-coordinate grid. These concepts are described in the following sections.

MACCS2 is divided into three primary modules: ATMOS, EARLY, and CHRONC. Three phases are defined as the emergency, intermediate, and long-term phases. The relationship among the code's three modules and the three phases of exposure are summarized below.

The ATMOS module performs all of the calculations pertaining to atmospheric transport, dispersion, and deposition, as well as the radioactive decay that occurs before release and while the material is in the atmosphere. It uses a Gaussian plume model with Pasquill-Gifford dispersion parameters. The phenomena treated include building wake effects, buoyant plume rise, plume dispersion during transport, wet and dry deposition, and radioactive decay and in-growth. The results of the calculations are stored for subsequent use by EARLY and CHRONC. In addition to the air and ground concentrations, ATMOS stores information on wind direction, arrival and departure times, and plume dimensions.

It is noted that dispersion calculations such as used in MACCS2 are generally recognized to be less applicable within 100 meters of a release than they are to further downwind distances (DOE 2004d); such close-in results frequently over-predict the atmospheric concentrations because they do not account for the initial momentum or size of the release, or for the impacts of structures and other obstacles on plume dispersion. Although most of the results presented in this SWEIS are for distances at least 100 meters downwind from a hypothesized release source, two (MEIs from the Chemistry and Metallurgy Research Building and MDA B) are not. The latter results should be interpreted in the above light.

The EARLY module models the period immediately following a radioactive release. This period is commonly referred to as the emergency phase. The emergency phase begins at each successive downwind distance point when the first plume of the release arrives. The duration of the emergency phase is specified by the user, and it can range between 1 and 7 days. The exposure pathways considered during this period are direct external exposure to radioactive material in the plume (cloud shine); exposure from inhalation of radionuclides in the cloud (cloud inhalation); exposure to radioactive material deposited on the ground (ground shine); inhalation of resuspended material (resuspension inhalation); and skin dose from material deposited on the skin. Mitigating actions that can be specified for the emergency phase include evacuation, sheltering, and dose-dependent relocation.

The CHRONC module performs all of the calculations pertaining to the intermediate and long-term phases. CHRONC calculates the individual health effects that result from both direct exposures to contaminated ground and from inhalation of resuspended materials.

The intermediate phase begins at each successive downwind distance point upon conclusion of the emergency phase. The user can configure the calculations with an intermediate phase that has a duration as short as 0 or as long as 1 year. In the zero-duration case, there is essentially no intermediate phase, and a long-term phase begins immediately upon conclusion of the emergency phase.

Intermediate models are implemented on the assumption that the radioactive plume has passed and the only exposure sources (ground shine and resuspension inhalation) are from ground-deposited material.

The mitigating action model for the intermediate phase is very simple. If the intermediate phase dose criterion is satisfied, the resident population is assumed to be present and subject to radiation exposure from ground shine and resuspension for the entire intermediate phase. If the intermediate phase exposure exceeds the dose criterion, then the population is assumed to be relocated to uncontaminated areas for the entire intermediate phase.

The long-term phase begins at each successive downwind distance point upon conclusion of the intermediate phase. The exposure pathways considered during this period are ground shine and resuspension inhalation.

The exposure pathways considered are those resulting from ground-deposited material. A number of protective measures, such as decontamination, temporary interdiction, and condemnation, can be modeled in the long-term phase to reduce doses to user-specified levels. The decisions on mitigating action in the long-term phase are based on two sets of independent actions: (1) decisions related to whether land at a specific location and time is suitable for human habitation (habitability), and (2) decisions related to whether land at a specific location and time is suitable for agricultural production (ability to farm). For the current SWEIS, no mitigation or special protective measures were assumed for the exposure calculations.

All of the calculations of MACCS2 are stored based on a polar-coordinate spatial grid with a treatment that differs somewhat between calculations of the emergency phase and calculations of the intermediate and long-term phases. The region potentially affected by a release is represented with a (r, Θ) grid system centered on the location of the release. Downwind distance is represented by the radius "r". The angle, "Θ", is the angular offset from the north, going clockwise.

The user specifies the number of radial divisions as well as their endpoint distances. The angular divisions used to define the spatial grid are fixed in the code. They correspond to the 16 points of the compass, each being 22.5 degrees wide. The 16 points of the compass are used in the United States to express wind direction. The compass sectors are referred to as the coarse grid.

Since emergency phase calculations use dose-response models for early fatalities and early injuries that can be highly nonlinear, these calculations are performed on a finer grid basis than the calculations of the intermediate and long-term phases. For this reason, the calculations of the emergency phase are performed with the 16 compass sectors divided into 3, 5, or 7 equal, angular subdivisions. The subdivided compass sectors are referred to as the fine grid.

Lifetime doses are the conventional measure of detriment used for radiological protection. These are 50-year dose commitments to a weighted sum of tissue doses defined by the International Commission on Radiological Protection and referred to as "effective dose equivalent." Lifetime doses may be used to calculate the stochastic health effect risk resulting from exposure to radiation. The calculated lifetime dose was used in cancer risk calculations.

D.9 ALOHA Code Description

Consequences of accidental chemical releases were determined using the ALOHA computer code (EPA 2004). ALOHA is an EPA and National Oceanic and Atmospheric Administration-sponsored computer code that has been widely used in support of chemical accident responses and also in support of safety and NEPA documentation for DOE facilities. The ALOHA code is a deterministic representation of atmospheric releases of toxic and hazardous chemicals. The code can predict the rate at which chemical vapors escape (such as from puddles or leaking tanks) into the atmosphere; a specified direct release rate is also an option.

ALOHA performs calculations for chemical source terms and resulting downwind concentrations. Source term calculations determine the rate at which the chemical material is released to the atmosphere, release duration, and the physical form of the chemical upon release. The term "cloud" is used in this document to refer to the volume that encompasses the chemical emission. In general, the released chemical may be a gas, a vapor, or an aerosol. The aerosol release may consist of either solid (fume, dust) or liquid (fog, mist, spray) particles that are suspended in a gas or vapor medium. Liquid particles are also referred to as droplets. The analyst specifies the chemical and then characterizes the initial boundary conditions of the chemical with respect to the environment through the source configuration input. The ALOHA code allows the source to be defined in one of four ways (direct source, puddle source, tank source, or pipe source) to model various accident scenarios. The source configuration input is used either to specify the chemical source term or to provide ALOHA with the necessary information and data to calculate transient chemical release rates and the physical state of the chemical upon release. ALOHA calculates time-dependent release rates for up to 150 time steps (DOE 2004c). ALOHA then averages the release rates from the individual time steps over one to five averaging periods, each lasting at least 1 minute (DOE 2004c). The five averaging periods are selected to most accurately portray the peak emissions. The five average release rates are inputs to the ALOHA algorithms for atmospheric transport and dispersion (DOE 2004c). ALOHA tracks the evolution of the mean concentration field of the five separate chemical clouds and calculates the concentration at a given time and location through superimposition. ALOHA limits releases to 1 hour.

Evolution of the mean concentration field of the chemical cloud is calculated through algorithms that model the turbulent flow phenomena of the atmosphere. The prevailing wind flows and associated atmospheric turbulence serve to transport, disperse, and dilute the chemical cloud that initially forms at the source. For an instantaneous or short-duration release, the chemical cloud will travel downwind as a puff. In contrast, a plume will form for a sustained or continuous release.

The wind velocity is a vector term defined by a direction and magnitude (wind speed). The wind direction and speed determine where the puff or plume will go and how long it will take to reach a given downwind location. For sustained or continuous releases, the wind speed has the additional effect of stretching out the plume and establishing its initial dilution. It also determines the relative proportion of ambient air that initially mixes with the chemical source emission. Atmospheric turbulence causes the puff or plume to mix increasingly with ambient air and grow (disperse) in the lateral and vertical direction as it travels downwind. Longitudinal expansion also occurs for a puff. These dispersion effects further enhance the dilution of the puff or plume. The two sources of atmospheric turbulence are mechanical turbulence and buoyant turbulence. Mechanical turbulence is generated from shear forces that result when adjacent parcels of air move at different velocities (either at different speeds or directions). Fixed objects on the ground, such as trees or buildings, increase the ground roughness and enhance mechanical turbulence in proportion to their size. Buoyant turbulence arises from vertical convection and is greatly enhanced by the formation of thermal updrafts that are generated from solar heating of the ground.

The ALOHA code considers two classes of atmospheric transport and dispersion based upon the assumed interaction of the released cloud with the atmospheric wind flow.

- For airborne releases in which the initial chemical cloud density is less than or equal to that of the ambient air, ALOHA treats the released chemical as neutrally buoyant. A neutrally buoyant chemical cloud that is released to the atmosphere does not alter the atmospheric wind flow; therefore, the term "passive" is used to describe the phenomenological characteristics associated with its atmospheric transport and dispersion. As a passive contaminant, the released chemical follows the bulk movements and behavior of the atmospheric wind flow.

- Conversely, if the density of the initial chemical cloud is greater than that of the ambient air, then the possibility exists for either a neutrally buoyant or a dense-gas type of atmospheric transport and dispersion. In dense-gas atmospheric transport and dispersion, the dense-gas cloud resists the influences of the hydraulic pressure field associated with the atmospheric wind, and the cloud alters the atmospheric wind field in its vicinity. Dense-gas releases can occur with gases that have a density greater than air due either to a high molecular weight or to being sufficiently cooled. A chemical cloud with sufficient aerosol content can also result in a bulk cloud density that is greater than that of the ambient air. Dense-gas releases undergo what has been described in the literature as "gravitational slumping."

Gravitational slumping is characterized by significantly greater lateral (crosswind) spreading and reduced vertical spreading compared to the spreading that occurs with a neutrally buoyant release.

In addition to the source term and downwind concentration calculations, ALOHA allows specification of concentration limits for the purpose of consequence assessment (such as assessment of human health risks from contaminant plume exposure). ALOHA refers to these concentration limits as level-of-concern (LOC) concentrations. Safety analysis work uses the ERPGs and TEELs for assessing human health effects for both facility workers and the public. While ERPGs and TEELs are not explicitly part of the ALOHA chemical database, ALOHA allows the user to input any value, including an ERPG or TEEL value, as the LOC concentration. The LOC value is superimposed on the ALOHA-generated plot of downwind concentration as a function of time to facilitate comparison. In addition, ALOHA will generate a footprint that shows the area (in terms of longitudinal and lateral boundaries) where the ground-level concentration reached or exceeded the LOC during puff or plume passage (the footprint is most useful for emergency response applications).

The ALOHA code uses a constant set of meteorological conditions (such as wind speed and stability class) to determine the downwind atmospheric concentrations. The sequential meteorological datasets used for the radiological accident analyses were reordered from high to low dispersion by applying a Gaussian dispersion model (such as that used by ALOHA) to a representative downwind distance. The median set of hourly conditions for each site (that is, mean wind speed and mean stability) was used for the analysis; this is roughly equivalent to the conditions corresponding to the mean radiological dose estimates of MACCS2.

ALOHA contains physical and toxicological properties for the chemical spills included in the SWEIS and for approximately 1,000 additional chemicals. The physical properties were used to determine which of the dispersion models and accompanying parameters were applied. The toxicological properties were used to determine the levels of concern. Atmospheric concentrations at which health effects are of concern (that is ERPG-2 or ERPG-3 levels) are used to define the footprint of concern. Because the meteorological conditions specified do not account for wind direction (that is, it is not known *a priori* in which direction the wind would be blowing in the event of an accident), the areas of concern can be defined by a circle of radius equivalent to the downwind distance at which the concentration decreases to levels less than the level of concern. In addition, the concentration at 328 feet (100 meters) (potential exposure to a noninvolved worker) and at the nearest public access, typically the site boundary distance, (exposure to the MEI) are calculated and presented.

APPENDIX E
CURRENT UNDERSTANDING OF THE GROUNDWATER REGIME AT LOS ALAMOS NATIONAL LABORATORY

APPENDIX E
CURRENT UNDERSTANDING OF THE GROUNDWATER REGIME AT LOS ALAMOS NATIONAL LABORATORY

This appendix summarizes the current understanding of groundwater flow at Los Alamos National Laboratory (LANL) and the conceptual models that have been developed for the purpose of numerical modeling of groundwater flow and contaminant transport. This appendix presents the components by which researchers develop their concepts of the geohydrologic system at LANL.

E.1 Introduction

A comprehensive study of the geology, hydrologic processes, and site characteristics of an area must be understood to formulate a conceptual model of a groundwater flow system. Geologic information must be used in conjunction with the hydrologic data to define hydrostratigraphic units. A geologic unit can be used as a model layer or several units can be combined into model layers if their hydrologic characteristics are similar. Knowledge of the geology is required to define the areal extent of the units. Inferences about the flow system's hydraulic behavior and transport characteristics are drawn from information about geologic structures, lithologic properties, and groundwater geochemistry.

The setting occupied by LANL is geologically and hydrologically complex. Before recent drilling activities were implemented, conceptual models and numerical simulations of regional groundwater flow that had been developed were based on sparse data (Keating, Robinson, and Vesselinov 2005). The knowledge base regarding recharge, discharge, and how waterborne contaminants interact with and move through rock fractures and rock matrix in the vadose zone into perched water zones and the regional aquifer below LANL is growing. In 2005, the LANL contractor was regularly sampling 74 surface monitoring stations and 137 groundwater-monitoring locations based on agreements with the New Mexico Environment Department and the U.S. Environmental Protection Agency. These activities have resulted in modification of the conceptual models (Newman and Robinson 2005). As a result of further agreements, the LANL contractor will be expanding its data collection activities while conducting further analysis of existing data. This understanding of the hydrologic and chemical components at the site will aid in the development of sound conceptual models of flow and transport through the fractures and the matrix of the vadose zone into the saturated zone. It is anticipated that the new data, coupled with improvement in numerical flow and transport models and improved calculational techniques, will enable better prediction of flow and transport of groundwater in the LANL region and more accurately define the ultimate impacts on the regional groundwater resources below LANL.

This appendix provides a framework for understanding the geohydrology and the development of numerical models. In 2005, a series of reports of investigations in the *Vadose Zone Journal* developed conceptual models and discussed flow and transport through the vadose zone to perched groundwater bodies and the regional aquifer below LANL. Some of the reports from this series are discussed. The descriptions are brief and references are provided.

E.2 Regional Setting

LANL and the adjacent communities of Los Alamos and White Rock are located on the Pajarito Plateau (**Figure E–1** and Chapter 4, Figure 4–9). The plateau is an accumulation of east-sloping volcanic material that lies over the western part of the Española Basin and extends from the Sierra de los Valles on the eastern rim of the Jemez Mountains to White Rock Canyon and the Española Valley west of the Rio Grande. The plateau covers an area of about 240 square miles (620 square kilometers), of which about 90 square miles (230 square kilometers) is in the central part of the plateau and includes the area covered by LANL (Broxton and Vaniman 2005) (Figure E–1). The plateau is drained by easterly flowing ephemeral and intermittent streams that have formed deeply incised canyons separated by elongated mesas. The mesas range in elevation from west to east from 7,700 feet (2,350 meters) on the slopes of the Sierra de los Valles to 6,200 feet (1,900 meters) at their ends overlooking the Española Valley (Broxton and Vaniman 2005).

The drainage of the high slopes of the Jemez region (Sierra de los Valles) extends across the tuff outcrops of LANL. Precipitation potential in the north-central part of New Mexico is strongly altitude-dependent. Precipitation in the form of rainfall and snowfall at the higher elevations is about 18 inches (46 centimeters) and about 14 inches (36 centimeters) on the semiarid lower slopes of the area (Broxton and Vaniman 2005). Flow across the Pajarito Plateau from the higher elevations to the Rio Grande has resulted in the mesa and canyon landscape of the area. The steeply cut canyons slope eastward from the Jemez Mountains toward the Rio Grande and are the cumulative result of the alternating humid and arid climatic cycles of the past 2.8 million years (Pleistocene glacial and interglacial). The canyon bottoms are covered with a relatively thin layer of alluvium. The mesa tops display little soil formation and are sparsely vegetated with water-efficient plants. Devitrification of the tuffs on the surface of the plateau has generated a nutrient-poor soil with smectitic clays as its principal argillaceous component. The mesa surfaces are generally quite flat and receive no runoff from the higher elevations. Soil moisture infiltration and runoff is controlled by plant growth and downward transport of precipitation that falls on the mesa surfaces.

E.3 Structural Setting

The tectonic episodes that occurred in southern Colorado and north-central New Mexico from the late Campanian stage of the Cretaceous Period (approximately 75 million years ago) through the Eocene Epoch (about 35 million years ago) formed the Rocky Mountains (Cather 2004). The mountain building (termed the Laramide orogeny) was caused by compression of the Earth's crust and formed two large basins that are separated by an uplifted area in north and central New Mexico and extend into southern Colorado. The structures formed were the San Juan Basin to the west and the Raton Basin to the east, which are separated by the San Luis Uplift. The southern part of the San Luis Uplift in the LANL vicinity has been called the Pajarito Uplift (Cather 2004). The Pajarito Uplift is bounded by the Picuris-Pecos fault zone in the Sangre de Cristo Mountains to the east and the Pajarito fault zone to the west (Broxton and Vaniman 2005).

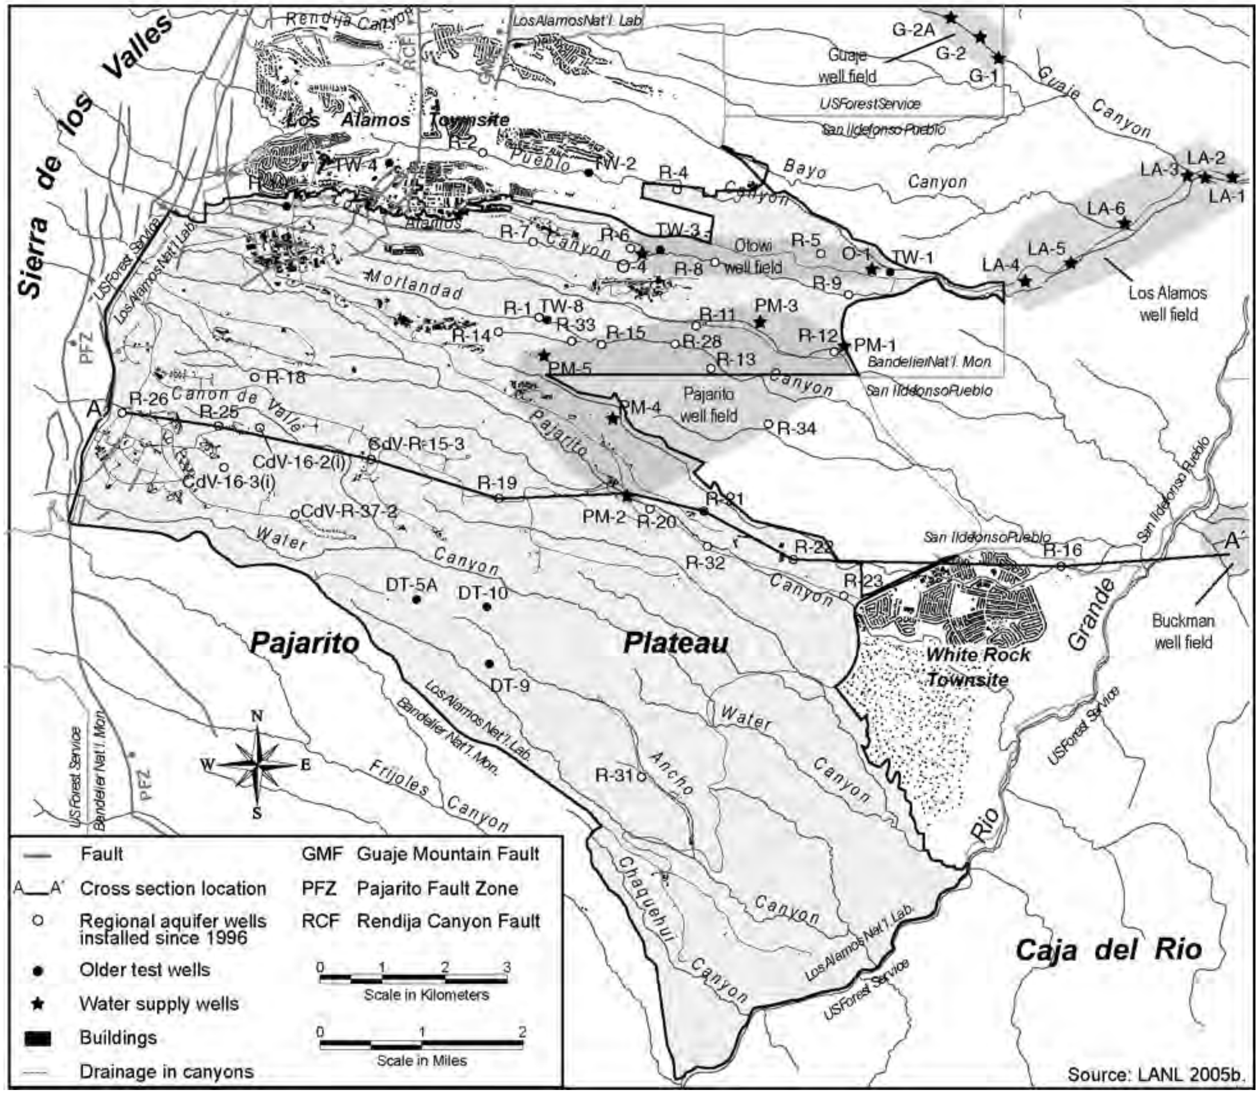

Figure E–1 Location Map of the Central Pajarito Plateau

At the end of the Eocene Epoch, three large-scale processes began and continued until the late Pleistocene Epoch: (1) widespread volcanism, (2) extension of the crust (rifting) from Colorado through New Mexico to west Texas, and (3) extensive erosion of the High Plains east of a rift zone that is delineated by the Rio Grande (from which the zone's name is derived) and the Colorado Plateau west of the Rio Grande rift (Smith 2004). The Pajarito Uplift and other uplifts began to undergo extensional inversion (lowering) along the rift zone. In northern New Mexico, the Rio Grande Rift formed a series of semi-coaxial, elongated, oppositely tilted grabens that became narrow, sediment-filled basins (Smith 2004, Broxton and Vaniman 2005, LANL 2005a) (**Figure E–2**). The basins along the axis of the rift are flanked by a series of discontinuous mountains (Smith 2004). The Española Basin is flanked by the Nacimiento Mountains and the Jemez Mountains to the west and the Sangre de Cristo Mountains to the east. The western margin of the basin is obscured by Jemez volcanics and the margin may be further west at the Laramide Nacimiento Uplift (Smith 2004).

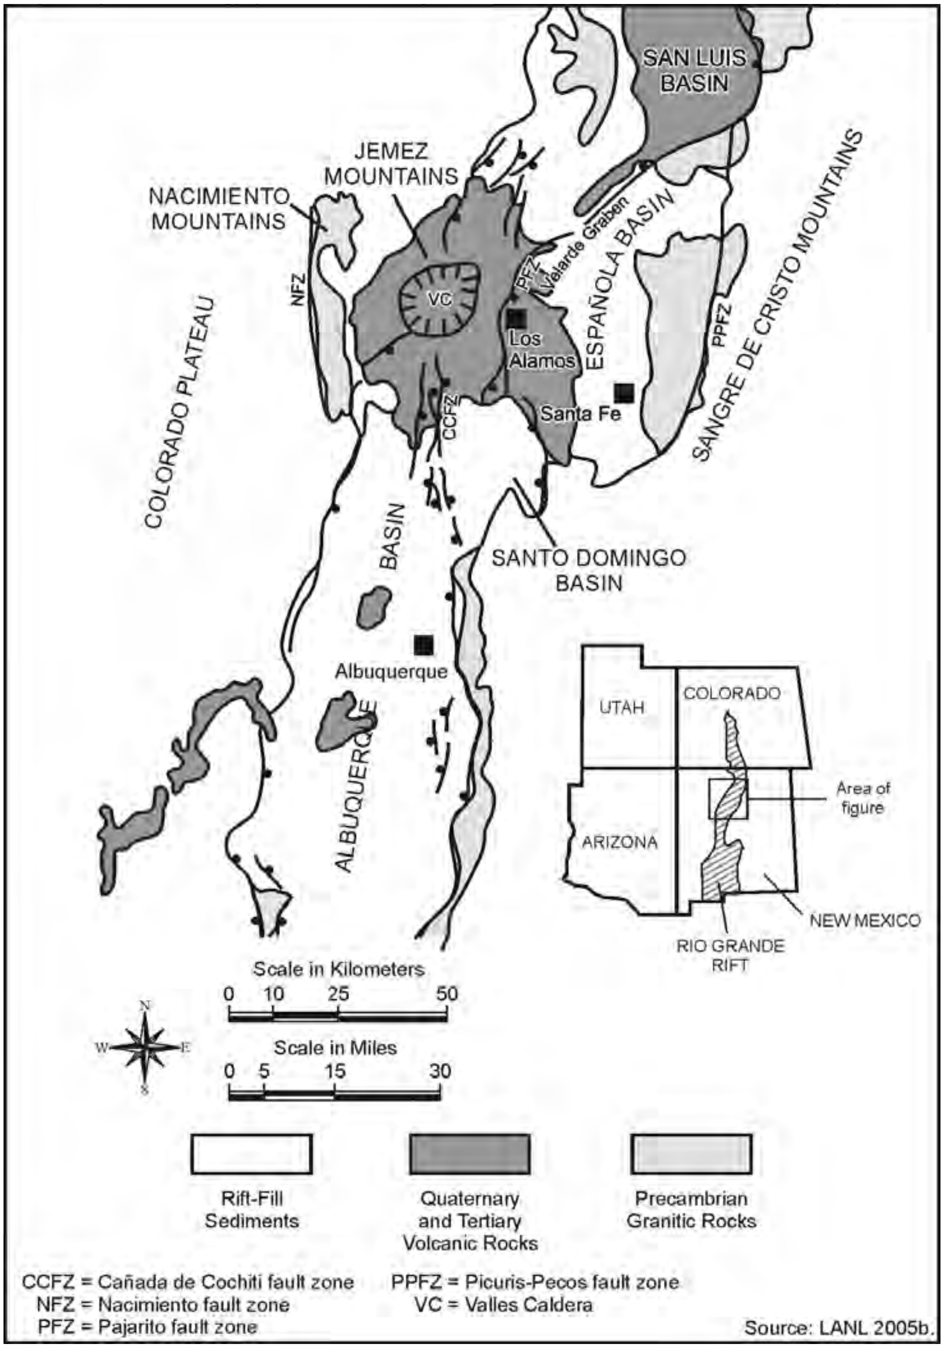

Figure E–2 Locations of Major Structural and Geologic Elements in the Vicinity of Los Alamos National Laboratory

Basins along the Rio Grande Rift are bounded by normal faulting that occurs along the margins and within the basins. The Española Basin is a west-tilting half graben bounded on the west edge by north-trending faults called the Pajarito fault zone (Figure E–2); on the north by northeast-trending transverse faults of the Embudo fault zone; and on the south by northwest-trending transverse faults called the Bajada fault zone (LANL 2005a). Gravity evidence indicates that deep within the Española Basin are three buried grabens associated with the Pajarito and Embudo fault zones (Smith 2004, Broxton and Vanimin 2005). One graben forms the north-trending Los Alamos sub-basin and is near Los Alamos. It is bounded by the Pajarito fault zone on the west and by the buried faults that lie east of the southern projections of Rendija Canyon and Guaje Mountain (Smith 2004, Broxton and Vaniman 2005).

The Pajarito fault zone forms a 400-foot (120-meter)-high escarpment on the western margin of the plateau that looks like a monocline, but examination along the strike reveals a simple normal fault, several small normal faults, and faulted and unfaulted monoclines (Broxton and Vaniman 2005).

Other major fault zones in the LANL area include the north-trending Rendija Canyon fault that is down-to-the-west, and the north-trending Guaje Mountain fault that is also down-to-the-west (Broxton and Vaniman 2005). The faults are parallel in the northern part of the plateau. Additional faults are buried beneath or within the Bandelier Tuffs under the Pajarito Plateau. Faulting also occurs in the older Santa Fe Group rocks on the eastern side of the Española Basin.

E.4 Volcanic Setting

Jemez Volcanic Field

The Jemez Mountains were formed by rift-related volcanism along the Jemez lineament (**Figure E–3**) where the Colorado Plateau abuts the Española Basin. The lineament is a feature that may be a reactivated zone of ancient crustal weakness that trends northeast from eastern Arizona through the Jemez Mountains into southeastern Colorado (Goff and Gardner 2004, Broxton and Vaniman 2005). The volcanic zone that forms the Jemez Mountains overlaps the Colorado Plateau and western Española Basin (Broxton and Vaniman 2005). The region around the Valles Caldera in the Jemez Mountains west of the Pajarito Plateau is the source of most of the volcano-derived material that forms the Pajarito Plateau (Broxton and Vaniman 2005).

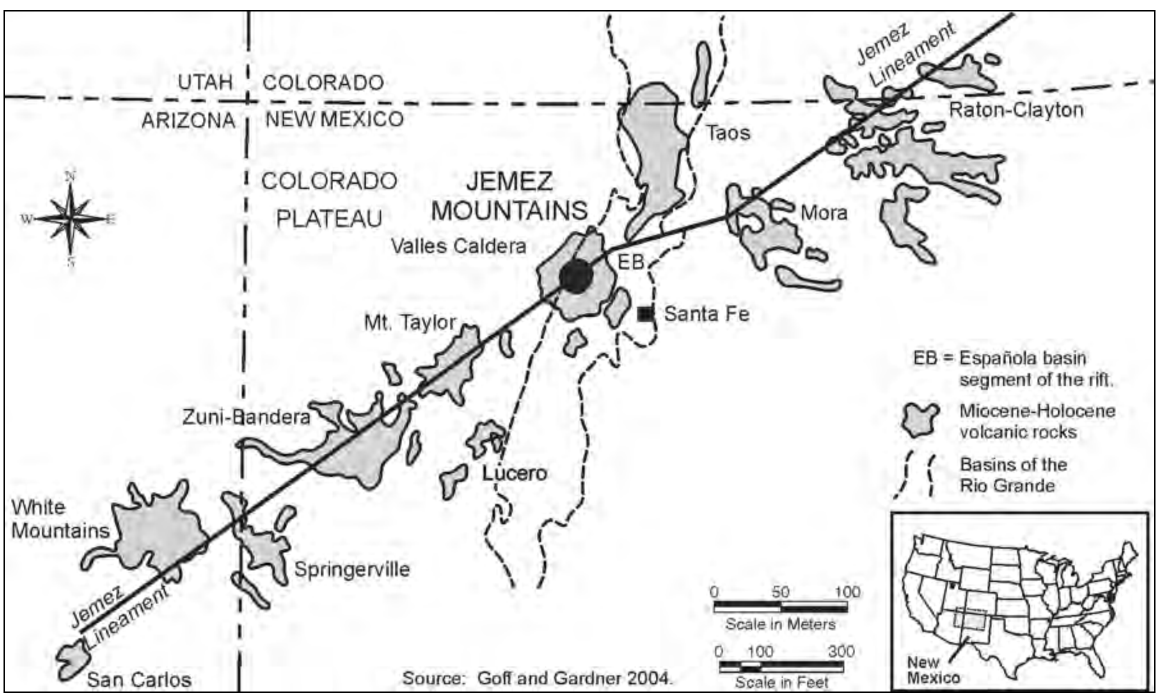

Figure E–3 Location Map of the Jemez Mountains and Valles Caldera with Respect to the Jemez Volcanic Lineament, the Colorado Plateau, and the Rio Grande Rift

For the past 14 million years, the structural province of this region has been extensively affected by tectonic forces. Volcanic activity and subsidence due to rifting were contemporaneous. The early Española Basin was the depositional site of alluvium derived from the Colorado Plateau and later from the Jemez Mountain volcanic field (to the west) and the Sangre de Cristo Mountains (to the east). The volcaniclastics from the Jemez Mountain volcanic field and the Precambrian basement rocks to the east and north formed large alluvial fans that intertongued, forming a vertical intergradation of wedge-shaped layers (Goff and Gardner 2004; Smith 2004; and Broxton and Vanimin 2005).

The Jemez Mountain volcanic field is divided into three groups. The oldest groups are the Keres Group in the south and the Polvadera Group in the north. These are succeeded by the Tewa Group in the central part and on the flanks of the Jemez Mountain volcanic field (Goff and Gardner 2004). This is not to imply that some of the volcanic eruptions that formed these three groups did not occur at the same time. Eruptions in different areas can overlap in time. The Lobato Basalt of the Polvadera Group was somewhat synchronous with the Keres Group basalts (Broxton and Vaniman 2005). LANL staff is conducting detailed examination of basalt and rhyolite outcrops and drill-hole data from beneath the Pajarito Plateau. The new data provide insight into the ages of the rocks and are being used to determine whether the rocks can be correlated throughout the volcanic field.

Knowledge gained from the study of the rock materials present in the LANL area is important to understanding hydrologic and chemical properties when developing conceptual models of groundwater flow and transport. A summary of the units present in the region, including their approximate ages and short descriptions, is given in **Table E–1**. Further descriptions and the relationships of these units with the alluvial units under the Pajarito Plateau are provided in Section E.5, Stratigraphic Framework of the Pajarito Plateau.

In the LANL area, on the east side of the Rio Grande, is the Caja del Rio Basalt Plateau (Figure E–1). It is an exposed part of the Cerros del Rio volcanic field that extends westward 7 miles (11 kilometers) underneath the Pajarito Plateau where it is covered by Bandelier Tuff (Goff and Gardner 2004; Broxton and Vaniman 2005). These volcanics are dissected by the Rio Grande, forming the steep-sided White Rock Canyon.

Caldera formation and subsequent collapse during the Late Pliocene to Late Pleistocene Epochs formed the Jemez Mountains and resulted in significant chemical evolution of the magma-, ash-, and tuff-forming phases. The Bandelier Tuff Formation consists of ashfalls, pumiceous beds, and flow tuffs and ranges up to tens of feet thick in the plateau area and is spread widely east and south of the main caldera. These tuffaceous deposits of the Bandelier Tuff, the Otowi, Cerro Toledo interval, and Tshirege define the geomorphology of the plateau and control the development of the terrain of canyons and mesas at LANL.

Table E–1 Summary of Jemez Mountain Volcanic Field Names, Rock Types, and Rock Ages

Group Name	*Unit Name*	*Description*
Middle Miocene Units		
Polvadera Group (Oldest unit in north part of LANL. Contemporaneous with parts of the Keres Group.)	Lobato Basalt (14 to 7.6 million years ago)	Multiple flows and cinder deposits coeval with Chamisa Mesa Basalt. Primarily olivine; dikes intruded Santa Fe Formation; interbedded with Santa Fe Formation.
Keres Group (Oldest unit in south part of LANL. Contemporaneous with parts of the Polvadera Group.)	Chamisa Mesa Basalt (13 to 9 million years ago)	Thin flows of basaltic lavas and cinder deposits that overlie rhyolitic tuff; forms mesa tops to the south and northeast of LANL. May be oldest unit in the Jemez Mountain volcanic field.
	Canovas Canyon Rhyolite (12.4 to 8.8 million years ago)	Domes, plugs, and pyroclasts (tuff, ash); weathered; intrudes Paliza Canyon Formation; rhyolite and basalt.
	Paliza Canyon Formation (10.6 to 7.1 million years ago)	Thick flows, domes, and pyroclasts; basalt, andesite and dacite composition.
	Peralta Member (6 to 7.1 million years ago)	Thick, tuffaceous deposits.
	Bearhead Rhyolite (6 to 7.1 million years ago)	Domes, intrusions, and pyroclasts; high silica rhyolites, plugs, domes, and tuffs.
	Cochiti Formation. (< 13 to < 6 million years ago)	Volcaniclastic rocks derived from Keres group rocks and interfingers with Santa Fe Group, Canovas Canyon Rhyolite, and Paliza Canyon Formation.
Late Miocene to Late Pliocene Units		
Polvadera Group	Tschicoma Formation (5 to 3 million years ago)	Large, overlapping domes and flows of dacite, rhyodacite, and andesite.
Late Pliocene to Late Pleistocene Units		
Tewa Group	Bandelier Tuff Pumice fall covered by ash-flow – High silica Rhyolite tuff; exposures at Pajarito Plateau in canyons; forms Pajarito Plateau east of and Jemez Plateau west of the Jemez Mountain Volcanic Zone.	
	Otowi Member (1.61 million years ago)	Guaje Pumice – Eruption formed the Toledo caldera, which was destroyed; less welded than Tshirege Member; basal pumice fall overlain by ash-flow tuffs.
	Cerro Toledo Interval	Cerro Toledo Rhyolite, Rhyolite domes.
	Tshirege Member (1.22 million years ago)	Tsankawi Pumice – Eruption formed the Valles Caldera that subsequently collapsed; basal pumice fall overlain by ash-flow tuffs.
Peripheral Lavas	Basalts of the Cerros del Rio (2.8 to < 1 million years ago)	Basalt lavas and dikes; relationship to Otowi unclear (Goff and Gardner 2004).

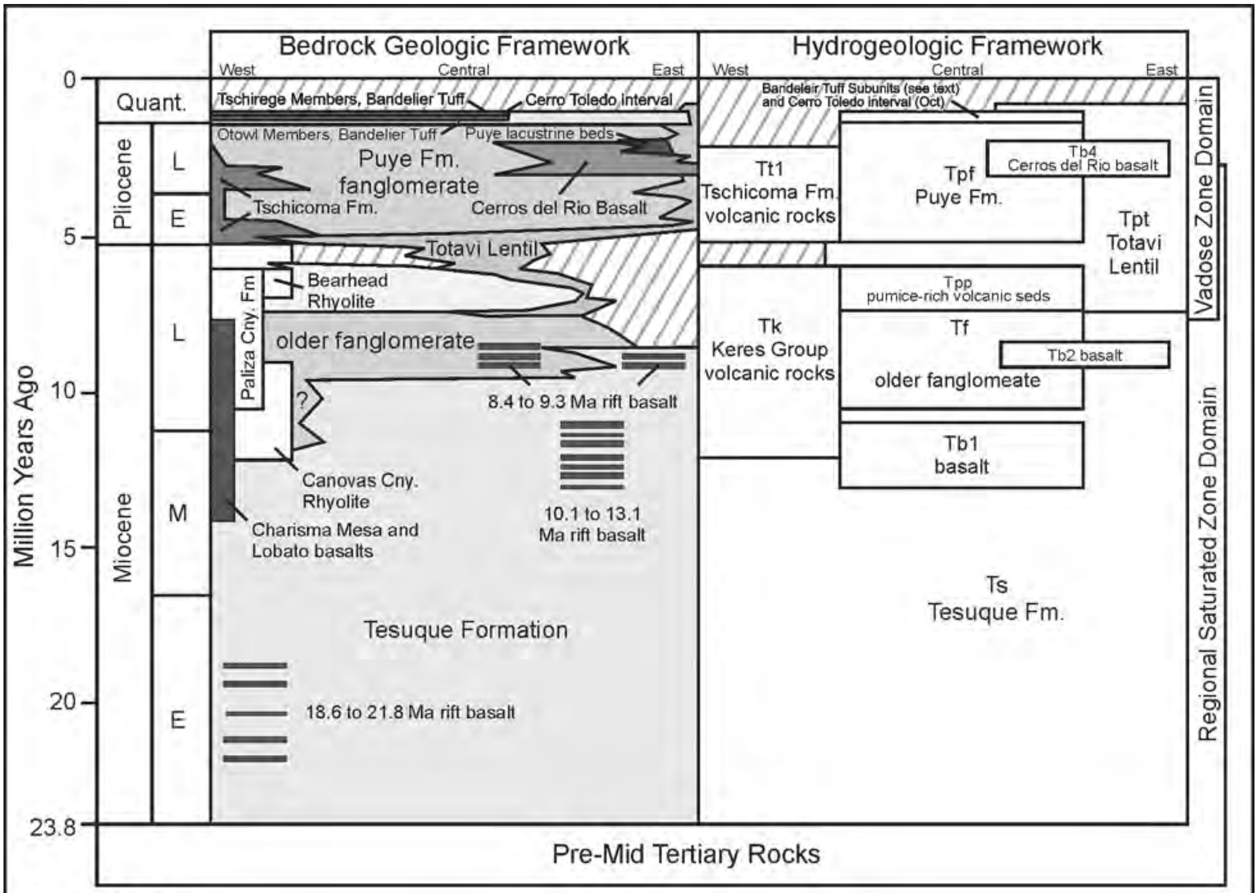
E.5 Stratigraphic Framework of the Pajarito Plateau

This section describes the stratigraphy of the Pajarito Plateau and shows how the volcanics described above fit in the sequence of deposition (**Figure E–4**). As mentioned above, volcaniclastics and sediments derived from the volcaniclastics from the Jemez Mountain volcanic field to the west of the Pajarito Plateau and sediment from the Precambrian basement rocks to the east and north formed alluvial fans that intertongued, forming a vertical intergradation of wedge-shaped layers.



Source: LANL 2005b.

Figure E–4 Pajarito Plateau Stratigraphy and Hydrogeologic Units

E.5.1 Santa Fe Group

The basins along the Rio Grande Rift average several tens of miles long and are filled with sediments that reach depths of a few tens of thousands of feet. This thick accumulation of sediments in the Española Basin was derived from Precambrian rocks exposed in the highlands north and east of the basin. The basin sediments in north-central New Mexico were first collectively termed the Santa Fe Formation, but the formation was later elevated to a group name and subdivided into several formations. The Tesuque Formation is subdivided into, in ascending order, the Bishop's Lodge, Nambe, Skull Ridge, Pojoaque, Chama-El Rito, and Ojo Caliente Members and the Chamita Formation. The Puye Formation was added and the Ojo Caliente was elevated to a formation (Broxton and Vaniman 2005). The age of the Tesuque ranges from about 30.45 to 8.48 million years ago. The name Tesuque Formation was used for the youngest formation of the Santa Fe Group in the Española Basin because it was felt that some of the members and formation designations could not be mapped properly because they were not defined over a large enough area (Smith 2004). Interfingered into these sediments are volcaniclastic sediments from the Jemez volcanic field (Broxton and Vaniman 2005).

Most of the rocks that were pre-Española Basin were stripped away in the Pajarito Plateau vicinity. Denudation of Paleozoic and Mesozoic rocks may have been due to erosion of the Pajarito Uplift (Cather 2004, Smith 2004), resulting in the absence of pre-Eocene rocks.

Mesozoic units may be present under the Pajarito Plateau, but at this time there is no supporting evidence (Broxton and Vaniman 2005). There are no exposures of the Santa Fe Group within the LANL boundaries; but on the eastern margins of the Pajarito Plateau and north of LANL, there are exposures in deep canyons such as Rendija Canyon and lower Los Alamos Canyon (**Figure E–5**). East of the Pajarito fault, the Santa Fe Group may be 6,650 feet (2,000 meters) thick, but much thinner (less than 1,640 feet [500 meters]) west of the fault, as indicated by examination of outcrops and drill-hole data (Goff and Gardner 2004, Broxton and Vaniman 2005). Because of the thickness of the Santa Fe Group, not much is known about units that are of hydrologic significance and are older than the Tesuque in the LANL region. Most of what is known about the Tesuque Formation's lithologic and hydrologic properties comes from drill holes.

Figure E–5 Deep Canyon Exposures

New drill hole data and exposures of rocks near the Rio Grande provide much of what is known about the stratigraphy, lithology, and ages of the Santa Fe Group in the LANL area. A recent attempt to address controversies dealing with stratigraphy and mechanisms that formed the Española Basin is reported in a synthesis of work performed up to the present (Smith 2004). Units believed to be of significance in the Pajarito Plateau area, in ascending order, are the Tesuque Formation, older fanglomerate deposits of the Jemez Mountain volcanic field, the Totavi Lentil and older river deposits, pumice-rich volcaniclastic rocks, and the Puye Formation (Broxton and Vaniman 2005).

Tesuque Formation

The Miocene Tesuque Formation has been characterized from data taken from partially penetrating water production wells for local communities west of the Rio Grande on the eastern edge of the Pajarito Plateau and from exposures east of the Rio Grande. The Tesuque Formation below the plateau is derived from arkosic sediments from the Precambrian Eon and sedimentary rocks of the Sangre de Christo Range to the east, and from Tertiary volcanic material to the north. The partly lithified fluvial sediments are thin-bedded (less than 10 feet, [3 meters]), massive to planar, cross-bedded, light pink to buff sandstones (Smith 2004; Broxton and Vaniman 2005). West of Española, the Tesuque Formation is interbedded with Lobato Basalt (Smith 2004). The Tesuque Formation dips to the west-northwest at about 11 degrees on the east side of the plateau (Broxton and Vaniman 2005).

Miocene Basalts

There are two groups of Miocene basalts underneath the east edge of the Pajarito Plateau. One group is 10.9 to 13.1 million years old near Guaje Canyon north of LANL, and the other is 8.4 to 9.3 million years old and extends from Bayo Canyon on the north end of the eastern part of the plateau to almost the southern end of LANL.

Older Fanglomerate

This unit of the Santa Fe Group is important because high-yield municipal water supply wells with low drawdown have been developed in these rocks. Recent data indicate that the older fanglomerates are widespread below the Pajarito Plateau (Broxton and Vaniman 2005). The unit is made up of volcanic detritus from the Keres Group and possibly from the Tschicoma Formation of the Polvadera Group. Data for the Otowi-4 well show that the older fanglomerate is a thick (1,650 feet [500 meters]) unit made up of dark, lithic sandstone with gravel and cobbles (Broxton and Vaniman 2005). An interpretive cross-section was developed using well data that indicate the older fanglomerate interfingers with the upper Tesuque Formation (Broxton and Vaniman 2005). This is consistent with data from Guaje Canyon wells that suggest that the fanglomerate may have accumulated as the Los Alamos sub-basin subsided (Broxton and Vaniman 2005).

Totavi Lentil and Older River Deposits

The Totavi Lentil (**Figure E–6**) is made up of poorly consolidated and well-rounded sands, gravels, and cobbles formed by the ancestral Rio Grande (Broxton and Vaniman 2005; Goff and Gardner 2004) and is used as a marker bed for supply wells beneath the Pajarito Plateau. The deposits at some locations are conformable with the Puye Formation and are used by some workers to delineate the base of the Puye Formation (Broxton and Vaniman 2005). The Totavi Lentil is highly variable in thickness and ranges from 50 feet (15 meters) to more than 323 feet (98 meters). New well data show a range in thickness of 30 to 100 feet (10 to 30 meters), but data from Well H-19 at the western limit of the Totavi Lentil indicate that the unit is only 10 feet (3 meters) thick.

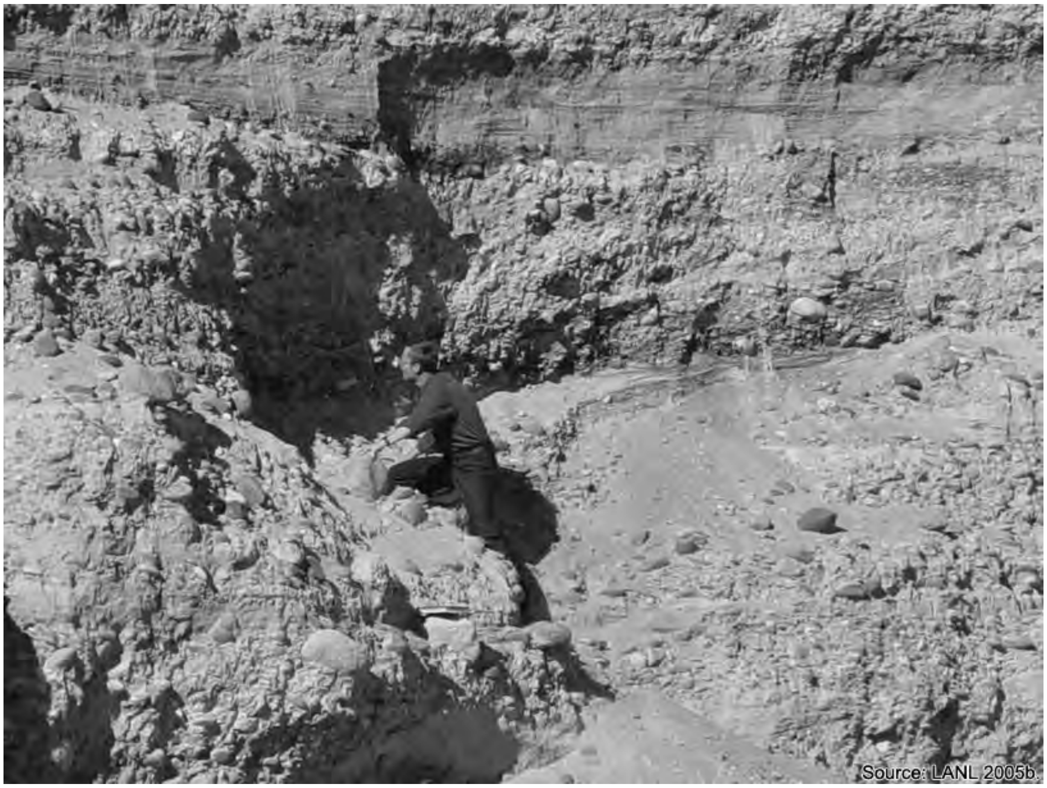

Figure E–6 Outcrop of Totavi Lentil Along SR 304

New well data show that the unit is coeval with several stratigraphic units and late Miocene river gravels and put the age of through-going rivers (rivers that are regional in nature with origins outside of the study area) at about 6.96 million years (Broxton and Vaniman 2005).

Pumice-Rich Volcaniclastic Rocks

The pumice-rich volcaniclastic rocks have well-bedded horizons of light-colored, reworked tephra-rich sedimentary deposits and subordinate primary ash- and pumice-fall deposits. The rocks consist mainly of tuffaceous sandstones with a few beds of gravels made of reworked lava (Broxton and Vaniman 2005). The deposits of pumice-rich volcaniclastic rocks become thinner eastward over the Pajarito Plateau and are made up of subangular to rounded lapilli (30 percent) and ash and lithic sands (70 to 90 percent). Samples of material from the saturated zone taken from wells in and near the Otowi Well Field (R-5, R-8, R-9, R-12) at the northeastern edge of LANL contained diagenetically altered volcanic glass replaced by smectite, but in other areas the lapilli are still vitric with only some surface oxidation and minor clay development (Broxton and Vaniman 2005). The source rocks may be from the Keres Group volcanism.

Tschicoma Formation

The Tschicoma Formation consists of thick dacite and low-silica rhyolite lava flows erupted from major peaks of the Sierra de los Valles highlands north and east of Valles Caldera and west of Los Alamos (Broxton and Vaniman 2005). The formation interfingers with the deposits of the Puye Formation, becomes thinner eastward across the Pajarito Plateau, and is absent at the eastern end of the plateau (Goff and Gardner 2004, Broxton and Vaniman 2005). The Tschicoma

Formation is lenticular, resulting in variable thicknesses (up to 2,500 feet [762 meters] in the Sierra de los Valles) (Broxton and Vaniman 2005).

Puye Formation

The Puye Formation is a large complex of alluvial fans made up of volcanic material and alluvium. It is well exposed north of the Pajarito Plateau; unconformably overlies the Santa Fe Group; and is intersected by most deep wells on the Pajarito Plateau (Goff and Gardner 2004, Broxton and Vaniman 2005). The formation's source rocks are the domes and flows of the Sierra de los Valles; consequently, the formation overlaps and postdates the Tschicoma Formation (Broxton and Vaniman 2005). The unit has two facies, fanglomerate and lacustrine. The fanglomerate is a widespread intertonguing mixture of stream flow, sheet flow, debris flow, block and ash fall, pumice fall, and ignimbrite deposits and may be up to 1,100 feet (330 meters) thick (Goff and Gardner 2004). The lacustrine facies include lake and riverine deposits in the upper part of the Puye; consist of fine sand, silt, and clay; and may be up to 30 feet (9 meters) thick. The lacustrine deposits are discontinuously exposed along Los Alamos Canyon (Broxton and Vaniman 2005).

Basaltic Rocks of the Cerros Del Rio Volcanic Field

These thick sequences of stacked lava unconformably overlie the Tesuque Formation and intertongue with the upper Puye under the Pajarito Plateau. Basalt outcrops occur east of the river and in Frijole Canyon and White Rock Canyon (Broxton and Vaniman 2005). The features are typical of basalt flows; that is, there is a flow base of vesicular basalt with scoria and clinkers, a collonade structure, a complex overlapping fractured zone, and a flow top with clinkers and scoria. The cooling rates of the basalts influenced the different zones of materials. The lower part of the interior units cooled more slowly than the upper part and formed columnar structures separated by vertical fractures. As cooling rates increased upward, the upper part developed into an array of web-like random fractures. The interflows consist of clastics, ash, and sedimentary deposits. The flows are generally 200 to 300 feet (61 to 183 meters) thick and reach a maximum of 983 feet (300 meters). There are some maar deposits formed when molten basalt encountered water (Broxton and Vaniman 2005).

E.5.2 Upper Pliocene and Quaternary Units

Bandelier Tuff

The Bandelier Tuff comprises the surface and near surface materials in the LANL area. It is an extensive, wedge-shaped pyroclastic unit that gets thinner as it extends eastward from Sierra de los Valles toward the eastern edge of the Pajarito Plateau and was deposited during a recent eruptive phase of the Jemez volcanic complex (1.6 to 1.2 million years ago) (Goff and Gardner 2004; Broxton and Vaniman 2005). The Bandelier Tuff is made up of two similar units, the Otowi Member (the oldest) and the Tschirege Member. The two members are divided into subunits, a basal pumice layer overlain by multiple tuff layers, and their characteristics are based mostly on thermal and depositional features. The two members are separated by a layer of tephras and volcaniclastics and make up the Cerro Toledo interval (Birdsell et al. 2005, Goff and Gardner 2004, Broxton and Vaniman 2005).

Otowi Member of the Bandelier Tuff

The Otowi Member (equivalent to the Qbo hydrologic unit discussed in Section E.6.3) is exposed in Los Alamos Canyon, the deeper canyons to the north at the edge of the Pajarito Plateau, and in the deeper canyons at the edge of the Jemez Plateau west of the Jemez Mountains (Goff and Gardner 2004; Birdsell et al. 2005; Broxton and Vaniman 2005). The basal layer of the Otowi Member, the Guaje Pumice (equivalent to the Qbog hydrologic unit discussed in Section E.6.3), is a pumice layer, ranges in thickness from about 7 to 50 feet (2 to 15 meters) (Birdsell et al. 2005), and averages about 30 feet (9 meters) (Broxton and Vaniman 2005). The pumice, a distinctive marker bed, is overlain by a series of poorly welded rhyolitic ash-flow units that collectively form an extensive, homogeneous rock unit. The Otowi Member is wedge-shaped and thins eastward away from its source, the caldera, over the central part of the plateau. The Otowi Member on the western part of the Pajarito Plateau has two thick zones ranging from 350 to 400 feet (100 to 125 meters) separated by an elongated zone ranging from less than 100 to 300 feet (30 to 90 meters). The thin zone is overlain with a thick deposit of Cerro Toledo sediments (equivalent to the Qct hydrologic unit discussed in Section E.6.3). Erosion removed a large amount of the Otowi Member in some parts of the plateau, leading to a suggestion that the thin zone is indicative of an east-trending drainage incised into the surface of the member (Broxton and Vaniman 2005).

Cerro Toledo Interval

The Otowi and Tshirege Members of the Bandelier Tuff are separated by a stratified sequence of volcaniclastics informally named the Cerro Toledo interval (Goff and Gardner 2004, Broxton and Vaniman 2005). The unit is exposed in Los Alamos Canyon and the deeper canyons to the north at the edge of the Pajarito Plateau. The Cerro Toledo is variable in thickness, ranging from 3 to 390 feet (1 to 120 meters) (Broxton and Vaniman 2005), and is composed of rhyolites that are representative of the Toledo caldera before it collapsed (Goff and Gardner 2004). Dacite and andesite detritus from the Tschicoma Formation are intertongued with reworked Otowi deposits and Cerro Toledo interval rhyolites (Goff and Gardner 2004, Broxton and Vaniman 2005).

Tschirege Member of the Bandelier Tuff

The Tschirege Member is the most distinctive and widely exposed unit on the Pajarito Plateau. It is somewhat more resistant to weathering and erosion in the western part of the plateau because the tuffs are strongly welded and form steep, narrow canyons that become wider downgradient where the tuff is not as strongly welded (Goff and Gardner 2004, Broxton and Vaniman 2005, Birdsell et al. 2005). Like the Otowi, the Tschirege Member has a basal pumice layer, the Tsankawi Pumice, that unconformably overlies the Cerro Toledo sediments (Goff and Gardner 2004; Broxton and Vaniman 2005). The pumice layer is much thinner than the Guaje Pumice and ranges in thickness from 20 to 30 inches (50 to 75 centimeters). The Tsankawi Pumice is overlain by a compound cooling sequence of four welded ash-flows (Goff and Gardner 2004). The thickness of the four units ranges from 200 feet (61 meters) in the north-central part of LANL to 600 feet (183 meters) at the southern edge of LANL (Broxton and Vaniman 2005). The degree of welding in the Tschirege increases westward on the plateau as one approaches the caldera that is the source of the tuff (Broxton and Vaniman 2005). The high temperatures were maintained longer due to the thicker deposits, which increases welding.

Cooling joints in the Otowi tuffs and poorly welded portions of the Tschirege are mostly lacking (Birdsell et al. 2005).

The four mappable cooling units of the Tschirege tuffs have been subdivided into subunits based on distinctive lithologic characteristics because the units occupy a "significant portion of the vadose zone" (Broxton and Vaniman 2005). The unit names are also used for the hydrologic units discussed in Section E.6.3. Briefly, from the oldest to the youngest, the designations for the units are:

> **Qbt 1g**. This unit is a porous, nonwelded tuff with no devitrification or vapor phase alteration of the glass (g). The unit has a resistant caprock that protects the soft tuffs underneath, forming steep cliffs.
>
> **Qbt 1v**. This unit is nonwelded, porous, crystalline tuff that has undergone vapor-phase (v) crystallization of pumice and glass shards. The lower part (Qbt 1vc) is a collonade tuff with columnar cooling joints. The tuff alternates between cliff-forming and slope-forming units.
>
> **Qbt 2**. This unit is a series of surge beds, forming brownish vertical cliffs. The unit conformably overlies Qbt 1v in some parts of LANL. The unit is dense and porosity is lower than the other units. Welding increases upward.
>
> **Qbt 3**. This unit is a nonwelded to partly welded, vapor-phase tuff that forms the cap rock of mesas. It grades upward from a soft basal unit that is a purple-gray, porous, unconsolidated, crystal-rich, nonwelded tuff to a partly welded, white cliff-forming tuff that becomes moderately to densely welded in the western part of LANL. Qb 3t, a subunit of Qbt 3, is moderately to densely welded ash-flow tuff in the far-western part of LANL and is transitional to Qbt 4.
>
> **Qbt 4**. This unit is a complex unit in the western part of LANL made up of nonwelded to partly welded ash-flow tuffs with pumice and surge deposits in the lower part of the unit and densely welded ash-flow tuffs that form caprocks. The unit has mostly undergone devitrification and vapor phase alteration, but locally there are thin rhyolitic, vitric ash-flow tuff deposits.

Alluvium

Alluvium of the Holocene and Pleistocene occurs on the canyon floors at LANL. Continuous alluvial deposits from the Pleistocene occur at the foot of the eastern slopes of Sierra de los Valles and on the Pajarito Plateau on top of the Bandelier Tuff (Broxton and Vaniman 2005). The alluvium on the floors of small canyons that head (begin) on the Bandelier Tuff consists of Bandelier Tuff detritus. Canyons that have headwaters farther west in the Sierra de los Valles have detritus from the Bandelier and the Tschicoma Formations. The alluvium consists of unconsolidated fluvial sands and gravels and forms stratified lenticular-shaped deposits along the canyon floors and at the mouths of canyons. The alluvium deposits intertongue with the colluvium, which may have blocks of material up to 10 feet (3 meters) in cross-section at the bases of the walls of the canyons. The deposits are cross-cut by the ephemeral or intermittent streams, forming complex deposits on the canyon floors and at the mouths of the canyons. The alluvial deposits vary in thickness within the canyons and from canyon to canyon. Alluvium thickness in Pueblo Canyon ranges from 11 feet (3.4 meters) on the west side of the plateau to about 18 feet (5.5 meters) at the confluence with Los Alamos Canyon (Broxton and Vaniman 2005; Robinson et al. 2005); at Mortandad Canyon, the range is from 1 to 2 feet (0.3 to 0.6 meters) at its headwaters to 100 feet (30 meters) at the eastern margin of LANL.

E.6 Hydrogeology

E.6.1 Comparison of the Bedrock Geologic Framework with the Hydrologic Framework

Cross-sections that represent subsurface geology result from the integration of:

- Structural geologic observations consisting mostly of the elevations of contacts between rock bodies of different character measured in wells,
- Stratigraphic descriptions of the character and thickness of individual rock bodies from wells and the study of outcrops, and
- Down-hole geophysical studies.

The observations from wells define the fundamental data necessary to accurately construct cross-sections. The cross-sections, structural contour maps, and interpreted character of the rocks around LANL serve as the framework for flow and transport models (Figure E–4). Cross-sections drawn from west to east across the Pajarito Plateau are presented in **Figures E–7** (along Los Alamos Canyon) and **E–8** (along Pajarito Canyon).

The comparison shows how the geologic units differ from the hydrologic units. The geologic units are combined because they possess similar hydrologic properties, which allows for modeling efficiency. This does not imply that the hydrologic units are homogeneous regions of unvarying properties. Large local internal variations in hydrologic properties have been noted and are due to rock texture, composition, and structure. The basis for defining the hydrologic units is that the gross character of a unit can be modeled relatively consistently. The following discussion compares the geologic and hydrologic frameworks (Broxton and Vaniman 2005).

E.6.2 Groundwater Occurrence

There are three modes of groundwater occurrence in the Pajarito Plateau: (1) perched alluvial groundwater in canyon bottoms; (2) zones of intermediate-depth perched groundwater whose location is controlled by availability of recharge and by subsurface changes in permeability; and (3) the regional aquifer beneath the Pajarito Plateau (Broxton and Vaniman 2005). In wet canyons, stream runoff percolates through the alluvium until downward flow is impeded by less permeable layers, maintaining shallow bodies of perched groundwater within the alluvium. Contaminant distributions in the groundwater under the Pajarito Plateau suggest that the three systems may be in communication under certain conditions (Robinson, McLin, and Viswanathan 2005). The hydrogeology of the Pajarito Plateau is typical of the semi-arid, sediment-filled basins along the Rio Grande Rift in that the basins receive recharge from mountain ranges along the margins (Broxton and Vaniman 2005). This section discusses alluvial, perched, and regional groundwater.

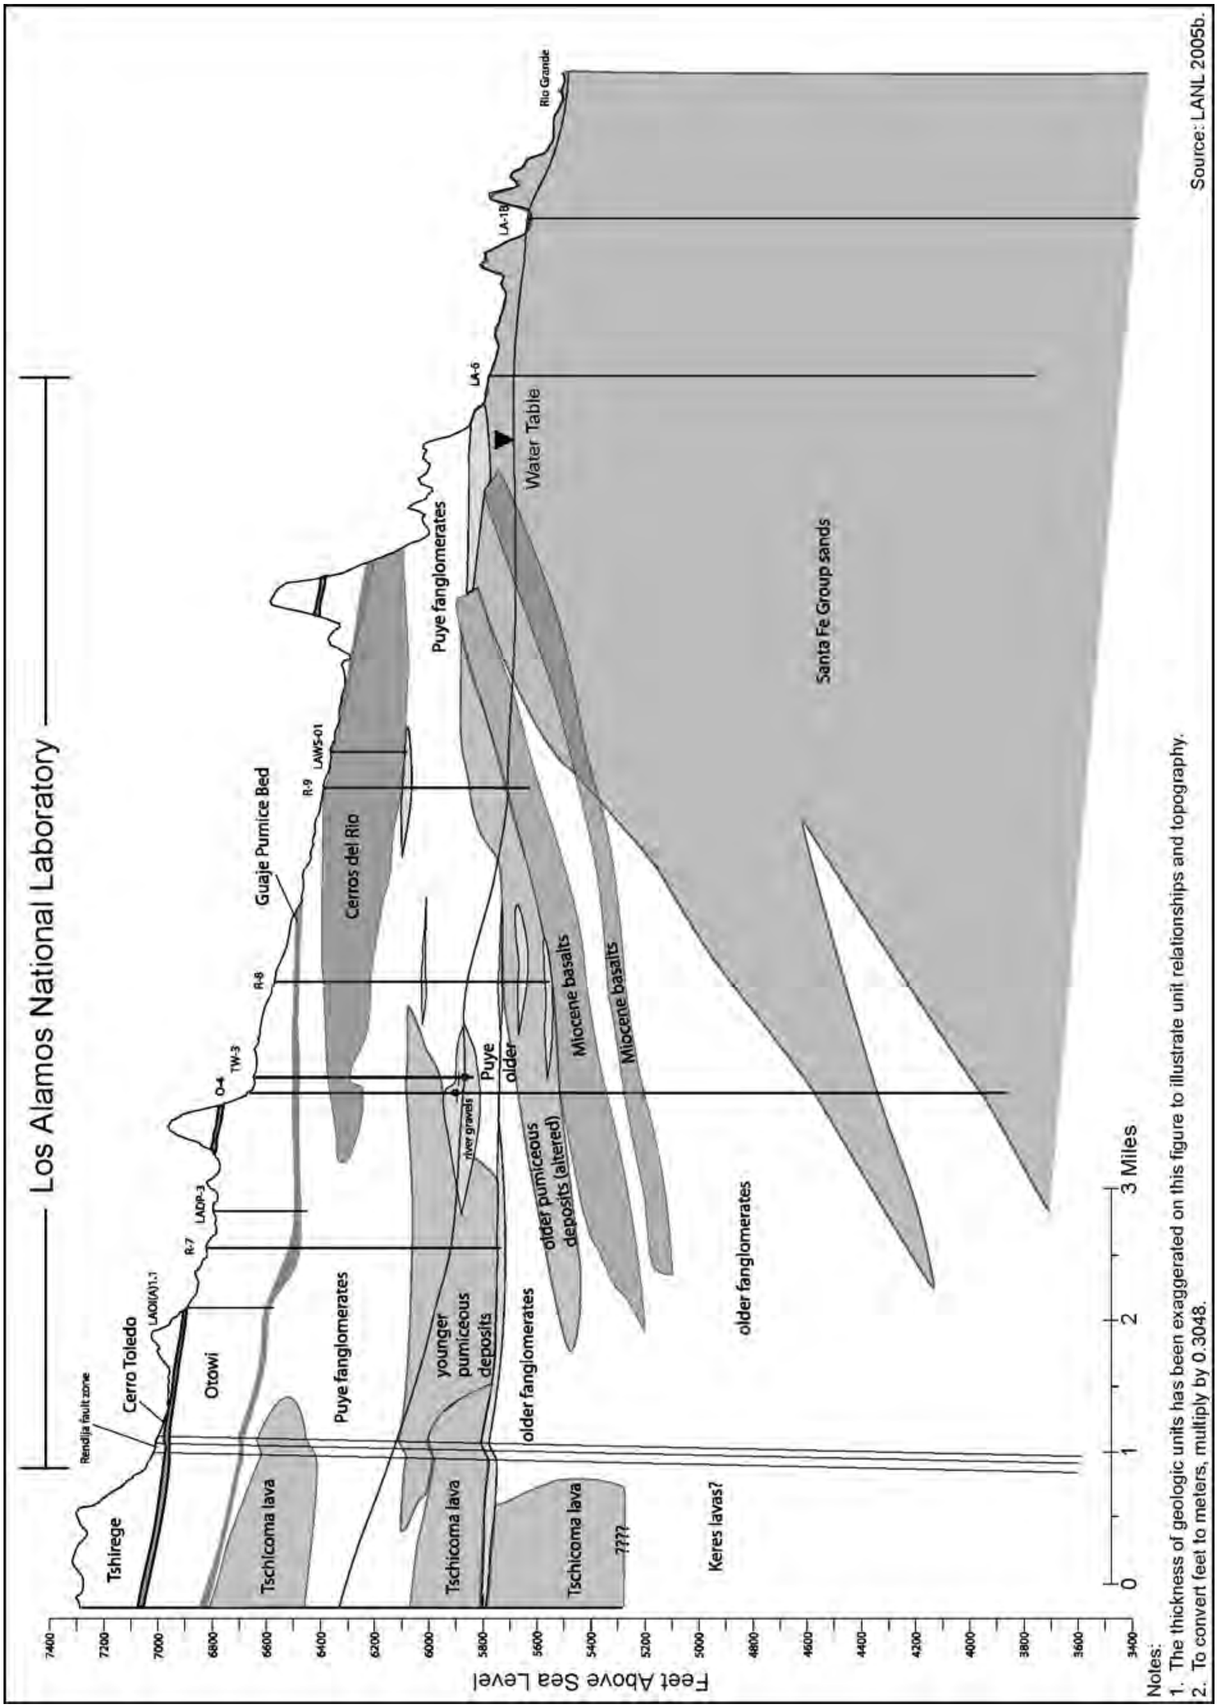

Figure E–7 Conceptual Cross-Section Across the Pajarito Plateau Along Los Alamos Canyon

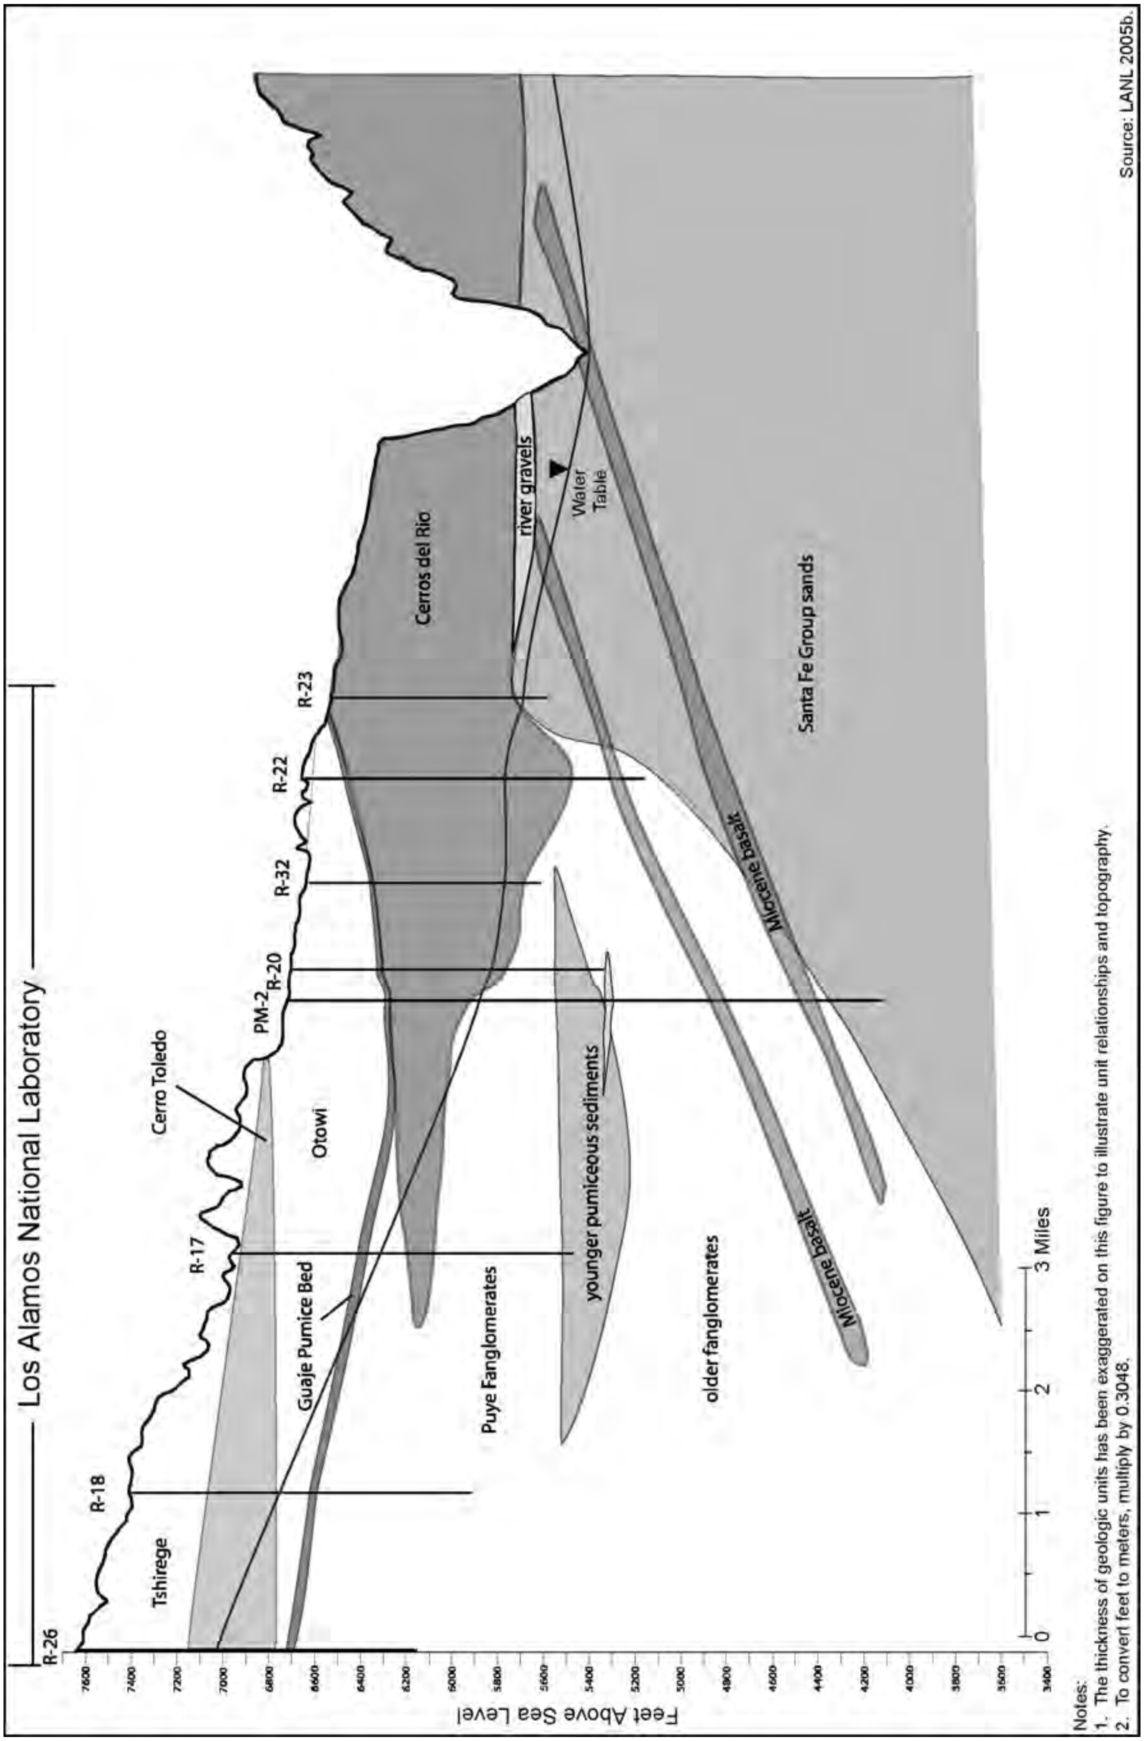


Notes:
1. The thickness of geologic units has been exaggerated on this figure to illustrate unit relationships and topography.
2. To convert feet to meters, multiply by 0.3048.

Source: LANL 2005b.

Figure E–8 Conceptual Cross-Section Across the Pajarito Plateau Along Pajarito Canyon

The geology of the regional aquifer was discussed above. Knowledge of the origin and depositional history of the rocks at LANL, coupled with groundwater sampling and aquifer testing, helps to determine the hydraulic properties of the regional aquifer. Single well tests of small volumes of rock have been conducted by withdrawing water from or injecting water into a well and measuring the rate of recovery of the original water surface. Multiple-well tests of large volumes of rock involve pumping a well and then making observations of the effects on nearby wells completed in the same interval. Extensive downhole geophysical studies are also a part of the deep-well program. Studies of rock properties and geochemical information with hydrologic testing results provide a basis for evaluating travel times and transport in the vadose zone (Keating, Robinson, and Vesselinov 2005). Summaries of these properties obtained from well tests, sampling programs, and analyses have been reported previously (Keating, Robinson, and Vesselinov 2005; Robinson, McLin, and Viswanathan 2005; Birdsell et al. 2005). Potentiometric maps, hydraulic gradients, and permeability data for the regional aquifer have also been discussed (Keating, Robinson, and Vesselinov 2005).

E.6.2.1 Alluvial Groundwater

Alluvial groundwater in the LANL area primarily occurs in canyons that originate in the Sierra de los Valles or in the Pajarito Plateau watersheds. Groundwater in the canyons is supported by seasonal runoff from the mountains, by episodic precipitation events on the plateau, perennial springs, and by discharge from LANL outfalls. Liquid wastewater from LANL released to the outfalls above the canyons was responsible for contamination of alluvial groundwater in the past. The wastewater also plays a part in the hydrogeology of the canyons.

As mentioned above in the stratigraphy section, the canyon floors are covered with alluvium of variable thickness and consist of fluvial sands, gravels, and cobbles. The alluvium is derived from the mountains to the west and from rocks that have been incised by the ephemeral and intermittent streams that formed the canyons (parts of some canyon streams have perennial flow). The alluvium is intermingled laterally with colluvium from the canyon walls. Groundwater in the canyons occurs above permeability barriers at the base of the alluvium above the Bandelier Tuff or above well-sorted tight sequences of canyon floor alluvium. Seasonal variation in the amount of snowmelt or storm runoff affects the saturated thickness and lateral extent of alluvial groundwater.

E.6.2.2 Deep Perched Groundwater

The extent and nature of deep perched water beneath Pajarito Plateau has been investigated to determine whether the alluvial systems on the plateau are in communication with the deep perched water or the regional aquifer and whether there is a potential for contaminants to travel to the regional groundwater (Robinson, Broxton, and Vaniman 2005). At the time of the investigation, 33 perched water zones had been identified in 29 wells. The study defined perched water "as a hydrologic condition in the rock or sediment above the regional aquifer in which the rock pores are completely saturated with water." Perched water may occur because of capillary barriers or because of low permeability barriers coupled with structures in the stratigraphic section. For example, faults may intersect hydraulically conductive zones with low permeability materials and block flow paths. Another cause may be that, when a saturated zone becomes unsaturated due to a decline in water level, water may become trapped in a zone of high permeability where it is unable to move to the new level.

The perched zones at LANL do not have enough water to warrant putting in municipal water supply wells, but the perched groundwater zones are important for four reasons: (1) the water is protected under state law; (2) transport rates through the unsaturated rocks are affected by the chemistry of the perched zones; (3) the zones restrict vertical movement of groundwater or may indicate the presence of fast-paths; and (4) the zones can be used for monitoring movement of groundwater toward the regional aquifer (Robinson, Broxton, and Vaniman 2005). The deep, perched zones get water from surface and alluvial groundwater associated with the large canyons that head in the Sierra de los Valles; deep, perched water below the smaller canyons on the plateau can also be recharged by liquid effluent from LANL. The deep, perched water zones have a saturated thickness ranging from 100 to 400 feet (30 to 120 meters) (Robinson, Broxton, and Vaniman 2005).

Perched water bodies are important elements of the hydrogeology of the site for several reasons. There is a probability that the zones can intercept contaminants being transported downward through the vadose zone. The perched water can be a permanent or long-term residence for contaminants because the chemical makeup of the rocks may result in adsorption. Perched water can also serve as a place where dilution occurs, lowering the concentration of contaminants. There is a possibility that perched zones may be intersected by streams in the lower parts of the canyons, resulting in lateral flow under the influence of gravity out of the canyon walls into the alluvial aquifer and subsequently to the Rio Grande.

E.6.2.3 Regional Groundwater

The regional aquifer below LANL is very deep (up to 1,200 feet [360 meters]) and is separated from the surface by a thick vadose zone with some perched water zones (Keating, Robinson, and Vesselinov 2005). The depth to the water of the regional aquifer on the eastern part of the plateau near the rim of White Rock Canyon is about 614 feet (200 meters), about 210 feet (65 meters) above the level of the Rio Grande (Broxton and Vaniman 2005). It has been reported that a well drilled in the lower Los Alamos Canyon near the Rio Grande flowed to the surface when installed in the regional aquifer, indicating confined or semi-confined conditions, and that there are seeps and springs in White Rock Canyon (Broxton and Vaniman 2005).

Sedimentary bedrock units at the top of regional saturation zones below the Pajarito Plateau at LANL include the Puye Formation (Tpf), pumiceous deposits (Tpp), older fanglomerate (Tf), and Tesuque Formation (Ts). The volcanic rocks in which groundwater occurs are the Cerros del Rio basalts (Tb4), the Tschicoma Formation (Tt), and Miocene basalt (Tb2) (Broxton and Vaniman 2005). Groundwater recharge to the regional aquifer under the Pajarito Plateau comes from underflow from the Sierra de los Valles and from drainages across the plateau (Kwicklis et al. 2005). The stratigraphy of the rocks is discussed in Section E.5. The most productive wells on the plateau occur in the central part of the plateau within the basin fill deposits consisting of the Puye Formation, the pumiceous deposits, the Totavi Lentil, the older fanglomerates, and the Tesuque Formation. The wells have screens up to 1,600 feet (500 meters) long spanning these units (Broxton and Vaniman 2005). The Tesuque is the primary productive unit in the eastern part of the plateau, in Guaje Canyon, and in the lower Los Alamos Canyon.

E.6.3 Hydrogeologic Units

Basal Confining Units

The rock units that occur below the regional aquifer are considered to be all of the units below the Tesuque Formation, including Precambrian igneous and metamorphic rocks, Paleozoic and Mesozoic sedimentary rocks, and mid-to-upper Tertiary terrestrial sediments.

Santa Fe Group Rocks

Hydrologic unit Ts is generally considered to be equivalent to the Tesuque Formation. The lithology of the unit is silty to sandy with some basalt and flow breccias (Tb1). The basalts are about 11 to 13 million years old and have intercalated sedimentary units. Water supply wells in the lower Los Alamos Canyon completed in this unit yield about 600 gallons per minute (2,200 liters per minute), and in the western part of LANL where the Ts is coarser, supply wells yield about 1,000 gallons per minute (3,800 liters per minute). Flow in the volcaniclastics and altered basalts is associated with fractures; the interflow breccias are plugged with secondary minerals (Broxton and Vaniman 2005).

Older Fanglomerate

This hydrogeologic unit (Tf) is a thick sequence of gravel and cobble beds and interbedded sandstones. It has been identified as the most productive zone (1,000 gallons per minute [3,800 liters per minute]) in the LANL area. The Tf is vertically heterogeneous and anisotropic because of the bedding, but may be strongly isotropic in the lateral direction. Reinterpretation of earlier well logs puts the contact with the Ts at the transition zone where coarse grain gravels and cobbles overlay sands and silts (Broxton and Vaniman 2005). Basalts (8.4 to 9.3 million years old) and intercalated sedimentary rocks in the Tf are designated as Tb2. Hydrologic unit Tk is intertongued with the Tf and is made up of Keres Group volcanic rocks.

Hydrologic unit Tpt represents the Totavi Lentil and older river deposits that make up a poorly consolidated conglomerate. Data from one water production well completed in this interval show that 18 percent of the water produced comes from only 2.5 percent of the screened interval (Broxton and Vaniman 2005). The hydrologic unit Tpp below the Tpt is a well-stratified, heterogeneous, pumice-rich, volcaniclastic rock. It is fine grained and more porous than the more coarsely grained overlying and underlying hydrologic units. The unit is anisotropic because, vertically, the alternating fine grained bedding is less hydraulically conductive than in the lateral direction. These pumice rich rocks also have a lower bulk density than Tpt and Tf (Broxton and Vaniman 2005; Birdsell et al. 2005).

Beneath the pumice deposits is the hydrologic unit Tpf that is similar to, but predates, the lacustrine deposits of the Puye Formation (Birdsell et al. 2005). The lacustrine deposits are equivalent, which may indicate that the rocks are contemporaneous (Broxton and Vaniman 2005). The Tpf is a deposit of coalesced alluvial fans and consists of much coarser material than the Tpp; like the Tpp, however, it is heterogeneous and anisotropic. Vertically, heterogeneity is due to layering; laterally, it is due to cross-cutting and variable grain size characteristic of fluvial deposits in an alluvial fan environment. It has been hypothesized that the hydraulic conductivity in the vertical direction is less than the hydraulic conductivity in the horizontal direction parallel to the bedding planes (Broxton and Vaniman 2005).

Basaltic Rocks of the Cerros del Rio Volcanic Field

The heterogeneous hydrologic unit Tb4 basalts are intercalated with subordinate amounts of upper Puye Formation and constitute the top of the regional aquifer at the southeast corner of LANL (Birdsell et al. 2005; Broxton and Vaniman 2005). As noted above, these basalts are exposed on the east side of the Rio Grande. In the LANL region, the basalts are located under the central and eastern part of the Pajarito Plateau. The connected porosity of the highly brecciated clinker and scoria zones and sediments at the tops and bottoms of the stacked lavas may extend for hundreds of yards or may be limited in some areas where the voids are filled with clay minerals (Birdsell et al. 2005; Broxton and Vaniman 2005). The dense lava flow interiors are impermeable, with flow of gases and liquid water restricted to fractures. Flow in the scoriated breccia zones is lateral along the beds and mostly vertical in the interflow zones.

Bandelier Tuff

The stratigraphic divisions presented in Table E–1 were retained for the hydrologic units because the rock properties for the stratigraphic subunits are laterally ubiquitous and traceable throughout the plateau (Broxton and Vaniman 2005). This section presents the hydrologic units of the Bandelier Tuff with descriptions from oldest to youngest (Broxton and Vaniman 2005, Birdsell et al. 2005, Springer 2005).

Ash-flow tuffs and fall deposits (the Guaje Pumice Bed) of the Otowi Member are hydrologic units Qbog and Qbo, respectively. Qbo is uniform with respect to vertical density and density-porosity profiles in the central and eastern parts of the plateau, but is more variable in the west where changes are more abrupt (Broxton and Vaniman 2005). The ash-flow tuffs of the Otowi do not have pervasive cooling joints found in the welded tuffs in the upper Bandelier (Birdsell et al. 2005). The Guaje Pumice Bed (fall deposits) at the base of the Otowi Member is designated hydrologic unit Qbog. It is well sorted and stratified; has less matrix ash than the other Bandelier units; and is an excellent marker bed between the Bandelier Tuff and the units below it.

The stratified volcaniclastic deposits of the Cerro Toledo Interval are designated as hydrologic unit Qct. Because the unit consists of rocks that are variable in grain size, sorting, and bedding thickness, a strong vertical anisotropy exists above Qct within the Bandelier (Broxton and Vaniman 2005). These characteristics provide a favorable setting for perched groundwater.

The upper Tshirege Member is a complex hydrologic unit of welded ash-flow tuffs separated by poorly welded tuffs and a basal unit of pumice fall deposits. The welded tuffs have joints and fractures caused by cooling and tectonic processes that die out in the nonwelded layers (Birdsell et al. 2005). The basal hydrologic unit Qbt t is equivalent to the Tsankawi Pumice Bed (Broxton and Vaniman 2005). Unit Qbt t is overlain by hydrologic subunits Qbt 1g and Qbt 1v. Qbt t and Qbt 1g are the only ash and pumice falls in the Tshirege that are made up of similar, unaltered volcanic glass.

Volcanic glass above Qbt 1g in hydrologic unit Qbt 1v has undergone post-depositional devitrification and vapor-phase crystallization. These processes may affect grain size and decrease effective porosity by creating poorly connected pore spaces (Broxton and Vaniman 2005). Unit Qbt 1vc is indurated and poorly welded with a system of well-developed columnar joints. Unit Qbt 1vu is generally nonwelded to partly welded, but lacks extensive jointing (Broxton and Vaniman 2005, Birdsell et al. 2005).

Hydrologic unit Qbt 2 is separated from the altered beds of unit Qbt v by a thin pyroclastic surge bed in the eastern part of the Pajarito Plateau; but in other parts of the plateau, Qbt 1v grades into Qbt 2. In the western part of the plateau, density and density-porosity profiles indicate that Qbt 2 has a cooling break present at its center. The break is not present in the eastern part of the plateau. Upper Qbt 2 is strongly welded, becomes less welded down-section, and has higher bulk densities than other Tshirege units.

Hydrologic unit Qbt 3 is strongly welded in the western part of the plateau and becomes less welded eastward. The strongly welded interior of Qbt 3 has a high bulk density and low density porosity. Hydrologic unit Qbt 4 is a nonwelded to strongly welded unit and is present only in the western Pajarito Plateau.

E.7 Conceptual Models

Potential contamination of the regional aquifer below LANL is of major concern. It is the responsibility of LANL to determine whether past contaminant releases pose a threat to human health. Flow and transport mechanisms through the vadose zone are being examined. This section discusses recent papers in the *Vadose Zone Journal* published on August 16, 2005. The papers collectively describe the work that has been completed or contemplated for the purpose of developing conceptual models of the hydrogeology and numerical models of groundwater flow and transport under the Pajarito Plateau in general and under LANL in particular. The journal articles summarize extensive observational data regarding deep perched water on the plateau and discuss the controls on the distribution of deep perched water and the ways perched zones may develop (Robinson et al. 2005). There is a description and a numerical model of the regional aquifer below the Pajarito Plateau that is used for determining fluxes and transport (Keating, Robinson, and Vesselinov 2005). There is a report on net infiltration on the plateau, which is a major concern when modeling groundwater flow under LANL and streamflow on the plateau (Kwicklis et al. 2005). A comprehensive discussion of a statistical analysis of hydrologic properties also is presented (Springer 2005). Several articles discuss the roles of matrix and fracture flow within the Bandelier Tuffs and basalts (Robinson, Broxton, and Vaniman 2005, Levitt et al. 2005, Stauffer and Stone 2005). There is also a summary paper that describes the hydrogeologic setting and site history of LANL (Newman and Robinson 2005).

Conceptual models constantly change as knowledge about hydrologic processes and events that control groundwater movement increases for a particular site. The following section includes a discussion of the conceptual models, numerical model development, modeling results, and conclusions. The papers are presented in the order of the hydrostratigraphy of the region: the vadose zone; the deep perched zones; and the regional aquifer.

E.7.1 Geochemical Conceptual Model

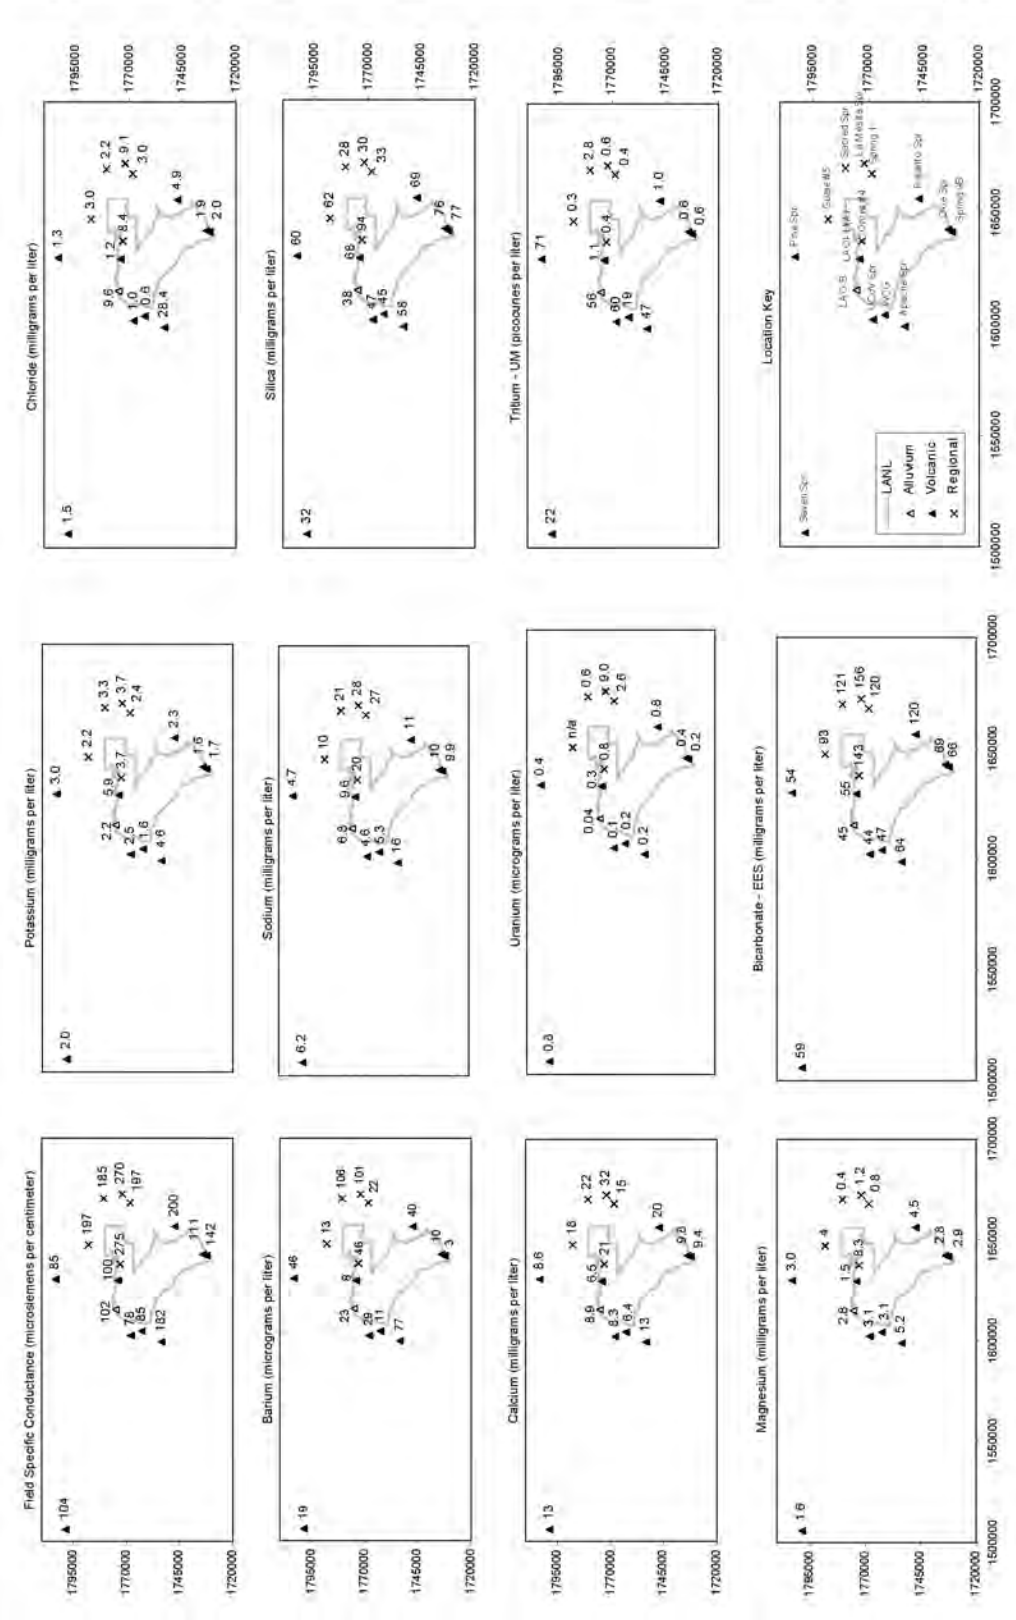
This section is a discussion of the geochemistry of the groundwater in the LANL region as presented in *Los Alamos National Laboratory's Hydrogeologic Studies of the Pajarito Plateau: A Synthesis of Hydrogeologic Workplan Activities (1998-2004) (Hydrogeologic Synthesis Report)* (LANL 2005b). First, the *Hydrogeologic Synthesis Report* discusses a geostatistical methodology of reducing the data from many sources outside the area that might have been contaminated and develops a groundwater chemistry baseline. Second, it presents conceptual models of each reach of canyon drainage that is thought to be unique in its natural and artificial flow and its contaminant transport history. Third, alternative models of contaminant transport to the perched water bodies and the regional groundwater are presented to relate the contaminant concentrations, recharge, and transport processes to probable sources, predominantly the canyon bottom alluvial aquifers. Last, it presents a discussion of conceptual models of the hydrogeology and geochemistry of the canyon springs.

The discussion of the components of geochemical conceptual models was broken into seven parts in the *Hydrogeologic Synthesis Report*. The components are:

- Natural geochemical composition of groundwater,
- Residence time of contaminant ions in the perched alluvial aquifer and the rocks of the vadose zone,
- Reactive minerals controlling groundwater composition and solute mobility,
- Adsorption and precipitation reactions,
- Redox conditions,
- Chemical speciation, and
- Colloids.

Natural Composition of Groundwater

Groundwater sampling to establish a baseline (background) of the chemistry of groundwater in the LANL area was conducted from 1997 to 2000. The composition of natural groundwater in the LANL area ranges from calcium-sodium bicarbonate water at the Sierra de los Valles to sodium-calcium bicarbonate water east and northeast of LANL. Sodium bicarbonate groundwater occurs in deep wells in the lower Los Alamos Canyon and along the Rio Grande and in springs in White Rock Canyon (LANL 2005b). This characterization of the natural groundwater permits the discrimination of natural components in the groundwater from manmade contaminants. **Figure E–9** shows the average concentrations of solutes, including specific conductance, major cations and anions, silica, tritium, and several trace elements such as uranium and barium from six sampling rounds.



Source: LANL 2005b.

Figure E–9 Average Spatial Distribution (n=6) for Key Analytes in Los Alamos National Laboratory Background Wells and Springs

Residence time

Residence time refers to the distribution of the ages of groundwater in the various groundwater environments under the Pajarito Plateau. Determining the residence time helps determine transport rates through the rocks. The residence time of natural major ions and trace elements in natural groundwater under the Pajarito Plateau increases from west to east and with depth in all modes of groundwater occurrence. Measurements of tritium in groundwater from within the Sierra de los Valles fractured volcanic rocks indicate that the groundwater is less than 60 years old; however, groundwater in the discharge area at White Rock Canyon ranges from 3,000 to 10,000 years old (LANL 2005b). Carbon-14 dating of regional groundwater in the LANL area indicates that a component of the groundwater is several tens of thousands of years old, becoming older from west to east. The presence of tritium indicates that younger water is mixing with the older water. Future studies are planned to determine the fractions of young and old water (LANL 2005b).

Reactive minerals

Groundwater reacts with the minerals in rocks through which it passes or in which it is stored. These reactions control basic chemical conditions such as pH and influence mineral precipitation and dissolution, as well as sorption of ions from groundwater by minerals. These are important controls on the evolution of groundwater as it migrates and on the mobility of contaminant ions.

In the natural groundwater, sodium, calcium, and bicarbonate are the most abundant major ion solutes. Silica is the second most abundant due to the interaction of volcanic glass with the groundwater. Average concentrations of natural arsenic and fluoride were highest in the Cerros del Rio basalts. Average concentrations of dissolved natural barium, boron, bromide, strontium, and uranium in the regional aquifer were highest at La Mesita Spring. Silica-rich rocks such as the Bandelier Tuffs contain more natural uranium than the basalts, which are silica-poor. Uranium in trace minerals such as zircon may exceed 1,000 parts per million, but zircon is highly refractory and has a low aqueous solubility ($10^{-15.4}$ molar at pH 7); consequently, it does not dissolve readily in the natural groundwaters at LANL. Some uranium is associated with volcanic glass in the Bandelier Tuff. In comparison with zircon, volcanic glass has a higher aqueous solubility ($10^{-27.1}$ molar at pH 7), but a low concentration of uranium. Therefore, even though the leachability is higher for volcanic glass, the concentration of uranium in perched water in the Bandelier Tuff is low (LANL 2005b).

Dissolved organic carbon is a component of groundwater derived from leaching solid organic matter from forests and grasslands. At LANL, organic matter is found in the perched water in the intermediate zones and in the regional aquifer and is typically less than 2 milligrams of carbon per liter. Higher concentrations are found in alluvial groundwater, soil, and surface water (20 milligrams of carbon per liter) (LANL 2005b). Ash from the Cerro Grande Fire in May 2000 increased the amount of leachable carbon in the LANL area. The increased concentration of total organic carbon can be used as a tracer for tracking recharge. Perched zones in the Cellos del Rio basalt in Los Alamos Canyon have exceeded 300 milligrams of carbon per liter.

Calcite, smectite, hydrous ferric oxide, manganese hydroxide, and zeolites are highly adsorptive for trace elements including chromium, lead, strontium, and thorium. As groundwater flows through the intermediate perched zones, the soluble silica glass that is present reacts with the groundwater and forms clay minerals, including kaolinite and smectite. Smectite increases the adsorption capacity of aquifer material under circumneutral (6.5 to 7.5) pH conditions. These interactions are only partially known in the specific groundwater environments beneath the Pajarito Plateau, but knowledge is expanding as new programs are being incorporated.

Adsorption and Precipitation

Adsorption and precipitation are the principal mechanisms that retard the transport of contaminants and keep them in residence in the vadose zone. These reactions are well documented for most of the contaminant ions present under the Pajarito Plateau. The specific groundwater environment in terms of pH and parallel mineral reactions are important controls on sorption and precipitation reactions. Definition of those relationships is an interactive process that is underway in the areas of specific concern at LANL (LANL 2005b). Geochemical processes increase concentrations (measured as total dissolve solids) of trace elements downward from the alluvial aquifer to perched water and on to the regional aquifer from west to east due to residence time and rock and water interactions such as adsorption-desorption (LANL 2005b). Relatively fresh water in the form of precipitation recharges the groundwater at the Sierra de los Valles and reacts with the rocks as it moves along flow paths, becoming more mineralized toward its discharge points. Notice in Figure E-9 that tritium decays along the flow path from west to east and that the concentration decreases within the noncontaminated intermediate perched water and the regional aquifer.

Redox Conditions

Redox condition refers to whether the local groundwater conditions are oxidizing or reducing. This influences mineral stability and sorption reactions and is another aspect of groundwater chemistry that controls contaminant mobility. As mentioned above, uranium is a naturally occurring trace element found in groundwater below the Pajarito Plateau. It is processed at LANL and is discussed at length in the *Hydrogeologic Synthesis Report* (LANL 2005b). As stated above, some other natural components of groundwater are calcium, bicarbonate, and silica compounds. The *Hydrogeologic Synthesis Report* (LANL 2005b) concludes that the temperature, pH, redox potential, and dissolved activities of the ions mentioned influence precipitation and dissolution of uranium compounds. These conclusions were based on geochemical calculations and the oxidizing conditions of natural groundwater beneath the Pajarito Plateau. The *Hydrogeologic Synthesis Report* (LANL 2005b) also concluded that, although it is useful to perform saturation index calculations to evaluate mineral equilibrium, most of the deep groundwaters are not in equilibrium with respect to the uranium compounds. Based on the results of the calculations they presented, adsorption processes appear to control dissolved concentrations of uranium in groundwater.

Chemical Speciation

Ions can exist as various stable isotopes and as parts of stable compounds (some organic) in groundwater. The form in which each contaminant ion exists influences its entry into precipitating minerals or sorption, and thus influences its mobility (LANL 2005b).

Colloids

The role of colloids in transport of contaminants at LANL is largely unknown and uninvestigated.

E.7.1.1 Contaminant Distributions

Anthropogenic contaminants in the groundwater at LANL generally derive from liquid effluent disposal into canyons or from surface impoundments on the mesa tops rather than from solid waste disposal. (Most solid waste disposal sites are located on mesa tops where there is little natural or artificial percolation to carry anthropogenic constituents to groundwater.) These effluents have degraded shallow perched water in some canyons (LANL 2005b). Canyons that have received radioactive effluent include Mortandad Canyon, Pueblo Canyon from its tributary Acid Canyon, and Los Alamos Canyon from its tributary DP Canyon. Effluents from high explosive processing and experiments contributed effluent to Water Canyon, its tributary Cañon de Valle, and Pajarito Canyon. Los Alamos County and the LANL contractor have operated sanitary treatment plants over the years (**Figure E–10**).

Effluent releases have impacted alluvial groundwater and in a few cases perched groundwater at depths of a few hundred feet. Little contamination from the perched groundwater zones under the mesas reaches the deep regional groundwater because the perched water is separated from the deep aquifer by hundreds of feet of unsaturated rock. LANL contaminants are found in groundwater below the alluvial aquifers in some canyons or below mesa tops where large retention ponds were located or where there were large-quantity discharges to the surface (LANL 2005b). The *Hydrogeologic Synthesis Report* (LANL 2005b) contains a summary of monitoring data by watershed and groundwater zone.

Observation of contaminant data and knowledge of geochemistry and the history of releases of contaminants provides a method of determining the rates and modes of groundwater flow through the subsurface to the regional aquifer. Nonreactive chemicals and compounds like tritium, perchlorate, and nitrate are used to determine how groundwater moves through the rocks. Some compounds or constituents (uranium, strontium-90, barium, some high explosive compounds, and solvents) are slowed by adsorption, precipitation-dissolution, oxidation-reduction, or radioactive decay, and some constituents (americium-241, plutonium) are strongly absorbed onto sediment and are nearly immobile (LANL 2005b).

Alluvial groundwater does not extend beyond LANL boundaries and has a short residence time. Tritium studies have shown that there is a rapid turnover of alluvial groundwater volume in the alluvial aquifers in the canyons and that contaminants do not accumulate. Since effluent limits were adopted in 2001, LANL has improved effluent quality and the once high values of tritium contamination are not present today. Since that time, tritium activity is barely detectable in Pueblo Canyon, DP Canyon, and Los Alamos Canyon and is below the maximum contaminant level in Mortandad Canyon.

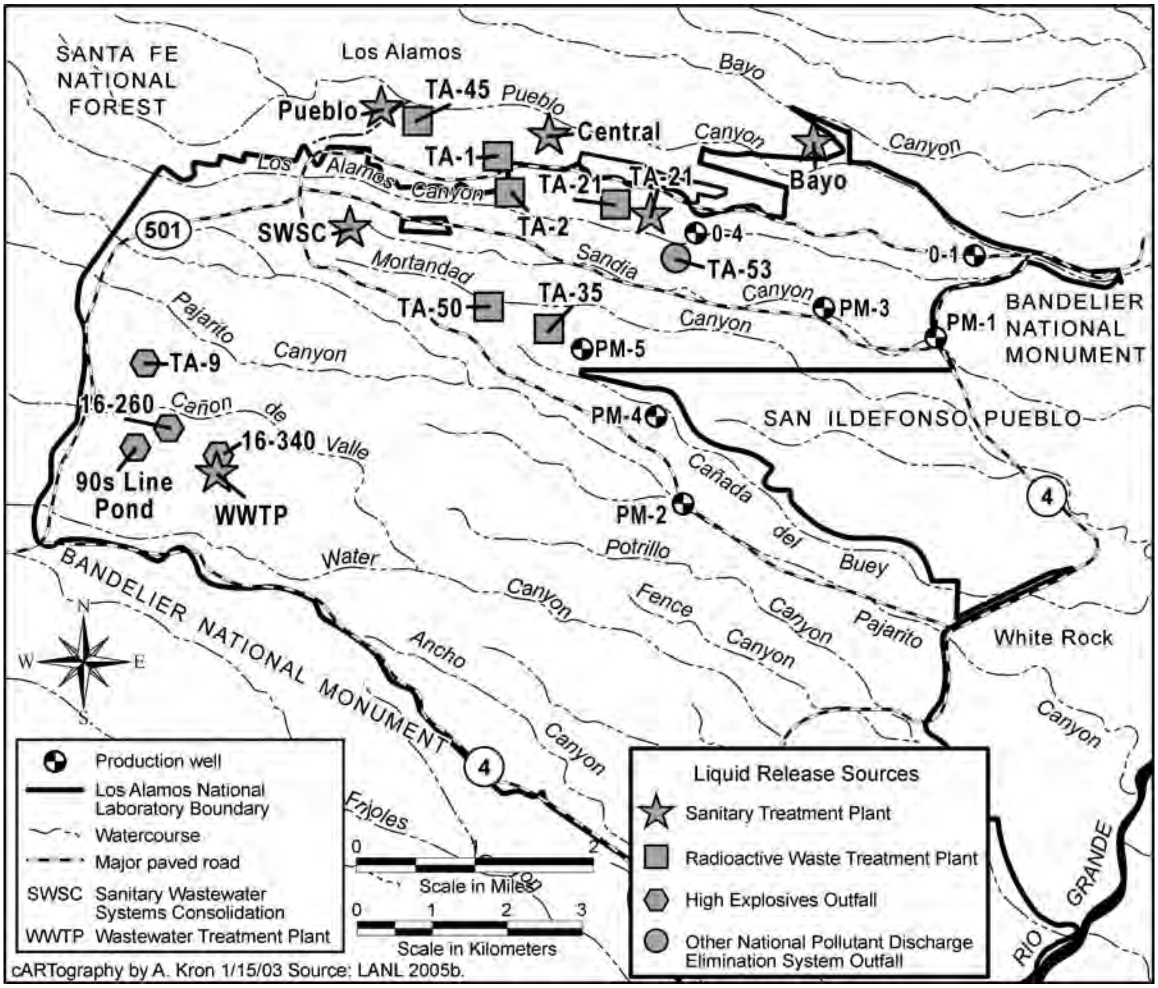


Figure E–10 Major Liquid Release Sources that have Potentially Affected Groundwater at Los Alamos National Laboratory (most of these are now inactive)

As mentioned above, perched groundwater is separated from alluvial groundwater by several hundred feet of unsaturated rock; even though recharge occurs slowly, contaminants in alluvial groundwater may reach the intermediate perched groundwater. Contaminant concentration data from the perched water zones below Mortandad Canyon indicate alluvial groundwater is the source of recharge to the intermediate groundwater by a process of infiltration (LANL 2005b).

The regional aquifer is separated from the intermediate perched groundwater by hundreds of feet of unsaturated rock. Recharge through these rocks to the regional aquifer occurs over a longer time than under the alluvial aquifers. Contaminants are found below alluvial groundwater in canyon bottoms or in perched water below mesa-tops where large amounts of effluents had been discharged to the surface. Tritium concentrations are much lower than values found in alluvial or intermediate groundwater due to dilution or to radioactive decay (LANL 2005b). Some high values are found in conjunction with effluent discharges near the liquid radioactive waste treatment plants shown in Figure E–10, at a past tritium disposal site (R-22 near Material Disposal Area G), and at a spring that had a value of 45 picocuries per liter, which may be due to a component of surface water because it is similar to rainfall and Rio Grande data (LANL 2005b).

Four alternative models are presented in the *Hydrogeologic Synthesis Report* (LANL 2005b). The models are described and examined to identify the strengths and weaknesses of the possible interpretations of available data. There is also a discussion of how the alternative models would change the current conceptual model and how the alternatives could be tested.

E.7.2 Geohydrologic Conceptual Model

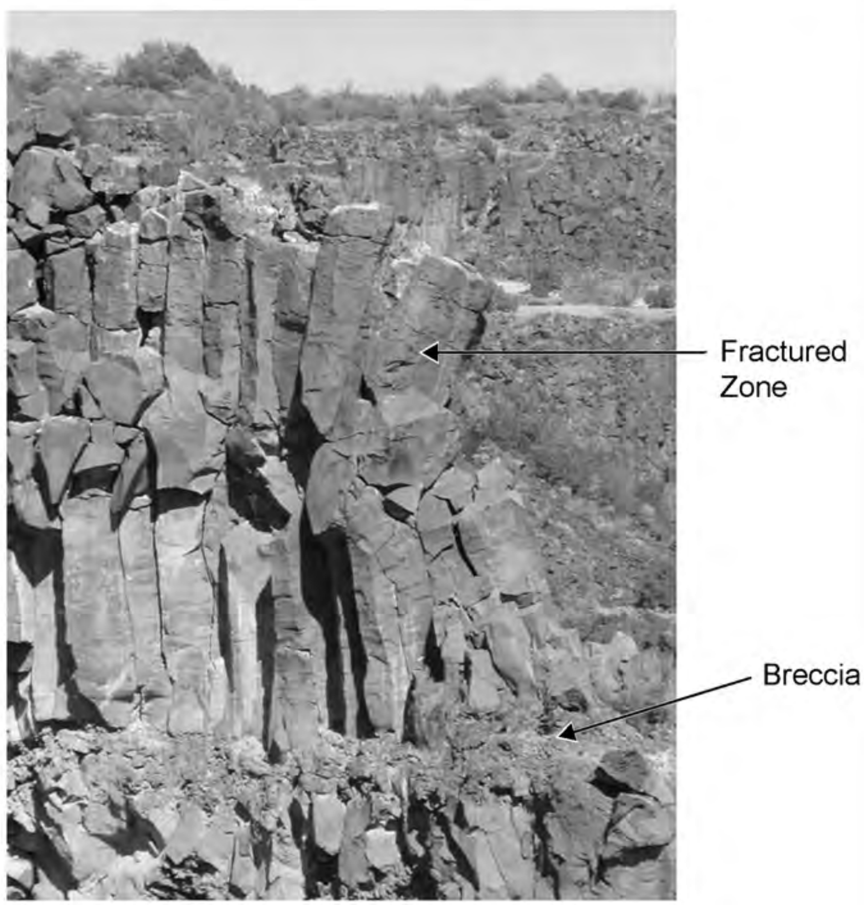
A conceptual model of the geohydrologic system at LANL is used for most numerical simulations by LANL workers and others (Robinson et al. 2005; Robinson, McLin, and Viswanathan 2005; Robinson, Broxton, and Vaniman 2005; Birdsell et al. 2005; Stauffer and Stone 2005; LANL 1995). The conceptual model was developed and supported based on field data. This section describes the components of the conceptual model and how they fit into the conceptual model.

Topography and Surface Water Setting. Deep canyons that begin in the Sierra de los Valles have large catchment areas, frequent surface flow, and perched alluvial groundwater (Birdsell et al. 2005). The wet canyons receive discharge from outfalls and wastewater treatment (anthropogenic water), as well as from infiltration of water from precipitation and shallow groundwater flow in the alluvium. Dry canyons originate on the plateau and have small catchment areas, infrequent flows, and no saturated alluvium in their floors. The dry canyons may display characteristics of the wet canyons if they receive anthropogenic water. In contrast to the wet canyons, there is little infiltration from these canyons. Mountain fronts receive more infiltration and this gives rise to localized perched water. Mountain front groundwater also flows laterally through fractures to nearby canyon walls, forming springs. As evidence for this conceptual model component, there are water budget studies (Kwicklis et al. 2005); moisture profile measurements and model simulations; major ion, stable-isotope, and contaminant concentration studies; and tracer tests in perched water for the mountain front case.

Anthropogenic Impacts. A second conceptual model component examines how anthropogenic activities significantly modified canyons and the intervening mesas of the Pajarito Plateau (Birdsell et al. 2005). Asphalt pavements have reduced evapotranspiration and built up subsurface moisture underneath. In addition, asphalt may focus runoff or may crack and cause infiltration where it may not have normally occurred. Effluent discharges to canyons from LANL or Los Alamos County sources have increased surface and groundwater flows, which have increased the infiltration rate to the vadose zone. In support of this component, water content measurements, contaminant transport measurements, and numerical simulations of paved areas and canyons influenced by LANL facilities are cited.

Flow and Transport Mechanisms. A third conceptual model component examines matrix and fracture flow transport mechanisms through the vadose zone to the regional aquifer (Robinson, McLin, and Viswanathan 2005; Birdsell et al. 2005; Springer 2005). Two principal hydrostratigraphic units with respect to vadose zone flow are the Bandelier Tuff and the Cerros del Rio basalts. Water movement in tuffs and basalts was examined. In poorly welded and fractured areas of the Bandelier Tuff, water moves into the fractures and is quickly absorbed into the high-permeability matrix; as a result, fractures play only a minor role in groundwater movement (Robinson, McLin, and Viswanathan 2005).

It was stated above that, at the Sierra de los Valles mountain front above the Pajarito fault zone west of LANL, the Bandelier tuffs are more densely welded than they are eastward under LANL toward the Rio Grande. Wellbore injection testing shows that water moves primarily in fractures of densely welded tuffs and basalts and is not absorbed as readily into the low-permeability rocks as it is into the fractures of poorly welded tuff (Robinson, McLin, and Viswanathan 2005; Birdsell et al. 2005). Typically, groundwater flow through basalts is controlled by cooling structures. Groundwater flow is vertical through the interior basalts where slow cooling occurred and columnar structures were formed with pronounced vertical fractures. **Figure E–11** is a photograph of the Cerros del Rio basalts below the Bandelier Tuff Otowi Member. Note the vertically fractured, dense interior columnar section and the more porous horizontal breccia zone. Groundwater flow is horizontal through these rapidly cooled breccias that make up the tops and bottoms of the basalt-flows. Groundwater flow is also horizontal in the interflow sediments. Perched water occurs in these porous brecciated zones underlying highly fractured basalt that overlies a massive unfractured flow interior (Birdsell et al. 2005). This conceptual model is supported by cited reports of water content measurements, major ion measurements, contaminant transport measurements, numerical simulations, field measurements at instrumented sites, and fluid injection tests (Birdsell et al. 2005).



Source: LANL 2005b.

Figure E–11 Outcrop of Cerros del Rio Basalt at White Rock Overlook (East of Los Alamos National Laboratory)

Vadose Zone Travel Times. Travel times in the vadose zone at LANL vary from several years to several decades. Travel time is shortest in fractured basalts, decades long where there are significant thicknesses of Bandelier Tuff, and in excess of thousands of years in dry canyons (Birdsell et al. 2005). The conceptual model was supported by numerical modeling of wet canyons (Robinson et al. 2005, as discussed in Section E.8.1), contaminant profiles in vadose zone boreholes, chloride and isotope profiles, and groundwater surveillance reports.

These conceptual model components provide a basis for numerical simulations of groundwater flow and transport through the vadose zone at LANL. Summaries of numerical modeling research at LANL are provided below.

E.8 Numerical Modeling Studies

This section describes numerical modeling activities by LANL workers. The numerical simulations mainly incorporate the conceptual model developed by Birdsell et al. (2005), as presented in the previous section.

E.8.1 A Vadose Zone Flow and Transport Model for Los Alamos Canyon, Los Alamos, New Mexico (Robinson et al. 2005)

Purpose: The purpose of this effort was to develop a large-scale numerical model to advance understanding of vadose zone flow and the transport of contaminants to the regional aquifer. This required applying a conceptual model to knowledge of the hydrostratigraphy, hydrologic conditions, and field measurements. Primarily, the purpose was to develop a numerical simulation of flow; but the transport of tritium in the form of tritiated water beneath Los Alamos Canyon was also modeled. Tritiated water is a good tracer and acted as a constraint on the numerical model (Robinson et al. 2005).

Conceptual Flow Model: The hydrologic system was characterized as an equivalent continuum model; that is, the model captured the characteristics of both the fractures and the matrix. The fractures are predicted to be dry until the capillary pressure of the matrix is a low value (saturated), fracture flow begins, and liquid permeability rises. The equivalent continuum model then behaves like a single continuum model (Robinson et al. 2005).

The infiltration rates used for the canyons and mesa tops were based on the Birdsell et al. (2005) conceptual model outlined above for wet canyons. Infiltration rates used in the simulation were calculated from previous studies using the rates from direct drainage from the alluvium to the vadose zone along the floor of Los Alamos Canyon (Birdsell et al. 2005). The highest rate (42.4 inches [1,076 millimeters] per year) occurs in the upper reaches of the canyon near the Guaje Fault zone where it is probably highly fractured due to faulting.

The source of contaminants used for this model was the Omega West reactor site that was used from 1943 to 1994 to house various reactors. Tritium was one of various radionuclides released into the canyon from a cooling water system leak discovered in 1993 that may have started in late 1969 or early 1970 (Robinson et al. 2005). It is used as a tracer because of its chemical state as a water molecule; it is not readily sorbed; and it does not precipitate out of solution or have complicated speciation processes.

Model Development: Information from 20 geological units was integrated into computational grids using a three-dimensional framework. Site-specific data from LANL's program of site characterization and their comprehensive drilling program, coupled with previous numerical modeling activities, were used for the framework. The accepted stratigraphic designation described previously was used (Broxton and Vaniman 2005). Los Alamos Canyon cuts deep into the Bandelier Tuff with the result that the Tshirege Member is not very thick at the canyon head and absent at the lower reach of the canyon. The Otowi Member is the first unit encountered below the canyon alluvium in much of the model domain. In the lower reach of the canyon, the Cerros del Rio basalts (Tb4) are below the alluvium.

Numerical Grids: The numerical model incorporated both two- and three-dimensional finite element grids. The model used was the Finite Element Heat and Mass code. This code was used because it was used in previous numerical modeling efforts at LANL for saturated and unsaturated flow and the code solved the equations needed for two-phase flow of air and water (Robinson et al. 2005; Birdsell et al. 2005). A two-dimensional grid was used for scoping and sensitivity analysis because it has a smaller number of nodes and elements and is computationally efficient.

Results: Model results suggest that the nonwelded and partially welded Bandelier Tuffs dampen episodic infiltration events; that is, the steady-state model shows that, if infiltration occurs all at once or is averaged over a year, the result yields a similar water content profile. Transients caused by anthropogenic activities over a decade or longer significantly affect predicted water content. Tritium transport modeling indicates that tritium has decayed and that most other contaminants released reside in the vadose zone. The model also suggests that, where the tuffs are absent, such as the lower Los Alamos Canyon near the confluence with Pueblo Canyon, there is a risk of contaminants getting to the regional groundwater.

E.8.2 Hydrologic Behavior of Unsaturated, Fractured Tuff: Interpretation and Modeling of a Wellbore Injection Test (Robinson, McLin, and Viswanathan 2005)

Purpose: This study interprets and models a reported injection test in the Tshirege Member of the Bandelier Tuff and examines different conceptual models. Four conceptual models were developed for flow and transport in fractured tuffs utilizing data from an early injection test in the Tshirege Member of the Bandelier Tuff.

Model Development: The first conceptual model tested was a single continuum model where fractures play no role in flow and transport. A second conceptual model was an equivalent continuum model that captures characteristics of both fractures and matrix. The third conceptual model was a dual-permeability model where it is assumed that the fractures and matrix represent two separate, but coupled, continua. The fourth conceptual model was a discrete fracture model that represents the fractures with distinct hydrologic properties within a model domain that includes the rock matrix. A numerical simulation was then run for each conceptual model. For kilometer-scale simulations, basalts are considered by some workers as a homogeneous continuum with a high permeability and low porosity (Stauffer and Stone 2005).

The same numerical grid, boundary conditions, and hydrologic properties were used for all of the numerical simulations of the conceptual models except for the discrete fracture model. For the discrete fracture model, idealized calculations were performed to develop a mechanistic explanation of how the hydrologic behavior of the tuffs changes when water is injected into a dry fracture.

Results: The study results suggest that flow and transport in the tuffs is through the matrix rather than fractures. This is the result of the high matrix permeability of the tuff. The matrix-dominated flow decreases travel velocities and increases retardation by sorption. Sorption is increased because more water comes in contact with the rock by absorbtion into the rock rather than by contact with the walls of a fracture. Rocks with rather high capillary suction properties would be expected to result in more lateral movement and spreading of a plume.

E.8.3 Development and Application of Numerical Models to Estimate Fluxes through the Regional Aquifer beneath the Pajarito Plateau (Keating, Robinson, and Vesselinov 2005)

Purpose: This study integrates new site-wide data into a model of the regional aquifer beneath the plateau and provides new insight into large-scale aquifer properties. This aquifer is the primary source of water for Santa Fe, Española, Los Alamos, various Pueblos, and LANL. There is a concern about dropping water levels because in 2002 there was a decrease in baseflow to the Rio Grande. There is also a concern that water quality is decreasing because of contamination from LANL sources. This study provides a comprehensive literature review for the aquifer and supplements it with interpretations of new data. This appendix synopsis of the study includes other supporting citations.

Recharge and Discharge: This study (Keating, Robinson, and Vesselinov 2005) discusses and cites various concepts of recharge to the regional aquifer. Early workers thought recharge occurred at various places: Sierra de los Valles, along stream channels on the western edge of the Pajarito Plateau, and in Valles Caldera. Water chemistry did not support these concepts. It was then proposed by various workers that recharge areas were either from the Sangre de Cristo Mountains to the east or from the north and east, but not from the west. Water balance and chloride mass-balance analyses indicate that basin recharge does occur in the mountains at the margins of the basins. Findings based on stable isotope ratios suggest that recharge to groundwater under Pajarito Plateau is from Sierra de los Valles and very little is from Valles Caldera (LANL 2005a). Some recharge is also from streamflow infiltration along arroyos and canyons on the plateau and some recharge, although volumetrically small compared to mountain recharge, is from the surface of the mesas. This study (Keating, Robinson, and Vesselinov 2005) reports that tritium data indicate that water below LANL is relatively young and derives from fast-path flow through the vadose zone. Tritium studies in groundwater discharging from springs within the Sierra de los Valles indicate that the water is about 60 years old. However, groundwater from springs in White Rock Canyon has no tritium and probably ranges in age somewhere between 3,000 to 10,000 years (LANL 2005a).

Discharge of groundwater from under the plateau is assumed by many workers to be to the Rio Grande at White Rock Canyon and may occur as lateral flow, upward flow, or flow from springs. One hypothesis being explored is that the springs come from draining perched aquifers. A second hypothesis is that discharge of groundwater from the regional aquifer may also be southeasterly to the lower Albuquerque Basin, but a structural high at the boundary of the

Española Basin and the Albuquerque Basin may be impeding flow. This would cause interflow upward to the surface. This hypothesis has not been resolved because no studies have been conducted in the lower part of the Española Basin (Keating, Robinson, and Vesselinov 2005).

Aquifer Properties: The hydrostratigraphic units were described above. It is apparent that the units are complex because of the tectonic, volcanic, and sedimentary processes that occurred in the LANL region. Santa Fe Group and Puye Formation rocks are made up of intertonguing alluvial fans separated by layers of volcaniclastics, lava deposits, breccia zones, and other materials, resulting in vertically anisotropic conditions. This is supported by short-term well tests where permeability data are derived from production wells with large screened intervals. The well test results show permeability perpendicular to bedding planes is less than permeability parallel to bedding planes (Keating, Robinson, and Vesselinov 2005). Anisotropy may also be the result of the numerous north-south faults in the basin interfering with spatial continuity of low- or high-permeability rocks. For instance, a layer may look as if it has good permeability, but when tested on a large scale, it may appear to have a poor hydraulic connection to other parts of the same unit because it is interrupted by a low-permeability fault zone.

Several conceptual models regarding the regional aquifer have been developed. The complex geologic structures and data from well tests have several interpretations. Earlier workers postulated the Santa Fe Group is under water table conditions near the Sierra de los Valles and becomes confined eastward. Specific storage data indicate that parts of the aquifer exhibit "leaky-confined" conditions because of semi-confining layers of rocks. Another conceptual model proposes that the anisotropic condition of the aquifer interferes with vertical movement of groundwater, making it appear to be confined during short-term pumping tests. A third conceptual model is that a laterally extensive low-permeability layer confines the lower part of the aquifer and is overlain by groundwater under water table conditions.

Model Development: Three numerical models were integrated: a three-dimensional hydrostratigraphic framework model, a three-dimensional numerical flow and transport model (based on the Finite Element Heat and Mass Transfer Model discussed above), and a model of recharge based on precipitation data. The model incorporates no-flow boundaries at the Santa Clara River to the north, the Valles Caldera to the west, the Rio Frijoles to the south, and the Rio Grande to the east. The upper boundary represents the top of the saturated zone, which has a constant thickness throughout the simulation. The eastern edge of the upper boundary of the model is the Rio Grande and has a specified head. The Buckman well field is a transient flux (sink) to simulate production.

Results: Groundwater flow in the numerical model was to the south-southeast and generally fits the conceptual models of flow. Calculated heads near wells R-9, R-12, R-22, and R-16 were not matched well with actual heads. The model showed that transport calculations would benefit from a refinement of the hydrostratigraphic framework. It was felt that a low-permeability layer separating the upper aquifer from the lower aquifer would allow a closer match of the calculated heads and fluxes with actual data. Calculated total recharge to the aquifer was within the range of early estimates and does occur to the west. The simple recharge model demonstrated that production water is coming from storage from the deeper zones in the aquifer rather than from the shallow zones that receive water from local recharge. Parameter uncertainty impacts the ability to make predictions of fluxes and velocities through individual units downgradient from

LANL. Estimated pore-water velocities varied from 3.3 feet per year (1 meter per year) to 415 feet per year (125 meters per year) in the deep Miocene basalt unit Tb2. This makes predictions of lateral contaminant movement difficult where the basalts are present and brings up the possibility that contaminants may have traveled a significant distance laterally (Keating, Robinson, and Vesselinov 2005). Uncertainties about porosity and permeability also lead to model uncertainty.

E.8.4 Observations and Modeling of Deep Perched Water beneath the Pajarito Plateau (Robinson, Broxton, and Vaniman 2005)

Purpose: The purpose of this study was to perform numerical simulations using vadose zone flow models of two deep perched water zones. One zone is relatively stagnant and the other more dynamic.

Conceptual Model: The conceptual model is also presented in Section E.7.2. Much has been learned about perched water in spite of some difficulties encountered. Small perched bodies are not easily identified because of the drilling techniques required. The lateral extent of deep perched water bodies is also difficult to determine because of the cost of drilling wells. Identification of perched water systems is mostly from observation of saturation in open boreholes using video logs, water measurements, electric logs, neutron logs, wells, and piezometers. Thirty-three occurrences of deep perched water across the Pajarito Plateau are reported (Robinson, Broxton, and Vaniman 2005). The depth to perched water ranges from 118 to 894 feet (36 to 272 meters). The principle occurrence of perched groundwater is in the large wet canyons (Los Alamos and Pueblo Canyons), the smaller watersheds (Sandia and Mortandad Canyons), and Cañon de Valle. Perched water is found in the Puye Fanglomerates, Cerros del Rio basalts, and Bandelier Tuffs (Robinson, Broxton, and Vaniman 2005). Perched water is less common under the dry mesas.

Some deep perched water contains mobile (nonsorbing) anthropogenic chemicals, but no direct measurements have been made to determine how the chemicals reached the perched water. Two conceptual models that are at present untestable are presented to explain the process: a low-velocity, stagnant water resting in a depression above the perching horizon and a high-velocity, laterally migrating fluid that travels on top of the perching horizon (Robinson, Broxton, and Vaniman 2005). Perching horizons in the low-velocity model slow the downward percolation of water, but seem to become dry when penetrated by a borehole and not recharged. In the high-velocity model, water percolates into a deep perched zone; then moves laterally to where the zone pinches out or reaches another vertical, permeable pathway; and then moves downward. This is repeated until it can no longer move downward or it reaches the regional aquifer. These two scenarios can occur together. Deep perched water does not appear to extend far below the dry mesas (Robinson, Broxton, and Vaniman 2005).

Model Development: A model that considers perching horizons as interfaces between hydrostratigraphic units was developed. It uses an interface reduction factor method to account for perched water. When mean values for hydraulic conductivity are used in a model, the water will move through the unsaturated zone and will not perch or move laterally. The derivation of an equation called the permeability reduction factor was added to the Finite Element Heat and Mass Transfer code. The reduction factor allows the user to enter a multiplier that will reduce the permeability at the interface of two hydrostratigraphic units and allow increased saturation. A two-dimensional model was then run using permeability reduction factors for simulating the perched zone. Models without the low-permeability barrier were run for comparison.

Results: The results were compared to information from wells LADP-3 and LAOI(A)-1.1, which penetrate the Guaje Pumice Bed-Puye Formation interface. The Guaje Mountain fault zone was used as the high-infiltration zone. The base case had no permeability reduction factor, but showed a slight increase in saturation at the Guaje Pumice Bed; however, no perching occurred. When the reduction factor was used, perching occurred and increased as the factor was lowered. Particle tracking showed that, as the reduction factor was decreased, migration of contaminants moved laterally. Some contaminants moved through the interface.

Perched water zones in the Pajarito Plateau and Yucca Mountain, Nevada, are being extensively studied and have some similarities. Both places have the low-permeability zones required for perching to occur. The low-permeability zone at Yucca Mountain is an extensive low-permeability zone of zeolites. At Pajarito Plateau, the low-permeability zones are limited in area and are associated with stratified sedimentary units and dense basalts.

Fluid velocity in the perched zones is unknown and hydrologic testing, tracer tests, or groundwater dating methods are required to determine the age of the groundwater. Anthropogenic chemicals found in perched zones in some wet canyons allow for some estimates of travel times that may be only on the order of decades.

APPENDIX F
ENVIRONMENTAL SAMPLE DATA

APPENDIX F
ENVIRONMENTAL SAMPLE DATA

Appendix F presents an analysis of 2001 through 2005 environmental monitoring analytical results for use in this *Site-Wide Environmental Impact Statement for Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico* (LANL SWEIS). In Appendix F these results are evaluated for the following three purposes:

- To summarize and present the 2001 through 2005 environmental sample data in a manner[1] analogous to that used in the *Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory, Los Alamos, New Mexico (1999 SWEIS)* (DOE 1999);
- To evaluate the effects of the Cerro Grande Fire of May 2000, at an aggregate level, on the concentration of radioisotope analytical results in groundwater, sediment, stormwater runoff, and soil samples in and around LANL (in Section F.2); and
- To provide conservative assessments of environmental concentrations of radioisotopes and chemicals (in Section F.3) for use in calculating the Offsite Resident (Los Alamos County resident), Recreational User, and Special Pathways receptor impacts presented in Appendix C, Section C.1.4.

Appendix F is not intended to replace or supplement the LANL annual Environmental Surveillance Reports (LANL 2002, 2004a, 2004b, 2005, 2006b). Those reports provide analyses of environmental measurement results along with statistical interpretation of the data and assessments of data importance. The statistical analysis in the LANL Environmental Surveillance Reports results in a determination as to whether each specific chemical or radioisotope (denoted an analyte) is conclusively present, that is, has actually been detected, in a sample. The data analysis in Appendix F is for the purposes described above and is not intended to indicate the presence of known contamination in the environment.

F.1 Environmental Monitoring Selection

Los Alamos National Laboratory (LANL) staff conducts an ongoing environmental monitoring program that encompasses locations within LANL, along the perimeter of LANL, and throughout the region of non-LANL land in the adjoining counties. This program provides an extensive set of measurements of radiological and hazardous chemical substances in the air, surface water or stormwater runoff, groundwater, sediment, and soil.

For radiological monitoring, periodic samples are obtained and measured for a wide range of radioisotopes, as well as gross alpha, beta, and gamma radiation. Monitored radioisotopes

---

[1] A similar approach is used in Section F.2 as was used to average the environmental data presented in the 1999 SWEIS. This allows the 2001 through 2005 environmental data in Section F.2 to be compared with the data from 1991 through 1996 presented in the 1999 SWEIS. The statistical treatment of data and the comparison between the two time frames does not account for differences in measurement techniques or instrument accuracy.

include americium-241, cesium-137, cobalt-60, iodine-129, neptunium-237, plutonium-238, plutonium-239, plutonium-240, potassium-40, radium-226, radium-228, sodium-22, strontium-90, technetium-99, tritium, uranium-234, uranium-235, uranium-236, and uranium-238. Radioisotope concentrations in the soil collected within and around LANL has been very low and, for the most part, has not increased over time. Soils are now sampled every 3 years. Tritium is measured in both solid and liquid samples because of its high affinity for the liquid state as tritiated water. Most of these radioisotopes have relatively long half-lives (greater than 10 years, except for cobalt-60, radium-228, and sodium-22), can have significant health impacts in sufficient quantities, and represent many of the radioisotopes that are handled, managed, and stored at LANL. They also constitute the entire range of high-energy emitters of alpha, beta, gamma, and neutron radiation.

During 2001 through 2005, radiological samples were obtained from 15 onsite canyons, as well as sites along LANL's borders. Further measurements were made of samples from the surrounding counties. These samples were used to measure radioactivity levels, and the data were subjected to statistical analysis. The data were subdivided into three principal regions of interest: Regional, Perimeter, and Onsite.

F.2 Evaluation of Los Alamos National Laboratory Environmental Sampling Data

Numerous studies and analyses have been performed on the effects of the Cerro Grande Fire at LANL. One area of major interest is the redistribution of radioisotopes in the environment in and around LANL due to this wildfire. The current measured[2] distribution of radioisotopes in the environment was used to calculate doses to special receptors as reported in Appendix C of this SWEIS. The current measured radioisotope distribution in soil, surface water or stormwater runoff, sediment, and groundwater was also used to calculate worker and public doses from a postulated wildfire accident in Appendix D.

As environmental measurements of radioisotopes in and around LANL now exist for 2001 through 2005 and the same data were developed for the *1999 SWEIS* for the years 1991 through 1996, a graphical presentation was prepared to compare the distribution for selected radioisotopes in each of the four environmental media (groundwater, sediment, soil, and surface water or stormwater runoff). Only those radioisotopes that were measured in both sets of data were presented graphically. **Figures F–1** through **F–23** present the mean measured concentration of a specific radioisotope at a specific location in or near LANL. One symbol represents the 2001 through 2005 data, while a different symbol represents the 1991 through 1996 data, resulting in a "scatter plot" for each radioisotope and medium. The use of this type of plot allows the observer to make general observations regarding any trend.

The data in these figures were based on measurements at Regional, Perimeter, and Onsite locations. Each mean measured concentration data point was calculated from annual measurements at one of the various locations. The radioisotopes of interest that were plotted are americium-241, cesium-137, plutonium-238, plutonium-239 and plutonium-240, strontium-90, and tritium. These isotopes represent relatively long half-life nuclides with potentially

[2] *In this appendix, the use of the terms measured or measurements refers to values derived from the sample analytical data in accordance with the statistical evaluation described in Section F.3.*

significant health hazards that may have been released by LANL facilities. For soil environmental data, only the mean for the composite Regional, Perimeter, and Onsite stations is presented because those are the only data available for both periods. In addition, strontium-90 data are not available for soil data from both time periods. Each sediment and soil graph also presents the LANL human health risk-based Screening Action Level (SAL) (LANL 2001) that LANL uses as a criterion for acceptable sediment and soil radioisotope mass concentration level except for tritium, which is defined as a volumetric concentration value. The SAL indicates whether further study or environmental remediation is required. These LANL SALs for sediments and soil were first developed in 2001 and are based on the U.S. Environmental Protection Agency (EPA) guidance limit of 15 millirem per year for residential, commercial, recreational, and industrial use of the land. The SAL calculation includes inhalation, ingestion, and external exposure pathways. The radionuclide SALs were calculated for a 1,000-year timeframe with no loss by erosion or leaching (LANL 2001).

The grouping of the data has changed over the years. To allow visual comparison in graphs, the data for 1991 through 1996 are related to 2001 through 2005 data as shown in **Table F–1**. **Figures F–1** through **F–6** are graphs for groundwater data for measured isotopes for the groundwater data sets as shown in Table F–1. Table F–1 also indicates the Section F.3 data tables that correspond to the 2001 through 2005 data sets.

Table F–1 Groundwater Data Set Comparison

Location Number	*1991 through 1996 Data Set Identifier*	*2001 through 2005*	
		Data Set Identifier	*Data from Table*
1	Alluvial Groundwater	Canyon Alluvial Groundwater Systems [a]	F–15, F–16
2	Spring from Basalt	Basalt Springs [b]	F–18
3	Main Aquifer	Regional Aquifer Wells [c]	F–10
4	Test Wells	Test Wells	F–12
5	Springs	Regional Aquifer Springs	F–14
6	Springs from Volcanics [d]	Water Gallery (2001-2003) [d]	F–18
7	San Ildefonso	San Ildefonso Pueblo	F–19
8	Intermediate Perched	Intermediate Perched Groundwater Systems [e]	F–17, F–18
9	Not Measured	Hydrogeologic Characterization Wells	F–11
10	Not Measured	Water Supply Wells	F–13
11	Not Measured	Santa Fe Water Supply Wells	F–20

[a] Canyon Alluvial Groundwater Systems encompasses Canyon Alluvial Wells and Canyon Alluvial Springs, which are separated into Table F–15 and Table F–16.
[b] Basalt springs is a subset of the Los Alamos Canyon data in Table F–18, Intermediate Perched Springs.
[c] Regional Aquifer Wells is a summation of Hydrogeologic Characterization Wells, Test Wells, and Water Supply Wells.
[d] Data from the location identified as Springs from Volcanics in 1991 through 1996 most closely correlates with data from Water Gallery (2001-2003). Water Gallery data are a subset of the Water Canyon data in Table F–18, Intermediate Perched Springs.
[e] Intermediate Perched Groundwater Systems encompasses Intermediate Perched Wells and Intermediate Perched Springs, which are separated into Table F–17 and Table F–18.

Figures F–7 through **F–12** are graphs for isotopes measured in sediments. The data points are in the order shown in **Table F–2**. Table F–2 also indicates the Section F.3 data table that corresponds to the 2001 through 2005 data sets. In 2001 through 2005 data, measurements in sediments were provided for Fence and Indio Canyons for some isotopes that were not considered in the 1991 through 1996 data. Plutonium-238 and tritium do not have measured values for Indio Canyon in the 2001 through 2005 data. For Bayo Canyon, strontium-90 and plutonium-239 and plutonium-240 do not have measured values in the 2001 through 2005 data.

Figures F–13 through **F–18** are graphs for stormwater runoff data for each measured isotope. Data points are in the canyon order provided in **Table F–3**. Table F–3 also indicates the Section F.3 data table that corresponds to the 2001 through 2005 data sets. The 1991 through 1996 data include Cañada del Buey and Chaquehui Canyons (unlike the 2001 through 2005 data). Cesium-137 data are not available for Chaquehui Canyon from 1991 through 1996. Plutonium-239 and plutonium-240 data are not available for Ancho Canyon from 2001 through 2005 data. Strontium-90 data are not available for Guaje Canyon from 1991 through 1996 and for Ancho Canyon for 2001 through 2005.

Groundwater data show a more marked shift in the transuranics toward higher concentrations in the 1991 through 1996 data than in the runoff or sediment data (see **Table F–4**). Unlike runoff and sediment, groundwater is much more slowly diluted or replenished, especially in the LANL region. Groundwater is also a potential source of drinking water for residences that use wells. In general, both transuranics and lighter radioisotopes showed higher concentrations in groundwater in the 1991 through 1996 data than in the 2001 through 2005 data. No measurements exceeded applicable (tritium and strontium-90) EPA limits for drinking water (40 CFR 141.66).

Table F–4 Comparison of Measured 2001 through 2005 Radioisotope Groundwater Data to 1991 through 1996 Data

Radioisotope	*Noticeably Larger Concentration Timeframe*	*Qualitative Trend Comments*
Americium-241	Equivalent	Other than one data point, both the 1991 through 1996 data and the 2001 through 2005 data are concentrated over one order of magnitude (0.01 to 0.1 picocuries per liter). The maximum data point of about 3 picocuries per liter is from 1991 through 1996, and is much higher than the largest 2001 through 2005 data point of 0.5 picocuries per liter. Most of the 2001 through 2005 data points are slightly lower than or equal to the 1991 through 1996 data points.
Cesium-137	1991 through 1996	All 2001 through 2005 data points are significantly lower in value than the 1991 through 1996 data points by as much as a factor of 10 to 20.
Plutonium-238	Equivalent	Both data sets are closely clustered over the same two orders of magnitude. The highest 2001 through 2005 data point is about 0.45 picocuries per liter; the largest 1991 through 1996 data point is about 0.08 picocuries per liter.
Plutonium-239, Plutonium-240	Equivalent	Both sets of data show a small spread over the same two orders of magnitude.
Strontium-90	1991 through 1996	Some (six out of eight data points) of the 2001 through 2005 data are lower in value than the 1991 through 1996 data by factors of 2 to 10.
Tritium	1991 through 1996	Most of the 2001 through 2005 data points are a factor of 2 to 4 times lower in value than the comparable 1991 through 1996 data points. It should be noted that the largest mean values for the 1991 through 1996 data and the 2001 through 2005 data are smaller than the U.S. Environmental Protection Agency annual drinking water limit of 20,000 picocuries per liter (assumed to be equivalent to a total body dose of 4 millirem) (40 CFR 141.66).

In qualitatively evaluating the graphical presentation of measured radioisotope concentrations in and around LANL between the 1991 through 1996 and 2001 through 2005 periods, only general observations can be made. More specific conclusions would require much more extensive statistical and measurement methodology analysis and would only quantify results in a statistical framework, which might not convey any more information to the reader. **Table F–5** presents the assessment of the differences between the two data sets for sediment.

As previously stated, qualitative interpretation of the data presented graphically for LANL sediment radioisotope concentrations is limited by the extent of this evaluation. However, some general conclusions can be drawn (see Table F–5). Transuranic isotope concentrations all have increased from the 1991 through 1996 period to the 2001 through 2005 period, while lower atomic weight radioisotopes have decreased. Because sediments are subject to the actions of water over time, it is reasonable to assume that the lighter weight radioisotopes (strontium-90, cesium-137, and tritium) would have been preferentially carried with the rainwater and

Table F–5 Comparison of Measured 2001 through 2005 Radioisotope Sediment Data to 1991 through 1996 Data

Radioisotope	*Noticeably Larger Concentration Timeframe*	*Qualitative Trend Comments*
Americium-241	Equivalent	Two 2001 through 2005 data points are about a factor of 10 times larger than the 1991 through 1996 data points. All other data points are close to each other. All data are below the LANL SAL.
Cesium-137	Equivalent	A third of the 2001 through 2005 data points are half the value of their 1991 through 1996 counterparts. Most of the data points from 2001 through 2005 are in the same range as the preponderance of 1991 through 1996 data points. All data are below the LANL SAL.
Plutonium-238	2001 through 2005	Both sets of data exhibit a similar large spread over three orders of magnitude, but 2001 through 2005 data points are greater than their 1991 through 1996 data points. All data are below the LANL SAL
Plutonium-239, Plutonium-240	2001 through 2005	Both sets of data showed a similar large spread of four orders of magnitude (from 0.001 to 10 picocuries per gram); all data are below the LANL SAL.
Strontium-90	1991 through 1996	Data points from both time periods are clustered over two orders of magnitude (from 0.01 to 1 picocurie per gram); nonetheless, all data are well below the LANL SAL. Most of the 2001 through 2005 data are lower than the 1991 through 1996 data by factors of 2 to 3. Three data points from 2001 through 2005 are greater than the 1991 through 1996 data points.
Tritium	1991 through 1996	The two sets of data are distinctly separate and are tightly confined to a narrow band. All of the 2001 through 2005 data points are a factor of 5 to 15,000 times smaller than the comparable 1991 through 1996 data points.

SAL = Screening Action Level.

surface runoff water, whereas a greater fraction of the heavier transuranics would have stayed in the sediment due to their higher density. It is also important to note that tritium is highly soluble, as tritiated water in rain and surface water. Another consideration is that the 12.2-year half-life of tritium would have resulted in the decay of a significant fraction of tritium between 1991 through 1996 and 2001 through 2005, which together represent a period of anywhere from 5 to 14 years. Assuming no dramatic changes in emissions of these measured radioisotopes from 1991 through 1996 to 2001 through 2005, the sediment data indicate that any radioactive material movement involving this sediment due to the Cerro Grande Fire was acted upon by the natural forces of rain and surface water that significantly depleted the sediment content of lighter-weight, more soluble radioisotopes.

Transuranic radioisotopes exist in larger concentrations in the 2001 through 2005 data than in the 1991 through 1996 data surface runoff; the opposite is true for all lighter radioisotopes such as tritium, strontium-90, and cesium-137 (see **Table F–6**). As in the case of sediment, the lighter radioisotopes would be transported farther by runoff than the heavier transuranic radioisotopes since the Cerro Grande Fire. As noted above, radioactive decay of tritium could also account for some of the difference in the data.

Table F–6 Comparison of Measured 2001 through 2005 Radioisotope Runoff Data to 1991 through 1996 Data

Radioisotope	*Noticeably Significant Larger Concentration Timeframe*	*Qualitative Trend Comments*
Americium-241	2001 through 2005	The 2001 through 2005 data are spread out between four orders of magnitude, whereas the 1991 through 1996 data are spread out within two orders of magnitude (from 0.01 to 1 picocurie per liter). Most of the 2001 through 2005 data are 2 to 50 times higher than the corresponding 1991 through 1996 data points.
Cesium-137	1991 through 1996	A majority of the 2001 through 2005 data points are significantly lower than the 1991 through 1996 data points by as much as a factor of 20. Only 2 of the 11 data points from 2001 through 2005 are higher than the 1991 through 1996 data points.
Plutonium-238	2001 through 2005	The data sets exhibit a large spread over four orders of magnitude. The 1991 through 1996 data extend from 0.001 to 1 picocuries per liter and the 2001 through 2005 data extend from 0.01 to 100 picocuries per liter. Most 2001 through 2005 data points are factors of 3 to over 100 greater than the 1991 through 1996 data points.
Plutonium-239, Plutonium-240	2001 through 2005	Both sets of data showed a large spread over four orders of magnitude, but the 1991 through 1996 data are spread over a range of 0.001 to 10 picocuries per liter and the 2001 through 2005 data are spread over a range of 0.1 to 100 picocuries per liter. The 2001 through 2005 data points are 6 to 80 times greater than the 1991 through 1996 data points.
Strontium-90	1991 through 1996	A large amount (10 of 11 data points) of the 2001 through 2005 data are lower than the equivalent 1991 through 1996 data by factors of 2 to 100. No 2001 through 2005 data points exceeded 10 picocuries per liter, but seven 1991 through 1996 data points are between 10 and 200 picocuries per liter.
Tritium	1991 through 1996	All of the 2001 through 2005 data points are a factor of 2 to 10 times smaller than the comparable 1991 through 1996 data points. It should be noted that the largest mean values of less than 6,700 picocuries per liter for the 1991 through 1996 data and about 1,000 picocuries per liter for the 2001 through 2005 data are much lower than the U.S. Environmental Protection Agency drinking water limit of 20,000 picocuries per liter.

Unlike the sediment, surface runoff water, and groundwater data, the soil data show that the 2001 through 2003 measurements are at equivalent concentration for most radioisotopes to the 1991 through 1996 data (see **Table F–7**). The redistribution due to the Cerro Grande Fire of these radioisotopes, formerly present in vegetation and trees, to the soil is a possible explanation. A review of actual radiological emissions from LANL facilities' stacks from 1999 through 2005 does not show any significant increase in emissions of these radioisotopes.

Table F–7 Comparison of Measured 2001 through 2003 Radioisotope Soil Data to 1991 through 1996 Data

Radioisotope (average worldwide soil concentration)	*Noticeably Larger Concentration Timeframe*	*Qualitative Trend Comments*
Americium-241 (0.01 picocuries per gram)	Equivalent	All measurement values are more than a factor of 1,000 below the LANL SAL, and Regional station data are equivalent to average worldwide concentrations.
Cesium-137 (0.4 picocuries per gram)	Equivalent	Both data sets are almost identical with the 1991 through 1996 data slightly (10 percent to 50 percent) higher. All data are a factor of 10 below the SAL and at or near the worldwide measured level.
Plutonium-238 (0.01 to 0.1 picocuries per gram)	Equivalent	The 2001 through 2003 data are lower than the comparable 1991 through 1996 data at Onsite and Perimeter stations. The data are a factor of about 10,000 times lower than the LANL SAL. Data are at or below worldwide average concentrations.
Plutonium-239, Plutonium-240 (0.01 to 0.1 picocuries per gram)	Equivalent	All measurement values are more than a factor of 400 below the LANL SAL. All measurements are at or below worldwide average levels.
Tritium	2001 through 2003	The 2001 through 2003 data are significantly higher for the Onsite and Perimeter stations by as much as a factor of 2 compared to the 1991 through 1996 data.

SAL = Screening Action Level.

Table F–8 presents several key parameters for radioisotopes measured by LANL including typical background concentrations, EPA drinking water limits, relative solubility, and soil adhesion characteristics.

Table F–8 Key Parameters of Radioisotopes Measured in the Los Alamos National Laboratory Environment

Radioisotope	*Background Concentration (EPA Drinking Water Limit)*	*Water Solubility*	*Soil Adhesion Characteristics (LANL soil is generally sandy-loam)*
Americium-241	0.01 picocuries per gram soil	Very insoluble	Ratio of sandy soil to water adhesion equals 1,900. Ratio of loam/clay to water adhesion is greater than 1,900.
Cesium-137	0.1 to 1 picocuries per gram soil; average 0.4 picocuries per gram	Very insoluble	Ratio of sandy soil to water adhesion equals 280. Ratio of clay/loam soil to water adhesion equals 2,000 to 4,000.
Plutonium-238, Plutonium-239, Plutonium-240	0.01 to 0.1 picocuries per gram soil	Very insoluble	Radio of sediment/soil to water adhesion equals 2,000.
Strontium-90	0.1 picocuries per gram soil (36 picocuries per liter)	Soluble	Ratio of sandy soil to water adhesion equals 15. Ratio of clay soil to water adhesion equals 110.
Tritium	10 to 30 picocuries per liter surface water (20,000 picocuries per liter)	Very soluble	No adhesion to soil; chemically identical to water.

EPA = U.S. Environmental Protection Agency.
Sources: ANL 2005a, 2005b, 2005c, 2005d, 2005e.

Several general and qualitative conclusions can be drawn by examination of the graphically presented environmental surveillance data on radioisotopes in and around the LANL site.

- Most radioisotopes measured in and around LANL exist in concentrations equivalent to worldwide averages based on non-LANL atmospheric releases.

- Many monitored radioisotope concentrations in groundwater decreased after 2000.
- All 2001 through 2005 tritium data for surface water and stormwater runoff and groundwater are 10 to 100 times lower than the EPA drinking water limit.
- The largest difference in data between 1991 through 1996 and 2001 through 2005 is that the 2001 through 2005 sediment tritium concentration data are 1,000 to 100,000 times smaller than the 1991 through 1996 data.
- In general, transuranic concentrations in sediment and surface water or stormwater runoff increased after 2000, while lighter radioisotope (strontium-90, cesium-137, and tritium) concentrations in sediments and surface water or stormwater runoff decreased after 2000.
- Changes in radioisotope concentration in surface water or stormwater runoff and sediment from 1991 through 1996 to 2001 through 2005 coincide with the radioisotopes that are much more soluble in water.
- Both sets of data show tritium in surface water or stormwater runoff at LANL from all the data at concentrations 10 to 100 times greater than the worldwide average.
- Most soil radioisotope concentrations increased after 2000 (possibly attributable to the redistribution of radioisotopes in biologic material that burned during the Cerro Grande Fire).
- The 2001 through 2003 soil data show a plutonium-238 concentration about 100 times greater than the 1991 through 1996 data and 10 to 100 times greater than worldwide averages.
- All 2001 through 2003 soil data are much lower (by orders of magnitude) than the relevant LANL SAL.

These aforementioned observations are based on a qualitative assessment of plots of mean measured radioisotope concentration data. Differences in measurement technique or instrument accuracy between the 1991 through 1996 data and the 2001 through 2005 data are not accounted for, nor are differences in LANL stack emissions from 1991 through 2005 incorporated. This evaluation has not accounted for other radioisotopes or hazardous chemicals. Spatial variations in measured concentrations are not included in this assessment.

F.3 Environmental Sample Data

Groundwater, sediment, and stormwater runoff data are collected and analyzed for individual canyons. Soil data are grouped under three regions of interest: regional locations, perimeter locations, and onsite locations. The measured values of radioisotope and radioactivity that are presented are derived from environmental surveillance analytical data. Groundwater, sediment, stormwater runoff, and soil values from annual environmental surveillance data tables are used to calculate “Detected per ESR,” “Used in This SWEIS,” “Analyzed,” “Minimum,” “Mean,” “Standard Deviation,” “Maximum,” and “95 percent Upper Confidence Limit (UCL)” values.

Analytical data are identified in a number of categories in this appendix. The “Analyzed” value is the total number of samples for which analyses were performed for a particular isotope or chemical. The “Detected per ESR” value is the number of analyzed samples that are determined to have detectable contamination as reported in the LANL environmental surveillance reports. The "Used in This SWEIS" value is the number of analyzed samples, in accordance with the guidanceprocess below, that are used in the following statistical analysis. The "Minimum" value is the smallest, positive measured analytical result for an isotope or chemical. The "Maximum" value is the greatest measured analytical result for an isotope or chemical. The "Mean" value is the average of the "Used in This SWEIS" samples for an isotope or chemical. The "Standard Deviation" value is a statistical measure of the amount by which each sample deviates from the mean. The "95 Percent UCL" value is a statistical representation of the concentration of a specific measured radioisotope, radioactivity, or chemical that is equal to or greater than 95 percent of all the expected measured values assuming a normal distribution.

Measurement of each parameter involves obtaining a known sample volume or mass, transporting it to an analytical laboratory, and subjecting the sample to the detection of a specific type and energy of radiation, which is detected and counted by an instrument for a set time. Each radioisotope has a unique set of radiation emission energies that identifies it just as fingerprints identify each human individual. A chemical or isotope is considered to be detected if it exceeds the lowest concentration that can be measured in a sample and reported with 99 percent confidence. It depends on the sample matrix, the instrument used, and the operator skill. For purposes of this SWEIS, the analytical results were evaluated in accordance with the following process:

- Any "Analyzed" sample for which the analytical result is less than zero is eliminated from further consideration.

- An "Analyzed" sample (in the following tables) for which the analytical result plus two standard deviations exceeds the instrument's minimum detectable activity is "Used in This SWEIS."

In applying the above process, analytical results below the instrument's minimum detectable activity are included as part of the conservative assessment approach to data treatment in this SWEIS, but will not be continued in future SWEIS updates. Future data treatments will include only those analytical results exceeding the minimum detectable activity.

The following process is then applied to the analytical results that are identified as "Used in This SWEIS."

- A minimum of two data values is required to calculate and present a Mean, Minimum, and Maximum value.

- A minimum of three data values is required to calculate and present a Standard Deviation and 95 Percent UCL value.

- The 95 Percent UCL value is calculated by first calculating the Mean and Standard Deviation on the Mean of the Used in This SWEIS data, then adding two Standard Deviations to the Mean Value.

Measured concentrations are in terms of picocuries per liter (pCi/L), picocuries per gram (pCi/g), micrograms per gram (µg/g) or micrograms per liter (µg/L) depending on whether the sample medium is solid or liquid and whether the parameter is measured in terms of radioactivity or mass.

The numbers of groundwater, sediment, surface water or stormwater runoff, and soil data samples from 2001 through 2005 that meet the criteria for "Used in This SWEIS" are shown in **Table F–9**. Table F–9 also shows the numbers of samples with "Detected" activity. The statistical analysis of measured samples (LANL 2002, 2004a, 2004b, 2005, 2006b) is presented in **Tables F–10** through **F–20** for groundwater (2001 to 2005), **Table F–21** for sediments (2001 to 2005), **Table F–22** for surface water or stormwater runoff (2001 to 2005), and **Table F–23** for soil (2001 to 2003). The most recent soil survey data available at the time of this analysis was from 2003.

The LANL environmental surveillance program uses statistical criteria to determine whether a particular radioisotope is actually detected in a sample. For a radioisotope to be detected, the sample measurement (the number of radioactive emissions counted in a given time period by a detector) must be equal to or greater than the minimum detectable activity and also must be equal to or greater than three times the total propagated uncertainty, which accounts for both the measurement instrumentation uncertainty as well as the sample background uncertainty. These criteria, which have been used for groundwater, sediment, surface water, and soil from 2001 through 2005, provide a high degree of confidence (99.7 percent) that a measurement result classified as detected is actually present in the sample. This is not the case for a number of the values indicated as "Used in This SWEIS." The number of detected measurements for each analyte, as reported in the Environmental Surveillance Reports, is presented in Tables F–10 through F–23 under the column heading of "Detected per ESR". The number of usable measurements for the purpose of this SWEIS is delineated under the column "Used in This SWEIS" in Tables F–10 through F–23. The number of usable measurements for each analyte is equal or greater than the LANL detected measurements because of the different method that was used in the SWEIS to select measurements. The method used in this SWEIS allows comparison with the environmental surveillance data presented in the *1999 SWEIS* (DOE 1999) which used a similar statistical approach to select usable measurements from the 1991 through 1996 environmental surveillance data. A usable measurement (Used in This SWEIS) in Tables F–10 through F–23 does not indicate that the analyte actually exists in the sample at a level greater than the analytical instrument was able to detect, but only that the measurement met the previously described guidance. There is a large difference between the number of environmental samples analyzed that are reported as detected and the number of samples that are reported as "Used in This SWEIS" for uranium. Uranium is a naturally occurring element in the LANL environment. The criterion for detected samples eliminates uranium concentrations below the 5 microcuries per gram whereas the "Used in This SWEIS" data do not screen out background uranium concentrations in environmental samples and therefore results in a higher number of numerical values. Only the usable measurements were used to develop the mean values and 95 percent UCL values shown in Tables F–10 through F–23. The 95 percent UCL values are used in Appendix C of this SWEIS to estimate human health impacts.

Table F–9 Number of Detectable Radiological Data Samples at Los Alamos National Laboratory Exceeding Analytical Thresholds

Radioisotope	Number of Samples Exceeding Analytical Thresholds (2001 through 2005)							
	Groundwater		Sediment		Surface Water or Stormwater Runoff		Soil (2001 through 2003)	
	Detected per ESR	Used in This SWEIS	Detected per ESR	Used in This SWEIS	Detected per ESR	Used in This SWEIS	Detected per ESR	Used in This SWEIS

ESR = Environmental Surveillance Reports, UCL = upper confidence limit, pCi/L = picocuries per liter, µg/L = micrograms per liter.

[a] Composite of canyon data. The corresponding data set identifier is indicated in Table F–1.

[b] Italicized subheadings identify individual canyons whose data are included in the composite.

ESR = Environmental Surveillance Reports, UCL = upper confidence limit, pCi/L = picocuries per liter, µg/L = micrograms per liter.

[a] Composite of canyon data. The corresponding data set identifier is indicated in Table F–1.

[b] Italicized subheadings identify individual canyons whose data are included in the composite.

ESR = Environmental Surveillance Reports, UCL = upper confidence limit, pCi/L = picocuries per liter, µg/L = micrograms per liter.

[a] Composite of canyon data. The corresponding data set identifier on Table F–1 includes data from Canyon Alluvial Wells (Table F–15) and Canyon Alluvial Springs (Table F–16).

[b] Italicized subheadings identify individual canyons whose data are included in the composite.

Sources: LANL 2002, 2004a, 2004b, 2005, 2006b.

ESR = Environmental Surveillance Reports, UCL = upper confidence limit, pCi/L = picocuries per liter, µg/L = micrograms per liter.

[a] Composite of canyon data. The corresponding data set identifier on Table F–1 includes data from Intermediate Perched Wells (Table F–17) and Intermediate Perched Springs (Table F–18).

[b] Italicized subheadings identify individual canyons whose data are included in the composite.

Sources: LANL 2002, 2004a, 2004b, 2005, 2006b.

ESR = Environmental Surveillance Reports, UCL = upper confidence limit, pCi/L = picocuries per liter, μg/L = micrograms per liter.

[a] Composite of canyon data. The corresponding data set identifier on Table F–1 includes data from Intermediate Perched Wells (Table F–17) and Intermediate Perched Springs (Table F–18).

[b] Italicized subheadings identify individual canyons whose data are included in the composite.

Table F–24 presents EPA and EPA-equivalent maximum contaminant levels (MCLs) (Title 40 *Code of Federal Regulations* [CFR], Part 141) for comparison between the groundwater, surface water or stormwater runoff concentrations presented in the above tables. The regulations at 40 CFR Part 141 only apply to drinking water systems.

Table F–24 Benchmark Concentrations for Analyzed Radionuclides for Groundwater, Surface Water, or Stormwater Runoff [a]

Constituent	Benchmark Concentration	
Americium-241	picocuries per liter	15 [b]
Cesium-137	picocuries per liter	93 [c]
Cobalt-60	picocuries per liter	173 [c]
Neptunium-237	picocuries per liter	15 [b]
Plutonium-238	picocuries per liter	15 [b]
Plutonium-239	picocuries per liter	15 [b]
Plutonium-240	picocuries per liter	15 [b]

Constituent	*Benchmark Concentration*	
Potassium-40	picocuries per liter	251 [c]
Radium-226, Radium-228	picocuries per liter	5 [b]
Sodium-22	picocuries per liter	407 [c]
Strontium-90	picocuries per liter	8 [b]
Tritium	picocuries per liter	20000 [b]
Uranium-234	micrograms per liter	30 [b]
Uranium-235	micrograms per liter	30 [b]
Uranium-236	micrograms per liter	30 [b]
Uranium-238	micrograms per liter	30 [b]
Uranium Total	picocuries per liter	10 [d]
Gross Alpha	picocuries per liter	15 [b]
Gross Beta	millirem per year	4 [b]
Gross Gamma	millirem per year	4 [b]

[a] Similar values are available for soils and sediments, but this would require more detailed analysis of agricultural and recreational use at a particular location.
[b] EPA maximum contaminant levels (40 CFR Part 141).
[c] EPA-equivalent maximum contaminant levels. Published value calculated to yield an annual dose equivalent of 4 millirem per year to the total body using Federal Guidance Report 11 dose factors.
[d] Calculated using sum of fractions rule and isotopic distribution for naturally occurring uranium.

The LANL environmental surveillance program also includes chemicals and elements, that are periodically measured at Regional, Perimeter, and Onsite stations. Samples of soil, sediment, surface water and groundwater were all measured for these chemicals and elements which are listed in **Tables F–25 and F–26** (LANL 2002, 2004a, 2004b, 2005, 2006b).

Table F–25 Chemicals Measured in the Los Alamos National Laboratory Environmental Surveillance Program

Chemical	*Chemical*	*Chemical*
Acenaphthene	2-Chloronaphthalene	Isophorone
Acenaphthylene	2-Chlorophenol	Isopropylbenzene
Acetone	Chrysene	4-Isopropyltoluene
4-Amino-2,6-dinitrotoluene	2,4-D	Methylene Chloride
2-Amino-4,6-dinitrotoluene	2,4-DB	2-Methylnaphthalene
Aniline	4,4'-DDD	2-Methylphenol
Anthracene	4,4'-DDE	4-Methylphenol
Aroclor-1016 (PCB)	4,4'-DDT	Naphthalene
Aroclor-1242 (PCB)	Dibenzofuran	3-Nitroaniline
Aroclor-1254 (PCB)	1,2-Dichlorobenzene	4-Nitroaniline
Aroclor-1260 (PCB)	1,3-Dichlorobenzene	Nitrobenzene
Azobenzene	1,4-Dichlorobenzene	N-Nitrosodimethylamine
Benzo(a)anthracene	3,3'-Dichlorobenzidine	N-Nitroso-di-n-propylamine
Benzo(a)pyrene	Dieldrin	1,2,3,4,6,7,8,9-Octachlorodibenzodioxin
Benzo(b)fluoranthene	Diethylphthalate	Pentachlorophenol
Benzo(g,h,i)perylene	Dimethyl Phthalate	Perchlorate
Benzo(k)fluoranthene	Di-n-butylphthalate	Phenanthrene
Benzoic Acid	Di-n-octylphthalate	Phenol
Benzyl Alcohol	2,4-Dinitrotoluene	Pyrene

Chemical	Chemical	Chemical
delta-BHC	1,4-Dioxane	Pyridine
Bis(2-chloroethoxy)methane	Endrin	RDX
Bis(2-ethylhexyl)phthalate	Ethylbenzene	Styrene
Bromodichloromethane	Fluoranthene	2,3,7,8-Tetrachlorodibenzofuran
Bromoform	Fluorene	Tetrachloroethene
2-Butanone	Heptachlor	Toluene
Butylbenzylphthalate	Heptachlor Epoxide	Trichloroethene
Carbazole	1,2,3,4,6,7,8-Heptachlorodibenzodioxin	1,1,1-Trichloroethane
4-Chloroaniline	Hexachlorobenzene	2,4,6-Trichlorophenol
Chlorodibromomethane	2-Hexanone	1,3,5-Trinitrobenzene
Chloroform	HMX	2,4,6-Trinitrotoluene
Chloromethane	Indeno(1,2,3-cd)pyrene	

PCB = polychlorinated biphenyls.

Table F–26 Elements Measured in the Los Alamos National Laboratory Environmental Surveillance Program

Element	Element	Element
Silver	Chromium	Antimony
Aluminum	Copper	Selenium
Arsenic	Iron	Tin
Boron	Mercury	Strontium
Barium	Manganese	Thallium
Beryllium	Molybdenum	Vanadium
Cadmium	Nickel	Zinc
Cobalt	Lead	

Measured environmental concentrations of the chemicals and elements listed in Tables F–25 and F–26 did not exceed EPA or New Mexico Environment Department standards with the following exceptions of perchlorate, hexavalent chromium, polychlorinated biphenyls (PCBs), and 1,4-dioxane. The number of “Detected per ESR” and “Used in This SWEIS” data points for these four chemicals are identical because the ESR source for these chemicals only reported data that were considered detected.

Perchlorate is a chemical of particular interest that has a high propensity to enter the groundwater. Perchlorate is used in rocket solid propellant, fireworks, lubricating oils, paint production, explosives, fabrics, and dye fixers. Perchlorate is formed naturally in the upper atmosphere and may also be created from fertilizers, mineral weathering, or electrochemical reactions. Perchlorate is soluble in water and has been shown to disrupt thyroid function and influence thyroid tumor formation if ingested in sufficient quantities. There is no Federal EPA MCL or MCL goal for perchlorate in drinking water. The EPA, however, has established a No Observed Effect Level (NOEL) of 23 parts per billion or 23 micrograms per liter for perchlorate, based on a daily oral exposure of 0.0007 milligram per kilogram per day for a 154-pound (70-kilogram) adult consuming 0.53 gallons (2 liters) of water per day. The EPA Drinking Water

Equivalent Level is 24.5 Micrograms per liter. The State of New Mexico has established an interim groundwater screening level of 1 part per billion or 1 microgram per liter. Between 2002 and 2005, 903 detectable sample measurements of perchlorate were made in groundwater samples at the environmental monitoring stations. A statistical analysis of these measurements is presented in **Table F–27**. Measured mean values of perchlorate at most LANL locations were below both the EPA NOEL and New Mexico screening limit. Only Mortandad and Pueblo Canyons exceeded the New Mexico limit, and only Mortandad Canyon exceeded the EPA NOEL (USACHPPM 2006, EPA 2006a, LANL 2006b, NAS 2005, NMAC 2006).

Hexavalent chromium, also known as chromium (VI), is one of three forms of the element chromium that occurs naturally, but can also be artificially produced. Hexavalent chromium is also a chemical of particular interest that is soluble in water and therefore has a high propensity to enter groundwater. Hexavalent chromium has been shown to damage or irritate the respiratory system and is identified by the EPA as a known carcinogen if inhaled in sufficient quantities. The EPA MCL for hexavalent chromium in drinking water is 100 micrograms per liter. The State of New Mexico has established a groundwater standard of 50 micrograms per liter for hexavalent chromium. Both the EPA and State of New Mexico hexavalent chromium water concentration limits are based on the measurement of filtered groundwater samples.

Measured hexavalent chromium concentrations in groundwater samples in and around LANL were significantly higher for unfiltered water than for filtered water. This has been attributed to drilling equipment and well-casing materials, which are composed of steel compounds that contain hexavalent chromium and to the presence of chromium-bearing minerals in aquifer materials. Between 2001 and 2005, 1,020 detectable sample measurements of hexavalent chromium were made in groundwater at the environmental monitoring stations. A statistical analysis of these filtered sample measurements is presented in **Table F–28**. Measured mean values for hexavalent chromium at all LANL locations from 2001 through 2005 were below both the EPA MCL and the New Mexico standard (EPA 2006b, LANL 2006b, NMAC 2006).

In 2005, chromium concentrations between 375 and 404 micrograms per liter were detected in Well R-28 in the regional aquifer below Mortandad Canyon. Additional sampling in 2006 indicated that chromium contamination was found in the regional aquifer in a limited area beneath Sandia and Mortandad Canyons and in perched groundwater beneath Mortandad Canyon. Chromium contamination was not detected in water supply wells. In recognition of these results, the LANL contractor has prepared an *Interim Measures Work Plan for Chromium Contamination in Groundwater* in 2006 (LANL 2006a). The goals of the Work Plan were to:

- Determine the primary sources of chromium contamination and the nature of operations associated with the releases;
- Characterize the present-day spatial distribution of chromium and related constituents;
- Collect data to evaluate the geochemical, physical, and hydrologic processes that govern chromium transport; and
- Collect and evaluate data to help guide subsequent investigations and remedy selection.

These activities were conducted and completed in the summer and fall of 2006 and the results were summarized in an interim measures investigation report to provide a basis for follow-on work (LANL 2006c). This report found that the main source of hexavalent chromium was chromium-treated cooling water from a TA-3 power plant at the head of Sandia Canyon during its operations between 1956 and 1972. Other sources of chromium were identified as past facility discharges into Mortandad Canyon and Los Alamos Canyon. Sampling data from one regional groundwater well in Sandia Canyon and one regional groundwater well in Mortandad Canyon contain clear evidence of LANL-derived chromium contamination. Additional data collection from other regional groundwater monitoring wells is needed to further assess the extent of LANL-derived chromium contamination. Recommendations included additional data collection on chromium and other chemicals for use in risk assessments and the selection of corrective action remedies.

PCBs are a family of 209 chlorinated hydrocarbon compounds that were produced in the U.S. until 1997. PCBs are chemicals of particular interest because they decompose slowly and can exist and cycle between air, water, and soil. PCBs were at one time used in flame retardants, inks, adhesives, dyes, paints, fluorescent lighting fixtures, electrical transformers, electrical capacitors, and other electrical equipment. PCBs have a strong affinity for airborne particles, sediments, and soil, but do not typically migrate to groundwater. PCBs also have the potential to accumulate in fish and animals. PCBs have been shown to cause skin conditions and damage the liver and have been identified by the EPA as a known carcinogen if inhaled or ingested in sufficient quantities. The EPA MCL for PCBs in drinking water is 0.5 micrograms per liter. The State of New Mexico has established a groundwater standard of 1 microgram per liter for PCBs.

Between 2004 and 2005, four detectable sample measurements of PCBs were made in groundwater at these stations. These measurements are presented in **Table F–29**. The PCB contamination was detected only once in each of four sampling stations; no PCBs were detected in any other groundwater samples collected from the four stations. These single occurrences may indicate that the samples in which PCBs were detected are not representative of the groundwater. Despite the detection of PCBs in stormwater runoff within the LANL site boundaries, available data show no discernible impacts on PCB concentrations in the Rio Grande. Three independent types of measures showed that PCB concentrations downstream of LANL to the Cochiti Reservoir were indistinguishable from concentrations upstream of LANL. Mean total PCB concentrations in fish from Abiquiu reservoir were statistically similar to mean total PCB concentrations in fish from the Cochiti Reservoir. The statistical similarity in PCBs upstream and downstream of LANL has also been shown for dissolved water concentrations. Additionally, sampling of Rio Grande surface water by the New Mexico Environment Department and LANL showed whole water concentrations of PCBs were similar upstream and downstream of LANL. These results indicated that there are other sources of PCBs in the Rio Grande. A preliminary analysis indicated that PCB concentrations greater than 0.1 nanogram per liter can be ascribed to background fallout levels of PCBs. This is within the magnitude of some values measured in the Rio Grande water column. Measured mean value of PCBs at LANL locations was below both the EPA MCL and the New Mexico standard (EPA 2006d, LANL 2006b, NMAC 2006).

1,4-Dioxane, also known as diethylene oxide and glycol ethylene ether is the name of an industrial solvent used in paints, varnishes, lacquers, cleaning and detergent preparations. It is of particular interest because it mixes readily with water and migrates rapidly in soil. It does not degrade and can exist and cycle between air, water, and soil. 1,4-Dioxane has been shown to damage the liver and kidneys and has been identified by the EPA as a probable carcinogen if inhaled or ingested in sufficient quantities. There is no EPA MCL for 1,4-dioxane in drinking water; however, the EPA Region 6 cancer risk level of 1 in 100,000 for 1,4-dioxane is 61 micrograms per liter and is applicable to LANL groundwater measurements in accordance with the Consent Order. In 2005, a total of seven detectable sample measurements of 1,4-dioxane were made in groundwater at Mortandad Canyon stations. A statistical analysis of these measurements was collated and is presented in **Table F–30**. Measured mean values of 1,4-dioxane at these LANL locations were above the EPA 1 in 100,000 cancer risk level (EPA 2006c, HHS 2006, LANL 2006b, NMAC 2006).

APPENDIX G
IMPACTS ANALYSES OF PROJECTS TO MAINTAIN EXISTING LOS ALAMOS NATIONAL LABORATORY OPERATIONS AND CAPABILITIES

APPENDIX G
IMPACTS ANALYSES OF PROJECTS TO MAINTAIN EXISTING LOS ALAMOS NATIONAL LABORATORY OPERATIONS AND CAPABILITIES

The projects discussed in this appendix are elements of the Expanded Operations Alternative as described in Chapter 3 of this *Final Site-Wide Environmental Impact Statement for the Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico* (SWEIS). The Expanded Operations Alternative reflects proposals that would expand the overall operations level at Los Alamos National Laboratory (LANL) above those established for the No Action Alternative. Additionally, the Expanded Operations Alternative includes a number of new projects whose purpose is not to expand the operations level, but to update existing facilities or provide new buildings in which to continue existing operations and capabilities. In some cases, the projects to maintain existing operations and capabilities have the potential to impact land use at LANL. However, not all new projects would affect land use, as many would involve actions within or modifications to existing structures or construction of new facilities within previously developed areas of LANL. This appendix presents the project-specific analyses for nine proposed construction or refurbishment projects that would be implemented or for which implementation decisions are needed within the timeframe under consideration in this SWEIS.

- Technical Area 3 (TA-3) Physical Science Research Complex (formerly the Center for Weapons Physics Research) (Section G.1)
- TA-3 Replacement Office Buildings (Section G.2)
- TA-48 Radiological Sciences Institute, including Phase I – The Institute for Nuclear Nonproliferation Science and Technology (Section G.3)
- TA-50 Radioactive Liquid Waste Treatment Facility Upgrade (Section G.4)
- TA-53 Los Alamos Neutron Science Center (LANSCE) Refurbishment (Section G.5)
- TA-55 Radiography Facility (Section G.6)
- TA-55 Plutonium Facility Complex Refurbishment (Section G.7)
- TA-62 (TA-3) Science Complex (Section G.8)
- TA-72 Remote Warehouse and Truck Inspection Station (Section G.9)

Collectively, the nine projects presented in this appendix represent one component of the National Nuclear Security Administration's (NNSA's) ongoing effort to replace much of the older workspace and physical infrastructure at LANL with corresponding modern equivalents, consolidate certain operations, and eliminate underutilized and redundant structures and buildings. To support this effort, NNSA has identified distinct areas to be addressed to ensure infrastructure sustainability. These include initiatives to reduce structure footprints and operating costs, and to improve safety, security, environmental protection, scientific interactions, and productivity. The proposed timeframes associated with construction or refurbishment and operation of the proposed facilities are depicted in **Figure G–1**.

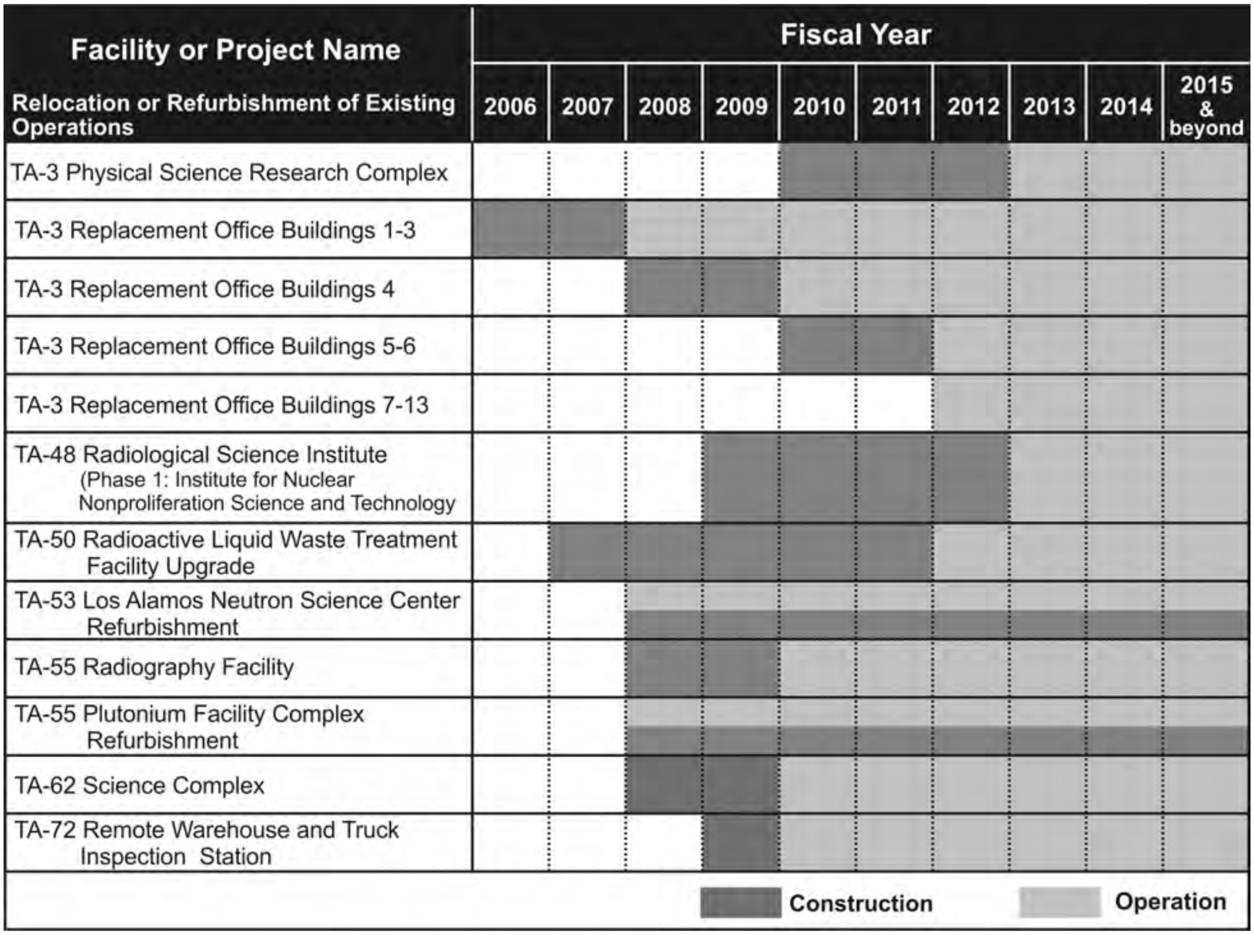

Figure G–1 Proposed Timeframes for Construction and Operation of Projects to Maintain Existing Los Alamos National Laboratory Operations and Capabilities

The projects included in this appendix are categorized into two broad groups: (1) those that would relocate existing operations to a completely new facility, with the former facility(ies) undergoing decontamination, decommissioning, and demolition (DD&D); and (2) those that would renovate or refurbish an existing facility to prolong its capabilities and bring it up to current standards. In keeping with congressional "one for one" space requirements, all proposed new building construction projects discussed in this appendix also include the DD&D of a comparable amount of space in older buildings or transportable structures that are no longer needed or that are unsuitable for future use. Standard construction practices applicable to all construction projects at LANL are described in the text box on the following page. The general process for DD&D of the structures is described in Appendix H.

Detailed project-specific work plans for DD&D of the structures would be developed and approved by NNSA before any actual work began. The plans would include those required for environmental compliance (such as stormwater pollution prevention plans) and monitoring activities (such as using real-time radiation monitors); all necessary legal and regulatory requirements in effect at the time would be undertaken before any DD&D activities were conducted.

Construction Work Elements

Design and Operation Standards: All new structures at LANL would be designed and constructed in compliance with applicable DOE Orders, requirements, and governing standards that have been established to protect public and worker health and the environment. DOE Order 420.1B (DOE 2005) requires that nuclear and nonnuclear facilities be designed, constructed, and operated so that the public, workers, and environment are protected from adverse impacts of natural phenomena hazards, including earthquakes. DOE Standard 1020-2002 (DOE 2002a) implements DOE Order 420.1B and provides criteria for the design of new structures, systems, and components and for evaluation, modification, or upgrade of existing structures, systems, and components so that DOE facilities safely withstand the effects of natural phenomena hazards, such as earthquakes. The criteria specifically reflect adoption of the seismic design and construction provisions of the International Building Code for DOE Performance Category 1 and 2 facilities. Prior to construction of any new facilities, an estimate of the seismic hazard at the proposed site would be conducted using the most current seismic information. The new facilities would also be designed to meet safety and engineering criteria specified in the *LANL Engineering Standards Manual*, OST220-03-01-ESM (LANL 2004b), and would meet current code requirements for electrical, plumbing, fire protection, and other utilities.

Facilities would be constructed according to Leadership in Energy and Environmental Design (LEED) standards (USGBC 2006). LEED for New Construction and Major Renovations is a green building rating system designed to guide and distinguish high-performance commercial and institutional projects, with a focus on office buildings. The standards used for new LANL buildings would increase energy use efficiency and probably achieve net reductions in energy use. LEED emphasizes state-of-the-art strategies for sustainable site development, water savings, energy efficiency, material selection, and indoor environmental quality. Under LEED standards, older, less-efficient buildings would be removed, and, in general, their former locations would be used for parking and open space.

Construction Safety and Health Plan: The work would be planned, managed, and performed to ensure that standard worker safety goals are met and that work would be performed in accordance with good management practices, regulations promulgated by the Occupational Safety and Health Administration, and LANL resource management plans. To prevent serious injuries, all site workers (including contractors, subcontractors, lessees and permit or easement holders or their contractors and subcontractors) would be required to submit and adhere to an approved construction safety and health plan.

Environmental Management: NNSA's goal for the construction of new facilities is to retain as much of the natural setting, vegetation, and overall environmental integrity of the site as practical. The site surrounding new buildings and parking would be professionally landscaped within the guidelines of the LANL Site and Architectural Design Principles (LANL 2002a) and LANL Sustainable Design Guide (LANL 2002b). Disturbance and removal of vegetation at the construction site would be limited to those areas necessary to accommodate building, roadway, parking, parking structure footprint, and work areas. Total tree removal would be allowed within only 50 feet (15 meters) of building footprints and 5 feet (1.5 meters) of parking and roadways. Trees greater than 10 inches (25.4 centimeters) in diameter measured 4.5 feet (1.35 meters) from the ground surface would not normally be cut and removed from areas with a slope less than 20 degrees at distances greater than 20 feet (6 meters) from building footprints or 10 feet (3 meters) from parking lots and roadways. No tree cutting or other disturbance would occur in areas with greater than 20 percent slope, except as periodically needed for wildland fire management purposes. Wildfire management planning is currently being developed in the *Los Alamos National Laboratory Wildland Fire Management Plan*, LA-UR-05-0286 (LANL 2005d). Management activities, such as tree thinning, could be put into effect at the proposed facilities. Tree thinning procedures would include incorporation of best management practices to prevent soil erosion and use of manual timber cutting on the steep slopes rather than mechanical methods.

National Pollutant Discharge Elimination System: No construction would be conducted within floodplains or wetlands. As appropriate, engineered best management practices for each building, parking structure, or roadway site would be implemented as part of a site stormwater pollution prevention plan executed under a National Pollutant Discharge Elimination System construction permit. Best management practices may include the use of hay bales, straw wattles, and silt fences. Prior to construction, topsoil from the site would be removed and stockpiled for later use in land restoration efforts at either this site or other sites. Soil stockpiles would be seeded and protected with silt fences to prevent erosion and impact on nearby drainages. Following construction, areas surrounding the buildings would be restored to enhance site drainage and stormwater capture for passive irrigation of landscaping. Recontoured areas would then be reseeded with a native grass mix to stabilize the site and planted with landscape vegetation closer to the buildings. Permanent site engineered controls for stormwater runoff may include stormwater retention ponds, curbing, permeable asphalt, or use of timber or stone as riprap to slow waterflow runoff. Vehicle fueling would not occur within drainages or floodplain areas.

Excavation and Dust Suppression: Dozers, backhoes, or graders may be used to remove tree stumps and rocks and to smooth the surface. Clearing or excavation activities during site construction would have the potential to generate dust. Standard dust suppression methods (such as water spraying or soil tackifiers) would be used to minimize dust generation during construction activities.

Cultural resources: If cultural remains were encountered during construction, activities would cease until their significance was determined and appropriate subsequent actions taken.

Ultimate disposition of the facilities constructed by the projects in this appendix would be considered at the end of their operations, usually several decades after construction. Facilities that would support missions involving radioactive and hazardous materials are required to be designed with consideration of the entire lifecycle of the facilities; this includes incorporating features into the design that would facilitate eventual facility DD&D. The impacts from the eventual disposition of the newly constructed facilities would be similar to or less than the impacts from the disposition of the facilities that they replace.

Purpose and Need

LANL's primary mission is to support national security. Nuclear technology and the associated radiological facilities at LANL are vital to this mission. The mission includes programs such as defense nuclear nonproliferation, emergency operations, domestic safeguards, and corresponding training operations and encompasses activities related to nuclear weapons, nuclear nonproliferation and arms control, homeland security, nuclear energy, radioactive waste management, environmental management, nuclear regulation, health and safety, nuclear medicine, and advanced materials science.

LANL has consistently applied state-of-the-art basic and applied scientific research in solving complex problems of national importance. The same attention to the state of infrastructure and facilities has not kept pace over the years. As a result, LANL's infrastructure is deteriorating to the point of jeopardizing its long-term ability to fulfill its stockpile stewardship mission. Many of the current structures in use at LANL are from 20 to 50 years old. A large percentage of the LANL workforce is located in facilities that are in marginal condition and frequently overcrowded. Buildings and structures built and occupied at LANL since the late 1940s are often incorrectly sized to effectively accommodate modern operations. The demands on the services, utilities, and communications were not anticipated when the buildings were designed. Current activities are conducted in scattered, old structures, many of which are obsolete and increasingly expensive to operate. Today, LANL has the oldest facilities and the greatest number of old facilities among the three national security laboratories and the Nevada Test Site. Approximately half of LANL's facilities are in poor or fair condition.

The liability and cost of aging infrastructure is an escalating problem throughout the U.S. Department of Energy (DOE) complex. Because the cost of operations and maintenance for aging LANL facilities is significant and growing, leaving this problem unaddressed would impact LANL's ability to carry out NNSA's stockpile stewardship mission. In the past, preventive facility maintenance has been deferred for higher priorities. The current DOE budgeting process allocates 5 to 8 percent less for infrastructure and repair than the industrial average. Over time, this practice has resulted in a backlog of repairs that threatens to overtake LANL's ability to effectively address these problems while pursuing research activities critical to NNSA's Defense Program mission. The majority of LANL facilities are reaching the end of their useful lives and would require major upgrade investments to meet future mission needs and ensure the health and safety of LANL employees. Even after such investment in upgrading aging facilities, the functionality of these buildings would remain marginal. These buildings and structures were neither built to current structural (including seismic), health, safety, and security standards, nor can they be easily or economically retrofitted to meet these standards or to accommodate present day office electronics, communications equipment, or heating and cooling systems. If these buildings are not replaced, they would eventually need to be shut down for safety reasons, and their missions would be compromised.

Employee safety would be improved by providing modern, well-designed workspaces. Current structures are poorly suited to today's demanding security needs. Many safety controls can be deployed by only new building design and construction. In addition, NNSA's purpose is to: (1) improve the quality of the facilities to carry out current and future anticipated research programs in support of NNSA's missions, (2) decrease and control operational and maintenance costs for LANL facilities, and (3) consolidate peer groups that need to interact frequently and provide a working environment that encourages collaboration, creative innovation, and efficiency.

Three of the projects proposed in this appendix are part of a TA-3 Revitalization Plan, which specifically addresses changes to one of LANL's most populated TAs; these include the Physical Science Research Complex in TA-3, construction and operation of Replacement Office Buildings in TA-3, and the Remote Warehouse and Truck Inspection Station in TA-72. Other projects address consolidation of LANL radiochemistry and nuclear nonproliferation capabilities in a new complex at TA-48, replacement of radioactive liquid waste treatment capabilities at TA-50, refurbishment of the LANSCE at TA-53, relocation of nondestructive examinations into a radiography facility at TA-55, refurbishment of the Plutonium Facility Complex in TA-55, and construction of a new Science Complex in either TA-62 or TA-3. Additional discussion of the purpose and need for the Radioactive Liquid Waste Treatment Facility Upgrade Project, TA-55 Radiography Facility Project, and Remote Warehouse and Truck Inspection Station Project are described below. The remaining projects are encompassed by the general purpose and need discussion above.

Purpose and Need for the Radioactive Liquid Waste Treatment Facility Upgrade Project

NNSA needs to provide reliable means for treating LANL-generated radioactive liquid wastes in compliance with DOE and other applicable regulatory requirements. Capability is needed for the treatment of liquid low-level radioactive waste, acidic transuranic waste, caustic transuranic waste, and small amounts of industrial wastewater that are generated in support of mission-critical and other work performed at LANL. Specifically, the ability to manage radioactive liquid waste is necessary for the continued performance of Stockpile Stewardship Program work in the Plutonium Complex and the Chemistry and Metallurgy Research Building. The current facility is over 40 years old and has liquid effluent discharges and air emissions resulting from liquid waste treatment that must meet current regulatory requirements. NNSA needs to provide for the ability to modify or expand treatment components as necessary to meet future regulatory requirements that may be more stringent than those currently in effect.

Purpose and Need for the Technical Area 55 Radiography Facility Project

Examination of nuclear items and components through radiography is a key process in U.S. nuclear weapons stockpile safety and reliability verification. Use of high-energy radiography capability formerly located at TA-8 required nuclear items and components to be temporarily moved out of TA-55 where the items and components are fabricated and stored. Transportation and examination at TA-8 required significant security resources. Movement of these nuclear items and components has become difficult. In addition, TA-8 facilities require extensive renovations to meet current requirements for a nuclear facility. High-energy radiography capability for nuclear materials is limited, affecting mission milestones and deadlines. NNSA needs to provide a more efficient high-energy radiography capability that eliminates the need for transporting nuclear items and components outside the security perimeter of TA-55.

Purpose and Need for the Remote Warehouse and Truck Station

The current warehouse facility is over 50 years old and has become cramped as LANL and NNSA have increased materials holding time requirements for materials in order to meet quality control inspection and chain-of-custody protocols. Additionally, LANL programs and activities have been expanding, resulting in increases in the amount of material processed at the current TA-3 warehouse facility. The current TA-3 warehouse facility is not properly equipped or constructed to meet current security requirements, including the need to segregate incoming vendor vehicles from government warehouse vehicles. Furthermore, the current location of the TA-3 warehouse facility requires offsite vehicles to travel through the densely populated TA-3 areas.

Overview of Projects

A brief introduction to each project is presented below, with detailed analysis of the environmental impacts associated with each project presented in the following sections. Chapter 4 of this SWEIS provides a detailed description of the affected environment at LANL. Therefore, the affected environment discussion is minimal in this appendix unless unique characteristics of the project or project area require further discussion.

Physical Science Research Complex (Technical Area 3)

Approximately 750 scientists from various divisions and disciplines located across LANL would be consolidated and collocated in this new facility, which would facilitate the science required for nuclear weapons stockpile stewardship and certification. The Physical Science Research Complex would be constructed in a developed area of TA-3 that currently has several existing structures in it; these structures would be demolished to accommodate the new facility.

Replacement Office Buildings (Technical Area 3)

The TA-3 Replacement Office Buildings would consolidate staff currently located in temporary structures or aging permanent buildings throughout TA-3 or from other parts of LANL. The complex would consist of 12 new buildings and related parking infrastructure. The replacement offices would include a Los Alamos Site Office Building. The number of staff housed in the overall Replacement Office Buildings would total approximately 900.

Radiological Sciences Institute, including Phase I – The Institute for Nuclear Nonproliferation Science and Technology (Technical Area 48)

NNSA proposes to build a new consolidated and integrated Radiological Sciences Institute. This project would serve two purposes: (1) modernization of LANL radiochemistry capabilities, and

(2) assumption of capabilities that could potentially be lost from LANL due to changes in other facilities (such as hot cell capabilities from the Chemistry and Metallurgy Research Building). The new institute would be constructed over 20 years, in a phased approach. Construction of the first phase, the Institute for Nuclear Nonproliferation for Science and Technology, is proposed to begin during the timeframe analyzed in this SWEIS. The Institute for Nuclear Nonproliferation Science and Technology would ultimately include a Security Category I and II training facility with a Security Category I vault, several Security Category III and IV laboratories, a field security test laboratory, a secure radiochemistry facility, and associated office support facilities. Further, Security Category III and IV material and capabilities from TA-18 that would remain at LANL would be relocated to the Institute for Nuclear Nonproliferation Science and Technology.

Radioactive Liquid Waste Treatment Facility Upgrade (Technical Area 50)

NNSA proposes to construct a new treatment facility adjacent to the existing Radioactive Liquid Waste Treatment Facility to ensure that LANL can maintain the capability to treat radioactive liquid waste safely, reliably, and effectively for the next 50 years with normal maintenance. The main building of the existing Radioactive Liquid Waste Treatment Facility would be retained; the three annexes that do not meet current seismic or wind-loading standards would undergo DD&D. The new structure would house equipment for treating liquid low-level radioactive waste and liquid transuranic waste and would provide flexibility to accommodate new technology that may be required in the upcoming years to meet more stringent discharge standards.

Los Alamos Neutron Science Center Refurbishment (Technical Area 53)

Since the LANSCE linear accelerator first accelerated protons in 1972, the facility mission has evolved considerably. However, investment in the physical infrastructure and technology has not been adequate to ensure long-term sustainable operation at high reliability. The LANSCE Refurbishment Project proposes to sustain reliable facility operations well into the next decade. The LANSCE Refurbishment Project would address the following priorities: (1) replacing facility equipment where necessary to address code compliance or end-of life issues that could severely impact facility operations; (2) enhancing cost-effectiveness by system refurbishments or improvements that stabilize decreasing facility reliability and maintainability; (3) stabilizing the overall beam availability and reliability in a manner that is sustainable over the longer term; and (4) accomplishing the above with minimal disruption to scheduled user programs.

Radiography Facility (Technical Area 55)

This project would enhance the safety and ease the logistics of LANL's stockpile management procedures. Nondestructive examinations using dye penetrant testing, ultrasonic testing, and x-ray radiography of nuclear items and weapons components are necessary elements of LANL's mission for stockpile management. Many steps of this process occur in TA-55, but final radiography was performed in TA-8. This required that the nuclear components and items be shipped between TA-55 and TA-8, a distance of 4.5 miles (7.2 kilometers), for this single step of the examination process. A rolling roadblock was required when the materials were transported, and a temporary material accountability area needed to be set up in TA-8 while the nondestructive examination procedures took place. These steps required significant security resources, making the process expensive, logistically difficult, and inefficient. NNSA proposes to construct a new high-energy nondestructive examination facility at TA-55 to eliminate the need for transporting these nuclear items to different locations at LANL during the examination process.

Plutonium Facility Complex Refurbishment (Technical Area 55)

The TA-55 Plutonium Facility Complex was constructed in the mid-1970s and has been in operation for approximately 30 years. Although systems in this complex function as designed, many are near the end of their design lives and have become increasingly difficult and expensive to maintain. NNSA has determined that an investment is needed in the near term to upgrade electrical, mechanical, safety, and other selected facility-related systems that are approaching the end of life. The proposed project comprises a number of subprojects considered for execution within the timeframe analyzed in this SWEIS.

Technical Area 62 (Technical Area 3) Science Complex

The Science Complex would consist of two buildings and one supporting parking structure that would be constructed in TA-3 or north of TA-3 in TA-62. This new complex would provide approximately 400,200 square feet (37,180 square meters) of office and light laboratory space in support of basic and applied scientific research and technology. One of the buildings would provide facilities for many of the bioscience activities currently conducted in the former Health Research Laboratory, now known as the Bioscience Facilities, located adjacent to the Los Alamos townsite.

Technical Area 72 Remote Warehouse and Truck Inspection Station

The current warehouse located at TA-3 provides centralized shipping, receiving, distribution, packaging, and transportation compliance and mail services for all LANL organizations. The facility is over 50 years old and has become cramped as LANL and NNSA have increased materials holding time requirements for purposes of quality control inspection and chain-of-custody protocols. The facility does not meet current security requirements. NNSA proposes construction of a consolidated warehouse facility and truck inspection complex in TA-72 to replace the current warehouse facility and LANL's temporary truck inspection station.

G.1 Physical Science Research Complex Construction and Operation Impact Assessment

This section provides an impact assessment for the construction and operation of a Physical Science Research Complex in TA-3 at LANL. Section G.1.1 provides background information on the construction project and a physical description of the Physical Science Research Complex. Section G.1.2 provides a description of the proposed project to construct and operate a Physical Science Research Complex in TA-3. Section G.1.3 provides an analysis of environmental consequences of the proposed project and the No Action Alternative.

G.1.1 Introduction

Over the past 3 years, a detailed analysis of the cost of operating and maintaining LANL facilities and a prioritization system to fund facilities and infrastructure upgrades have been developed. NNSA has been evaluating and implementing methods to reduce facility costs and has identified distinct areas that must be addressed to ensure future infrastructure sustainability. These areas include facility consolidation and cost reduction initiatives to reduce facility footprints and operating costs, as well as the improvement of safety, security, environmental protection, scientific interactions, and productivity. A TA-3 Revitalization Plan has been developed to address the upgrade of LANL's most populated area. The proposed construction and operation of the Physical Science Research Complex in TA-3 is one such consolidation and strategic planning effort being considered at LANL.

Theoretical and computational weapons physics research requires the use of delicate equipment and highly sensitive computers in carefully regulated laboratory environments. However, many such activities at LANL are currently conducted in scattered, 20- to 50-year-old facilities, many of which are obsolete and increasingly expensive to operate. The lack of adequate building infrastructure has resulted in experiments being conducted in spaces never intended to serve as laboratories. The space that has been made available to conduct this research is spread across TA-3, TA-35, and TA-53, rather than being consolidated in a single facility resulting in inefficiencies among the staff. Recent and ongoing construction actions have been undertaken to correct these deficiencies and address the modernization of several such facilities in TA-3, including the Nonproliferation and International Security Center, the Nicholas C. Metropolis Center for Simulation and Modeling, and the National Security Science Building. The Physical Science Research Complex would complete the theoretical and computational research core in TA-3. The project would consolidate and relocate critical operations necessary for continued support of the stockpile stewardship mission. The proposed Physical Science Research Complex would be located in TA-3, just west of the Nonproliferation and International Security Center.

G.1.2 Options Considered

The two options identified for the Physical Science Research Complex are the No Action Option and the proposed project option.

G.1.2.1 No Action Option

Under the No Action Option, LANL stockpile stewardship mission staff would continue to operate at current levels at existing geographically dispersed facilities at TA-3, TA-35, and TA-53. Corrective maintenance and actions would continue to be performed as facility infrastructure failures occur. Staff consolidation in a state-of-the-art research center would not occur, nor would the proposed DD&D of vacated older buildings and structures.

G.1.2.2 Proposed Project

The proposed project is the construction and operation of a new Physical Science Research Complex in a currently developed area of TA-3 (see **Figure G–2**). The Physical Science Research Complex would provide a new, modern facility and would consolidate staff currently located throughout TA-3, in TA-35, and in TA-53 in temporary structures or aging permanent buildings in failing and poor condition. Approximately 750 upper-level management, technical, and administrative staff whose work directly supports the Stockpile Stewardship Program would be consolidated in this facility. Currently, these individuals are located in outdated buildings or transportables (office trailers) in TA-3, TA-35, and TA-53 (LANL 2006a). The Physical Science

Research Complex would consist of up to four buildings, providing approximately 350,000 square feet (32,500 square meters) of space to house offices, light laboratories, computer rooms, analytical facilities, and support and common areas. Each building would be four stories tall; three of the four buildings would be designated as classified buildings and require security controls and fencing (LANL 2006a). In total, the facility would have a combined footprint of approximately 128,000 square feet (11,900 square meters). Approximately 30 percent of the total floor space would be composed of light-to-medium experimental laboratories, consisting primarily of laser laboratories (LANL 2006a). The Physical Science Research Complex would be sited south of the National Security Science Building where the Administration Building parking lot, guard station, Integrated Management Building and associated transportables, and part of the Administration Building A wing are located today.

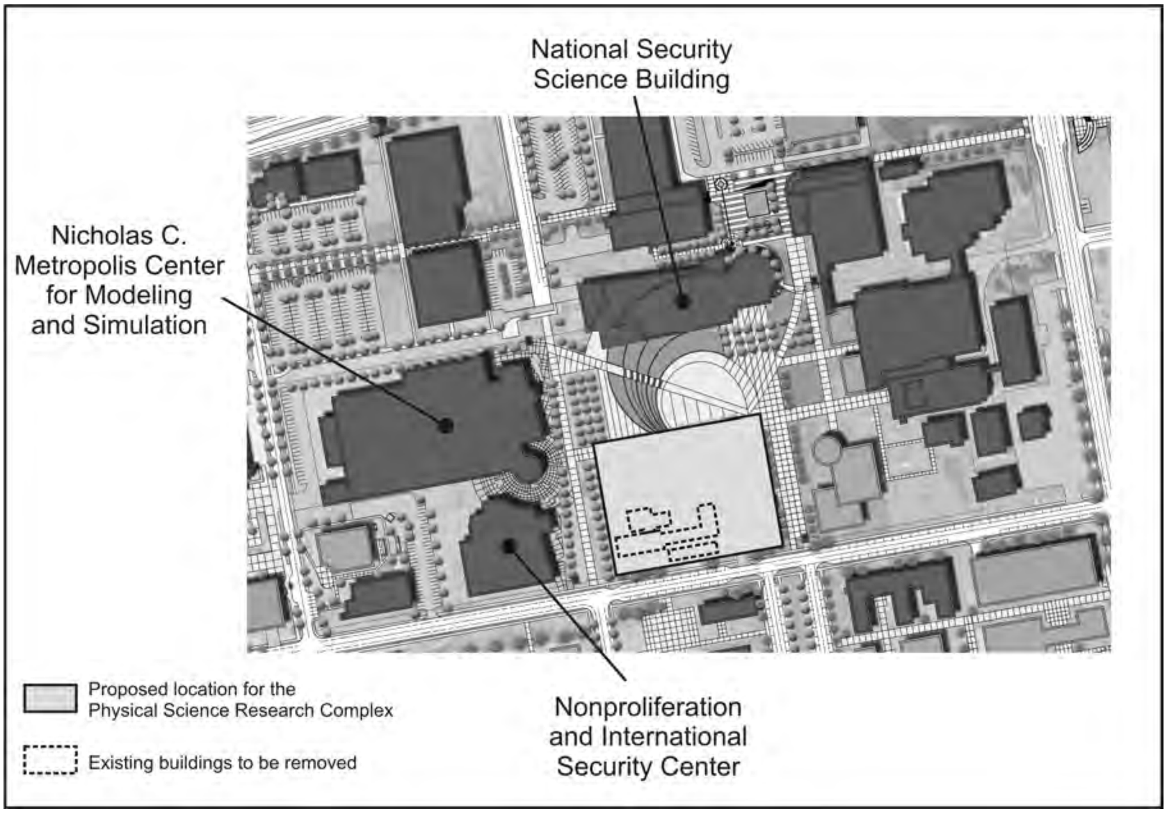

Figure G–2 Proposed Location for the Physical Science Research Complex

The light laboratories would have an efficient heating, ventilating, and air conditioning system with an ability to control temperature within 2 to 3 degrees; specialized flooring to limit vibration; extensive electrical grounding; and pressurized air, helium, and nitrogen gas available for use. No wet chemistry is expected to be conducted in the Physical Science Research Complex. The complex would include a clean room and vault space for classified weapons designers and would require a substantial amount of electricity (LANL 2006a). Common areas would include three auditoriums of different sizes, various-sized conference rooms, a 20,000-square-foot (1,900-square-meter) computer room with access floor, a computer equipment room, a vault-type room for offices, a computer machine room, a kitchen, and equipment storage rooms (LANL 2006a).

As shown in Figure G–2, construction and operation of the Physical Science Research Complex would occur at a location in TA-3 that includes approximately 74,000 square feet (6,900 square meters) of existing structures. These structures (TA-03-0028, -0142, -0510, -1559, -1566, and 1663) would undergo DD&D to accommodate construction of the proposed new facility. Once constructed, the Physical Science Research Complex would also house staff and capabilities from approximately 22 other LANL structures. In total, about 30 buildings and structures located across TA-3, TA-35, and TA-53 comprising about 867,000 square feet (80,550 square meters) would be removed under the proposed project. Physical Science Research Complex construction is scheduled to begin in 2010 and take approximately 2 years to complete. The associated DD&D of buildings within the proposed footprint of the Physical Science Research Complex would occur at the beginning of this timeframe, with subsequent DD&D of other buildings in TA-3, TA-35, and TA-53 occurring after their respective staff have relocated to the Physical Science Research Complex. At this time, project-specific work plans have not been prepared that would define the actual methods, timing, or workforce to be used for DD&D of these structures. Typical processes and methods for DD&D as discussed in Appendix H would be used for this proposed project.

G.1.3 Affected Environment and Environmental Consequences

An initial assessment of the potential impacts of the proposed project identified resource areas for which there would be no or only negligible environmental impacts. Consequently, for the following resource areas, a determination was made that no further analysis was necessary:

- *Land Resources* – The proposed site is in an already-developed area of TA-3 and the proposed land use is consistent with land use plans. Only the visual environment is included in the impacts discussion.

- *Water Resources* – The proposed site is located in an already-developed area of TA-3, and operations would not result in new discharges.

- *Ecological Resource*s – The proposed project is located in an already-developed area of TA-3; in general, wildlife is expected only around the periphery of TA-3.

- *Socioeconomics and Infrastructure* – No new employment is expected. Construction and DD&D workers would be drawn from the pool of construction workers employed on various projects at LANL. Only infrastructure impacts are included in the impacts discussion.

- *Environmental Justice* – The proposed project is confined to an already-developed area of TA-3, with no disproportionate human health impacts to low-income or minority populations expected.

- *Facility Accidents* – The proposed project would not implement new activities associated with radiological materials; only industrial accidents may occur.

This impact assessment focuses on those areas of the affected environment where potential impacts would occur: visual environment, geology and soils, air quality and noise, human health, cultural resources, site infrastructure, waste management, and transportation.

G.1.3.1 No Action Option

Under the No Action Option, NNSA would not construct the Physical Science Research Complex at TA-3 and LANL stockpile stewardship mission staff would continue to occupy existing structures spread among three TAs at the site. Benefits that would result from consolidating personnel in a modern facility would not occur. Outdated structures and temporary buildings that presently accommodate personnel would continue to contribute adversely to the visual character of TA-3 and other areas. Benefits in the areas of resource efficiency and conservation that would be realized by vacating currently occupied energy-inefficient structures would not take place. Expenses for repairs and replacement of aging heating, ventilation, and air conditioning systems and other building components would increase. As building systems and other components fail and cannot be replaced or repaired, affected buildings would be partially or completely closed and the staff relocated. No disturbance of existing TA-3 land or building sites would occur. The proposed vacating and DD&D of outdated facilities and temporary buildings would not occur, and no construction or DD&D waste requiring disposal would be generated.

G.1.3.2 Proposed Project

Land Resources—Visual Environment

Construction Impacts—Impacts on visual resources resulting from construction of the Physical Science Research Complex would be temporary in nature and could include increased levels of dust from heavy equipment.

Operations Impacts—The existing buildings are part of the "dense mixed development" within TA-3 that constitutes an adverse visual impact because it contains unusually discordant structures (NNSA 2001). The proposed Physical Science Research Complex would be visually compatible with nearby office and computing structures and would enhance the overall architectural character of the Core Development Area.

DD&D Impacts—Impacts on visual resources resulting from DD&D of vacated buildings under the proposed project would be temporary in nature and could include increased levels of dust from heavy equipment. Once these activities are completed, the general appearance of TA-3, TA-35, and TA-53 should benefit from the removal of outdated and vacated structures.

Geology and Soils

The site for the Physical Science Research Complex lies within a part of the Pajarito Fault system characterized by subsidiary or distributed fault ruptures; two small, closely spaced faults are located below TA-3. The annual probability of surface rupture in areas beyond the principal or main trace of the Pajarito Fault, such as at the Physical Science Research Complex site, is less than 1 in 10,000 (LANL 2004c). To account for seismic risk, the Physical Science Research Complex would be designed and constructed in accordance with current DOE seismic standards and applicable building codes.

Construction Impacts—Approximately 499,000 cubic yards (381,000 cubic meters) of soil would be disturbed during building excavation within areas already disturbed by previous facility construction; there would be no impact on undisturbed LANL soils. Construction of the new buildings would require removal of soils as well as new excavation of shallow bedrock in some areas. As a result, construction and DD&D activities would generate excess soil and excavated bedrock that may be suitable for use as backfill. This uncontaminated backfill material would be stockpiled at an approved material management area at LANL for future use. Best management practices would be implemented to prevent erosion and migration of disturbed materials from the site caused by stormwater or other water discharges or wind.

DD&D Impacts—DD&D activities associated with existing facilities would have a negligible additional impact on geologic and soil resources at LANL, as the affected facility areas are developed and adjacent soils are already disturbed. Additional ground disturbance would be necessary to establish laydown yards and waste management areas in the vicinity of the facilities to be razed. Available paved surfaces, such as parking lots in the vicinity of the facilities to be demolished, would be used to the extent possible.

The major indirect impact on geologic and soil resources at the DD&D locations would be associated with the need to excavate any contaminated tuff and soil from beneath and around facility foundations. Borrow material (such as crushed tuff and soil) would be required to fill the excavations to grade, but such resources would be available from onsite borrow areas (see Section 5.2) and in the vicinity of LANL. LANL staff would survey potentially affected areas to determine the extent and nature of any contamination and required remediation in accordance with established procedures. All excavated contaminated media would be characterized and managed according to waste type and all applicable LANL procedures and regulatory requirements.

Air Quality and Noise

Construction Impacts—Construction of new facilities at TA-3 would result in temporary increases in air quality impacts from construction equipment, trucks, and employee vehicles. Criteria pollutant concentrations were modeled for the site work and erection construction phases of the TA-3 Physical Science Research Complex's largest new facilities and compared to the most stringent standards. Construction modeling considered particulate emissions from activity in the construction area and emissions from various earthmoving and material-handling equipment. The maximum ground-level pollutant concentrations off site and along the perimeter road to which the public has regular access would be below the ambient air quality standards, except for possible short-term concentrations of nitrogen oxides and carbon monoxide. Estimated concentrations for particulate matter with an aerodynamic diameter less than or equal to 10 micrometers (PM_{10}) would be greatest for the site work phase. Estimated maximum PM_{10} concentrations are an annual average of 3.5 micrograms per cubic meter and a 24-hour average of 72.1 micrograms per cubic meter. The maximum annual and short-term concentrations for construction would occur at the site boundary or roadway north-to-northeast of TA-3. Soil disturbance during construction could result in small radiological air emissions, but would be controlled by best management practices, thereby resulting in no impacts on workers or the public.

Construction of the new Physical Science Research Complex at TA-3 would result in a temporary increase in noise levels from construction equipment and activities. Some disturbance of wildlife near the area may occur as a result of construction equipment operation. There would be no change in noise impacts on the public outside of LANL as a result of construction activities, except for a small increase in traffic noise levels from construction employee vehicles and materials and debris shipments. Noise sources associated with construction at TA-3 are not expected to include loud impulsive sources such as blasting.

Operations Impacts—Criteria and toxic air pollutants could be generated from the operation and testing of an emergency generator, if an additional one is necessary. Also, the use of various chemicals in laboratories and other activities would result in criteria and toxic air pollutant emissions. Emissions from the diesel generator would occur during periodic testing and would result in little change in air pollutant concentrations, and expected air quality impacts on the public would be minor.

Little or no change in toxic pollutant emissions or air pollutant concentrations at LANL is expected under this option. Toxic pollutants released from laboratories would vary by year with the activities performed and are expected to be similar to the current combined emissions from the existing buildings and capabilities that would be consolidated at TA-3. The emissions would continue to be small and below Screening-Level Emission Values (see Appendix B). Therefore, the air quality impacts on the public would be minor. Additionally, operations would have no significant radiological air emissions.

Noise impacts of operating the new Physical Science Research Complex at TA-3 are expected to be similar to those of existing operations at TA-3. Although there would be small changes in traffic and equipment noise (for example, new heating and cooling systems) near the area, there would be little change in noise impacts on wildlife and no change in noise impacts on the public outside of LANL as a result of operating these new facilities.

DD&D Impacts—DD&D of buildings being replaced by the Physical Science Research Complex would result in temporary increases in air quality impacts of construction equipment, trucks, and employee vehicles. Criteria pollutant concentrations were not modeled for the DD&D of buildings at TA-3, but would be less than those from construction of the new facilities. DD&D of buildings at other TAs would be similar to DD&D activities taking place at various areas at LANL. Concentrations off site and along the roads to which the public has regular access would be below ambient air quality standards. Soil disturbance during demolition could result in small radiological air emissions, but would be controlled by best management practices, thereby resulting in no impacts on workers or the public.

DD&D of excessed buildings and structures in TA-3, TA-35, and TA-53 would result in some temporary increase in noise levels near the area from construction equipment and DD&D activities. Some disturbance of wildlife near the area may occur as a result of construction equipment operation. There would be no change in noise impacts on the public outside of LANL as a result of DD&D activities, except for a small increase in traffic noise levels from DD&D employee vehicles and materials and debris shipments.

Human Health

Construction Impacts—Potentially serious exposures to various hazards or injuries would be possible during the construction and DD&D phases of the proposed project. Adverse effects could range from relatively minor (such as lung irritation, cuts, or sprains) to major (such as lung damage, broken bones, or fatalities) (DOE 2004, BLS 2003). The potential for industrial accidents is based on both DOE and Bureau of Labor Statistics data on construction injuries and fatalities. Based on an estimated 1.99 million person-hours to construct the new facilities, no fatal accidents are expected to occur. Nonfatal injuries are estimated to be between 23 (DOE 2004) and 84 (BLS 2003).

To prevent serious exposures and injuries, all site construction contractors would be required to submit and adhere to a Construction Safety and Health Plan and undergo site-specific hazard training. No potential offsite human health effects of construction hazards are expected.

Operations Impacts—Physical Science Research Complex operation is expected to have a beneficial effect on the LANL staff working environment, as working conditions would be improved by use of proper lighting, heating, ventilation, and air conditioning, and ergonomic equipment and furniture. Office, administrative, and light laboratory activities would constitute most of the Physical Science Research Complex operations, and applicable safety and health training and worksite criteria would be required for these workers.

DD&D Impacts—A potential source of impacts on noninvolved workers and members of the public would be associated with the release of radiological contaminants during the DD&D process. Any emissions of contaminated particulates would be reduced by the use of plastic draping and enclosures, coupled with high-efficiency particulate air (HEPA) filters. Construction and demolition workers would be actively involved in potentially hazardous activities such as heavy-equipment operations; soil excavations; and handling, assembly, or DD&D of various building materials. Potentially serious exposures to various hazards or injuries are possible during the DD&D phase of the proposed project. Adverse effects could range from relatively minor (such as lung irritation, cuts, or sprains) to major (such as lung damage, broken bones, or fatalities). The potential for industrial accidents is based on both DOE and the Bureau of Labor Statistics data on construction injuries and fatalities. Based on an estimated 286,000 person-hours to demolish the new facilities, no fatal accidents would occur. Nonfatal injuries are estimated to be approximately 3 (DOE 2004) to 12 (BLS 2003).

To prevent serious exposures and injuries, all site construction contractors would be required to submit and adhere to a Construction Safety and Health Plan and undergo site-specific hazard training. Appropriate personal protection measures, such as personal protection device use (gloves, hardhats, steel-toed boots, eyeshields, and earplugs or ear covers) would be a routine part of construction activities. The proposed project is not expected to have an effect on the health of any demolition workers under normal operations conditions.

DD&D of certain buildings and structures in TA-3 would involve removal of some asbestos-contaminated material, which would be conducted according to existing asbestos management programs at LANL which are in compliance with strict asbestos abatement guidelines. Workers would be protected by personal protective equipment and other engineered and administrative controls. As a result of the controls that would be established, no asbestos would be released that could be inhaled by members of the public.

Cultural Resources

DD&D Impacts—The proposed site of the Physical Science Research Complex is in an already-developed area of TA-3. However, TA-03-0028 is a potentially significant historic building that would be removed. Prior to its demolition it would be assessed for inclusion in the National Register of Historic Places. The current Administration Building (TA-03-0043) has been formally declared as eligible for the National Register of Historic Places and a Memorandum of Agreement has been signed regarding required documentation prior to its removal.

Socioeconomics and Infrastructure

Construction Impacts—Utility infrastructure resources would be required for Physical Science Research Complex construction. Standard construction practice dictates that electric power needed to operate portable construction and supporting equipment be supplied by portable diesel-fired generators. Therefore, no electrical energy consumption would be directly associated with construction. A variety of heavy equipment, motor vehicles, and trucks would be used, requiring diesel fuel, gasoline, and propane for operation. Liquid fuels would be brought to the site as needed from offsite sources and, therefore, would not be limited resources. Water would be needed primarily to provide dust control, aid in soil compaction at the construction site, and possibly for equipment washdown. Water would not be required for concrete mixing, as ready-mix concrete is typically procured from offsite resources. Portable sanitary facilities would be provided to meet the workday sanitary needs of project personnel on the site. Water needed for construction would typically be trucked to the point of use, rather than provided by a temporary service connection. Construction is estimated to require 2.6 million gallons (10 million liters) of liquid fuels and 14.4 million gallons (54 million liters) of water for the entire project.

The existing LANL infrastructure would be capable of supporting requirements for new facility construction without exceeding site capacities, resulting in a negligible impact on site utility infrastructure. Utility lines are located adjacent to the proposed building sites and would require minimal trenching to connect them to the new structures. Minor repairs to existing underground sewer or water lines may be necessary (NNSA 2001).

Operations Impacts— Physical Science Research Complex operations would result in estimated annual electrical and water requirements of 45,000 megawatt-hours and 9.6 million gallons (36 million liters), respectively (LANL 2006a). This power and water use would be similar to or less than the facilities that are being replaced. Although LANL does not meter water or electrical use at most buildings, nor does it track waste generated at individual buildings, the Physical Science Research Complex is expected to operate with more energy-efficient utility systems than the current structures. Water consumption is also expected to decrease with the DD&D of existing resource-inefficient structures currently in operation. As such, Physical Science Research Complex operation is expected to have no or negligible incremental impact on utility infrastructure capacities at LANL.

DD&D Impacts—Activities associated with DD&D of facilities to be replaced by the Physical Science Research Complex are projected to require 129,000 gallons (488,000 liters) of liquid fuels and 4.1 million gallons (16 million liters) of water. DD&D activities would be staggered over an extended period of time. As a result, impacts of these activities on LANL's utility infrastructure are expected to be very minor on an annualized basis. Standard practice dictates that utility systems serving individual facilities be shut down as they are no longer needed. As DD&D activities progress, interior spaces, including associated equipment, piping, and wiring, would be removed prior to final demolition. Thus, existing utility infrastructure would be used to the extent possible and would then be supplemented or replaced by portable equipment and facilities as DD&D activities proceed.

Waste Management

Construction Impacts—Physical Science Research Complex construction would result in approximately 1,600 cubic yards (1,200 cubic meters) of waste, consisting primarily of debris such as gypsum board, pallets, and wire generated in the course of normal construction. Waste types and quantities generated by removal of the structures would be within the capacity of the existing waste management system and would not result in a substantial impact on existing waste management disposal operations.

No known potential release sites are present within the proposed footprint of the Physical Science Research Complex site (LANL 2006a). Should any potential release site be disclosed during subsurface construction work, LANL's environmental restoration project staff would review the site, stipulate procedures for working within that site area, and perform remediation as needed consistent with DOE and the Compliance Order on Consent (Consent Order) (NMED 2005) requirements.

Operations Impacts—Solid waste generated during Physical Science Research Complex operations would be disposed of at the Los Alamos County Landfill or other appropriate solid waste landfill. The amount of waste generated during Physical Science Research Complex operations would not increase substantially from current volumes generated at the existing structures. Sanitary waste would be removed from the facility via sanitary wastewater lines to the Sanitary Wastewater Systems Plant.

DD&D Impacts—DD&D of associated buildings would produce approximately 195,000 cubic yards (149,000 cubic meters) of waste, including low-level radioactive waste, mixed low-level radioactive waste, hazardous waste, sanitary waste, and nonhazardous solid waste. DD&D would also generate about 314,000 pounds (142,000 kilograms) of chemical waste and 311 cubic yards (238 cubic meters) of asbestos waste. This waste would be packaged according to applicable requirements and sent to the LANL asbestos transfer station for shipment off site to a permitted asbestos disposal facility along with other asbestos waste generated at LANL. The anticipated amount of waste would not be beyond the disposal capacity of existing on and offsite disposal facilities. **Table G–1** summarizes waste types and volumes expected to be generated during DD&D activities. Although excessed LANL transportables are usually donated to the public, it has been assumed for purposes of analysis that they would also be dispositioned as demolition debris. About 8.9 percent of waste produced during DD&D activities is bulk low-level radioactive wastes. For purposes of analysis, NNSA has evaluated both the on and offsite disposal of low-level radioactive waste to ensure that the environmental consequences of either waste management option were considered. Potential available offsite disposal sites include the Nevada Test Site near Mercury, Nevada, and a commercial facility.

Table G–1 Estimated Waste Volumes from Physical Science Research Complex Decontamination, Decommissioning, and Demolition Activities (cubic yards)

Low-Level Radioactive Waste	*Mixed Low-Level Radioactive Waste*	*Solid* [a]	*Hazardous*	*Asbestos*
17,400	< 1	177,000	3	311

[a] Includes demolition and sanitary waste.
Note: To convert cubic yards to cubic meters, multiply by 0.76455.

For disposal of generated low-level radioactive waste, two capability scenarios were evaluated. Low-level radioactive waste could be disposed of on site or shipped off site, with the selected disposal path determined based on TA-54 disposal capacity and disposal priorities.

Scenario 1. Under this scenario, NNSA would pursue offsite disposal of the low-level radioactive waste resulting from DD&D of the buildings and structures, including concrete, soil, steel, and personal protective equipment. Among other possible offsite disposal locations, both the Nevada Test Site, a DOE waste disposal facility, and a commercial facility have the capacity to accept these quantities of waste.

Scenario 2. Under this scenario, low-level radioactive waste would be disposed of on site in TA-54. The current disposal site footprint has limited waste capacity, although expansion into Zone 4 is planned. Onsite disposal capacity is expected to be adequate for the amount of low-level radioactive waste that would be generated by the DD&D activities.

All other wastes generated by the DD&D activities would be handled, managed, packaged, and disposed of in the same manner as the same wastes generated by other activities at LANL. Most mixed low-level radioactive waste generated at LANL is sent off site to other DOE or commercial facilities for treatment and disposal. The estimated volume of mixed low-level radioactive waste generated is small, and offsite disposal capacity is adequate.

Small amounts of hazardous waste would also be generated during DD&D activities. These wastes would be handled, packaged, and disposed of according to LANL's hazardous waste management program and are within its capacity.

Demolition debris and sanitary waste would be managed at the Los Alamos County Landfill or transported to an offsite landfill. For the purposes of analysis, it was assumed that these wastes would be disposed of at an offsite location. DD&D would generate nonradiological asbestos waste. This waste would be packaged according to applicable requirements and sent to the LANL asbestos transfer station for shipment off site to a permitted asbestos disposal facility along with other asbestos waste generated at LANL. Offsite disposal capacity would be adequate.

Transportation

Construction Impacts—Construction personnel would park on site and at remote designated parking areas. Truck traffic volumes carrying waste material to local or regional landfill sites would increase during these periods.

Operations Impacts—Once construction is completed, operation of the Physical Science Research Complex would account for the relocation of approximately 250 personnel from TAs other than TA-3. Using a ratio of 0.45 vehicles per employee, approximately 113 more vehicles may be added to TA-3 roadways and parking areas as a result of Physical Science Research Complex personnel relocation (DOE 1998).

DD&D Impacts—The generated DD&D wastes would need to be transported to storage or disposal sites using over-the-road truck transportation. These sites could be at LANL TA-54 or an offsite location. Transportation has potential risks to workers and the public from incident-free transport, such as radiation exposure as the waste packages are transported along the routes and highways. There is also increased risk from traffic accidents (without release of radioactive material) and radiological accidents (in which radioactive material is released).

The effects of incident-free transportation of construction and DD&D wastes on the worker population and general public are presented in **Table G–2**. Effects are presented in terms of the collective dose in person-rem resulting in excess latent cancer fatalities (LCFs) in Table G–1. Excess LCFs are the number of cancer fatalities that may be attributable to the proposed project and estimated to occur in the exposed population over the lifetimes of the individuals. If the number of LCFs is less than one, the subject population is not expected to incur any LCFs resulting from the actions being analyzed. The risk for development of excess LCFs is highest for workers under the offsite disposition option. This is because the dose is proportional to the duration of transport, which in turn is proportional to travel distance. As shown in Table G–2, disposal of low-level radioactive waste at Nevada Test Site, which is located farthest from LANL, would lead to the highest dose and risk, although the dose and risk are low for all disposal options.

Table G–2 Incident-Free Transportation Impacts – Physical Science Research Complex

Disposal Option	*Low-Level Radioactive Waste Disposal Location*	*Crew*		*Public*	
		Collective Dose (person-rem)	*Risk (LCF)*	*Collective Dose (person-rem)*	*Risk (LCF)*
Onsite disposal	LANL TA-54	0.037	2.2×10^{-5}	0.01	6.0×10^{-6}
Offsite disposition	Nevada Test Site	4.65	0.0028	1.35	0.00081
	Commercial facility	4.51	0.0027	1.32	0.00079

LCF = latent cancer fatality, TA = technical area.

Table G–3 presents the impacts of traffic and radiological accidents. This table provides population risks in terms of fatalities due to traffic accidents from both the collisions themselves and from excess LCFs from exposure to releases of radioactivity. The analyses assumed that all nonradiological wastes would be transported to offsite disposal facilities.

The results in Tables G–2 and G–3 indicate that no traffic fatalities and no excess LCFs are expected from the transportation of generated waste derived from the DD&D of excessed buildings and structures at TA-3, TA-35, and TA-53.

Table G–3 Transportation Accident Impacts – Physical Science Research Complex

Low-Level Radioactive Waste Disposal Location [a]	*Number of Shipments* [b]	*Distance Traveled (10^6 kilometers)*	*Accident Risks*	
			Radiological (excess LCFs)	*Traffic (fatalities)*
LANL TA-54	10,897	4.16	Not analyzed [c]	0.0013
Nevada Test Site	10,897	6.76	1.2×10^{-8}	0.0036
Commercial facility	10,897	6.50	9.6×10^{-9}	0.0033

LCF = latent cancer fatality, TA = technical area.
[a] All nonradiological wastes would be transported off site.
[b] Approximately 10 percent of shipments are radioactive wastes. Others include 90 percent industrial and sanitary waste and about 0.1 percent asbestos and hazardous wastes.
[c] No traffic accident leading to releases of radioactivity for onsite transportation is hypothesized.
Note: To convert kilometers to miles, multiply by 0.6214.

G.2 Replacement Office Buildings Impact Assessment

This section provides an assessment of environmental impacts for the proposed Replacement Office Buildings at TA-3. Section G.2.1 provides background information on the proposed project to build a Replacement Office Building Complex and two parking structures and to DD&D two structures. Section G.2.2 provides a brief description of the proposed options for the replacement offices. Section G.2.3 presents the environmental consequences of the No Action Option and the proposed project (construction and operation of the proposed Replacement Office Buildings at TA–3).

G.2.1 Introduction

NNSA is working to reduce the number of substandard structures across LANL and to relocate staff and activities into more efficient and safe structures. Staff currently occupies trailers and other temporary structures that have exceeded their intended lifespan. NNSA has a congressional mandate to remove facilities at the same rate as new construction. NNSA is in the process of reducing non-office and inefficient office space, focusing on increased use and replacement of inefficient structures.

Over the past 3 years, a detailed analysis of the cost of operating and maintaining LANL facilities and a prioritization system to fund structural and infrastructure upgrades were developed. NNSA evaluated and implemented methods to reduce facility costs and identified distinct areas to be addressed to ensure infrastructure sustainability. These areas include structure consolidation and cost reduction initiatives to reduce structure footprints and operating costs as well as improve safety, security, environmental protection, scientific interactions, and productivity. A TA-3 Revitalization Plan, developed to address the upgrade of LANL's most populated areas and the construction of Replacement Office Buildings in TA-3, is one such consolidation and strategic planning effort being considered at LANL.

G.2.2 Options Considered

The two options identified for the Replacement Office Buildings are the No Action Option and proposed project option.

G.2.2.1 No Action Option

Under the No Action Option, no action would be taken. The site would not be changed and no Replacement Office Buildings or parking structures would be constructed. No DD&D activities would occur. Employees intended for the proposed office buildings would remain at their current locations throughout TA-3, and no consolidation would occur.

G.2.2.2 Proposed Project

The proposed project would be located partially on undeveloped land south of West Jemez Road and partially in the area of the existing Wellness Center and would consist of 12 new buildings (1 would be available to house NNSA's Los Alamos Site Office) and two new parking structures, one north of Mercury Road and one to the south of West Jemez Road. The Wellness Center and a warehouse would be demolished to accommodate this project. The current Los Alamos Site Office Building would also be demolished. Impacts of the Los Alamos Site Office Building DD&D were analyzed in the *Final Environmental Impact Statement for the Conveyance and Transfer of Certain Land Tracts Administered by the U.S. Department of Energy and Located at Los Alamos National Laboratory, Los Alamos and Santa Fe Counties, New Mexico* (DOE 1999c). Three office buildings that were proposed before the larger project was envisioned were categorically excluded from further National Environmental Policy Act (NEPA) evaluation under DOE's NEPA implementing regulations. However, these three buildings are integral to this office complex and are included in the impacts analysis. The complex would provide new, modern structures and would consolidate staff located primarily throughout TA-3 in temporary structures or aging permanent buildings in failing and poor condition. LANL staff located in other TAs may also be housed in the new Replacement Office Buildings. The surface parking area near Mercury Road would become a parking structure in the distant future. **Figure G–3** shows the currently proposed layout of the Replacement Office Building complex.

The buildings would be sited partially on undeveloped land south of West Jemez Road and partially in the area of the existing Wellness Center. The Replacement Office Buildings would include construction of a 45,000-square-foot (4,200-square-meter) Los Alamos Site Office Building, which would house approximately 150 staff. Construction of the Los Alamos Site Office Building has begun. The remaining office buildings would consist of two-story structures, each with a footprint of 8,000 to 9,000 square feet (740 to 840 square meters). These new buildings would provide approximately 15,000 to 17,500 gross square feet (1,400 to 1,600 square meters) of office space and house approximately 50 to 70 staff each. The number of administrative staff housed in the overall Replacement Office Buildings would total approximately 900. This staff would migrate from other offices in various locations throughout LANL and would not constitute new hires.

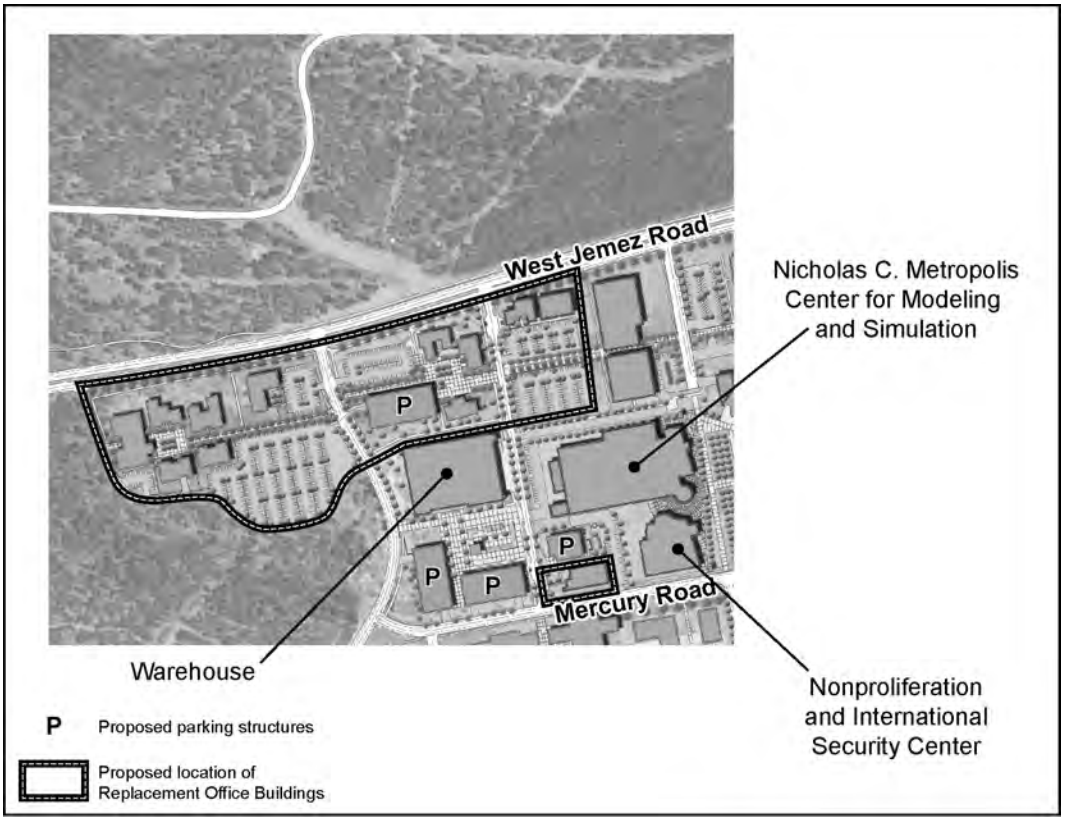

Figure G–3 Replacement Office Building Complex Proposed Layout

G.2.3 Affected Environment and Environmental Consequences

For the Replacement Office Buildings, the affected environment descriptions include only those resource areas that would be impacted. The analysis of environmental consequences relies on the affected environment descriptions in Chapter 4 of this SWEIS. Where information specific to the TA-3 affected environment is available and aids understanding potential impacts of constructing and operating the Replacement Office Buildings, it is included.

An initial assessment of the potential impacts of the proposed project identified resource areas for which there would be no or only negligible environmental impacts. Consequently, for the following resource areas, a determination was made that no further analysis was necessary:

- *Socioeconomics and Infrastructure* – No new employment is expected. Construction and DD&D workers would be drawn from the pool of construction workers employed on various projects at LANL. Only infrastructure impacts are included in the impacts discussion.

- *Environmental Justice* – The proposed project is mainly confined to already-developed areas of TA-3, with no disproportionate human health impacts to low-income or minority populations expected.

- *Facility Accidents* – The proposed project would not implement new activities associated with radiological materials; only industrial accidents may occur.

This impact assessment focuses on those areas of the affected environment where potential impacts would occur: land resources, geology and soils, water resources, air quality and noise, ecological resources, human health, cultural resources, site infrastructure, waste management, and transportation.

G.2.3.1 No Action Option

Under the No Action Option, LANL administrative staff would continue to operate at existing scattered LANL locations. The Replacement Office Buildings would not be constructed at TA-3, nor would the Wellness Center or the Warehouse undergo DD&D. Poor quality office space and the effectiveness of current staff to recruit and retain qualified employees would remain a problem. Current DOE seismic standards or applicable building codes would not be met, and use of the buildings would be phased out over time as commercial lease space or space within LANL became available or trailers could be brought on site. Outdated structures and temporary buildings that presently accommodate personnel would continue to contribute adversely to the visual character of the TA-3 area. No disturbance of existing TA-3 land or building sites would occur. There would be no construction or building removal debris to require disposal. Utility usage would remain the same as existing usage in the near future. Continued expenses for repairs and replacement of aging heating, ventilation, and air conditioning systems and other building components would increase. As building systems and other components fail and cannot be replaced or repaired, affected buildings would be partially or completely closed and the staff relocated. Benefits that would result from consolidating personnel in a modern facility that fosters better communication and collaboration between scientists and administrative personnel would not occur. Likewise, benefits would not result in the areas of resource efficiency and conservation by vacating currently occupied energy-inefficient structures.

G.2.3.2 Proposed Project

The Replacement Office Buildings Project also includes DD&D of the existing Wellness Center and warehouse located in the northwest section of TA-3. The following discussion summarizes potential impacts during construction, operations, and DD&D, as appropriate.

Land Resources—Land Use

Construction Impacts—Construction of the Replacement Office Building Complex, including parking lots and construction laydown areas, would require 13 acres (5.3 hectares) of previously undisturbed land within TA-3 that is presently designated as Reserve.

Operations Impacts—Additional acreage would be required within previously disturbed portions of the TA that are designated as Physical and Technical Support. Future land use plans have designated the proposed site area in the undeveloped portion of TA-3 as Physical and Technical Support. Thus, placement of the Replacement Office Buildings and a parking lot within the western part of TA-3 would be consistent with these plans.

Land Resources—Visual Resources

Construction Impacts—Impacts on visual resources resulting from construction of the Replacement Office Building Complex would result in short-term impacts on the visual environment, including increased dust generation due to construction activities.

Operations Impacts—Once complete, the project would result in a change in both near and distant views of TA-3. The project site is partially located within a forested area along West Jemez Road, which would be replaced with buildings and a parking lot. Although landscaping along West Jemez Road could help mitigate views, the new buildings and parking lot would be readily visible from the road and nearby areas. Views from Pajarito Road would also change; however, this would impact primarily employees, as the road is restricted from public use. Also, because the size of developed portions of TA-3 would increase and the area of woodland decrease, distant views of the TA would change as a result of construction of the Replacement Office Building Complex. However, the overall effect would be minimal due to the present highly developed nature of that part of LANL.

Geology and Soils

The Replacement Office Buildings site lies within a part of the Pajarito Fault system characterized by subsidiary or distributed fault ruptures; two small, closely spaced faults are located in TA-3. The annual probability of surface rupture in areas beyond the principal or main trace of the Pajarito Fault, such as at the Replacement Office Buildings site, is less than 1 in 10,000 (LANL 2004c). This probability is less than the required performance goal for the facility and in accordance with DOE standards. Additionally, the Replacement Office Buildings would be designed and constructed in accordance with current DOE seismic standards and applicable building codes.

The proposed area for the facility includes both disturbed and undisturbed soils. The undisturbed soils maintain the present vegetative cover. They are arid soils consisting largely of sandy loam material alluvially deposited from tuff units on higher slopes to the west and eroded from underlying geologic units. In general, the soils are poorly developed, with relatively little horizon differentiation and organic matter accumulation. These factors, combined with the dry moisture regime of the area, result in only a limited number of plant species being able to subsist on the soil medium, which, in turn, supports a very limited number of wildlife species.

Construction Impacts—Construction of the Replacement Office Buildings would include both areas already disturbed by previous facility construction and areas not previously disturbed. The impact on LANL undisturbed (native) soils would be proportional to the total area of new construction. Approximately 369,000 cubic yards (282,000 cubic meters) of soil and rock would be excavated for building construction. As a result, construction activities would generate excess soil and excavated bedrock that may be suitable for use as backfill. Uncontaminated backfill material would be stockpiled at an approved material management area at LANL for future use. Best management practices would be implemented to prevent erosion and migration of disturbed materials from the site caused by stormwater or other water discharges or wind.

Operations impacts—Office building operations would not result in additional impacts on geologic and soil resources at LANL.

DD&D Impacts—DD&D activities associated with existing facilities would have a negligible additional impact on geologic and native soil resources at LANL, as the affected facility areas are already developed and adjacent soils are already disturbed. Additional ground disturbance would be necessary to establish laydown yards and waste management areas in the vicinity of the facilities to be razed. Available paved surfaces, such as parking lots in the vicinity of the facilities to be demolished, would be used to the extent possible.

The major indirect impact on geologic and soil resources at the DD&D locations would be associated with the need to excavate any contaminated tuff and soil from beneath and around facility foundations. Borrow material (such as crushed tuff and soil) would be required to fill the excavations to grade, but such resources are available from onsite borrow areas (see Chapter 5, Section 5.2) and in the vicinity of LANL. LANL staff would survey potentially affected contaminated areas to determine the extent and nature of any contamination and required remediation in accordance with LANL procedures. All excavated material would be characterized before removing it for disposal.

Water Resources

The proposed site is predominantly flat, with a slight slope toward the adjacent steep-sided canyon to the southwest. During storm events, unchanneled stormwater runoff from the mesa drains into the canyon.

Construction Impacts—Little or no effect on surface water resources is anticipated during construction of the Replacement Office Buildings. The proposed project would not result in disturbance of watercourses or generation of liquid effluents that would be released to the surrounding environment.

Under the current U.S. Environmental Protection Agency (EPA) Construction General Permit Program, permits are required for all LANL construction activities or other projects that disturb 1 or more acres (0.4 or more hectares) of land. Conditions of the permit require the development and implementation of a stormwater pollution prevention plan. Silt fences, hay bales, or other appropriate best management practices would be employed to minimize stormwater transport of fine particulates (disturbed during construction) into surface water in the vicinity of TA-3.

Operations Impacts—There would be an increase in stormwater runoff associated with the new office building because of the increase in impervious areas of buildings and parking lots. The replacement of buildings should not change the stormwater runoff from these TAs significantly.

Air Quality and Noise

Construction Impacts—Construction of new facilities at TA-3 would result in temporary increases in air quality impacts of construction equipment, trucks, and employee vehicles. Criteria pollutant concentrations were modeled for the site work and erection construction phases of TA-3's largest new facilities and compared to the most stringent standards. The maximum ground-level concentrations off site and along the perimeter road to which the public has regular access would be below the ambient air quality standards, except for possible short-term concentrations of nitrogen oxides and carbon monoxide. Estimated concentrations for PM_{10} would be greatest for the site work phase. Estimated maximum PM_{10} concentrations are an annual average of 3.8 micrograms per cubic meter and a 24-hour average of 78.5 micrograms per cubic meter. The maximum annual and short-term concentrations for construction would occur at the site boundary or roadway north-to-northeast of TA-3. Modeling considered particulate emissions from activity in the construction area and emissions from various earthmoving and material-handling equipment.

Construction of new office facilities at TA-3 would result in some temporary increase in noise levels from construction equipment and activities. Some disturbance of wildlife near the area may occur as a result of construction equipment operation. There would be no change in noise impacts on the public outside of LANL as a result of construction activities, except for a small increase in traffic noise levels from construction employees' vehicles and materials shipments. Noise sources associated with construction at TA-3 are not expected to include loud impulsive sources such as blasting.

Operations Impacts—Operation of the Replacement Office Buildings at TA-3 would not result in an increase of criteria pollutant emissions above the existing level because the total number of employee trips to LANL would remain the same.

Noise impacts of operating the new office complex at TA-3 are expected to be similar to those from overall existing operations at TA-3. Although there would be a small change in traffic and equipment noise (for example, new heating and cooling systems) near the area, there would be little change in noise impacts on wildlife and no change in noise impacts on the public outside of LANL as a result of operating these new structures.

DD&D Impacts—DD&D of buildings being replaced by new facilities would result in temporary increases in air quality impacts of construction equipment, trucks, and employee vehicles. Maximum ground-level concentrations offsite and along the perimeter road to which the public has regular access would be below the ambient air quality standards, except for short-term concentrations of nitrogen oxides, carbon monoxide, and PM_{10}.

Demolition of the Wellness Center and warehouse would result in some temporary increase in noise levels from construction equipment and activities. Some disturbance of wildlife near the area may occur as a result of construction equipment operation. There would be no change in noise impacts on the public outside of LANL as a result of demolition activities, except for a small increase in traffic noise levels from construction employees' vehicles and materials shipments.

Ecological Resources

Construction Impacts—Construction of the Replacement Office Building Complex would involve clearing and grading 13 acres (5.3 hectares) of ponderosa pine and mixed conifer forest within TA-3. This would result in loss of less-mobile wildlife, such as reptiles and small mammals, and cause more-mobile species, such as birds or large mammals, to be displaced. The success of displaced animals would depend on the carrying capacity of the area into which they moved. If the area were at its carrying capacity, displaced animals would not be likely to survive. Indirect impacts of construction, such as noise or human disturbance, could also impact wildlife living adjacent to the construction zone. Such disturbance would span the construction period. These impacts could be mitigated by clearly marking the construction zone to prevent equipment and workers from disturbing adjacent habitat and by properly maintaining equipment. Construction of the new buildings and parking lot would not impact wetlands, as none are located in or near the construction zone.

The northern portion of TA-3 falls within the Los Alamos Canyon Mexican spotted owl (*Strix occidentalis lucida*) Area of Environmental Interest. Potential impacts to the Mexican spotted owl were evaluated in a biological assessment prepared by DOE. This assessment noted that although 11.2 acres (4.5 hectares) of buffer habitat would be disturbed, spotted owls have been not been detected in Los Alamos Canyon in recent years. The report concluded that if all reasonable and prudent alternatives are taken, actions associated with the construction of the Replacement Office Building Complex may affect, but are not likely to adversely affect, the Mexican spotted owl. Reasonable and prudent alternatives include ensuring that all lighting complies with the New Mexico Night Sky Protection Act, appropriate erosion and runoff controls be employed, unnecessary disturbance to vegetation be avoided, and all exposed soils be revegetated as soon as feasible (LANL 2006b). The U.S. Fish and Wildlife Service (USFWS) has concurred with this assessment (see Chapter 6, Section 6.5.2).

Areas of Environmental Interest for the bald eagle (*Haliaeetus leucocephalus*) and southwestern willow flycatcher (*Empidonax traillii extimus*) do not include any part of TA-3. However, recognizing that the bald eagle forages over all of LANL and that some habitat degradation is associated with the Replacement Office Building Complex project, the biological assessment concluded that provided appropriate reasonable and prudent alternatives are implemented to protect adjacent foraging habitat, the project may affect, but is not likely to adversely affect, the bald eagle. In addition to the reasonable and prudent alternatives noted above for the Mexican spotted owl, those for the bald eagle could include not disturbing winter roosting trees, monitoring the presence or absence of eagles during project activities, and keeping noise and disturbance to a minimum. Since the nearest southwestern willow flycatcher Area of Environmental Interest is more than 4.6 miles (7.4 kilometers) from the project site, the biological assessment concluded that the proposed project would have no effect on this species (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to the bald eagle and southeastern willow flycatcher (see Chapter 6, Section 6.5.2).

Operations Impacts—Operation of the Replacement Office Building Complex would have minimal impact on terrestrial resources within or adjacent to TA-3. Because the wildlife residing in the area has already adapted to levels of noise and human activity associated with current operation, it is unlikely that it would be adversely affected by similar types of activity involved with operation of the new buildings. Areas not permanently disturbed (for example, construction laydown areas) would be landscaped; however, this would provide little habitat to native wildlife.

Human Health

Construction Impacts—During construction of the Replacement Office Buildings, some construction-related accidents would potentially occur. The potential for industrial accidents is based on both DOE and Bureau of Labor Statistics data on construction injuries and fatalities (DOE 2004, BLS 2003). Based on an estimated 1.35 million person-hours to construct the new facilities, no fatal accidents would occur. Nonfatal injuries are estimated to be approximately 15 (DOE 2004) to 57 (BLS 2003).

DD&D Impacts—Health and safety impacts of demolition activities would be similar to those expected during construction activities. Based on an estimated 7,600 person-hours for DD&D of the existing facilities (including the current Los Alamos Site Office Building), no fatal accidents would occur, and nonfatal injuries are not expected (DOE 2004, BLS 2003).

Cultural Resources

A total of eight archaeological sites have been located within TA-3. Sites include lithic scatters, trails and stairs, and a wagon road. Two archaeological sites are eligible for listing on the National Register of Historic Places, four are of unknown eligibility, and two are not eligible. There are no National Register of Historic Places-eligible archaeological resources located in the vicinity of the proposed Replacement Office Building Complex; however, one site of undetermined status, a historical trail, is located to the south of the parking lot. Although three National Register of Historic Places-eligible buildings are located in TA-3, none are situated near the proposed new complex. One traditional cultural property is present within TA-3.

Construction Impacts—There are no cultural resource sites eligible for the National Register of Historic Places within the vicinity of the Replacement Office Buildings. However, the historic trail located to the south of the parking lot must be managed as a National Register of Historic Places-eligible site until formally determined otherwise. Due to its proximity to the proposed project, there could be potential adverse effects of construction. As noted above, one traditional cultural property is located within TA-3. However, it would not be affected by construction or operation of the Replacement Office Building Complex.

Operations Impacts—Operation of the Replacement Office Buildings and associated parking lots would not impact any cultural resources.

Socioeconomics and Infrastructure

Construction Impacts—Utility infrastructure resources would be required for Replacement Office Buildings construction. Standard construction practice dictates that electric power needed to operate portable construction and supporting equipment be supplied by portable diesel-fired generators. Therefore, no electrical energy consumption would be directly associated with construction. A variety of heavy equipment, motor vehicles, and trucks would be used, requiring diesel fuel, gasoline, and propane for operation. Liquid fuels would be brought to the site as needed from offsite sources and, therefore, would not be limited resources. Water would be needed primarily to provide dust control, aid soil compaction at the construction site, and possibly for equipment washdown. Water would not be required for concrete mixing, as ready-mix concrete is typically procured from offsite resources. Portable sanitary facilities would be provided to meet the workday sanitary needs of project personnel on the site. Water needed for construction would typically be trucked to the point of use, rather than provided by a temporary service connection.

For Replacement Office Buildings construction, total liquid fuel consumption is estimated to be 1.8 million gallons (6.8 million liters). Total water consumption is estimated to be 9.6 million gallons (36 million liters). The existing LANL infrastructure would be capable of supporting the requirements for new facility construction without exceeding site capacities, resulting in negligible impact on site utility infrastructure.

Operations Impacts—In general, utility infrastructure requirements for operation of the new office structures would be limited to building connections, and no upgrades to existing utilities would be required. Usage in the proposed structures would be equivalent to or less than that of the replaced structures because contemporary building design includes water and energy conservation features. As such, Replacement Office Buildings operation is expected to have no or negligible incremental impact on utility infrastructure capacities at LANL.

DD&D Impacts—Activities associated with DD&D of facilities to be replaced by the Replacement Office Buildings are projected to require 356,000 gallons (1.35 million liters) of liquid fuels and 11.3 million gallons (43 million liters) of water. DD&D activities would be staggered over an extended period of time. As a result, impacts of these activities on LANL's utility infrastructure are expected to be very minor on an annualized basis. Standard practice dictates that utility systems serving individual facilities be shut down as they are no longer needed. As DD&D activities progress, interior spaces, including associated equipment, piping, and wiring, would be removed prior to final demolition. Thus, existing utility infrastructure would be used to the extent possible and would then be supplemented or replaced by portable equipment and facilities as DD&D activities proceed.

Waste Management

Construction Impacts—Replacement Office Building Complex construction would generate approximately 1,700 cubic yards (1,300 cubic meters) of construction waste, primarily construction debris and associated solid waste. Construction debris is not hazardous and may be disposed of in a solid waste landfill. A substantial portion of construction debris at LANL is routinely recycled; in 2003, approximately 89 percent of the uncontaminated construction and demolition waste was recycled, and those rates are expected to continue (LANL 2004d).

Operations Impacts—Operations at the new Replacement Office Building Complex would generate sanitary wastes. However, because the offices are a replacement for existing office space, no increase in waste is expected.

DD&D Impacts—Demolition activities would generate approximately 6,900 cubic yards (5,300 cubic meters) of demolition debris and sanitary waste. The demolition debris would be transferred to appropriate offsite recycling or disposal facilities. As with construction debris, as much as 89 percent of the demolition debris could potentially be recycled. Although no radiological waste is anticipated as a result of the demolition activities of the Wellness Center and warehouse, 31 cubic yards (24 cubic meters) of low-level radioactive waste was estimated in case contaminated materials were encountered during the demolition activities. This waste would be disposed of at TA-54. Because the estimated volume is small, no impacts on disposal capacity are expected.

Transportation

Construction Impacts—Construction personnel would park onsite and at remote designated parking areas. Truck traffic volume carrying construction materials to LANL and waste to local and regional landfill sites would increase. This increase in traffic would not have any significant impact on the adjacent road systems, including West Jemez Road. As stated earlier, a substantial portion of construction debris at LANL is routinely recycled.

DD&D Impacts—Demolition activities would generate a small amount of low-level radioactive wastes that would be disposed of onsite or shipped offsite. The demolition debris would be transported to offsite recycling or disposal facilities. As with construction debris, a majority of demotion debris could potentially be recycled.

G.3 Radiological Sciences Institute, Including Phase I – The Institute for Nuclear Nonproliferation Science and Technology Impact Assessment

This section provides an assessment of environmental impacts for the proposed Radiological Sciences Institute at LANL's TA-48. Section G.3.1 provides background information on the proposed project to replace deteriorated structures scattered over six TAs with the Radiological Sciences Institute. Section G.3.2 provides a description of the proposed options for the Radiological Sciences Institute. Section G.3.3 presents environmental consequences of the No Action Option and the proposed project (construction and operation of the proposed Radiological Sciences Institute at TA-48 and DD&D of the replaced facilities).

G.3.1 Introduction

The proposed project site is located in TA- 48, approximately 1 mile (1.6 kilometers) southeast of TA-3 along Pajarito Road and also includes a small portion of the western edge of TA-55. The Radiological Sciences Institute would provide state-of-the-art facilities for wet chemistry, metallurgy, safeguards (domestic and international), material protection control and accountability, machining and manufacturing, training schools, and underground storage of special nuclear material (LANL 2006a). This project would also involve DD&D of 52 deteriorating structures (80 percent of LANL's radiological facilities) (LANL 2006a). The project would consolidate radiological laboratories and working spaces to a significantly smaller footprint of modern, flexible facilities in up to 13 buildings located at TA-48.

The missions proposed for relocation to the Radiological Sciences Institute include (but are not limited to) support for weapons manufacturing, material property evaluations for stockpile stewardship, support for domestic and international safeguards, training for International Atomic Energy Agency inspectors, training and support for national emergency response to threats involving radioactive sources, biological research, detection and sensor technologies, various chemistry and chemical engineering missions, radioisotope production and distribution, and basic energy science. New and developing projects that require radiological facilities include missions such as homeland security, advanced fuel cycle initiatives, separation processes for commercial-reactor spent fuel, production capability for nuclear fuels for space missions, powder metallurgy for space and medical applications, nonproliferation, threat reduction, nuclear material control and accountability, alternative energy systems, advanced fusion, and nuclear-weapons-related research.

Much of the radiological infrastructure at LANL is 40 to 60 years old, and the ability to continue critical national missions is threatened. Current facilities are rapidly approaching obsolescence, with operation and maintenance costs associated with increased safety, security, regulatory, and operating requirements becoming prohibitive. Radiological competence and mission commitments need to be met at LANL (LANL 2006a). The existing radiological facilities were built in accordance with building codes and safety and security requirements that are now outdated (LANL 2006a). NNSA needs to replace aging structures with modern buildings designed to meet usage needs.

Table G–4 shows the types of buildings currently in use by different programs that would be replaced by the Radiological Sciences Institute Project, including their building numbers, approximate age, facility condition, and existing floor space. **Table G–5** lists the names and functions of the 30 permanent structures that would be replaced by the Radiological Sciences Institute.

Table G–4 Summary of Los Alamos National Laboratory Radiological Buildings Proposed for Decontamination, Decommissioning, and Demolition Radiological Sciences Institute Project

Program	*Structure*	*Building Numbers* [a]	*Area (gross square feet)*	*Predominant Condition*	*Predominant Building Age (years)*
Chemistry	10 permanent buildings	46-24, 46-31, 46-158, 46-200, 46-250, 48-1, 48-8, 48-17, 48-26, 59-1	167,409	Poor to failing	40-59
	8 transportable	48-27, 48-29, 48-33, 48-34, 48-46, 48-47, 48-208, 48-214			
	2 trailers	48-149, 48-154			
Materials Science and Technology	5 permanent buildings	3-29, 3-35, 3-169, 3-66, 3-451	258,922	Poor to failing	40-59
	2 trailers	3-1524, 3-1525			
Nuclear Nonproliferation	13 permanent buildings	18-1, 18-28, 18-30, 18-129, 18-141, 18-147, 18-227, 18-297, 3-66, 35-2, 35-27, 35-115, 35-347	180,099	Poor to failing	40-59
	1 transportable	35-253			
	8 trailers	18-288, 18-300, 18-301, 35-239, 35-261, 35-262, 35-263, 35-382

Radiological Machining and Inspection	1 permanent building	3-102	29,365	Adequate	40-59
Totals	52 structures		635,795		

[a] 100 percent of most building functions would be moved to the Radiological Sciences Institute. Buildings whose functions would be only partially replaced by the Radiological Sciences Institute and the corresponding percentages are: 3-29, 7 percent (the hot cells); 35-2, 33 percent; 46-24, 50 percent; 46-31, 25 percent; 46-158, 15 percent; 46-200, 50 percent; 59-1, 25 percent.

Notes: Facilities associated with the Institute for Nuclear Nonproliferation Science and Technology Phase I DD&D include the International Atomic Energy Agency schoolhouse portion of 3-66; Buildings 35-2 (33 percent), 35-27, 35-115, 35-247; and all TA-18 buildings. DD&D of these facilities is not part of the Institute for Nuclear Nonproliferation Science and Technology and would be handled separately.

To convert square feet to square meters, multiply by 0.092903.

Table G–5 Name, Function, and Number of Employees of Permanent Buildings Proposed for Decontamination, Decommissioning, and Demolition by the Radiological Sciences Institute Project

Technical Area Building [a]	*Name*	*Current Use*	*Employees* [b]
46-24 (50%)	Laboratory and Office Building	Optics laboratories	24
46-31 (25%)	Test Building No. 2	Optics laboratories	3
46-158 (15%)	Laser-Induced Chemistry Laboratory	Optics laboratories	1
46-200 (50%)	Chemistry and Laser Laboratory	Chemistry laboratory	2
46-250	Analytical Chemistry	Chemistry laboratory	7
48-1	Radiochemistry Building	Chemical laboratory (nuclear)	149
48-8	Isotope Separator Building	Machine shops	2
48-17	Assembly Checkout Building	Assembly facilities	3
48-26	Office Building	Office	2
59-1 (25%)	Occupational Health Laboratory	Radiation effects laboratory	46
3-29 (7%)	Chemistry and Metallurgy Research Laboratory (Hot Cells)	Nuclear laboratory	24
3-169 [c]	Warehouse (Sigma)	General storage	125
3-66 [c]	Sigma Building	Laboratories (nuclear)	125
3-451	Micro Machining Facility	Physics laboratory	8
3-1524	Laboratory and Office Building	Laboratories (nuclear)	2
35-2 [c]	Laboratory and Office Building (Nuclear Safeguards Research)	Laboratories (nuclear)	93
35-27 [c]	Nuclear Safeguard Laboratory	Laboratories (nuclear)	72
35-115	Solvent Storage Shed	Hazardous and flammable storage	0
35-347	Garage	General storage	0
18-1 [d]	Staging Area	Fabrication facility	1
18-28	Warehouse	Programmatic general storage	1
18-30	Main Building	Office	222
18-129	Reactor Sub-Assay Building	Nuclear physics laboratory	10
18-141	Ultra-Sonic Cleaning Building	Nuclear physics laboratory	0
18-147	Office Building	Office	6
18-227	Accelerator Device Laboratory	Accelerator building	0
18-256	Butler Building	Applied physics laboratory	0
18-297	Storage Building	General storage	0
3-102 [c]	Technical Shops Addition (Radiological Machine Shop)	Nuclear contaminated storage	0
Total			1,074 [e]

[a] Unless noted by a percentage shown in parentheses, 100 percent of the floor space and building function would be moved to the Radiological Sciences Institute.
[b] One hundred percent of employees currently located at each building are listed, except for those buildings where only a portion of the function is to be transferred to the Radiological Sciences Institute. In those instances, the number of employees that would move to the Radiological Sciences Institute was assumed to be proportional to the percentage of floor space in the building that the Radiological Sciences Institute would replace.
[c] Identified as a radiological facility in the *SWEIS Yearbook – 2003* (LANL 2004d).
[d] All TA-18 functions from the Pajarito Site, except the Solution High-Energy Burst Assembly (SHEBA), would be moved to the Radiological Sciences Institute.
[e] Total includes permanent buildings listed in this table and 146 employees located in transportables and trailers not included in the table.
Source: LANL 2006a.

G.3.2 Options Considered

The two options identified for the Radiological Sciences Institute are the No Action Option and the proposed project option.

G.3.2.1 No Action Option

Under the No Action Option, the current use of existing radiological facilities throughout LANL would continue. At least two facilities are currently planned for DD&D under other actions: the TA-18 and Chemistry and Metallurgy Research Buildings. The facilities have exceeded their design life and are rapidly becoming obsolete and seriously deteriorating; corrective maintenance actions would continue as failures occur. Maintenance cost would continue to escalate to support the aging facilities until they must be shut down. Upgrade costs to meet currently applicable building codes and safety and security requirements are prohibitive and would provide only a limited lifespan to existing facilities. LANL would systematically lose radiological competence, and mission commitments would not be met. Failures of the existing facilities and equipment would delay programmatic work, possibly damage equipment, and possibly pose a risk to personnel safety, campaigns, critical experiments, and related activities. Because nearly 70 percent of all LANL radiological facilities are 40 to 60 years old, they would experience more and more severe failures over time, until corrective maintenance is no longer possible and the facilities would have to be shut down if unreliability adversely impacts safety or the environment.

G.3.2.2 Proposed Project

Under the proposed project, the Radiological Sciences Institute would be constructed and 52 obsolete structures scattered over six TAs would undergo DD&D. This analysis assumes the Radiological Sciences Institute would consist of up to 13 facilities. Phase I of the Radiological Sciences Institute Project would include 5 buildings associated with the Institute for Nuclear Nonproliferation Science and Technology, for which construction would begin in 2009, with an estimated occupancy in fiscal year 2012. New construction for the Institute for Nuclear Nonproliferation Science and Technology would include a Security Category I and II laboratory with a Security Category I vault, several Security Category III and IV laboratories, a field test laboratory, a secure radiochemistry facility, and associated office support facilities, further described below.

- *Security Category I and II Facility* – a small Nuclear Hazard Category 2 laboratory located within a security Isolation Zone and within the Perimeter Intrusion Detection and Assessment System (PIDAS) adjacent to TA-55 but physically isolated from the programmatic activities and personnel inside TA-55. The facility would provide the ability to utilize and store Security Category I and II quantities of materials (including rollup of various numbers of Security Category III and IV quantities).

- *Security Category III and IV Laboratories* – an independent radiological facility incorporating both open and secured laboratories, used for research and development, testing, and evaluation of technology directly applied to nuclear nonproliferation programs.

- *Secure Radiochemistry Facility* – a secure, low-background-dissolving and radiochemistry capability for the receipt and processing of classified samples to meet the requirements of current and future national security programs. The building would be a vault-type room.

- *Field Test Laboratory* – an outdoor vehicle portal and long-standoff nuclear material monitoring and detection field laboratory to be used to develop and demonstrate advanced nuclear detection technology suitable for deployment in border-protection situations and in other environments requiring long-distance monitoring.

- *Office Support Facility* – an office complex sized to accommodate the staff in the Institute for Nuclear Nonproliferation Science and Technology, to include both open and secured office space, and mechanical, electrical, and software design, fabrication, and assembly facilities for building prototype instruments and supporting research and development needs.

The Radiological Sciences Institute would consolidate radiological activities in an optimally designed, efficient, safe, and secure set of buildings. Facilities would be included for wet chemistry, metallurgy, safeguards (domestic and international), material protection control and accountability, machining and manufacturing, and nonproliferation training schools. The complex would also include a Security Category I underground vault for storage of special nuclear material, eliminating (through underground tunnels) routine material transport on public roads. Also, the complex would be designed to accommodate multiple concurrent radiological activities and Security Categories (III and IV) and temporary Security Category II International Atomic Energy Agency training schools. A Nuclear Hazard Category 3 operations building for specific co-located actinide chemistry operations and safeguards would also be included. In addition to the programs and functions listed above, others that would be moved to the Radiological Sciences Institute and have measurable quantities of emissions or waste include those of the Sigma Complex (Buildings TA-3-66, -35, and -169), the Pajarito Site (TA-18 buildings, except the Solution High-Energy Burst Assembly (SHEBA Project), the Radiological Machine Shop at TA-3 (TA-3-102), the Chemistry and Metallurgy Research hot cells (located at TA-3-29), and the Radiochemistry Facility currently located in TA-48.

This project would also involve DD&D of 52 obsolete structures (80 percent of LANL's radiological facilities), accounting for approximately 636,000 gross square feet (59,100 square meters) of building space located in six TAs (TA-3, TA-18, TA-35, TA-46, TA-48, and TA-59) (LANL 2006a). There are about 1,074 employees located in buildings that would be replaced by the Radiological Sciences Institute (see Table G–5). Of that total, 293 are in existing buildings at TA-48 slated for replacement (193 in permanent structures and 100 in transportables or trailers). Phase I of the Radiological Sciences Institute (the Institute for Nuclear Nonproliferation Science and Technology) would occupy approximately 145,000 net square feet (13,500 square meters), a reduction of about 50,000 net square feet (4,600 square meters) relative to the facilities to be replaced, and would house approximately 450 to 500 technical and support staff (LANL 2006a).

G.3.3 Affected Environment and Environmental Consequences

For Radiological Sciences Institute construction and operation, the affected environment is primarily TA-48, although the region of influence for each resource evaluated may extend beyond TA-48 and LANL. For DD&D of buildings replaced by the Radiological Sciences Institute, the affected environment is primarily TA-3, TA-35, TA-46, TA-48, and TA-59. DD&D of buildings in TA-18 is not part of the impacts evaluation for the Radiological Sciences Institute, but rather is included as part of the TA-18 Closure, Including Remaining Operations Relocation, and Structure DD&D Impacts Assessment (see Appendix H). Also, the DD&D impacts for the Chemistry and Metallurgy Research Building hot cells (Wing 9 of Building 3-29) are not part of the Radiological Sciences Institute evaluation, but are included as part of the proposed project analyzed in the *Environmental Impact Statement for the Chemistry and Metallurgy Research Building Replacement Project at Los Alamos National Laboratory* (DOE 2003). The impacts of TA-18 operations and the hot cells that would be moved to the Radiological Sciences Institute are included in the affected environment baseline for comparison with the impacts of the new Radiological Sciences Institute.

The analysis of environmental consequences relies on the affected environment descriptions in Chapter 4 of this SWEIS. Where information specific to TA-48 (or the TAs impacted by DD&D activities) is available and aids understanding the Radiological Sciences Institute affected environment, it is included here. An initial assessment of the potential impacts of the proposed project identified resource areas for which there would be no or only negligible environmental impacts. Consequently, for the following resource areas, a determination was made that no further analysis was necessary:

- *Socioeconomics and Infrastructure* – No new employment is expected. Construction and DD&D workers would be drawn from the pool of construction workers employed on various projects at LANL. Only infrastructure impacts are included in the impacts discussion.

- *Environmental Justice* – The proposed project is mainly confined to already-developed areas, with no disproportionate human health impacts to low-income or minority populations expected.

This impact assessment focuses on those areas of the affected environment where potential impacts would occur: land resources, geology and soils, water resources, air quality and noise, ecological resources, human health, cultural resources, site infrastructure, waste management, transportation, and facility accidents.

G.3.3.1 No Action Option

Under the No Action Option, LANL radiochemistry capabilities would not be modernized and would not take on capabilities that could potentially be lost from LANL due to changes in other facilities (the Chemistry and Metallurgy Research and Pajarito Site). No disturbance of existing land or building sites would occur. There would be no construction or building removal debris to require disposal. Utility use would remain essentially the same as the present use. Continued expenses for repairs and replacement of aging heating, ventilation, and air conditioning systems and other building components would increase. As building systems and other components fail and cannot be replaced or repaired, affected buildings would be partially or completely closed and the staff relocated. Personnel would remain scattered throughout LANL, and collaboration between scientists and administrative personnel would be hindered. Under the No Action Option, the inefficiencies of using outmoded and deteriorating buildings would continue.

No changes in emissions or air pollutant concentrations are expected under the No Action Option. Under this option, radiological air emissions would continue to be generated from operations at the Sigma Complex (TA-3-66), Machine Shops (TA-3-102), Radiochemistry (TA-48), and hot cells (Wing 9) at the Chemistry and Metallurgy Research Building. No increases in emissions or additional radionuclides are expected under the No Action Option.

Human Health

The consequences of continued operations at facilities that release radiological air emissions, and would be consolidated in the proposed Radiological Sciences Institute (Sigma Complex [TA-3-66], Machine Shops [TA-3-102], and Radiochemistry [TA-48]), on public and worker health under the No Action Option are presented below. A discussion of the terminology used in the human health evaluation and basic radiological health effects and the methodologies used to evaluate consequences can be found in Appendix C of this SWEIS.

Public Health—The collective dose to the public from all airborne radioactive emissions from these three facilities was estimated to a 50-mile (80-kilometer) radius from each facility. The total population dose from all three facilities, shown in **Table G–6**, is estimated to be 0.18 person-rem per year, which is a small part of the total population dose (30 person-rem) from all Key Facilities at LANL. This population dose would result in no additional fatalities in the 50-mile (80 kilometer) radius population of close to 300,000.

Table G–6 Annual Radiological Impacts on the Public from Operations under the Radiological Sciences Institute Project No Action Option

	Population Dose within 50 Miles (80 kilometers)	*Facility-Specific MEI Dose*	*MEI Location (feet)*
Sigma (TA-3-66)	0.16 person-rem	0.026 millirem	N 3,560 LANL boundary
Machine Shops (TA-3-102)	0.013 person-rem	0.0023 millirem	N 3,380 LANL boundary
Radiochemistry (TA-48)	0.0065 person-rem	0.0019 millirem	NNE 2,920 Royal Crest Trailer Park
Total dose	0.18 person-rem	Not applicable	
Cancer fatality risk	0.00011	1.6×10^{-8} (Sigma)	
Regulatory dose limit [a]	Not applicable	10 millirem	
Background radiation dose [b]	120,000 person-rem	400 millirem	

MEI = maximally exposed individual, TA = technical area.

[a] Title 40 of the *Code of Federal Regulations*, Part 61, establishes an annual limit of 10 millirem via the air pathway to any member of the public from DOE operations. There is no standard for a population dose.

[b] The annual individual dose from background radiation at LANL ranges from a low of about 300 millirem to a high of about 500 millirem (see this SWEIS, Appendix C). The population living within 50 miles (80 kilometers) of TA-48 was estimated to be 299,508 in 2000.

Note: To convert feet to meters, multiply by 0.3048.

Sources: Chapter 5 and Appendix C of this SWEIS.

A maximally exposed individual (MEI) is a hypothetical member of the public residing at the LANL site boundary who would receive the maximum dose from facility emissions. Each facility has a different location for its MEI, based on many factors, including the climate, distance, type and amount of radiological air emissions, and physical form of the radionuclides. The location and estimated dose for each of the three facilities that have radiological air emissions are listed in Table G–6; these doses do not include exposures from other sources at LANL. The highest of the three MEI doses is from emissions at the Sigma Complex. This MEI would receive an estimated annual dose of 0.026 millirem from operations as compared to the LANL site-wide MEI, who would receive 7.8 millirem per year from emissions from all LANL facilities. To put these doses into perspective, comparisons with doses from natural background radiation and the regulatory limit of 10 millirem established in Title 40 *Code of Federal Regulations* [CFR] Part 61 are included in the table.

In general, collective total effective dose equivalent by Key Facility or TA is difficult to determine because these data are assigned to the individual worker, not to a specific TA or building. In addition, members of many groups and organizations receive doses at several locations. Under the No Action Option, the average worker doses expected at the Sigma Complex, Machine Shops, and Radiochemistry would be similar to those in the 6-year period from 1999 through 2004.

Hazardous Chemical Impacts—No chemical-related health impacts would be associated with this option. As stated in Chapter 5, Section 5.6, of this SWEIS, the quantities of chemicals that could be released to the atmosphere during routine normal operations are minor and would be below screening levels used to determine the need for additional analysis. Under normal operating conditions, workers would be protected from hazardous chemicals by adherence to Occupational Safety and Health Administration and EPA occupational standards that limit concentrations of potentially hazardous chemicals in the workplace.

Waste Management

The impacts of managing waste from continued operations at the Radiochemistry Facility, Sigma Complex, Pajarito Site (TA-18), and Machine Shops (Building 03-102 only) would be the same as those currently experienced at these facilities because the same types and quantities of waste would be generated and subsequently managed.

Some gains in waste management efficiencies are expected over the next few years, and these gains would be realized under both the No Action Option and the proposed project (that is, whether or not the Radiological Sciences Institute is constructed and operated). Significant reductions in the volume of radioactive liquid discharges are expected over the next few years as improvements are made to the beryllium laundry operations, electroplate bath condensate system, and perchloric acid exhaust duct washdown process. Based on historical data and planned improvements, the projected discharge volume of radioactive liquids is 845,000 gallons (3.2 million liters) per year (LANL 2006a).

Chemical waste generation rates are expected to be 31,000 pounds (14,000 kilograms) per year. Low-level radioactive waste generation rates are estimated to be 157 cubic yards (120 cubic meters) per year. Mixed low-level radioactive waste and transuranic waste generation rates are expected to be very low, approximately 1.3 cubic yards (1 cubic meter) per year for each category. No mixed transuranic waste is expected to be generated (LANL 2006a).

Facility Accidents

Potential accidents under the No Action Option estimated to have the highest impacts would involve radiological operations and materials associated with Chemistry and Metallurgy Research Wing 9 hot cell operations. Five accident scenarios were selected to represent the bounding impacts of accidents. Information used to estimate the impacts of these accidents is shown in **Table G–7**. The material at risk in a hot cell is estimated to be 10.6 ounces (300 grams) of plutonium-238 equivalent and an additional 28.7 pounds (13 kilograms) of plutonium-238 equivalent in iridium cans inside two layers of textured graphite (general purpose heat source modules).

Table G–7 Bounding Radiological Accident Scenarios under the Radiological Sciences Institute Project No Action Option

Accident	*Source Term* [a] *(curies)*	*Release Energy (watts)*	*Annual Frequency*
Hot cell fire involving plutonium-238 in general purpose heat source modules	5.13 plutonium-238	2.04×10^{6}	1.0×10^{-4}
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules	22.572 plutonium-238 1.386 plutonium-239	2.04×10^{6}	2.4×10^{-4}
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules	5.13 plutonium-238 0.315 plutonium-239	0	2.4×10^{-3}
Spill of plutonium-238 residue from 0.5-gallon (2-liter) bottles outside of hot cell	0.001283 plutonium-238	0	0.1
Hot cell plutonium-238 spill with no confinement	0.4104 plutonium-238	0	0.01

a. A release height of 4.9 feet (1.5 meters) is assumed for all accidents. Specific activity is 0.063 curies per gram for plutonium-239 and 17.1 curies per gram for plutonium-238.

Assuming that an accident occurred, estimated consequences for a noninvolved worker located 330 feet (100 meters) from the accident, the onsite worker population, the MEI located at West Jemez Road, and the offsite population are shown in **Tables G–8** through **G–10**. Estimated risks that take accident frequency into account to these same receptors are shown in Table G–10.

The hypothetical accidents with the highest radiological impacts would be the seismic-induced building collapse with no fire and the seismic-induced building collapse with a fire involving plutonium-238 in general purpose heat source modules. If either of these accidents were to occur, the consequences are estimated to be 2.9 or 8.6 increased LCFs for the offsite population, 0.047 or 0.052 increased risk of an LCF for the MEI, and 0.21 or 0.18 increased risk of an LCF for a noninvolved worker located at a distance of 330 feet (100 meters) from the accident, respectively. After taking into account the frequency (or probability) of each accident, the seismic-induced building collapse with no fire is estimated to have the highest risks. For this accident, the annual risks are estimated to be 0.0069 LCFs for the offsite population, 0.00011 increased risk of LCFs for the MEI, and 0.00049 increased risk of an LCF for a noninvolved worker located at a distance of 330 feet (100 meters) from the accident.

Table G–8 Radiological Accident Offsite Population Consequences under the Radiological Sciences Institute Project No Action Option

Accident	MEI		Population to 50 Miles (80 kilometers)	
	Dose (rem)	LCF [a]	Dose (person-rem)	LCF [b, c]
Hot cell fire involving plutonium-238 in general purpose heat source modules	9.18	0.0055	3,060	1.84
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules	43	0.052	14,400	8.64
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules	39	0.047	4,770	2.86
Spill of plutonium-238 residue from (0.5-gallon (2-liter) bottles outside of hot cell	0.012	7.4×10^{-6}	1.12	0.00067
Hot cell plutonium-238 spill with no confinement	3.96	0.0024	359	0.22

MEI = maximally exposed individual, LCF = latent cancer fatality.
[a] Increased risk of an LCF to an individual, assuming the accident occurs.
[b] Increased number of LCFs for the offsite population, assuming the accident occurs.
[c] Offsite population size is approximately 300,000 persons.

Table G–9 Radiological Incident Onsite Worker Consequences under the Radiological Sciences Institute Project No Action Option

Accident	Noninvolved Worker at 330 Feet (100 meters)	
	Dose (rem)	LCF [a]
Hot cell fire involving plutonium-238 in general purpose heat source modules	32.5	0.039
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules	152	0.18
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules	171	0.21
Spill of plutonium-238 residue from 0.5-gallon (2-liter) bottles outside of hot cell	0.045	2.7×10^{-5}
Hot cell plutonium-238 spill with no confinement	14.3	0.0086

LCF = latent cancer fatality.
[a] Increased risk of an LCF to an individual, assuming the accident occurs.

The impacts of the other postulated accidents are shown in Tables G–8 through G–10. Comparing the seismic accident that includes a fire with one that does not include a fire, the former has higher offsite population and MEI impacts, while the latter has higher individual worker and worker population impacts. This is because the buoyant effects of a fire loft the radioactive plume over the onsite workers, while the greater releases associated with this scenario would impact the general population farther downwind. In contrast, the absence of a fire and its buoyant effects has a greater impact on close-in individuals like the noninvolved worker at 330 feet (100 meters) and the large worker population at the Chemistry and Metallurgy Research Building.

Table G–10 Radiological Accident Offsite Population and Worker Risks under the Radiological Sciences Institute Project No Action Option

Accident	*Onsite Worker (LCFs)*	*Offsite Population (LCFs)*	
	Noninvolved Worker (at 330 feet [100 meters]) [a]	***MEI*** [a]	***Population to 50 Miles (80 kilometers)*** [a, b]
Hot cell fire involving plutonium-238 in general purpose heat source modules	3.9×10^{-6}	5.5×10^{-7}	0.00018
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules [c]	4.4×10^{-5}	1.2×10^{-5}	0.0021
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules [c]	0.00049	1.1×10^{-4}	0.0069
Spill of plutonium-238 residue from 0.5-gallon (2-liter) bottles outside of hot cell	2.7×10^{-6}	7.4×10^{-7}	6.7×10^{-5}
Hot cell plutonium-238 spill with no confinement	8.6×10^{-5}	2.4×10^{-5}	0.0022

LCF = latent cancer fatality, MEI = maximally exposed individual.

[a] Increased risk of an LCF to an individual per year.

[b] Offsite population size is approximately 300,000 persons.

[c] An updated probabilistic seismic hazard analysis has been completed for LANL (LANL 2007), which results in higher peak horizontal ground acceleration values for the same annual probability of exceedance. In the seismic accident analyses for the Chemistry and Metallurgy Research Building, the radioactive source term was conservatively based on the assumption that all structures, systems, and components failed, therefore, the updated probabilistic seismic hazard analysis is not expected to change the accident consequences or risks.

G.3.3.2 Proposed Project

Land Resources—Land Use

Construction Impacts—Construction of the Radiological Sciences Institute, including parking lots and construction laydown areas, would require 33.6 acres (13.6 hectares) of land. Of the land area required for the Radiological Sciences Institute, approximately 12.6 acres (5.1 hectares) are undeveloped (LANL 2006a).

Operations Impacts—Upon project completion, 32 acres (13 hectares) would be occupied by permanent facilities. While the land use designation of much of the site would remain Reserve, some Reserve areas and the currently designated Experimental Science area would be redesignated in the future as Nuclear Materials Research and Development (LANL 2003b).

The Radiological Sciences Institute would be constructed in TA-48 and a small portion of TA-55 located within the Pajarito Corridor West Development Area. Construction of the Radiological Sciences Institute within TA-48 would take place in areas designated within that plan as available for Primary Development and Proposed Parking, as well as within the currently developed portion of the site which is identified as Potential Infill. Although the Radiological Sciences Institute would result in the use of previously undeveloped land and involve a change in land use designation in TA-48, its construction would be compatible with future land use plans. The small portion of the western edge of TA-55 that would be affected by the Radiological Sciences Institute is classified as Nuclear Materials and Research. Under this option, land use within this area would not change from its current land use designation of Nuclear Materials Research and Development.

DD&D Impacts—DD&D of buildings proposed for replacement is not expected to result in a change in land use at the respective TAs. These structures are within built-up areas that would continue to be used for other purposes. Once removed, the land upon which these buildings stood would be available for future development.

Land Resources—Visual Resources

The buildings that would be replaced by the Radiological Sciences Institute are all in currently developed areas consisting of industrial and office buildings, transportables, and trailers. The buildings are primarily located in TAs along Pajarito Road, except buildings in TA-3. As with TA-48, the views are industrial in nature and are viewed primarily by site personnel.

Construction Impacts—Construction of the Radiological Sciences Institute would result in a change in both near and distant views of TA-48 and the western edge of TA-55. Short-term impacts would include the construction activity itself as well as increased dust generation. Although landscaping is planned along Pajarito Road following construction, new buildings and parking lots would be more visible from the road than current facilities due to their increased number and size. Additionally, a number of buildings, as well as parking lots, would be located closer to the road than are the current Advanced Radiochemistry Diagnostics Building and associated facilities. These changes in the visual environment would mainly impact LANL employees. Additionally, new development of TA-48 would be visible at the entrance to the controlled access along Pajarito Road and to viewers in the southeast quadrant of TA-3.

Distant views from the higher elevations to the west of TA-48 (as well as the western edge of TA-55) would also change as a result of construction of the Radiological Sciences Institute, as the size of the developed area would increase as well as the number of buildings and parking lots. However, the overall effect on the view would be minimal due to the present nature of development on the mesa.

DD&D Impacts—Although removal of buildings that the Radiological Sciences Institute would replace would positively affect visual resources, the level of improvement would be small. Near views of LANL facilities along the mesa are seen mostly by LANL employees. From higher elevations to the west, the Pajarito Mesa presents the appearance of a mosaic of industrial buildings within a ponderosa pine forest. Removal of a limited number of buildings would not appreciably change the view.

Geology and Soils

The 9-mile-long (14-kilometer-long) Rendija Canyon Fault is located approximately 0.5 miles (0.8 kilometers) east of the Radiochemistry Laboratory at TA-48. Geologic mapping shows that there is no faulting in the near surface directly beneath TA-48. The closest fault is located about 300 feet (90 meters) southwest of the Radiochemistry Laboratory (LANL 2004c). This small fault trace exhibits only about 2 feet (0.6 meters) of offset. Most of these small faults have been inferred to represent ruptures subsidiary to the major faults, and, as such, their potential rupture hazard is very small (Gardner et al. 1999). Additionally, all buildings in the Radiological Sciences Institute would be designed in accordance with current DOE seismic standards and applicable building codes.

The proposed area for the facility includes undisturbed soils that maintain the present vegetative cover. They are arid soils consisting largely of sandy loam material alluvially deposited from tuff units on higher slopes to the west and eroded from underlying geologic units. In general, the soils are poorly developed with relatively little horizon differentiation and organic matter accumulation. These factors, combined with the dry moisture regime of the area, result in only a limited number of plant species being able to subsist on the soil medium, which, in turn, supports a very limited number of wildlife species.

Construction Impacts—Approximately 802,000 cubic yards (613,000 cubic meters) of soil would be disturbed during building excavation. These estimates are based on building footprints and do not include the impact of short-term construction support activities such as the use of equipment laydown yards. The impact of such support areas would be minimized by locating these facilities in developed areas such as parking lots.

Adherence to standard best management practices for soil erosion and sediment control, including watering, during construction would serve to minimize soil erosion. After construction, disturbed areas would lie within the footprint of the new buildings and roadway, with temporarily disturbed areas stabilized and revegetated, so they would not be subject to long-term soil erosion.

For construction of the Security Category I underground vault for special nuclear material storage and the associated tunnel, excavation depths of up to 45 feet (14 meters) into the mesa may be necessary. Excavation of welded tuff could necessitate blasting to speed construction. A site survey and foundation study would be conducted as necessary to confirm site geologic characteristics for facility engineering purposes. In addition, prior to commencing ground disturbance, NNSA would survey potentially affected contaminated areas to determine the extent and nature of any contamination and required remediation in accordance with LANL procedures.

Aggregate (sand, gravel, crushed stone) and other geologic resources would be required to support Radiological Sciences Institute construction activities at TA-48, but such resources are readily available from onsite borrow areas and otherwise abundant in the vicinity of Los Alamos County.

Operations Impacts—Radiological Sciences Institute operations would not result in additional impacts on geologic and soil resources at LANL. Any new facilities and uses within TA-48 would be evaluated, designed, and constructed in accordance with DOE Order 420.1B and sited to minimize risk from geologic hazards, including earthquakes.

DD&D Impacts—DD&D activities associated with existing radiological facilities would have a negligible additional impact on geologic and soil resources at LANL, as the affected facility areas are already developed and adjacent soils are already disturbed. Additional ground disturbance would be necessary to establish laydown yards and waste management areas in the vicinity of the facilities to be razed. Available paved surfaces, such as parking lots in the vicinity of the facilities to be demolished, would be used to the extent possible.

The major indirect impact on geologic and soil resources at DD&D locations would be associated with the need to excavate any contaminated tuff and soil from beneath and around facility foundations. Borrow material (such as crushed tuff and soil) would be required to fill the excavations to grade, but such resources are readily available from onsite borrow areas and otherwise abundant in the vicinity of Los Alamos County. LANL staff would survey potentially affected contaminated areas to determine the extent and nature of any contamination and required remediation in accordance with LANL procedures and the Consent Order. All excavated material would be characterized before removing it for disposal.

Water Resources

All radioactive liquid effluents are directed to the Radioactive Liquid Waste Treatment Facility in TA-50 and sanitary liquid effluents to the Sanitary Wastewater Systems Plant in TA-46. Any potential contamination sources, such as aboveground storage tanks, are controlled through a Spill Prevention Control and Countermeasures Plan.

For TAs that would be impacted by DD&D activities, there are currently two National Pollutant Discharge Elimination System (NPDES) outfalls (which discharged 3.81 million gallons [14.4 million liters] in 2005) associated with the Sigma Complex at TA-3 (LANL 2006f). There is also one NPDES outfall (which discharged 0.92 million gallons [3.48 million liters] in 2005) associated with the Chemistry and Metallurgy Research Building at TA-3, but it is not associated with the Wing 9 hot cells.

Construction Impacts—Little or no effect on surface water resources is anticipated during construction of the Radiological Sciences Institute. The proposed project would not result in disturbance of watercourses or generation of liquid effluents that would be released to the surrounding environment. Silt fences, hay bales, or other appropriate best management practices would be employed and specified in a stormwater pollution prevention plan to ensure that fine particulates created during construction would not be transported by stormwater into surface water features in the vicinity of TA-48.

Operations Impacts—The proposed project should produce minimal effects on surface water resources during operations. There are three NPDES outfalls associated with facilities moving to the Radiological Sciences Institute. The Sigma Complex currently has two NPDES outfalls (03A-022 and 03A-024) (LANL 2006a), and the Chemistry and Metallurgy Research Building has one NPDES outfall (03A-021) (LANL 2006a), but it is not associated with the Chemistry and Metallurgy Research Building hot cell operations that would be moved into the Radiological Sciences Institute.

There would be more stormwater runoff from the new facility because of the increase in impervious areas of buildings and parking lots. This may be offset by the decreased stormwater runoff from the demolished facilities.

Aboveground storage tanks may be added to the Radiological Sciences Institute, but the number would not exceed the current number of aboveground storage tanks associated with the operations slated to be moved to the Radiological Sciences Institute. Radioactive and sanitary liquid effluents from the Radiological Sciences Institute would continue to be discharged to the Radioactive Liquid Waste Treatment Facility and Sanitary Wastewater Systems Plant, respectively.

The proposed project should produce minimal effects on groundwater resources during operations. Potable and industrial water use during operation of the Radiological Sciences Institute would not vary significantly from current volumes used for operations at the various radiological facilities that would be incorporated at the Radiological Sciences Institute. The cooling tower at Building 48-1 and the Sigma Building 3-66 would be incorporated into a new cooling tower system for the Radiological Sciences Institute. The cooling tower cycle increase program would reduce the amount of water used by this new system. Groundwater quality should not be affected by the operation of the Radiological Sciences Institute, as no new potential contamination sources would be added.

DD&D Impacts—Although several of the NPDES outfalls at the facilities to be demolished have already been blocked off and no longer discharge industrial effluent to the environment, the possibility of accidental discharges through these drains would be eliminated when the buildings at TA-3-66, TA-18, and TA-35 are demolished (LANL 2006a). Elimination of the 14 buildings at TA-18 that would be replaced by the Radiological Sciences Institute also would eliminate a potential source of contamination in the Pajarito Canyon 100-year floodplain. As noted above, increased impervious areas at the Radiological Sciences Institute that would create more stormwater runoff may be offset by the decreased stormwater runoff from demolished buildings and parking lots.

Air Quality and Noise

Nonradiological air pollutant emission sources at TA-48 include three natural-gas-fired boilers and emissions from various toxic chemicals. Emissions from boilers for 2003 are reported in **Table G–11**. **Table G–12** shows emissions of other pollutants from the Machine Shop at TA-3 and activities at TA-18 that could be transferred to TA-48.

Table G–11 Nonradiological Air Pollutant Emissions at Technical Area 48 – 2003 (tons per year)

Pollutant	*Boiler BS-1*	*Boiler BS-2*	*Boiler BS-6*
Criteria Pollutants			
Carbon monoxide	0.455	0.455	0.609
Nitrogen oxides	0.542	0.542	0.725
Particulate matter	0.041	0.041	0.055
PM_{10}	0.041	0.041	0.055
$PM_{2.5}$	0.041	0.041	0.055
Sulfur oxides	0.003	0.003	0.004
Volatile organic compounds	0.030	0.030	0.040

PM_{10} and $PM_{2.5}$ = particulate matter with aerodynamic diameters of 10 and 2.5 micrometers, respectively, or less.
Source: LANL 2006e.

Table G–12 Nonradiological Air Pollutant Emissions at Technical Area 3 Machine Shops and Technical Area 18 – 2005 (tons per year)

Pollutant	*Machine Shop (TA-3)*	*TA-18 Pajarito Site*
Ethanol	0.012	0.0035
Kerosene	0.0012	0
Zinc chloride fume	0	0.00013

TA = technical area.
Source: LANL 2006f.

Radiological air emissions for 1999 – 2005 are presented in Chapter 4, Section 4.4.3.1. Doses associated with radiological emissions at LANL are discussed in the section on human health. Emissions from three facilities that are projected to be consolidated in the proposed Radiological Sciences Institute are, or have been, monitored for radiological air emissions. Both the Machine Shops at TA-3 and Radiochemistry Complex at TA-48 have monitored point sources. Monitoring at the Sigma Complex (TA-3) was discontinued in 2000; it was determined that because of sufficiently low emissions, stack monitoring was no longer necessary for compliance. There are radiological air emissions from TA-18, but because the source of those emissions, SHEBA, would not be moved to the Radiological Sciences Institute, those data are not included here.

Estimated emission rates for toxic air pollutants emitted at TA-48 were compared to screening-level emission values for the *Site-Wide Environmental Impact Statement for the Continued Operation of Los Alamos National Laboratory, Los Alamos, New Mexico (1999 SWEIS)* (DOE 1999a). A screening-level emission value was developed for each chemical. A screening level emission value is a theoretical maximum emission rate that, if emitted at that TA over a short-term (8-hour) or long-term (1-year) period, would not exceed a health-based guideline value. This screening-level emission value was compared to the emission rate that would result if all the chemicals purchased for use in the facilities at a TA over the course of 1 year were available to become airborne. At TA-48, chemicals have been emitted at levels below the screening levels identified.

Construction Impacts—Construction of new facilities at TA-48 would result in temporary increases in air quality impacts of construction equipment, trucks, and employee vehicles. Criteria pollutant concentrations were modeled for the site work and erection construction phases of the TA-48 Radiological Sciences Institute's largest new facilities. Maximum ground-level concentrations off site and along the perimeter road to which the public has regular access would be below ambient air quality standards, and the air quality impacts on the public would be minimal. Estimated concentrations for PM_{10} would be greatest for the site work phase. Estimated maximum PM_{10} concentrations are an annual average of 2.3 micrograms per cubic meter and a 24-hour average of 31.9 micrograms per cubic meter. The maximum annual and short-term concentrations for construction would occur at the site boundary north of TA-48. Construction modeling considered particulate emissions from activity in the construction area and emissions from various earthmoving and material-handling equipment.

Although no radiological releases to the environment are expected in association with construction activities at TA-48, the potential exists for contaminated soils and possibly other media to be disturbed during excavation and other site activities. A large potential release site encircles all of TA-48-1 and TA-48-45 (LANL 2006a). To determine the extent and nature of any contamination, an assessment of the affected areas would be performed prior to commencing ground disturbance. As needed, any contamination found would be remediated before continuing, and appropriate personal protection equipment would be required for working in this area.

In addition, there are other potential release sites within TA-48 (LANL 2006a). These sites and others at LANL are being investigated and assessed consistent with DOE requirements and the Consent Order. If it is determined that the potential release sites pose an unacceptable risk to the public or to LANL workers, the sites would be cleaned up before proceeding.

Construction of the new Radiological Sciences Institute at TA-48 would result in some temporary increase in noise levels near the area from construction equipment and activities. Some disturbance of wildlife near the area may occur as a result of construction equipment operation. There would be no change in noise impacts on the public outside of LANL as a result of construction activities, except for a small increase in traffic noise levels from construction employees' vehicles and materials shipments. Noise sources associated with construction at TA-48 may include loud impulsive sources such as blasting.

Operations Impacts—Under the proposed project, criteria and toxic air pollutants would be generated from the operation and testing of an emergency generator, use of various chemicals in laboratories, and other activities. Emissions from the diesel generator would occur during periodic testing resulting in little change in air pollutant concentrations. Air quality impacts on the public would be minor.

Little or no change in toxic pollutant emissions or air pollutant concentrations at LANL is expected under this option. For facilities that would be combined at TA-48, toxic pollutants released from laboratories would be similar to those from current uses as shown under the No Action Option and would vary by year with the activities performed. Emissions would continue to be below screening-level emission values, and air quality impacts on the public would be minor.

Projected annual radiological air emissions from the Radiological Sciences Institute were estimated to be the combined total of the projected emissions from the individual facilities whose functions would be moved to the Radiological Sciences Institute. The projected emissions are shown in **Table G–13**. The individual facility air emissions combined together in the Radiological Sciences Institute at TA-48 are described in detail in this SWEIS, Appendix C (Human Health). Impacts of radiological air emissions released during normal operations are discussed under Human Health.

Noise impacts of operation of the new Radiological Sciences Institute at TA-48 are expected to be similar to those from existing operations at TA-48. Although there would be a slight increase in traffic and equipment noise near the area (for example, new heating and cooling systems), there would be minimal change in noise impacts on wildlife and no change in noise impacts on the public outside of LANL as a result of operating these new facilities.

Table G–13 Radiological Air Emissions from the Radiological Sciences Institute

Radionuclide	*Emission Rate (curies per year)*
Arsenic-72	1.21×10^{-4}
Arsenic-73	2.55×10^{-3}
Arsenic-74	1.33×10^{-3}
Beryllium-7	1.65×10^{-5}
Bromine-77	9.35×10^{-4}
Germanium-68	8.97×10^{-3}
Krypton-85	1.00×10^{2}
Rubidium-86	3.08×10^{-7}
Selenium-75	3.85×10^{-4}
Xenon-131m	4.50×10^{1}
Xenon-133	1.50×10^{3}
Other activation products [a]	5.58×10^{-6}
Plutonium-239	1.21×10^{-5}
Uranium-234	6.60×10^{-5}
Uranium-235	4.84×10^{-7}
Uranium-238	1.95×10^{-3}
Mixed fission products [b]	1.54×10^{-4}

[a] Other activation products are a mixed group of activation products represented by strontium-90 and yttrium-90 in equilibrium.

[b] Mixed fission products are rep resented by strontium-90 and yttrium-90 in equilibrium.

Source: Appendix C of this SWEIS.

DD&D Impacts—DD&D of buildings at TA-3, TA-18, TA-35, TA-46, TA-48, and TA-59 would result in temporary increases in air quality impacts from construction equipment, trucks, and employee vehicles. Maximum ground-level concentrations at the site boundary would be below the ambient air quality standards, except for possible short-term concentrations of carbon monoxide. Concentrations off site and along the perimeter road to which the public has regular access would be below ambient air quality standards, and it is expected that air quality impacts on the public would be minor.

DD&D of buildings at TA-3, TA-35, and TA-48 would result in some release of radionuclides. The potential exists for contaminated soils, building debris, and possibly other media to be disturbed during demolition of these facilities. The release of radionuclides would be minimized by proper decontamination of buildings prior to demolition and the use of appropriate containment devices. Radiological air emissions would be comparable to or less than those emitted during normal operations. Impacts of these radiological air emissions released during DD&D of the buildings under the proposed project are discussed under Human Health.

DD&D of buildings at TA-3, TA-18, TA-35, TA-46, TA-48, and TA-59 would result in some temporary increase in noise levels near the area from construction equipment and activities. Some disturbance of wildlife near the area may occur as a result of demolition activity. There would be no change in noise impacts on the public outside of LANL as a result of these activities, except for a small increase in traffic noise levels from employee vehicles and debris shipments.

Ecological Resources

Effects of the Cerro Grande Fire within TA-48 varied from a burn severity of medium to low or unburned. Those portions of the TA in the vicinity of the Radiochemistry Building (Building 48-1) were categorized as being burned at the low or unburned severity level (DOE 2000). The buildings that would be replaced by the Radiological Sciences Institute are all located in currently developed industrial and office areas. While buildings situated in TA-3, TA-35, TA-46, TA-48, and TA-59 are located within the ponderosa pine forest vegetation zone and those in TA-18 are in the pinyon (*Pinus edulis* Engelm.)- juniper (*Juniperus monosperma* [Engelm.] Sarg.) woodland vegetation zone, wildlife use of the areas in the immediate vicinity of the buildings would be limited. Due to the presence of people, activity, and security fencing, no large animals are usually found within developed areas.

Four wetlands occur in TA-48, three of which are located within Mortandad Canyon between TA-48 and TA-60. These wetlands, which total about 1.1 acres (0.4 hectares), are characterized by coyote willow (*Salix exigua* Nutt.), Baltic rush (*Juncus balticus* Willd.), cattail (*Typha* spp.), and wooly sedge (*Carex lanuginose* Michx.). The fourth wetland is located between TA-48 and TA-55; cattail is the dominant plant. This wetland is less than 0.1 acre (0.04 hectares) in size (ACE 2005).

Surface water flow within that portion of Mortandad Canyon on the northern boundary of TA-48 is ephemeral. Thus, there are no fish or other permanent aquatic resources present within TA-48. Further, there are no permanent water bodies in any of the TAs within which buildings are to be removed.

Although there are no threatened or endangered species in the TA-48 area (LANL 2006a), portions of the TA are located within both the core habitat and buffer zone of the Mexican spotted owl for the Sandia-Mortandad Canyon Area of Environmental Interest. However, the buffer and core areas encompass only the eastern portion of the TA. They do not include developed areas (or areas adjacent to developed areas) on the mesa. Additionally, a small portion of the southeast corner of TA-48 and the western edge of TA-55 fall within the buffer zone of the Pajarito Canyon Mexican spotted owl Area of Environmental Interest. Areas of Environmental Interest are established under the *LANL Threatened and Endangered Species Habitat Management Plan* to protect important breeding or wintering habitat for certain sensitive species. Areas of Environmental Interest for the bald eagle and southwestern willow flycatcher do not include any part of TA-48 (LANL 1998).

Of those TAs where buildings are to be demolished in connection with the new Radiological Sciences Institute (TA-3, TA-18, TA-35, TA-46, and TA-59), only TA-3 and TA-35 fall within the core areas of the Los Alamos Canyon and Sandia-Mortandad Canyon Areas of Environmental Interest, respectively, of the Mexican spotted owl. However, only those buildings to be removed at TA-35 are within developed core habitat. None of these TAs falls within Areas of Environmental Interest for the bald eagle or southwestern willow flycatcher (LANL 1998).

Construction Impacts—Although construction of some of the new facilities associated with the Radiological Sciences Institute would involve previously disturbed land, about 12.6 acres (5.1 hectares) of ponderosa pine forest at TA-48 and within the small area of TA-55 would be cleared (LANL 2006a). This would result in decreased less-mobile wildlife such as reptiles and small mammals, and cause more-mobile species, such as birds or large mammals, to be displaced. The success of displaced animals would depend on the carrying capacity of the area into which they move. If the area were at its carrying capacity, displaced animals would not likely survive. Indirect impacts of construction, such as noise or human disturbance, could also impact wildlife living adjacent to the construction zone. Such disturbance would span the construction period. The work area would be clearly marked to prevent construction equipment and workers from disturbing adjacent natural habitat.

Construction of the Radiological Sciences Institute would not directly impact wetlands located in Mortandad Canyon or the small wetland situated between TA-48 and TA-55. Best management practices would reduce the potential for indirect impacts to wetlands at TA-48.

While there are no threatened or endangered species in the TA-48 area, portions of the TA are located within both the core and buffer zones of the Sandia-Mortandad Canyon and Pajarito Canyon Mexican spotted owl Areas of Environmental Interest. However, only a small portion of the Radiological Sciences Institute may be built within buffer habitat; most new structures would not be in core or buffer zones. Thus, the biological assessment prepared by DOE concluded that with the application of reasonable and prudent alternatives such as reseeding and erosion protection, the project may affect, but is not likely to adversely affect, the Mexican spotted owl (LANL 2006b). The USFWS has concurred with this assessment (see Chapter 6, Section 6.5.2).

Areas of Environmental Interest for the bald eagle and southwestern willow flycatcher do not include any part of TA-48 or TA 55. Recognizing that the bald eagle forages over all of LANL and that some habitat degradation is associated with construction of the Radiological Sciences Institute, the DOE biological assessment concluded that with appropriate reasonable and prudent alternatives (see Section G.2.3.2) the project may affect, but is not likely to adversely affect, the bald eagle. Since the nearest southwestern willow flycatcher Area of Environmental Interest is over 3 miles (4.8 kilometers) from the project site it was determined that there would be no effect on this species (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to bald eagle and southeastern willow flycatcher (see Chapter 6, Section 6.5.2).

Operations Impacts—Operation of the Radiological Sciences Institute would have minimal impact on terrestrial resources within or adjacent to TA-48. Because the wildlife residing in the area has already adjusted to current levels of noise and human activity associated with current operation, it would not likely be adversely affected by similar types of activity involved with operation of the new facility. Areas not permanently disturbed by the new facility (for example, construction laydown areas) would be landscaped. While these areas would provide some habitat for wildlife, species composition and density would differ from preconstruction conditions.

DD&D Impacts—Removal of existing structures that the Radiological Sciences Institute is to replace would generate increased noise and levels of human disturbance. However, impacts would be temporary and would have minimal effect on wildlife, as these structures exist within disturbed areas and wildlife in adjacent areas is accustomed to human activity. Upon demolition of the buildings, the land would be revegetated and could be available for other uses. Because revegetation would primarily be for purposes of soil stabilization, there would be little benefit for wildlife. Also, if the land were redeveloped, there would be little change in its value as wildlife habitat; however, if development did not take place and native species were used in the revegetation effort, wildlife could benefit. Specific effects would depend on the nearness of existing development and natural habitat.

Since wetlands do not exist in the immediate area of any of the buildings to be removed in association with the new Radiological Sciences Institute, there would be no direct impacts on this resource. The use of best management practices would prevent erosion and subsequent sedimentation of any wetlands located in the canyons.

As noted above, of the buildings to be demolished in connection with the Radiological Sciences Institute, only those located in TA-35 occur within developed core habitat for the Mexican spotted owl. The removal of these buildings could produce noise greater than 6 decibels A-weighted (dB[A]) above background levels in undeveloped core habitat to the north in Mortandad Canyon. However, provided that reasonable and prudent alternatives are followed, the biological assessment concluded that demolition may affect, but is not likely to adversely affect, the Mexican spotted owl. Reasonable and prudent alternatives include muted back-up indicators on heavy equipment and reseeding and erosion protection. Also, activities involving heavy equipment would not be permitted to take place between March 1 and May 15, or until the completion of surveys for spotted owls. If owls were determined to be present, work restrictions would be extended until August 31. Potential impacts from DD&D activities to the bald eagle and southwestern willow flycatcher would not be expected (LANL 2006b). The USFWS has concurred with the biological assessment as it relates to impacts to the Mexican spotted owl, bald eagle and southeastern willow flycatcher from building demolition (see Chapter 6, Section 6.5.2).

Human Health

Construction Impacts—No radiological risks would be incurred by members of the public from construction activities. Construction workers would be at a small risk for construction-related accidents and radiological exposures. They could receive doses above natural background radiation levels from exposure to radiation from other past or present activities at the site. Any contamination that might be present in the soil would have been determined during site characterization and cleaned up accordingly. Workers would be protected through appropriate training, monitoring, and management controls. Their exposure would be limited to ensure that doses were kept as low as reasonably achievable (ALARA).

The potential for industrial accidents is based on both DOE and Bureau of Labor Statistics data on construction injuries and fatalities. Based on an estimated 3.12 million person-hours to construct the new facilities, no fatal accidents would occur. Nonfatal injuries are estimated to be 35 (DOE 2004) to 132 (BLS 2003).

Operations Impacts—Radiological Sciences Institute operations would not exceed the combined current operational limits. **Table G–14** shows that the annual collective dose to the population living within a 50-mile (80-kilometer) radius of the new Radiological Sciences Institute at TA-48 would be 0.26 person-rem, far less than the total population dose (30 person-rem) from all Key Facilities at LANL. This population dose would result in no additional fatalities in the population.

Table G–14 Annual Radiological Impacts on the Public from Radiological Sciences Institute Operations [a]

	Population Dose within 50 Miles (80 kilometers)	*MEI Dose*	*MEI Location (feet)*
Dose	0.26 person-rem	0.077 millirem	NNE 2,920 Royal Crest Trailer Park
Cancer fatality risk [b]	0.00016	4.6×10^{-8}	–
Regulatory dose limit [c]	Not applicable	10 millirem	–
Background radiation dose [d]	120,000 person-rem	400 millirem	–

MEI = maximally exposed individual.
[a] The stack parameters were conservative estimates used for the purpose of calculating a dose. A stack height of 10 meters, diameter of 1 meter, and exit velocity of 1 meter per second were used.
[b] Based on a risk estimate of 0.0006 LCFs per person-rem (see Appendix C of this SWEIS).
[c] 40 CFR Part 61 establishes an annual dose limit of 10 millirem via the air pathway to any member of the public from DOE operations. There is no standard for a population dose.
[d] The annual individual dose from background radiation at LANL ranges from a low of about 300 millirem to a high of about 500 millirem (see Appendix C of this SWEIS). The population living within 50 miles (80 kilometers) of TA-48 was estimated to be 299,508 in 2000.
Note: To convert feet to meters, multiply by 0.3048.

An MEI is a hypothetical member of the public residing at the LANL site boundary who would receive the maximum dose. The MEI, located at the Royal Crest Trailer Park, would receive an estimated annual dose of 0.077 millirem from Radiological Sciences Institute operations, as shown in Table G–14. This dose corresponds to an increased annual risk of developing a fatal cancer of 4.6×10^{-8}, or about 1 chance in 22 million for each year of operation.

Depending on the new facility layouts and consolidation of activities, the worker doses may vary from those at the existing facilities. Worker doses would be similar to those under the No Action Option or potentially less due to the improved facility design.

Neither additional chemicals nor an increase in chemical inventories is expected over those associated with current operating levels at the proposed new facility. Therefore, there would be no chemical-related health impacts on workers or the public expected under this option. The quantities of most chemicals that could be released to the atmosphere during routine normal operations are minor and would be below screening levels used to determine the need for additional analysis.

DD&D Impacts—Nonradiological DD&D health impacts could include construction-type injuries and possible fatalities. Based on an estimated 1 million person-hours for DD&D of the existing facilities, no fatal accidents would occur. Nonfatal injuries are estimated to be 12 (DOE 2004) to 45 (BLS 2003).

Demolition of the buildings might also involve removal of some asbestos-contaminated material. Removal of this material would be conducted according to existing asbestos management programs at LANL in compliance with strict asbestos abatement guidelines. Workers would be protected by personal protective equipment and other engineered and administrative controls, and no asbestos would be released that could be inhaled by members of the public.

Potential radiological DD&D health impacts were evaluated for members of the public and workers. The main radiological impacts would result from DD&D of the Sigma Complex (TA-3-66), Machine Shop (Building TA-3-102), and Radiochemistry site (TA-48). Quantitative information has not been presented, as project-specific work plans have not been prepared nor have the buildings in question been completely characterized with regard to types and locations of contamination. The Chemistry and Metallurgy Research Building Wing 9 was not included in the DD&D analysis, as it has previously been considered in a prior NEPA compliance document (DOE 2003). In addition, DD&D impacts of other partial buildings were not included. In addition to those listed above, several other buildings were reviewed with regard to health impacts because they were monitored for radiological air emissions in the past, currently house radiological sources, or have potential for radiological air emissions based on past functions. The review indicated that there would be no health impacts of their DD&D on members of the public or workers.

During early DD&D stages, when interior equipment is being removed from the buildings in question, doses to the public would be comparable to or less than those estimated for normal operation (see Table G–6). The building structures would be intact, with operating filtering systems for the stacks, while the decontamination and decommissioning were taking place. No additional nuclides would be introduced during these stages. Worker doses during decontamination and equipment removal may be higher than during normal operations but would be managed to remain under the DOE Administrative Control Level of 2,000 millirem per year and ALARA (DOE 1999b).

The primary source of potential consequences to workers and members of the public would be associated with the release of radiological air emissions during the demolition stage. Any radiological air emissions would be reduced by plastic draping and an enclosure, coupled with HEPA filters. Potential releases of radioactive particulates from disposition activities are expected to be lower than releases from past normal operations.

Cultural Resources

Surveys have identified two archaeological resource sites within TA-48, both of which are eligible for the National Register of Historic Places. The prehistoric site is a one- to three-room structure, whereas the historic site is a rock and wood enclosure. Additionally, the Radiochemistry Building and a number of other buildings have been determined to be potentially significant historic buildings. However, none of the buildings or structures have been formally evaluated for National Register of Historic Places eligibility status, and are, therefore, considered eligible and managed as such until a formal assessment determination has been made. There are no cultural resource sites in the small area of TA-55 that could be affected by the proposed Radiological Sciences Complex.

Four of the five TAs where structures would be removed as a part of the proposed project contain cultural resource sites. These are briefly summarized in **Table G–15**.

Table G–15 Affected Cultural Resource Sites – Radiological Sciences Institute

Technical Area	*Number of Cultural Resource Sites*	*Types of Resources Present*	*National Register of Historic Places Eligibility* [a]
3	8	Lithic scatter; trail and stairs; wagon road	3/2
18	3	Cavates; historic structure; rock shelter	3/0
35	0		
46	19	Pueblo roomblocks; lithic and ceramic scatters, one- to three-room structures, wagon road, cavates	9/2
59	1	Wagon road	0/0

[a] Number of sites that are eligible (the first number) or undetermined eligibility (the second number).

Traditional cultural properties are properties that are eligible for the National Register of Historic Places because of their association with cultural practices or beliefs of a living community that are (1) rooted in that community's history, and (2) important in maintaining its cultural identity. Consultations to identify traditional cultural properties were conducted with 19 American Indian tribes and 2 Hispanic communities in connection with the preparation of the *1999 SWEIS* (DOE 1999a). As noted in Section 4.7.3 of this SWEIS, traditional cultural properties are present throughout LANL and adjacent lands; however, to protect such sites specific features or locations are not identified (Knight and Masse 2001). Traditional cultural properties are not expected in developed areas of any TA involved in the Radiological Sciences Institute Project.

Construction Impacts—New construction in the area of the prehistoric or historic sites would require that the site boundaries be marked and fenced. Fencing would prevent accidental intrusion and disturbance to the site(s). If either of the two National Register of Historic Places-eligible prehistoric or historic sites could not be avoided by the proposed construction activities and protected by fencing, then a data recovery plan would need to be prepared and site excavation conducted prior to construction.

Radiological Sciences Institute construction and operation impacts on traditional cultural properties are unlikely, as most development would take place within previously disturbed portions of TA-48. Also, because the site would remain developed, potential views of TA-48 from any traditional cultural properties located in the vicinity would remain largely unchanged.

DD&D Impacts—Before demolition could begin on parts of the Radiochemistry Building or structures within TA-3, TA-18, TA-35, TA-46, and TA-59, a cultural resources assessment would be performed, as well as any subsequent compliance requiring documentation. NNSA, in conjunction with the State Historic Preservation Office, would implement documentation measures such as preparing a detailed report containing the history and description of the affected properties. These measures would be incorporated into a formal memorandum of agreement between NNSA and the New Mexico Historic Preservation Division to resolve adverse effects on eligible properties. The Advisory Council on Historic Preservation would be notified of the memorandum of agreement and would have an opportunity to comment. DD&D of buildings to be replaced by the new Radiological Sciences Institute would not impact traditional cultural properties, as all are located within developed portions of LANL.

Socioeconomics and Infrastructure

Construction Impacts—Utility infrastructure resources would be required for construction of the new Radiological Sciences Institute. Standard construction practice dictates that electric power needed to operate portable construction and supporting equipment be supplied by portable diesel-fired generators. Therefore, no electrical energy consumption would be directly associated with construction. A variety of heavy equipment, motor vehicles, and trucks would be used, requiring diesel fuel, gasoline, and propane for operation. Liquid fuels would be brought to the site as needed from offsite sources and, therefore, would not be a limited resource. Water would be needed primarily to provide dust control, aid in soil compaction at the construction site, and possibly for equipment washdown. Water would not be required for concrete mixing, as ready-mix concrete is typically procured from offsite resources. Portable sanitary facilities would be provided to meet the workday sanitary needs of project personnel on the site. Water needed for construction would be trucked to the point of use, rather than provided by a temporary service connection.

For construction of all 13 buildings, total liquid fuel consumption is estimated to be 4.2 million gallons (16 million liters). Total water consumption is estimated to be 22.4 million gallons (85 million liters). The existing LANL infrastructure would be capable of supporting requirements for new facility construction without exceeding site capacities, resulting in a negligible impact on site utility infrastructure.

Operations Impacts—No net increase in utility infrastructure demands for operation of the new Radiological Sciences Institute is expected, as its operational demands with more resource-efficient utility systems would be equal to or less than those of the facilities that the new Radiological Sciences Institute would replace. As such, operation of the Radiological Sciences Institute is expected to have no or negligible incremental impact on utility infrastructure capacities at LANL.

DD&D Impacts—Activities associated with DD&D of facilities to be replaced by the Radiological Sciences Institute are projected to require 101,000 gallons (384,000 liters) of liquid fuels and 3.1 million gallons (12 million liters) of water. DD&D activities would be staggered over an extended period of time. As a result, annual impacts of these activities on LANL's utility infrastructure would be minimal. Standard practice dictates that utility systems serving individual facilities be shut down as they are no longer needed. As DD&D activities progress, interior spaces, including associated equipment, piping, and wiring, would be removed prior to final demolition. Thus, existing utility infrastructure would be used to the extent possible and would then be supplemented or replaced by portable equipment and facilities as DD&D activities proceed, as previously discussed for construction activities.

Waste Management

The Radiochemistry Facility at TA-48 currently generates sanitary wastes, liquid radioactive wastes, and solid radioactive (low-level and transuranic) and chemical wastes, including mixed wastes. Sanitary wastes are delivered by a dedicated pipeline to the sanitary wastewater systems plant at TA-46. Radioactive liquid wastes are transported via dedicated piping to the Radioactive Liquid Waste Treatment Facility at TA-50. Low-level radioactive wastes are disposed of at

TA-54; all other radioactive, chemical, and mixed wastes are sent off site for treatment or disposal. Historical chemical and radioactive waste generation information is provided in **Table G–16** for TA-48. Table G–16 also includes historical waste generation information for the Sigma Complex, the Machine Shops, and those activities at the Pajarito Site that may be transferred to TA-48.

Table G–16 Waste Generation for the Radiochemistry Facility, Pajarito Site, Sigma Complex, and Machine Shops at Technical Area 3 (1998 to 2003)

		Radiochemistry Facility TA-48	*Pajarito Site TA-18* [a]	*Sigma Complex TA-3*	*Machine Shops TA-3* [b]
Transuranic waste (cubic yards)	Range	0 to 2	0 to 0	0 to 0	0 to 0
	Average	less than 1	0	0	0
Low-level radioactive waste (cubic yards)	Range	23 to 102	0 to 41	less than 1 to 264	20 to 535
	Average	58	13	94	127
Mixed low-level radioactive waste (cubic yards)	Range	less than 1 to 8	0 to 10	0 to 7	0 to less than 1
	Average	3	1	1	less than 1
Chemical waste (pounds)	Range	3,340 to 410,350	0 to 3,760	1,940 to 71,420	340 to 58,370
	Average	80,020	650	26,120	10,800

TA = technical area.

[a] TA-18 waste data include data for SHEBA which would not be moved to the Radiological Sciences Institute. Therefore, data presented for TA-18 are conservative (high) estimates of waste quantities.

[b] The Machine Shops data were compiled jointly for two buildings, the Nonhazardous Materials Machine Shop (Building 03-39) and the Radiological Hazardous Materials Machine Shop (Building 03-102). Only activities from Building 03-102 would be transferred to the Radiological Sciences Institute. Therefore, the values shown are conservative estimates of waste management impacts on the affected environment.

Note: To convert cubic yards to cubic meters, multiply by 0.76455; pounds to kilograms, by 0.4536.

Sources: LANL 2003b, 2004d, 2005c, 2006f.

Construction Impacts—Radiological Sciences Institute construction would generate approximately 2,800 cubic yards (2,100 cubic meters) of waste, primarily construction debris and associated solid waste. Construction debris is not hazardous and may be disposed of in a solid waste landfill. Recent LANL tracking and projection efforts have identified construction and demolition debris as a separate category of nonroutine sanitary (solid) waste. A substantial portion of construction debris at LANL is routinely recycled; in 2003, approximately 89 percent of the uncontaminated construction and demolition debris was recycled, and those rates are expected to continue (LANL 2004d).

Operations Impacts—Radiological Sciences Institute operations are expected to generate sanitary wastes, liquid radioactive wastes, and solid radioactive (low-level and transuranic) and chemical wastes, including mixed wastes. Because the Radiological Sciences Institute would be a new facility, design features would minimize wastes through enhanced processing, avoidance of cross-contamination, and nonhazardous product substitutions. Sanitary wastes would be delivered by dedicated pipeline to the Sanitary Wastewater Systems Plant at TA-46. Radioactive liquid wastes would be transported via dedicated piping to the Radioactive Liquid Waste Treatment Facility at TA-50. Other radioactive and chemical wastes would be managed at the waste management facilities or to a centralized waste storage facility within the Radiological Sciences Institute, where wastes may be stored for less than 90 days. Low-level radioactive wastes would be disposed of at TA-54 or at an offsite facility; all other radioactive and chemical wastes would be sent off site for treatment or disposal.

Because the Radiological Sciences Institute would consolidate operations already under way at the Radiochemistry Facility, Sigma Complex, Pajarito Site (TA-18), and Machine Shops (Building 03-102 only), the same general level of waste generation is expected to continue. Estimates of future waste generation rates were calculated based on historical rates and planned process improvements.

Projected discharge volumes of radioactive liquids are 845,000 gallons (3.2 million liters) per year (LANL 2006a). Chemical waste generation rates are expected to be 31,000 pounds (14,000 kilograms) per year. Low-level radioactive waste generation rates are estimated to be 157 cubic yards (120 cubic meters) per year. Mixed low-level and transuranic waste, including mixed transuranic waste; generation rates are expected to be very low, approximately 1.3 cubic yards (1 cubic meter) per year for each category (LANL 2006a).

DD&D Impacts—DD&D activities are expected to generate significant quantities of debris, including some radioactively contaminated debris. With the exception of low-level radioactive waste, most DD&D waste would be transferred to appropriate offsite treatment, recycling, or disposal facilities. **Table G–17** lists potential DD&D waste volumes from facilities that would be replaced by the Radiological Sciences Institute. Uncontaminated demolition debris may be recycled at on or offsite facilities. Chemical and radioactive wastes generated through decontamination processes would be managed at the waste management facilities. The large quantity of low-level radioactive waste may be disposed of on site or sent to an offsite facility. Solid wastes would be transferred to a permitted municipal landfill.

Table G–17 Decontamination, Decommissioning, and Demolition Waste Volumes for Buildings to be Replaced by the Radiological Sciences Institute

DD&D Waste Type	*Cubic Yards*
Low-level radioactive waste [a]	95,700
Mixed low-level radioactive waste	1,020
Remote-handled low-level radioactive waste	479
Contact-handled transuranic waste	1,130
Remote-handled transuranic waste	11
Demolition debris [b]	76,800
Hazardous waste with asbestos	605
Solid hazardous waste with organics	9
Solid hazardous waste with metals	373

DD&D = decontamination, decommissioning, and demolition.
[a] Consists of 71,800 cubic yards (54,900 cubic meters) of bulk waste, 23,500 cubic yards (18,000 cubic meters) of packaged waste, and 479 cubic yards (366 cubic meters) of remote-handled waste.
[b] Demolition waste includes solid and sanitary wastes.
Note: To convert cubic yards to cubic meters, multiply by 0.76455.

Transportation

Pajarito Road would provide access to the Radiological Sciences Institute.

Construction Impacts—Traffic on Pajarito Road could be disrupted due to temporary increases during construction.

Operations Impacts—Under the proposed project, interstate waste transportation would decrease over the long term. However, local traffic would increase.

DD&D Impacts—The large amounts of waste generated by Radiological Sciences Institute DD&D activities would have to be transported to storage or disposal sites using over-the-road truck transportation. These sites could be LANL TA-54 or an offsite location. Transportation has potential risks to workers and the public from incident-free transport, such as radiation exposure as the waste packages are transported along the routes and highways. Traffic accidents could result both in injuries or deaths from collisions and in an additional radiological dose to the public from radioactivity that may be released during the accident.

The effects of incident-free transportation of construction and DD&D wastes on the worker population and general public are presented in **Table G–18**. Effects are presented in terms of the collective dose in person-rem resulting in excess LCFs. Excess LCFs are the number of cancer fatalities that may be attributable to the proposed project, estimated to occur in the exposed population over the lifetimes of the individuals. If the number of LCFs is less than one, the subject population is not expected to incur any LCFs resulting from the actions being analyzed.

Table G–18 Incident-Free Transportation Impacts – Radiological Sciences Institute

Disposal Option	Low-Level Radioactive Waste Disposal Location [a]	Crew		Public	
		Collective Dose (person-rem)	Risk (LCF)	Collective Dose (person-rem)	Risk (LCF)
Onsite disposal	LANL TA-54	3.56	0.0021	1.06	0.00064
Offsite disposition	Nevada Test Site	31.34	0.0188	8.90	0.0053
	Commercial Facility	30.0	0.018	8.62	0.0052

LCF = latent cancer fatality, TA = technical area.
[a] Transuranic wastes would be disposed of at the Waste Isolation Pilot Plant (WIPP).

The risk of development of excess LCFs is highest for the workers under the offsite disposition option. This is because the dose is proportional to the duration of transport, which in turn is proportional to travel distance. As shown in Table G–18, disposal of low-level radioactive waste at the Nevada Test Site, which is located farthest from LANL, would lead to the highest dose and risk, although the dose and risk are low for all disposal options. **Table G–19** presents the impacts of traffic and radiological accidents. This table provides population risks in terms of fatalities due to traffic accidents from both the collisions themselves and from excess LCFs from exposure to releases of radioactivity. The analyses assumed that all transuranic and nonradioactive wastes would be transported to offsite disposal facilities.

Because all estimated LCFs and traffic fatalities, as shown in Tables G–18 and G–19, are much less than 1.0, the analysis indicates that no excess fatal cancers would result from this activity, either from dose received from packaged waste on trucks or potentially received from traffic collisions and accidental release.

Table G–19 Transportation Accident Impacts – Radiological Sciences Institute

Low-Level Radioactive Waste Disposal Location [a, b]	*Number of Shipments* [c]	*Distance Traveled (million kilometers)*	*Accident Risks*	
			Radiological (excess LCFs)	*Traffic (fatalities)*
LANL TA-54	10,469	2.20	4.2×10^{-9}	0.027
Nevada Test Site	10,469	17.03	5.1×10^{-6}	0.174
Commercial facility	10,469	15.54	4.9×10^{-6}	0.158

LCF = latent cancer fatality, TA = technical area.
[a] All nonradiological wastes would be transported offsite.
[b] Transuranic wastes would be disposed of at WIPP.
[c] Approximately 58.7 percent of shipments are radioactive wastes. Others include 41 percent industrial and sanitary waste and about 0.6 percent asbestos and hazardous wastes.
Note: To convert kilometers to miles, multiply by 0.6214.

Facility Accidents

Operations Impacts—Potential accidents that might occur at the proposed Radiological Sciences Institute that are estimated to have the highest impacts would involve radiological operations and materials that were transferred from Chemistry and Metallurgy Research Wing 9 hot cell operations. Six accident scenarios were selected to represent the bounding impacts of accidents at the Radiological Sciences Institute. Information used to estimate the impacts of these accidents is shown in **Table G–20**. The material at risk in a hot cell is estimated to be 10.6 ounces (300 grams) of plutonium-238 equivalent and an additional 2.2 pounds (1 kilogram) of plutonium-239. The new Radiological Sciences Institute vault is assumed to contain this same entire inventory.

Table G–20 Bounding Radiological Accident Scenarios – Radiological Sciences Institute

Accident	*Source Term* [a] *(plutonium-238 curies)*	*Release Energy (watts)*	*Annual Frequency*
Hot cell fire involving plutonium-238 in general purpose heat source modules	5.13 plutonium-238	2.04×10^{6}	0.0001
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules	22.572 plutonium-238 1.386 plutonium-239	2.04×10^{6}	2.4×10^{-5}
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules	5.13 plutonium-238 0.315 plutonium-239	0	0.00024
Spill of plutonium-238 residue from 0.5-gallon (2-liter) bottles outside of hot cell	0.001283 plutonium-238	0	0.1
Hot cell plutonium-238 spill with no confinement	0.4104	0	0.01
Main vault fire	10.26 plutonium-238 0.126 plutonium-239	2.04×10^{6}	$<1 \times 10^{-6}$

[a.] A release height of 4.9 feet (1.5 meters) is assumed for all accidents. Specific activity is 0.063 curies per gram for plutonium-239 and 17.1 curies per gram for plutonium-238.

Assuming that an accident occurred, estimated consequences for a noninvolved worker located 330 feet (100 meters) from the accident, the MEI located at the trailer park, and the offsite population are shown in **Tables G–21** and **G–22**. Estimated risks that take accident frequency into account to these same receptors are shown in **Table G–23**.

Table G–21 Radiological Accident Offsite Consequences – Radiological Sciences Institute

Accident	*MEI*		*Population to 50 Miles (80 kilometers)* [b, c]	
	Dose (rem)	*LCF* [a]	*Dose (person-rem)*	*LCF*
Hot cell fire involving plutonium-238 in general purpose heat source modules	6.31	0.0038	2,770	1.7
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules	29.6	0.036	13,000	7.8
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules	19.4	0.012	4,650	2.8
Spill of plutonium-238 residue from 0.5-gallon (2-liter) bottles outside of hot cell	0.0066	4.0×10^{-6}	1.1	0.00065
Hot cell plutonium-238 spill with no confinement	2.12	0.0013	350	0.21
Main vault fire	12.8	0.0077	5,620	3.4

MEI = maximally exposed individual, LCF = latent cancer fatality.
[a] Increased risk of an LCF to an individual per year.
[b] Increased number of LCFs for the offsite population per year.
[c] Offsite population size is approximately 300,000 persons located within a 50-mile (80-kilometer) radius.

Table G–22 Radiological Accident Onsite Worker Consequences – Radiological Sciences Institute

Accident	*Noninvolved Worker at 330 Feet (100 meters)*	
	Dose (rem)	*LCF* [a]
Hot cell fire involving plutonium-238 in general purpose heat source modules	32.5	0.039
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules	152	0.18
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules	171	0.21
Spill of plutonium-238 residue from 0.5-gallon (2-liter) bottles outside of hot cell	0.045	2.7×10^{-5}
Hot cell plutonium-238 spill with no confinement	14.3	0.0086
Main vault fire	65.9	0.079

LCF = latent cancer fatality.
[a] Increased risk of an LCF to an individual, assuming the accident occurs.

The accident scenarios with the potential for the highest radiological impacts to the MEI are the seismic-induced building collapse with no fire and the seismic-induced building collapse with a fire involving plutonium-238 in general purpose heat source modules. If either of these accidents were to occur, the consequences are estimated to be 2.8 or 7.8 increased LCFs for the offsite population, 0.012 or 0.036 increased risk of LCFs for the MEI, and 0.21 or 0.18 increased risk of an LCF for a noninvolved worker located at a distance of 330 feet (100 meters) from the accident, respectively. After taking into account the frequency (or probability) of each accident, the hot cell plutonium-238 spill with no confinement is estimated to have the highest risks. For this accident, the annual risks are estimated to be 0.0021 LCFs (1 chance in 480) for the offsite population, 1.3×10^{-5} increased risk (1 chance in 77,000) of LCFs for the MEI, and 8.6×10^{-5} increased risk (1 chance in 12,000) of an LCF for a noninvolved worker located at a distance of 330 feet (100 meters) from the accident.

Table G–23 Radiological Accident Offsite Population and Worker Risks – Radiological Sciences Institute

Accident	Onsite Worker (LCFs)	Offsite Population (LCFs)	
	Noninvolved Worker at 330 Feet (100 meters) [a]	*MEI* [a]	*Population to 50 Miles (80 kilometers)* [b, c]
Hot cell fire involving plutonium-238 in general purpose heat source modules	3.9×10^{-6}	3.8×10^{-7}	0.00017
Seismic-induced building collapse and fire involving plutonium-238 in general purpose heat source modules [d]	4.4×10^{-6}	8.5×10^{-7}	0.00019
Seismic-induced building collapse with no fire involving plutonium-238 in general purpose heat source modules [d]	4.9×10^{-5}	2.8×10^{-6}	0.00067
Spill of plutonium-238 residue from 0.5-gallon (2-liter) bottles outside of hot cell	2.7×10^{-6}	4.0×10^{-7}	6.5×10^{-5}
Hot cell plutonium-238 spill with no confinement	8.6×10^{-5}	1.3×10^{-5}	0.0021
Main vault fire	$< 7.9 \times 10^{-8}$	$< 7.7 \times 10^{-9}$	$< 3.4 \times 10^{-6}$

LCF = latent cancer fatality, MEI = maximally exposed individual.
[a] Increased risk of an LCF to an individual per year.
[b] Increased number of LCFs for the offsite population per year.
[c] Offsite population size is approximately 300,000 persons located within a 50-mile (80-kilometer) radius.
[c] An updated probabilistic seismic hazard analysis has been completed for LANL (LANL 2007), which results in higher peak horizontal ground acceleration values for the same annual probability of exceedance. In the seismic accident analyses for the Radiological Sciences Institute, the radioactive source term was conservatively based on the assumption that all structures, systems, and components failed, therefore, the updated probabilistic seismic hazard analysis is not expected to change the accident consequences or risks.

Seismic accidents considered for the proposed Radiological Sciences Institute are estimated to have a probability of release of 0.1 (the same as at the Chemistry and Metallurgy Research Building); the Radiological Sciences Institute would be designed to withstand the evaluation-basis earthquake. In comparing a seismic accident scenario that includes a fire with one that does not include a fire, both located within the Radiological Sciences Institute, the former has higher potential for causing offsite population and MEI impacts, while the latter has higher individual worker impacts. This is because the buoyant effects of a fire loft the radioactive plume over the onsite workers, while the greater releases associated with this scenario would impact the general population farther downwind. In contrast, the absence of a fire and its buoyant effects has a greater impact on close-in individuals like the noninvolved worker at 330 feet (100 meters) and the nearby worker population.

G.4 Radioactive Liquid Waste Treatment Facility Upgrade Impact Assessment

This section provides an assessment of environmental impacts for the proposed Radioactive Liquid Waste Treatment Facility Upgrade. Section G.4.1 provides background information on the proposed project. Section G.4.2 provides a description of the proposed options for the Radioactive Liquid Waste Treatment Facility Upgrade. Section G.4.3 presents environmental consequences of the No Action Option and project options for the Radioactive Liquid Waste Treatment Facility Upgrade. The main volume of this SWEIS contains information about the general environmental setting of LANL and environmental impacts associated with continued operations of the site.

G.4.1 Introduction

The Radioactive Liquid Waste Treatment Facility treats radioactive liquid wastes generated at other LANL facilities and houses analytical laboratories supporting waste treatment operations. The principal capabilities and activities conducted at the Radioactive Liquid Waste Treatment Facility include: (1) waste characterization and packaging, including identification and quantification of constituents of concern in waste streams and packaging and labeling waste according to U.S. Department of Transportation regulations; (2) waste transportation including inspection and cross-checking for acceptance; (3) liquid and solid chemical materials and radioactive waste storage; (4) waste pretreatment; (5) radiological liquid waste treatment using a number of treatment processes, including ultrafiltration and reverse osmosis; and (6) secondary waste treatment.

The original Radioactive Liquid Waste Treatment Facility (Building 50-1) as shown in **Figure G–4** was constructed in 1963. Between 1963 and 1986, three annexes were attached to the north, south, and east sides of the original building. With the addition of these annexes, the current facility has a total floor area of approximately 42,300 square feet (3,900 square meters). The North Annex has a footprint of about 5,000 square feet (450 square meters); the East Annex has a footprint of about 7,000 square feet (630 square meters); and the South Annex has a footprint of about 7,500 (700 square meters).

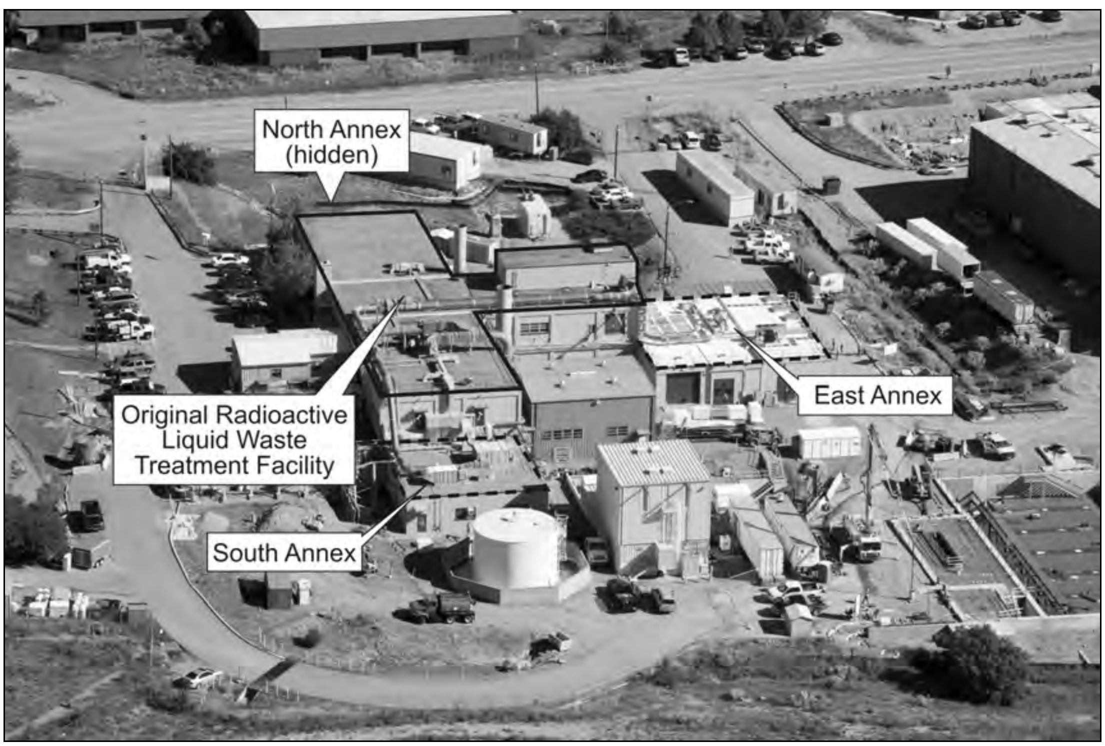

Figure G–4 Existing Radioactive Liquid Waste Treatment Facility

The Radioactive Liquid Waste Treatment Facility is the only facility available at LANL to treat a broad range of transuranic liquid wastes and low-level radioactive liquid waste. However, the ability of this facility to operate reliably is becoming increasingly uncertain. The original building is over 40 years old and has exceeded its design life. Similarly, the clarifiers, rotary vacuum filter, and heating, ventilation, and air conditioning systems, installed in 1963, are also over 40 years old. The infrastructure and treatment equipment require increasing maintenance attention to keep them operational, and replacement parts are increasingly difficult to acquire; replacement components for some older systems are no longer commercially produced. Corrosion of pipes and tanks has resulted in leaks. Radioactive Liquid Waste Treatment Facility materials and components are failing with increased frequency, and key systems could potentially fail within the next 5 to 10 years.

The current Radioactive Liquid Waste Treatment Facility treats all liquid radioactive waste generated at LANL except for that generated at TA-53 and occasionally that from TA-21. A system of pipes collects radioactive wastewater from various facilities, such as the Plutonium Facility at TA-55 and the Chemistry and Metallurgy Research Facility at TA-3, and transfers the wastewater to influent tanks at the Radioactive Liquid Waste Treatment Facility. In a few cases, trucks bring radioactive wastewater from other facilities to the Radioactive Liquid Waste Treatment Facility.

The influent waste stream contains two types of radioactive components: (1) tritiated water, and (2) radioactive solids that are either dissolved or suspended in the liquid. The existing and the proposed Radioactive Liquid Waste Treatment Facility treatment processes are designed to treat the dissolved or suspended solids, but are not able to extract tritiated water. Tritiated wastewater is discharged via a permitted outfall if it meets discharge criteria or is trucked to TA-53's evaporation ponds if it exceeds discharge criteria. Tritiated wastewater has not been trucked to the TA-53 evaporation ponds since 2003.

Although the treatment processes cannot remove tritiated water, they do extract suspended and dissolved radioactive solids from the liquid waste and concentrate the solids by removing additional liquid. The treated liquid is either returned to the low-level radioactive waste influent tank or released to a permitted outfall in Mortandad Canyon. Solid radioactive waste is placed in 55-gallon (208-liter) drums. Drums of solids that meet the waste acceptance criterion regarding liquid content are trucked to TA-54 for storage or disposal. Concentrated liquids resulting from the evaporator portion of the treatment process are sent by truck to a permitted commercial treatment facility in Tennessee for drying, a trip of about 1,400 miles (2,700 kilometers). Typically, about six shipments are made each year. The treatment facility returns the dried solids to TA-54. Drums of solidified transuranic waste from liquid treatment are stored at TA-54 pending preparation for shipment to WIPP near Carlsbad, New Mexico; low-level radioactive waste is disposed of in TA-54.

Future preparation of transuranic waste for shipment is expected to occur in a new TRU (Transuranic) Waste Facility in TA-54 (Appendix H, Section H.3.2.2.2). Some of the functions needed for preparation of transuranic waste from the Radioactive Liquid Waste Treatment Facility may be optionally duplicated in a separate structure co-located with the Radioactive Liquid Waste Treatment Facility. The environmental analysis conducted for the TRU Waste Facility bounds this possibility.

Because many treatment processes work best with water that contains certain ranges of minerals and chemicals and with certain quantities of water, design of the new facility would consider historical usage and future mission requirements. The lower-bound waste volumes assume the generators of radioactive wastewater implement various waste minimization and pollution prevention projects. Calculations of the upper-bound waste volumes assume these waste minimization and pollution prevention projects do not occur and changes in LANL's mission (in particular an increase in pit production up to 80 pits per year) would result in generation of more radioactive wastewater. **Table G–24** shows the quantities of wastewater that the new facilities would be designed to process annually. Upper-bound quantities would be about twice as large.

Table G–24 Design Basis Influent Volumes – Radioactive Liquid Waste Treatment Facility Upgrade

Influent	*Lower Bound (gallons per year)*
Low-level radioactive waste	2,507,000
Acidic transuranic waste	3,700
Caustic transuranic waste	2,600

Note: To convert gallons to liters, multiply by 3.7854.

G.4.2 Options Considered

For the Radioactive Liquid Waste Treatment Facility Upgrade, one No Action Option (see Section G.4.2.1) and three action options (see Sections G.4.2.2, G.4.2.3, and G.4.2.4) are proposed to address facility needs. Additionally, two auxiliary actions to reduce or eliminate the discharge are also proposed (see Section G.4.2.5). The auxiliary actions (evaporation tanks or mechanical evaporation) may be incorporated as part of the No Action Option or any of the three action options. Section G.4.2.6 presents options considered, but dismissed.

G.4.2.1 No Action Option

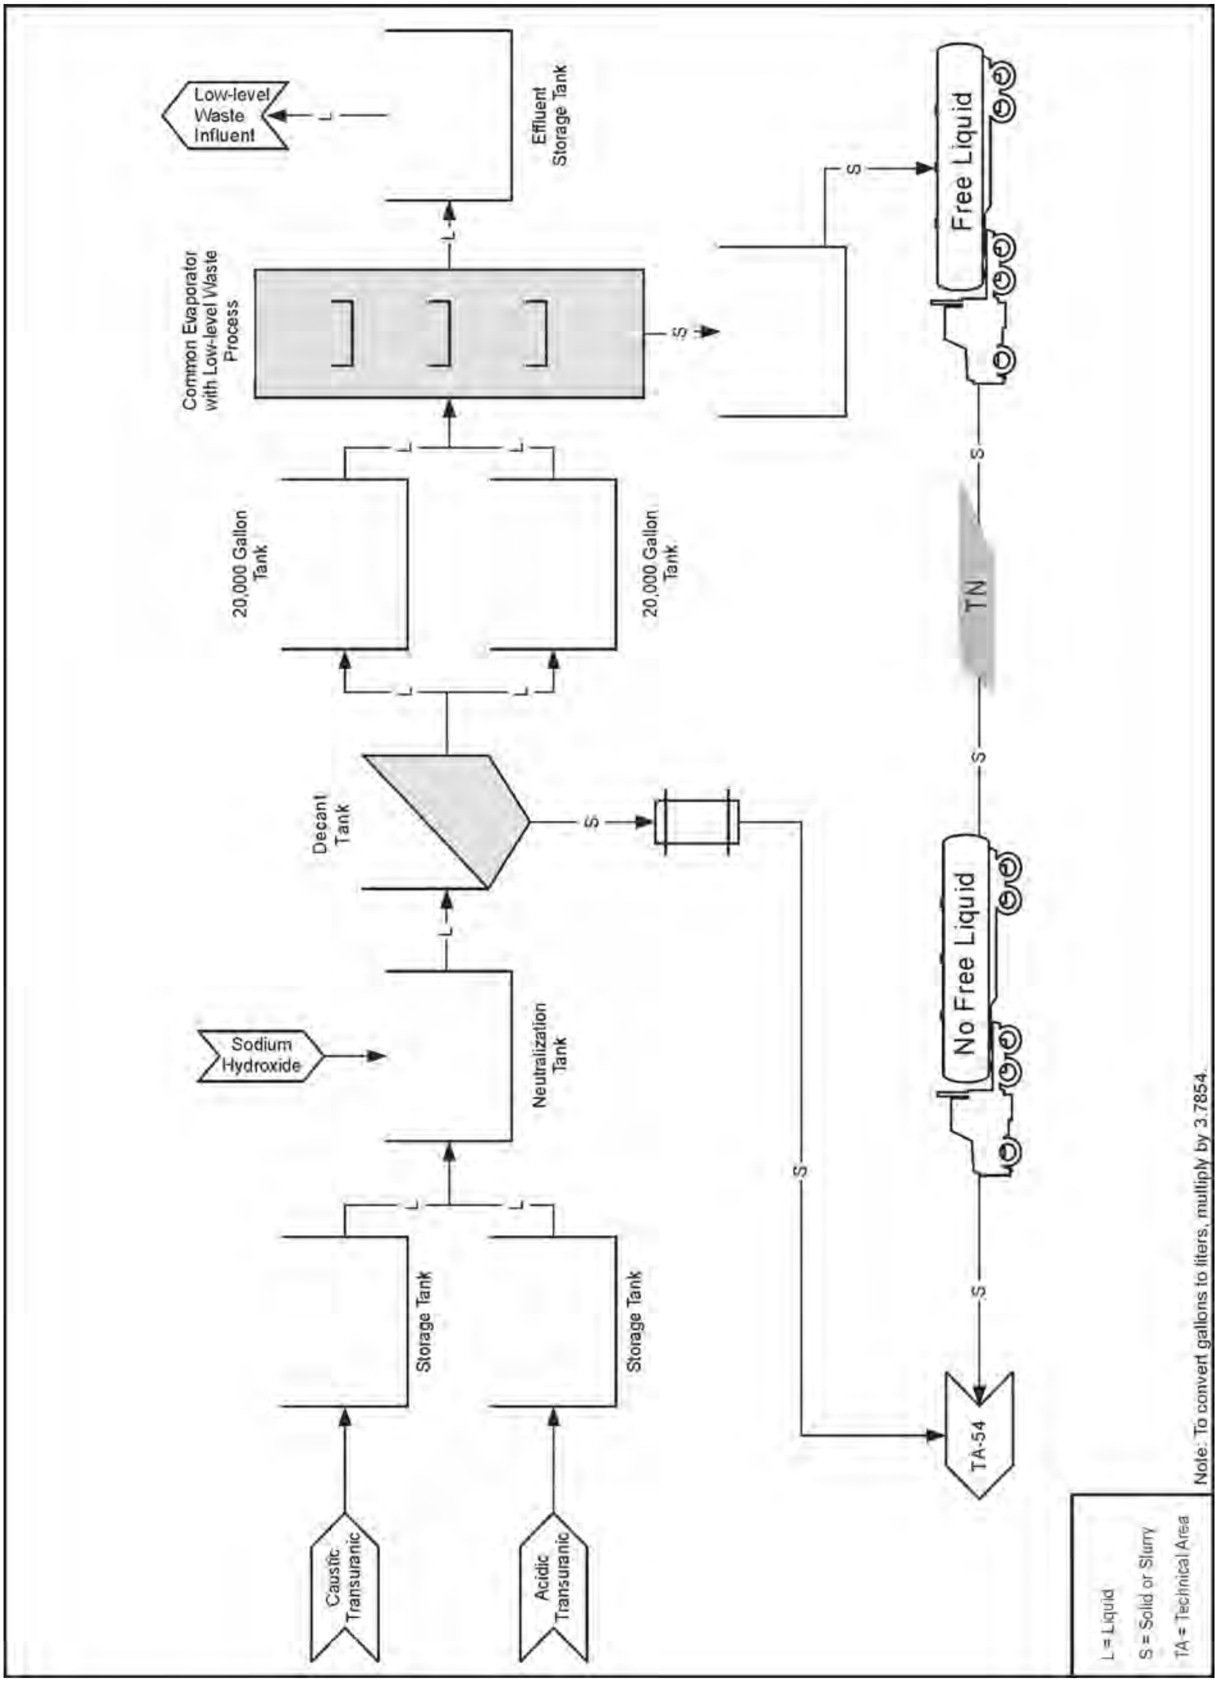
Under the No Action Option, the Radioactive Liquid Waste Treatment Facility would continue to process transuranic and low-level radioactive wastewater in the existing building. No new construction would occur. The annexes to the original Radioactive Liquid Waste Treatment Facility, which do not meet seismic and wind-loading standards, would not be removed. No existing contaminated materials would be removed. Existing processes would continue to treat liquid transuranic waste and liquid low-level radioactive wastes separately. Treatment processes would result in generation of transuranic sludge, low-level radioactive waste sludge, solid low-level radioactive waste, secondary liquid low-level radioactive wastes (evaporator bottoms), and treated effluent. The transuranic sludge would be solidified (cemented), then transported to TA-54 for storage, characterization, and shipment to WIPP for disposal. The low-level radioactive waste sludge would be dewatered, packaged, and shipped to TA-54 for disposal. Solid low-level radioactive wastes would be packaged and shipped to TA-54 for disposal. Secondary liquid low-level radioactive wastes would be transported by truck to an offsite treatment plant where it would be dried, and the resultant solids would be returned to LANL for disposal at TA-54 as solid low-level radioactive wastes, if it meets waste acceptance criteria. Optionally, effluent from the existing facility could be evaporated as discussed in Section G.4.2.5. The existing treatment processes for transuranic waste are shown in **Figure G–5**.

Under the No Action Option, LANL staff would continue to perform routine repairs, safety improvements, and replacement-in-kind of equipment on an as-needed basis. LANL would continue to meet current discharge standards, but may not be able to meet future discharge standards if they become more stringent and the auxiliary actions are not implemented. The existing Radioactive Liquid Waste Treatment Facility would continue to process radioactive liquid wastes until key systems irreparably fail or until the facility can no longer meet discharge standards. System failure or failure to meet discharge standards is estimated to occur sometime within the next 10 years. Therefore, this No Action Option does not meet NNSA's purpose and need to maintain treatment capability at LANL for 50 years.

G.4.2.2 Option 1: Single Liquid Waste Treatment Building Option – Proposed Project

Under the proposed project, NNSA would construct new low-level radioactive waste and transuranic liquid waste treatment facilities to achieve greater reliability, redundancy, and flexibility. A new waste treatment building would have a footprint of about 10,800 square feet (1,000 square meters). The building would consist of a partially below-grade basement, a main floor, and a mezzanine for a total area of 20,700 square feet (1,923 square meters), and would be accompanied by a new central utilities building. NNSA would also modify low-level radioactive and transuranic waste processes to become more effective and better able to incorporate future technology. Portions of the existing Radioactive Liquid Waste Treatment Facility, as described below, would be demolished. The existing facility would not be renovated but would continue to be used for offices and chemical analyses. New equipment would be purchased; some existing equipment may be used to supplement the new equipment and to provide redundancy. Additionally, either one of the auxiliary actions (evaporation tanks or mechanical evaporation) described in Section G.4.2.5 may be added to this option.

The proposed location of the single new low-level radioactive waste and transuranic facility is west of the existing Radioactive Liquid Waste Treatment Facility in an existing parking area (see **Figure G–6**). The building would be sited near the point where transuranic waste lines enter TA-50 to minimize the distance this wastewater must flow to reach the treatment facility. NNSA would conduct DD&D of the East Annex. The existing transuranic storage tank vault (TA-50-66) and the transformer on the north side of the existing Radioactive Liquid Waste Treatment Facility would also be demolished. Some wastewater collection pipes and utilities in the immediate vicinity of the Radioactive Liquid Waste Treatment Facility may be rerouted. Some remediation of contaminated soils would be required.



Note: To convert gallons to liters, multiply by 3.7854.

Figure G–5 Existing Treatment Processes for Transuranic Waste

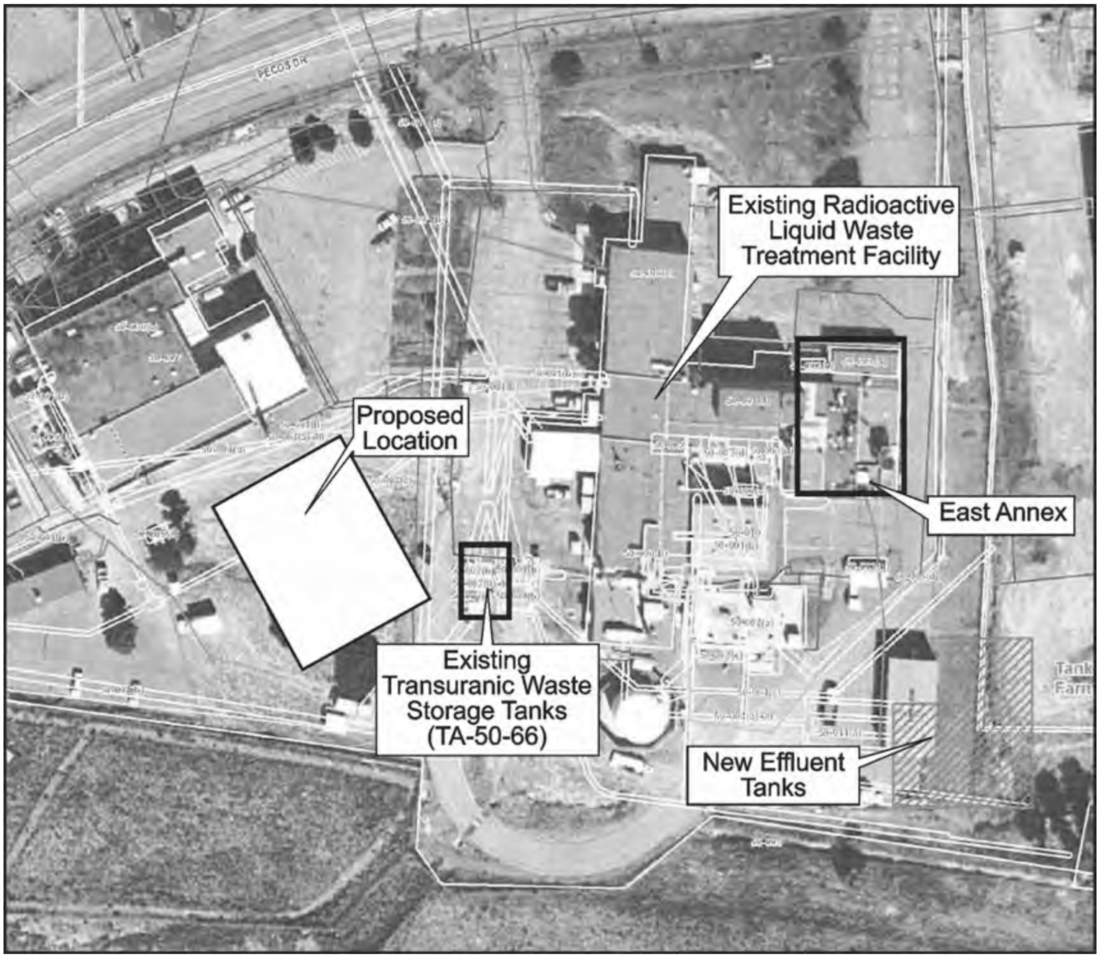


Figure G–6 Proposed Project Location

The proposed low-level radioactive waste treatment process consists of removing suspended and dissolved solids from the liquid waste stream, concentrating the solid waste stream by removing additional liquid, packaging the resulting solid radioactive waste, and ultimately releasing the remaining liquids to a permitted outfall or to evaporative processes. **Figure G–7** shows the proposed low-level radioactive waste treatment process. This process would receive waste via pipeline from the low-level radioactive waste influent tanks and distillate from the transuranic waste treatment process. Some industrial wastewater that cannot be treated by other LANL wastewater treatment systems may also be treated (LANL 2005e). In a typical year, the system could receive approximately 2.5 million gallons (9.5 million liters) of liquid low-level radioactive waste, although the upper bound influent volume may be up to 5 million gallons (20 million liters). The proposed transuranic waste treatment process is shown in **Figure G–8**. The transuranic influent tanks can store approximately 25,000 gallons (96,000 liters) per year of transuranic acid wastewater and 9,000 gallons (34,000 liters) per year of transuranic caustic wastewater. Redundant tanks would handle overflows and drainage.

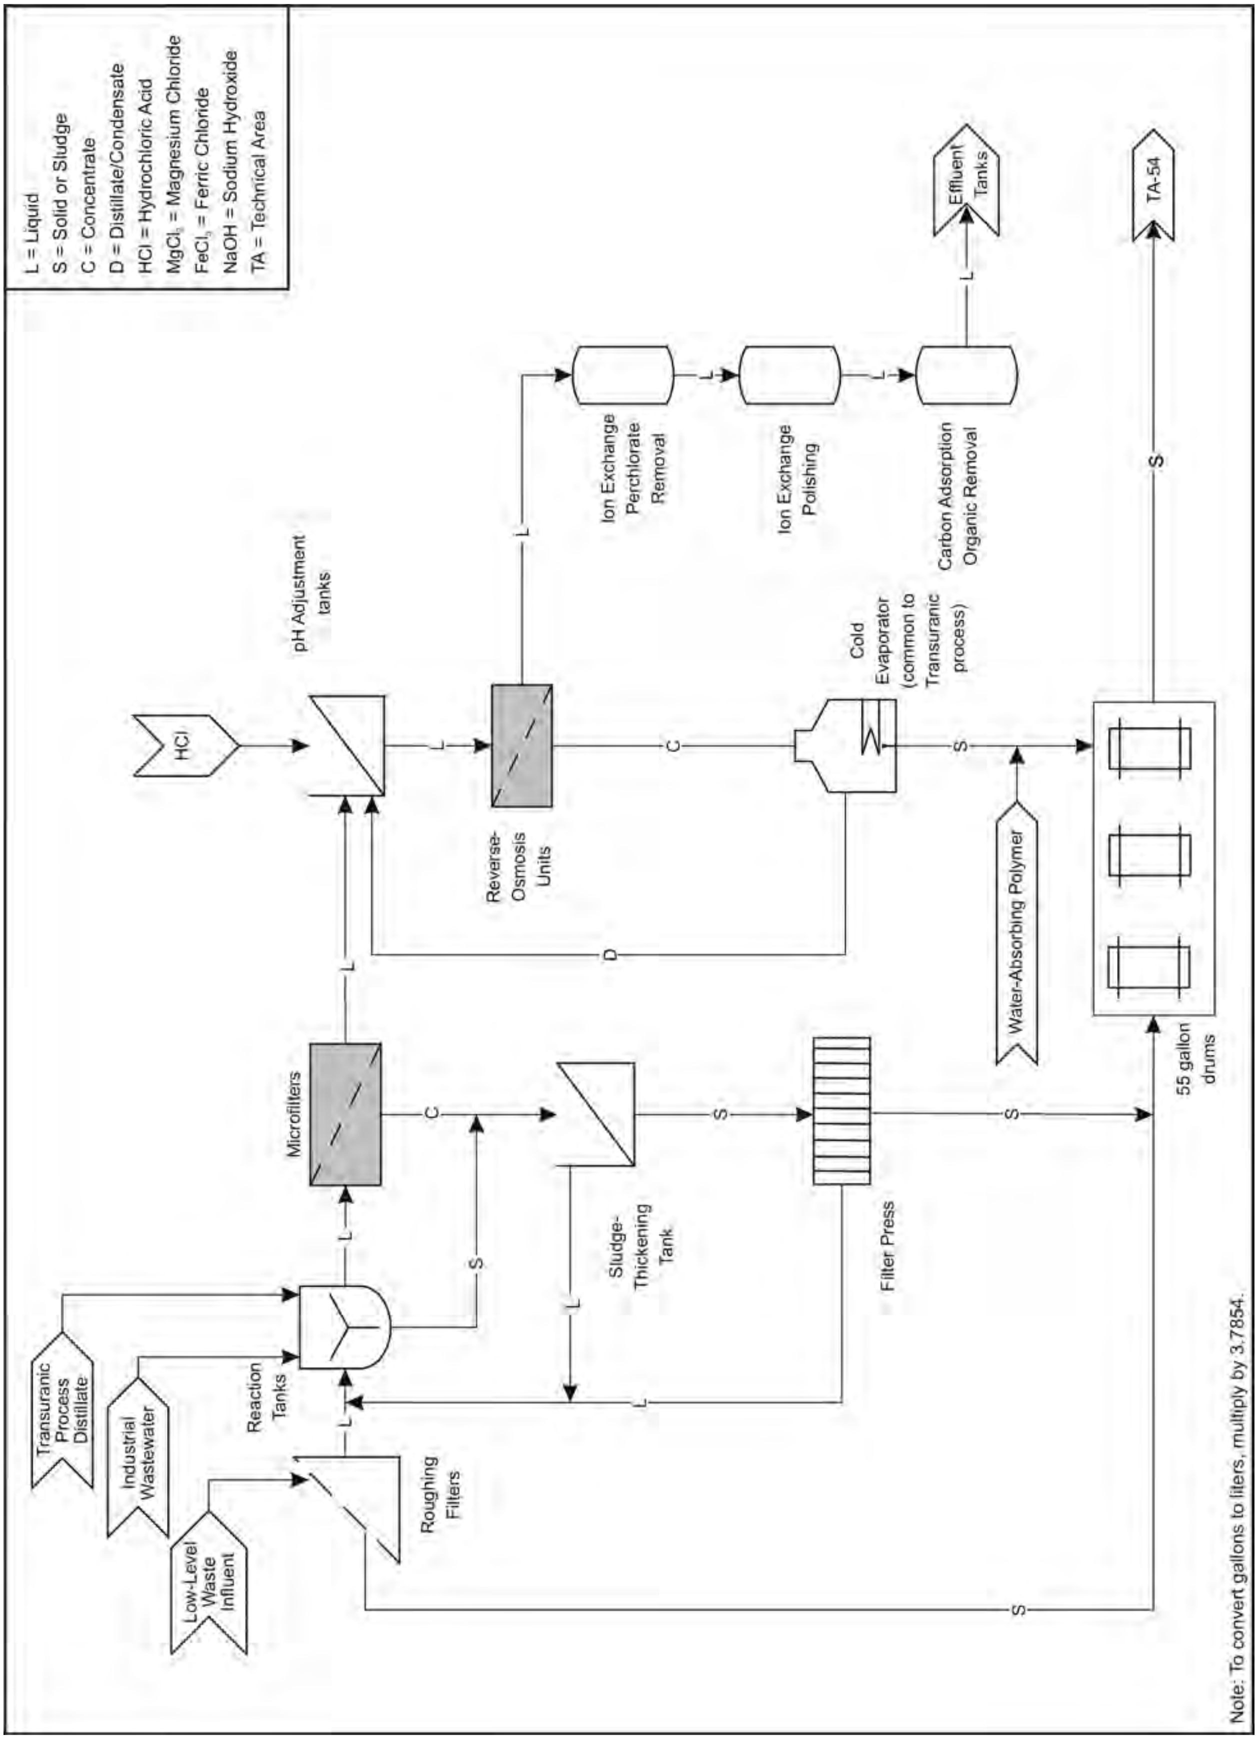

Figure G–7 Proposed Low-Level Radioactive Waste Treatment Process

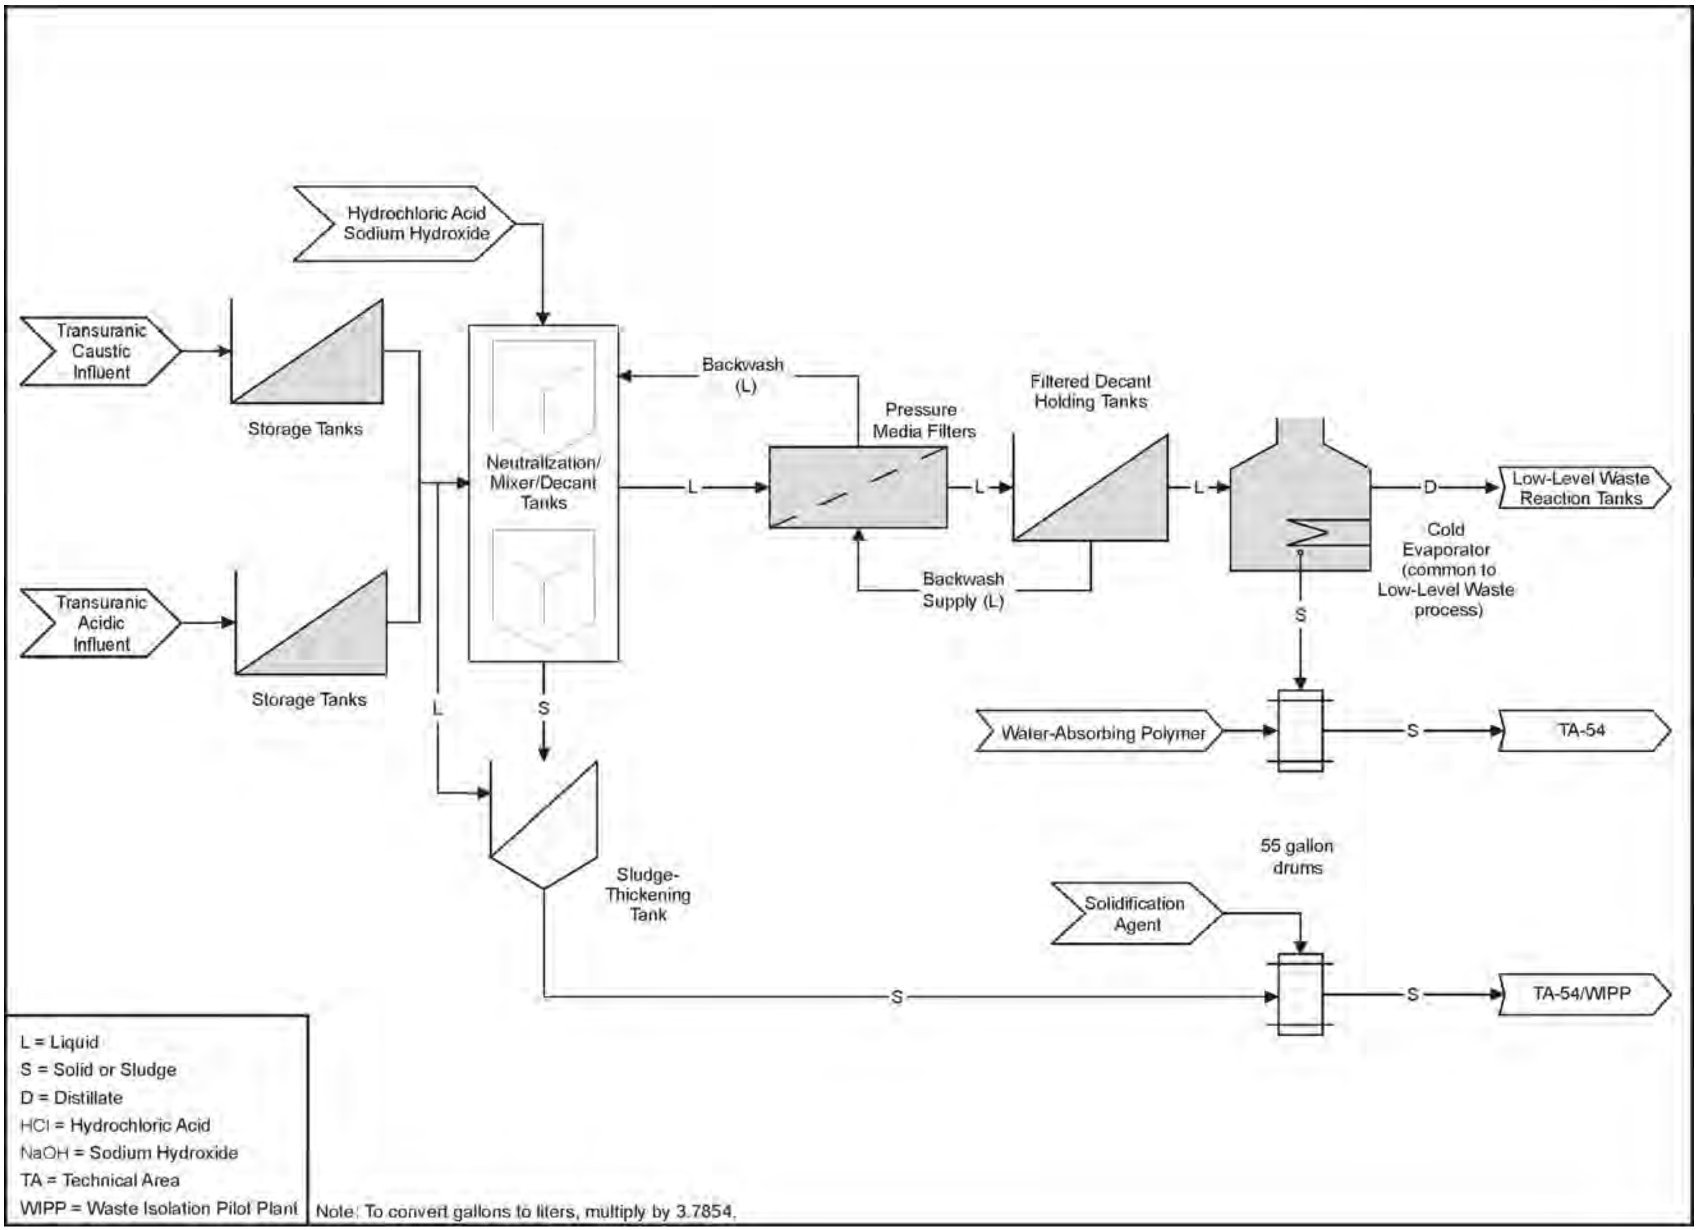

Figure G–8 Proposed Transuranic Waste Treatment Process

G.4.2.3 Option 2: Two Liquid Waste Treatment Buildings Option

This option would involve construction and operation of two new treatment facilities: one for low-level radioactive waste and one for transuranic waste (see **Figure G–9**). A central utilities building would also be constructed. The new low-level radioactive waste facility would have a footprint between 25,000 and 35,000 square feet (2,323 to 3,150 square meters) and would be located on the north side of the Radioactive Liquid Waste Treatment Facility. The transuranic waste facility would be located close to the point where transuranic waste lines enter TA-50, southwest of the existing Radioactive Liquid Waste Treatment Facility, to minimize the distance this wastewater must flow to reach the treatment facility. The transuranic waste facility would require approximately 15,000 square feet (1,350 square meters) of floor space. Like the low-level radioactive waste facility, it would contain processing areas, mechanical rooms, a control room, and access control areas. Additionally, either one of the auxiliary actions (evaporation tanks or mechanical evaporation) described in Section G.4.2.5 may be added to this option.

Locating the new low-level radioactive waste facility north of the existing Radioactive Liquid Waste Treatment Facility would necessitate demolition of the North Annex, in addition to the East Annex, as well as a transformer located on the north side of the existing facility. The existing transuranic waste storage tank vault (TA-50-66) would be demolished. Some remediation of contaminated soils would be required. The new facilities would use the same treatment process as that described for the proposed project. All other aspects of this option are the same as those of the proposed project (Option 1).

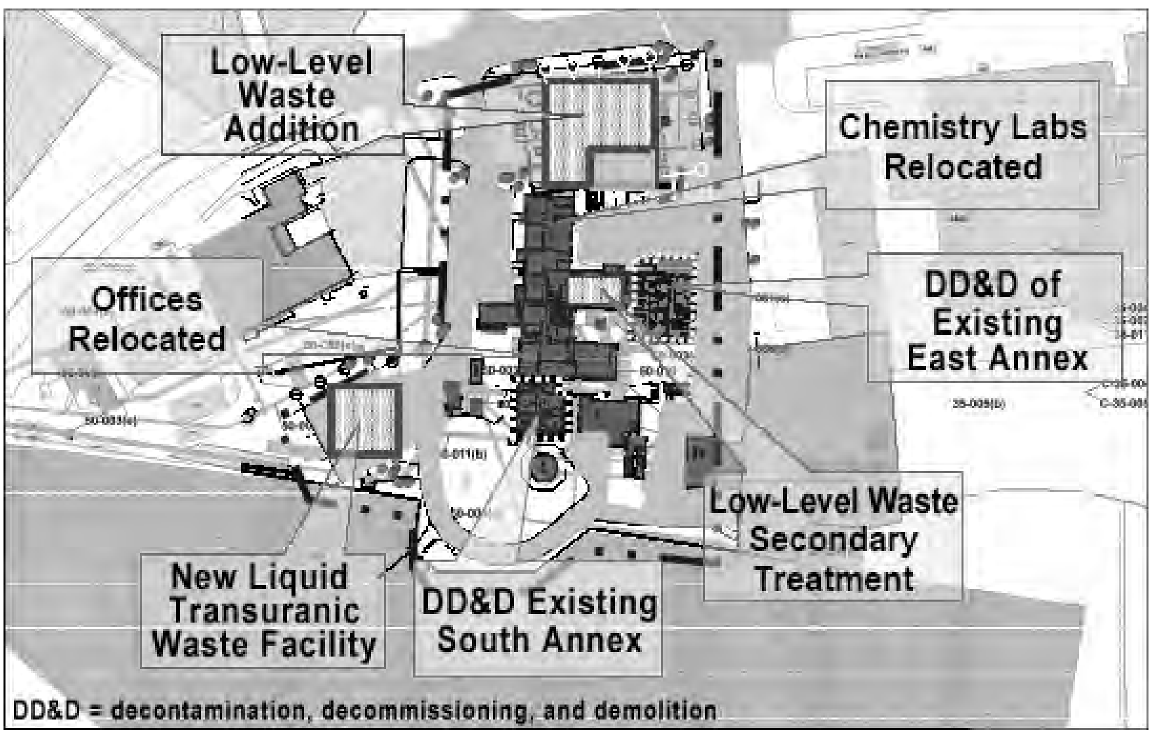

Figure G–9 Proposed Layout under the Two Liquid Waste Treatment Buildings Option

As a variation on this option, treatment functions to be housed in two facilities may be housed in multiple facilities in addition to the central utilities building. For example, separate structures may be constructed for portions of the transuranic waste treatment train rather than being consolidated into one structure.

G.4.2.4 Option 3: Two Liquid Waste Treatment Buildings and Renovation Option

Under Option 3, new buildings would be constructed to house the low-level radioactive waste and transuranic waste treatment processes, as in Option 2. As for Option 2, two new treatment buildings are envisioned, in addition to a central utilities building, although separate functions of the liquid waste treatment trains may be optionally housed in separate structures. In addition, the existing Radioactive Liquid Waste Treatment Facility would be renovated and reused for offices, chemistry laboratories, and drying of various solid residues (secondary waste) from the low-level radioactive waste treatment system.

Upon completion of the new facilities, the low-level radioactive waste and transuranic waste processes would be established in the new facilities and renovation of the existing facility would begin. When renovation is completed, equipment needed to dry the solid residues would be installed and operated in the renovated facility. In the interim, solid wastes would continue to be shipped off site for dewatering. The wastewater streams would be treated in the same way as under the proposed project (Option 1), and the treated effluent would similarly be discharged into Mortandad Canyon, reused, or evaporated. One of the auxiliary actions (evaporation tanks or mechanical evaporation) described in Section G.4.2.5 may be added to this option.

This Two Liquid Waste Treatment Buildings and Renovation Option (Option 3) would entail major structural and infrastructure changes to the existing Radioactive Liquid Waste Treatment Facility. Existing external walls would be removed and replaced with seismically appropriate materials and construction as required to meet LANL engineering standards for Hazard Category 2 facilities. Electrical and plumbing systems that do not meet current building codes would be replaced. Piping that does not conform to spill control requirements would also be replaced. The North, South, and East Annexes would be demolished, as they do not meet seismic requirements; failure of these structures could have a detrimental effect on existing and new construction. Under this option, the process of characterizing, demolishing, and removing contaminated materials would be the same as that under the proposed project (Option 1).

G.4.2.5 Auxiliary Actions

For the Radioactive Liquid Waste Treatment Facility Upgrade, two auxiliary actions are proposed to reduce or eliminate this discharge. The auxiliary actions could be applied to the No Action Option or any of the action options.

The first auxiliary action consists of constructing evaporation tanks and allowing the wastewater to evaporate using passive solar energy. The tanks would consist of up to three individual tanks constructed of lined, self-supporting concrete structures having walls approximately 4 feet high. Each tank would be open on top and have a surface area for evaporation of about an acre, with a total surface tank area of about 3 acres (1.2 hectares). The tanks would be surrounded by a security fence slatted with inserts to provide a wind screen. Except for periodic cleaning to eliminate the buildup of dissolved solids in the water, the tanks would be managed to always retain a minimum level of water. During cleaning, salt (and blown-in dirt) on the floor and sidewalls of the tanks would be flushed to a sump for solids removal, and the filtrate from solids removal returned to the evaporation tanks. The evaporation tanks could be constructed at a site in TA-52, located about a mile east of the Radioactive Liquid Waste Treatment Facility. A pipeline would be constructed to transport effluent from the Radioactive Liquid Waste Treatment Facility to the evaporation tanks.

The second auxiliary action option consists of the use of mechanical evaporation. Evaporative equipment would be purchased and installed at or near the proposed low-level radioactive waste treatment building.

G.4.2.6 Options Considered but Dismissed

Two additional action options were considered but dismissed from further evaluation. The first of these would be to construct the new radioactive liquid waste treatment facilities in another location. This site option was dismissed because the collection system, which is already in place to deliver wastewater to the current Radioactive Liquid Waste Treatment Facility, would need to be rebuilt in new locations. Constructing a new collection system has the potential for negative impacts on a number of resources without a benefit over the options being considered. The existing facility is in reasonable proximity to the source of most of the transuranic wastewater. Any other location would entail additional collection infrastructure and a longer distance over which wastewater would be transferred. In addition, the current facility has an existing NPDES permit to discharge at its current location.

The second option considered but dismissed from further evaluation would be to renovate the existing Radioactive Liquid Waste Treatment Facility to house the new transuranic waste and low-level radioactive waste treatment processes. This option is not feasible, as the capability to treat radioactive liquid wastewater must be maintained so that LANL missions are not impacted. Engineering and process reviews have determined that it is not feasible to install additional treatment equipment in the existing facility while the current treatment process is operating due to lack of space. The existing treatment processes must be maintained with no more than 10 days of downtime to ensure that mission-critical activities in facilities that generate liquid radioactive waste can be maintained. The time required to renovate the existing facility would far exceed 10 days.

G.4.3 Affected Environment and Environmental Consequences

This section presents an analysis of environmental consequences for each of the four options presented in Section G.4.2. Affected environment descriptions are also included where information is available that is specific to the project site and has not been included in Chapter 4 of this SWEIS. Detailed information about the LANL environment is presented in the main volume of this SWEIS. The auxiliary actions (see Section G.4.2.5) are not evaluated separately, but are largely evaluated as part of each of the action options (Options 1, 2, and 3). These auxiliary action evaluations would be also applicable to the No Action Option.

Proposed sites for the new transuranic and low-level radioactive waste buildings are within the developed area of TA-50, adjacent to the existing Radioactive Liquid Waste Treatment Facility. The area has been designated as an industrial area focused on Nuclear Materials Research and Development in *LANL's Comprehensive Site Plan*. Mortandad Canyon, which lies north of the proposed project, is largely undeveloped.

An initial assessment of the potential impacts of the proposed project identified resource areas for which there would be no or only negligible environmental impacts. Consequently, for the following resource areas, a determination was made that no further analysis was necessary.

- *Noise* – Would be managed with standard worker protective measures; no impact on the public due to location.

- *Socioeconomics and Infrastructure* – No new employment is expected. Construction and DD&D workers would be drawn from the pool of construction workers employed on various projects at LANL. Only infrastructure impacts are included in the impacts discussion.

- *Environmental Justice* – The proposed project is mainly confined to already-developed areas of TA-50, with no disproportionate human health impacts to low-income or minority populations expected.

- *Facility Accidents* – Potential facility accidents associated with this proposed project are addressed as part of the No Action Alternative of this SWEIS.

Resource areas examined in this analysis include: land resources, geology and soils, water resources, air quality, ecological resources, human health, cultural resources, site infrastructure, waste management, and transportation.

G.4.3.1 No Action Option

No changes in air emissions or biological resources are expected under the No Action Option. Although the Radioactive Liquid Waste Treatment Facility is currently able to meet existing discharge standards, the facility may not meet more stringent discharge standards in the future. Implementation of the auxiliary action options would greatly reduce or eliminate liquid effluent discharges and therefore beneficially effect water quality. Construction impacts from particulate or radioactive emissions would not occur. There would be no effects on land resources, cultural resources, human health, transportation, traffic, or infrastructure under the No Action Option.

Between 1998 and 2004, the Radioactive Liquid Waste Treatment Facility received a range of about 2.2 million to 5.9 million gallons (8.4 million to 22.3 million liters) of low-level radioactive waste influent per year (LANL 2005e). During that same period, solid low-level radioactive waste volumes ranged from 173 to 510 cubic yards (132 to 390 cubic meters) per year (LANL 2003b, 2004d, 2006a).

During 2005, the facility treated and discharged about 1.8 million gallons (6.8 million liters) of effluent to a permitted outfall. Also during 2005, 339 cubic yards (259 cubic meters) of solid low-level radioactive waste, very small quantities of mixed low-level radioactive waste, and

15.9 pounds (7.2 kilograms) of chemical waste were generated. About 75 cubic yards (57.5 cubic meters) of the low-level radioactive waste was construction soil and debris from installing influent storage tanks for the Cerro Grande Rehabilitation Project (LANL 2006f).

Under the No Action Option, low-level radioactive waste volumes are expected to be similar to the past few years of Radioactive Liquid Waste Treatment Facility operation, when more-efficient treatment equipment was brought online and radioactive solids were more effectively removed than in previous years. Because the treatment process would not be improved under the No Action Option, the amount of solid low-level radioactive waste to be generated would be largely a product of the influent volume and contamination concentrations. The average influent volume for 2003–2004 was 2.7 million gallons (10.3 million liters), while average low-level radioactive waste generation was 488 cubic yards (373 cubic meters) (LANL 2003b, 2004d, 2006a). Influent and waste generation levels were smaller than those averages in 2005 (LANL 2006f). If all pollution prevention measures and mission changes are implemented as scheduled, low-level radioactive waste influent volumes are expected to decrease slightly from current levels by about the year 2014 (LANL 2005e). Solid low-level radioactive waste volumes are expected to decrease slightly as well.

Similarly, because the treatment process would not be improved under the No Action Option, transuranic waste quantities would be a function of the influent volume and influent contamination concentrations. For the years 1998-2002, the Radioactive Liquid Waste Treatment Facility received on average 1,412 gallons (5,346 liters) of caustic transuranic and 8,792 gallons (33,276 liters) of acid transuranic influent per year. In that same period, the Radioactive Liquid Waste Treatment Facility produced approximately about 6.5 to 7.8 cubic yards (5 to 6 cubic meters) of solid transuranic and mixed transuranic waste annually. Under the No Action Option, the transuranic waste influent would approximately double if mission changes and pollution prevention measures are implemented. The amount of transuranic solid waste generated by treatment of the influent is likely to increase in a similar way.

Construction and operation of the evaporation tanks would have the same impacts as those detailed for Options 1, 2, and 3 in Section G.4.3.2.

G.4.3.2 Option 1: Single Liquid Waste Treatment Building Option – Proposed Project

Land Resources—Land Use

Land in TA-50 where the new building would be constructed is in the immediate vicinity of the Radioactive Liquid Waste Treatment Facility, a highly developed area with a land use designation of Waste Management (see Section 4.1 for a land use map and description). If evaporation tanks were constructed, the pipeline to them would be routed east through TA-63 and TA-52 in areas with current land use designations of Physical and Technical Support, Experimental Science, and Reserve. The proposed location of the evaporation tanks near the border of TA-52 and TA-5 is designated Reserve (LANL 2003b).

Construction Impacts—Construction of the new liquid waste management building would occur in a developed area and result in no changes to current or future land use designations. If the option to construct evaporation tanks is implemented, the land use designation for the tank areas and along a portion of the pipeline would likely change from Reserve to Waste Management. The tanks themselves could occupy approximately 3 acres (1.2 hectares), but a somewhat larger area (up to 4 acres [1.6 hectares]) would undergo a change in land use designation. Removing this land from the Reserve designation was not previously accounted for in land use plans (LANL 2004d).

Land Resources—Visual Resources

As noted previously in the land use discussion, the area in which the treatment buildings would be constructed is a highly developed area. This area currently has an industrial look, with a mix of buildings of different design. The area proposed for construction of the tanks is currently undeveloped and wooded.

Construction Impacts—There would be temporary local visual impacts associated with construction of the new treatment building, and during excavation from the use of construction equipment. The current natural setting in the area of the evaporation tanks, and a portion of the pipeline, would be disrupted by removal of vegetation, establishment of a construction staging area, and construction activities. Construction would entail excavation of soils to construct the tanks and pipeline, and possibly the temporary establishment of a soil pile. Excess soils would be removed and used or stockpiled elsewhere.

Operations Impacts—The new treatment building would not result in a change to the overall visual character of the area within TA-50. The facility would be a maximum of two stories and constructed in accordance with site guidelines, which establish acceptable color schemes for building exteriors. Establishment of evaporation tanks would result in a permanent change to the visual environment in the area near the border of TA-52 and TA-5. Although this change would result in a noticeable break in the forest cover when seen from higher elevations to the west of LANL, due to their low profile and the presence of nearby forest vegetation, the tanks would not likely be visible from the east. Additionally, the tanks would be surrounded by a fence that would be colored to blend with the surrounding environment. Following regrowth of vegetation, the area disturbed for pipeline construction would not be noticeable.

DD&D Impacts—Removal of the East Annex and TA-50-66 would result in temporary local visual impacts in the form of construction equipment and the presence of partially demolished buildings. Long-term effects would be a slightly improved local visual environment, once the annex and TA-50-66 are removed.

Geology and Soils

The existing Radioactive Liquid Waste Treatment Facility is categorized as a potential release site; other potential release sites representing possible historic spills, polychlorinated biphenyls, or leakage of radioactive wastewater are present in the vicinity of the proposed construction at TA-50. A large radioactive waste material disposal area (MDA), designated MDA C, is immediately south of the existing Radioactive Liquid Waste Treatment Facility. NNSA is implementing environmental investigation and remediation measures for MDA C and other potential release sites at TA-50 in accordance with DOE requirements and the Consent Order.

TA-50 is approximately 0.8 miles (1.25 kilometers) east of the nearest mapped fault, a subsidiary of the Rendija Canyon Fault (see Section 4.2 of this SWEIS). However, previous study indicates that the level of seismic risk is low and is manageable through facility design. Any new facilities would be designed in accordance with current DOE seismic standards and applicable building codes.

Because building construction would occur within areas already disturbed by previous facility construction, there would be no impact on native soils. Construction of the new facilities would require removal of facility soils as well as new excavation of shallow bedrock in some areas. As a result, construction activities would generate excess soil and excavated bedrock that may be suitable for use as backfill. Uncontaminated backfill would be stockpiled at an approved material management area at LANL for future use. Best management practices would be implemented to prevent erosion and migration of disturbed materials from the site caused by stormwater, other water discharges, or wind.

Construction Impacts—Approximately 36,000 cubic yards (28,000 cubic meters) of soil and rock would be disturbed during building excavation. If construction of the evaporation tanks and associated pipeline also occurs, an additional 69,000 cubic yards (53,000 cubic meters) of excavation work would be required. Nevertheless, the proposed project would initiate removal of contaminated areas adjacent to the Radioactive Liquid Waste Treatment Facility and would have a positive effect. The East Annex and TA-50-66 would also be demolished, and remediation of associated potential release sites would be initiated.

Operations Impacts—There would be minimal operations impacts on geology and soils. Evaporation of liquid effluent would eliminate addition of contaminants to soil and sediment below the existing permitted outfall. As noted above, construction activities may remove contaminated media, resulting in a reduced potential for contamination spread from past releases.

DD&D Impacts—Contaminated material would be removed from the areas affected by demolition and construction, and would be managed according to waste type and LANL procedures.

Water Resources

The Radioactive Liquid Waste Treatment Facility currently releases treated effluent to Mortandad Canyon at a permitted outfall. Other industrial outfalls and stormwater also discharge into Mortandad Canyon, both upstream and downstream from the Radioactive Liquid Waste Treatment Facility. Mortandad Canyon crosses lands belonging to the Pueblo of San Ildefonso before discharging into the Rio Grande. Existing contaminants are known to be present in Mortandad Canyon. A permeable reactive membrane barrier designed to trap contaminants and to prevent their movement downstream toward the Pueblo of San Ildefonso is located downstream from TA-50.

Construction Impacts—Construction could result in movement of contaminated and uncontaminated materials. The effects of construction would be mitigated by implementation of a stormwater pollution prevention plan to contain sediments and prevent erosion.

Operations Impacts—The overall effect of implementing the proposed project is expected to be positive. This option would ensure that both current and projected future discharge requirements could be met. During operations, effluent water quality is expected to improve due to improved processing and potentially more-stringent discharge requirements. If discharges are eliminated or greatly decreased through recycling or evaporation, movement of contaminants in groundwater and surface water in Mortandad Canyon is expected to decrease. If liquid discharge is not reduced or completely eliminated by recycling or evaporation, the permeable reactive membrane barrier is expected to mitigate the downstream movement of contaminants. The potential for spills of contaminated water would be greatly reduced by replacing single-walled piping with double-walled pipes and by use of secondary containment structures.

DD&D Impacts—Demolition could result in mobilization of particulates that could be entrained in offsite sediments. However, erosion control measures specified in a stormwater pollution prevention plan would be implemented. Movement of contaminated or uncontaminated materials is, therefore, expected to be negligible.

Air Quality

The Radioactive Liquid Waste Treatment Facility contributes less than 1 microcurie of radioactive emissions to LANL's total radioactive emissions. Likewise, Radioactive Liquid Waste Treatment Facility emissions of criteria air pollutants (nitrogen oxides, sulfur oxides, particulate matter, carbon monoxide, and volatile organic compounds) and other hazardous air pollutants are small relative to LANL's overall emissions.

Construction Impacts—Construction and demolition would result in temporary increases in particulate emissions.

Operations Impacts—Sufficient information to assess emissions and doses from a new treatment building is not yet available. The effect of the proposed project on air quality is expected to be minimal. During operations, radioactive air emissions are expected to be within an order of magnitude of current air emissions. Because current radioactive air emissions are very low, radioactive emissions from the processes to be implemented under any of the new construction options would likely not be major contributors to the total LANL radioactive emissions. Stack monitoring requirements would be adjusted as necessary based on the final design. New combustion equipment installed as part of any of the new construction options would be low-nitrogen-oxide emitters compared to existing equipment. Radiological and nonradiological emissions associated with solar evaporation of effluent are expected to be small, and dominated by evaporation of water containing tritium.

DD&D Impacts—Demolition of the East Annex and the transuranic waste influent storage tanks (TA-50-66) would likely produce radioactive or hazardous emissions. These emissions would be temporary, but released particulates could be dispersed to other areas. Because of the presence of contaminated soils and structural materials, there is potential to release radioactive or other hazardous constituents. Standard measures for controlling fugitive emissions would be employed.

Ecological Resources

The Radioactive Liquid Waste Treatment Facility is located within a highly developed industrial area of TA-50 and contains no important biological resources. However, the evaporation ponds would be located in an open field containing scattered trees. Mortandad Canyon contains breeding and foraging habitat for the Mexican spotted owl. The industrial area where the Radioactive Liquid Waste Treatment Facility is located is within developed Mexican spotted owl core habitat and its developed buffer zone. The area where the evaporation tanks would be located is also within the buffer and cores zones of the Sandia and Mortandad Canyon Area of Environmental Interest (LANL 2000).

Construction Impacts – Construction of the new Radioactive Liquid Waste Treatment Facility would not disturb any natural habitat. The biological assessment prepared by DOE, however, determined that constructing the evaporation tanks and pipeline would remove about 5.4 acres (2.2 hectares) of undeveloped core and buffer habitat of the Mexican spotted owl (LANL 2006b). It was also determined that construction of the Radioactive Liquid Waste Treatment Facility would likely result in noise levels greater than 6 dB(A) above background levels in the core zone; however, these levels should attenuate to below this level within 0.25 miles (0.4 kilometers) of the construction site. The biological assessment concluded that with the application of reasonable and prudent alternatives the project may affect, but is not likely to adversely affect, the Mexican spotted owl. Reasonable and prudent alternatives would include not permitting work to start between March 1 and the completion of surveys aimed at determining if owls were present in order to avoid a sudden increase in noise levels during the breeding season (LANL 2006b). Additional reasonable and prudent alternatives would be similar to those addressed in Section G.3.3.2. The USFWS has concurred with this assessment (see Chapter 6, Section 6.5.2).

The bald eagle Area of Environmental Interest is not located near the proposed project site. However, because the entire LANL site is considered potential bald eagle foraging area, there may be some habitat degradation associated with the project. Provided reasonable and prudent alternatives are implemented to protect adjacent foraging habitat from detrimental cumulative effects (see Section G.2.3.2), the DOE biological assessment concluded that construction of the Radioactive Liquid Waste Treatment Facility may affect, but is not likely to adversely affect, the bald eagle. Because the proposed project is not within or upstream of the southwestern willow flycatcher Area of Environmental Interest, the biological assessment determined that the project would not affect this species (LANL 2006b). The USFWS has concurred with the DOE biological assessment as it relates to the bald eagle and southeastern willow flycatcher (see Chapter 6, Section 6.5.2).

Operations and DD&D Impacts – No direct effects on sensitive species are expected from Radioactive Liquid Waste Treatment Facility Operations. However, a biological assessment prepared by DOE predicted that if water is evaporated and not discharged to Mortandad Canyon the reduction in flow would decrease the extent of perennial and intermittent stream reaches and associated wetland and riparian habitat. This could in turn reduce the abundance and diversity of prey species for the Mexican spotted owl. Thus, the biological assessment concluded that zero discharge may adversely affect the Mexican spotted owl (LANL 2006b). But after reviewing the assessment, the USFWS determined that the affects to the Mexican spotted owl would be insignificant and discountable, and would not result in adverse affects (see Chapter 6, Section 6.5.2).

DD&D effects are expected to be temporary and to have no direct impact on sensitive species.

Human Health

The Radioactive Liquid Waste Treatment Facility has very low radioactive emissions. These emissions do not have a distinguishable effect on the projected dose to the public. Current Radioactive Liquid Waste Treatment Facility operations are conducted with a commitment to maintaining radiological doses to workers at ALARA levels.

Construction Impacts—Construction would have potential for affecting only worker health. Based on an estimated 141,000 projected person-hours and accident rates for construction at DOE sites and for the general construction industry, 2 to 6 recordable injuries and no fatalities could be expected from construction of the new treatment buildings and associated structures. If the evaporation tanks and pipeline were built, an additional 420,000 person-hours would be required, with a possibility of 5 (DOE 2004) to 18 (BLS 2003) recordable injuries.

Operations Impacts—Emissions from operating the new treatment processes would remain very low, so there would be no distinguishable contribution to the dose to the public from all LANL activities. Emissions from effluent evaporation would be small and dominated by tritium, assuming operation of the evaporation tanks as described in Section G.4.2.5. The potential quantity of evaporated tritium would be minimal compared to the quantity of tritium emitted from other Key Facilities (for example, the Tritium Facility and the Plutonium Facility). The associated radiation dose would be small and enveloped by the impacts to the public discussed in Chapter 5, Section 5.6.1.

Worker health and safety at the facility would improve during operations under this option for two reasons: (1) the new buildings, equipment, and infrastructure would be more reliable and require less maintenance; and (2) because the buildings and process are being designed together (rather than retrofitting new equipment into an old building), when maintenance is needed, prolonged periods of time in zones with potential for radiation doses would be less than those in the current Radioactive Liquid Waste Treatment Facility. Maintenance of the evaporation tanks including periodic cleaning may cause occupational exposures to workers. However, radiation doses would be maintained to levels as low as reasonably achievable below DOE occupational dose limits in 10 CFR Part 835, and exposures to non-radioactive materials would be maintained well below established occupational exposure limits.

DD&D Impacts—Under this option, workers could be exposed to radiologically or chemically contaminated materials during demolition activities. Worker risks would be mitigated by use of personal protective equipment and pre-established safety procedures. Based on an estimated 56,000 person-hours and construction accident rates, 1 to 2 recordable injuries could be expected to occur from DD&D (DOE 2004, BLS 2003).

Cultural Resources

There are no archaeological remains within the developed area of TA-50. Archaeological sites in the vicinity of the proposed evaporation tanks and pipeline would be avoided. The existing Radioactive Liquid Waste Treatment Facility qualifies as a historic building. Any removal of process equipment or demolition of portions of the structure requires historic building documentation to mitigate any adverse effects.
