2018 Long-Term Stewardship Conference

Are natural processes transforming
conventional disposal cell covers into
evapotranspiration covers?

Should we enhance beneficial processes?

Long-Term Cover Performance

Natural Changes

Questions

1. Will soil formation increase permeability and percolation?
2. Will plants take up and accumulate contamination?
3. Will soil formation and ecological succession increase radon diffusion and flux?
4. Will dust deposition influence erosion and ecological succession?
5. Are evapotranspiration (ET) covers a sustainable alternative?
6. Is Mother Nature transforming conventional covers into ET covers? Can we enhance this?

1. Will soil formation increase permeability and percolation in the radon barrier?

K_s – saturated hydraulic conductivity

Shiprock, New Mexico

Lakeview, Oregon

Low-Permeability Radon Barrier

K_s - Geometric Means

2. Will plants take up and accumulate contamination?

- Sampled 10 plants on cover and 10 plants in reference area
- Dried, weighed, and ground-plant material in a Wiley Mill, and sieved on a 40 mesh screen
- Microwave acid digestion, ICP MS for elements of concern
- Ra-226 measured as emanation of Rn-222 after in-growth in a scintillation cell

Lowman, Idaho:
ponderosa pine and
redosier dogwood

Plants and Contaminants at Selected UMTRCA Sites

UMTRCA Site	Plants sampled: <i>Genus species</i>	Elements of Concern
Tuba City, Arizona	<i>Atriplex canescens</i> (ATCA) <i>Bassia scoparia</i> (BASC)	As, Mo, Pb, Se, ²²⁶ Ra, Th, U
Lowman, Idaho	<i>Pinus ponderosa</i> (PIPO) <i>Cornus sericea</i> (COSE)	Th, U
Bluewater, New Mexico	<i>Atriplex canescens</i> (ATCA) <i>Ulmus pumila</i> (ULPU)	Mo, ²²⁶ Ra, Se, Th, U
L-Bar, New Mexico	<i>Atriplex canescens</i> (ATCA) <i>Ericameria nauseosa</i> (ERNA)	As, Mo, Pb, Se, ²²⁶ Ra, Th, U
Lakeview, Oregon	<i>Artemisia tridentata</i> (ARTR) <i>Purshia tridentata</i> (PUTR)	Th, U
Falls City, Texas	<i>Prosopis glandulosa</i> (PRGL)	As, Cd, Mo, Se, U
Sherwood, Washington	<i>Pinus ponderosa</i> (PIPO) <i>Purshia tridentata</i> (PUTR)	Th, U
Split Rock, Wyoming	<i>Ericameria nauseosa</i> (ERNA)	Mn, U

Uranium

■ Disposal Cell
■ Reference Area

Mean bars labeled with different letters are significantly different ($P < 0.05$)

National Research Council (2005)
Maximum Tolerance Level
in Animal Diets: 100 $\mu\text{g g}^{-1}$

Selenium

Mean bars labeled with different letters
are significantly different ($P < 0.05$)

■ Disposal Cell Cover

■ Reference Area

National Research Council (2005)
Maximum Tolerance Level
in Animal Diets: 5 ug g⁻¹

Radium-226

Mean bars labeled with different letters
are significantly different ($P < 0.05$)

UMTRCA Soil Standard: 5 to 15 pCi g⁻¹

3. Will soil development and ecological succession increase radon diffusion and flux?

- Measured radon flux in paired plots of contrasting conditions (e.g., with and without vegetation)
- Radon flux measured with activated charcoal and a solid-state α detector (RAD7)
- Four flux chambers sizes used to evaluate potential scale effects

Radon Flux ($\text{Bq}/\text{m}^2\text{s}$)

5. Are evapotranspiration (ET) covers a sustainable alternative?

Summary and Conclusion

- Saturated hydraulic conductivity is 10^2 to 10^3 greater than the design target for conventional covers
- Mean radon fluxes remain below the 0.74 Bq/m²s regulatory standard
- Concentrations of uranium and other elements are higher in woody plants growing on vs off some conventional covers, but remain well below risk-screening thresholds
- Maximum annual percolation was 17.3% and 0.5% of precipitation for conventional and ET covers, respectively
- Enhancing plant succession increased ET and helped reduce percolation flux in a conventional cover from 12.1% to 0.1% of precipitation within three drier years
- Results so far support the premise of allowing or enhancing ecological conversion of selected conventional covers into ET covers
